- **Run Analysis**—The SignalTap II Embedded Logic Analyzer runs until the trigger event occurs. When the trigger event occurs, monitoring and data capture stops when the acquisition buffer is full.
- **AutoRun Analysis**—The SignalTap II Embedded Logic Analyzer continuously captures data until the **Stop Analysis** button is clicked, ignoring all trigger event conditions.
- **Stop Analysis**—SignalTap II analysis stops. The acquired data does not appear automatically if the trigger event has not occurred.
- **Read Data**—Captured data is displayed. This button is useful to view the acquired data, even if the trigger has not occurred.

Running with a Power-Up Trigger

If you have enabled and set up a Power-Up Trigger for an instance of the SignalTap II Embedded Logic Analyzer, the captured data may already be available for viewing if the trigger event occurred after device configuration. To download the captured data or to check if the Power-Up Trigger is still running, in the Instance Manager, click **Run Analysis**. If the Power-Up Trigger occurred, the logic analyzer immediately stops, and the captured data is downloaded from the device. The data can now be viewed on the **Data** tab of the SignalTap II Editor. If the Power-Up Trigger did not occur, no captured data is downloaded, and the logic analyzer continues to run. You can wait for the Power-Up Trigger event to occur, or, to stop the logic analyzer, click **Stop Analysis**.

Running with Runtime Triggers

You can arm and run the SignalTap II Embedded Logic Analyzer manually after device configuration to capture data samples based on the Runtime Trigger. You can do this immediately if there is no Power-Up Trigger enabled. If a Power-Up Trigger is enabled, you can do this after the Power-Up Trigger data is downloaded from the device or once the logic analyzer is stopped because the Power-Up Trigger event did not occur. Click **Run Analysis** in the SignalTap II Editor to start monitoring for the trigger event. You can start multiple SignalTap II instances at the same time by selecting all of the required instances before you click **Run Analysis** on the toolbar.

Unless the logic analyzer is stopped manually, data capture begins when the trigger event evaluates to `TRUE`. When this happens, the captured data is downloaded from the buffer. You can view the data in the **Data** tab of the SignalTap II Editor.

Performing a Force Trigger

Sometimes when you use an external logic analyzer or oscilloscope, you want to see the current state of signals without setting up or waiting for a trigger event to occur. This is referred to as a “force trigger” operation, because you are forcing the test equipment to capture data without regard to any set trigger conditions. With the SignalTap II Embedded Logic Analyzer, you can choose to run the analyzer and capture data immediately or run the analyzer and capture data when you want.

To run the analyzer and immediately capture data, disable the trigger conditions by turning off each **Trigger Condition** column in the node list. This operation does not require a recompilation. In the Instance Manager, click **Run Analysis**. The SignalTap II Embedded Logic Analyzer immediately triggers, captures, and downloads the data to the **Data** tab of the SignalTap II Editor. If the data does not download automatically, click **Read Data** in the Instance Manager.

If you want to choose when to capture data manually, it is not required that you disable the trigger conditions. To start the logic analyzer, click **Autorun Analysis**; to capture data, click **Stop Analysis**. If the data does not download to the **Data** tab of the SignalTap II Editor automatically, click **Read Data**.

You can also use In-System Sources and Probes in conjunction with the SignalTap II Embedded Logic Analyzer to force trigger conditions. The In-System Sources and Probes feature allows you to drive and sample values on to selected nets over the JTAG chain. For more information, refer to the *Design Debugging Using In-System Sources and Probes* chapter in volume 3 of the *Quartus II Handbook*.

Runtime Reconfigurable Options

Certain settings in the **.stp** file are changeable without incurring a recompilation when you are using Runtime Trigger mode. All Runtime Reconfigurable features are described in Table 14–10.

Table 14–10. Runtime Reconfigurable Features

Runtime Reconfigurable Setting	Description
Basic Trigger Conditions and Basic Storage Qualifier Conditions	All signals that have the trigger check box enabled can be changed to any basic trigger condition value without recompiling.
Advanced Trigger Conditions and Advanced Storage Qualifier Conditions	Many operators include runtime configurable settings. For example, all comparison operators are runtime-configurable. Configurable settings are shown with a white background in the block representation.This runtime reconfigurable option is enabled through the **Object Properties** dialog box.
Switching between a storage-qualified and a continuous acquisition	Within any storage-qualified mode, you can switch between to continuous capture mode easily without recompiling the design. You enable this feature by selecting the check box for **disable storage qualifier**.
State-based trigger flow parameters	Refer to Table 14–5 for a list of Reconfigurable State-based trigger flow options.

Runtime Reconfigurable options can potentially save time during the debugging cycle by allowing you to cover a wider possible scenario of events without the need to recompile the design. The trade-off is that there may be a slight impact to the performance and logic utilization of the SignalTap II IP core. Runtime re-configurability for Advanced Trigger Conditions and the State-based trigger flow parameters can be turned off, boosting performance and decreasing area utilization.

You can configure the **.stp** file to prevent changes that normally require recompilation. To do this, in the **Setup** tab, select **Allow Trigger Condition changes only** above the node list.

Example 14–4 illustrates a potential use case for Runtime Reconfigurable features. This example provides a storage qualified enabled State-based trigger flow description and shows how you can modify the size of a capture window at runtime without a recompile. This example gives you equivalent functionality to a segmented buffer with a single trigger condition where the segment sizes are runtime reconfigurable.

Example 14–4. Trigger Flow Description Providing Runtime Reconfigurable "Segments"

```
state ST1:
if ( condition1 && (c1 <= m) )    // each "segment"  triggers on condition
                                  //1
begin                             // m  = number of total "segments"
   start_store;
   increment c1;
   goto ST2:
End

else (c1 > m )                  //This else condition handles  the last
                                //segment.
begin
    start_store
    Trigger (n-1)
end

state ST2:
if ( c2 >= n)                  //n = number of samples to capture in each
                               //segment.
begin
    reset c2;
    stop_store;
    goto ST1;
end

else (c2 < n)
begin
    increment c2;
    goto ST2;
end
```

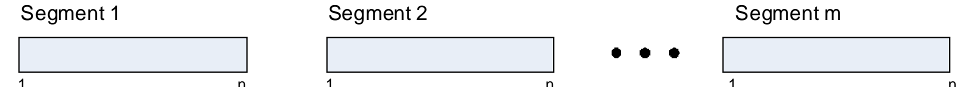
Note to Example 14–4:

(1) *m* x *n* must equal the sample depth to efficiently use the space in the sample buffer.

Figure 14–46 depicts a segmented buffer described by the trigger flow in Example 14–4.

During runtime, the values *m* and *n* are runtime reconfigurable. By changing the *m* and *n* values in the preceding trigger flow description, you can dynamically adjust the segment boundaries without incurring a recompile.

Figure 14–46. Segmented Buffer Created with Storage Qualifier and State-Based Trigger *(Note 1)*



Note to Figure 14–46:

(1) Total sample depth is fixed, where *m* x *n* must equal sample depth.

You can add states into the trigger flow description and selectively mask out specific states and enable other ones at runtime with status flags.

Example 14–5 shows a modified description of Example 14–4 with an additional state inserted. This extra state is used to specify a different trigger condition that does not use the storage qualifier feature. Status flags are inserted into the conditional statements to control the execution of the trigger flow.

Example 14–5. Modified Trigger Flow Description of Example 14–4 with Status Flags to Selectively Enable States

```
state ST1 :

if (condition2  && f1)                    //additional state added for a non-segmented
                                          //acquisition   Set f1 to enable state
begin
     start_store;
     trigger
end

else if (! f1)
     goto ST2;

state ST2:
if ( (condition1 && (c1 <= m)   && f2)    // f2  status flag used to mask state.  Set f2
                                          //to enable.
begin
   start_store;
   increment c1;
   goto ST3:
end

else (c1 > m )
   start_store
   Trigger (n-1)
end

state ST3:
if ( c2 >= n)
begin
   reset c2;
   stop_store;
   goto ST1;
end

else (c2 < n)
begin
   increment c2;
   goto ST2;
end
```

SignalTap II Status Messages

Table 14–11 describes the text messages that might appear in the SignalTap II Status Indicator in the Instance Manager before, during, and after a data acquisition. Use these messages to know the state of the logic analyzer or what operation it is performing.

Table 14–11. Text Messages in the SignalTap II Status Indicator

Message	Message Description
`Not running`	The SignalTap II Logic Analyzer is not running. There is no connection to a device or the device is not configured.
`(Power-Up Trigger) Waiting for clock` *(1)*	The SignalTap II Logic Analyzer is performing a Runtime or Power-Up Trigger acquisition and is waiting for the clock signal to transition.
`Acquiring (Power-Up) pre-trigger data` *(1)*	The trigger condition has not been evaluated yet. A full buffer of data is collected if using the non-segmented buffer acquisition mode and storage qualifier type is continuous.
`Trigger In conditions met`	Trigger In condition has occurred. The SignalTap II Embedded Logic Analyzer is waiting for the condition of the first trigger condition to occur. This can appear if Trigger In is specified.
`Waiting for (Power-up) trigger` *(1)*	The SignalTap II Logic Analyzer is now waiting for the trigger event to occur.
`Trigger level <x> met`	The condition of trigger condition *x* has occurred. The SignalTap II Embedded Logic Analyzer is waiting for the condition specified in condition *x + 1* to occur.
`Acquiring (power-up) post-trigger data` *(1)*	The entire trigger event has occurred. The SignalTap II Embedded Logic Analyzer is acquiring the post-trigger data. The amount of post-trigger data collected is user-defined between 12%, 50%, and 88% when the non-segmented buffer acquisition mode is selected.
`Offload acquired (Power-Up) data` *(1)*	Data is being transmitted to the Quartus II software through the JTAG chain.
`Ready to acquire`	The SignalTap II Embedded Logic Analyzer is waiting for the user to arm the analyzer.

Note to Table 14–11:

(1) This message can appear for both Runtime and Power-Up Trigger events. When referring to a Power-Up Trigger, the text in parentheses is added.

In segmented acquisition mode, pre-trigger and post-trigger do not apply.

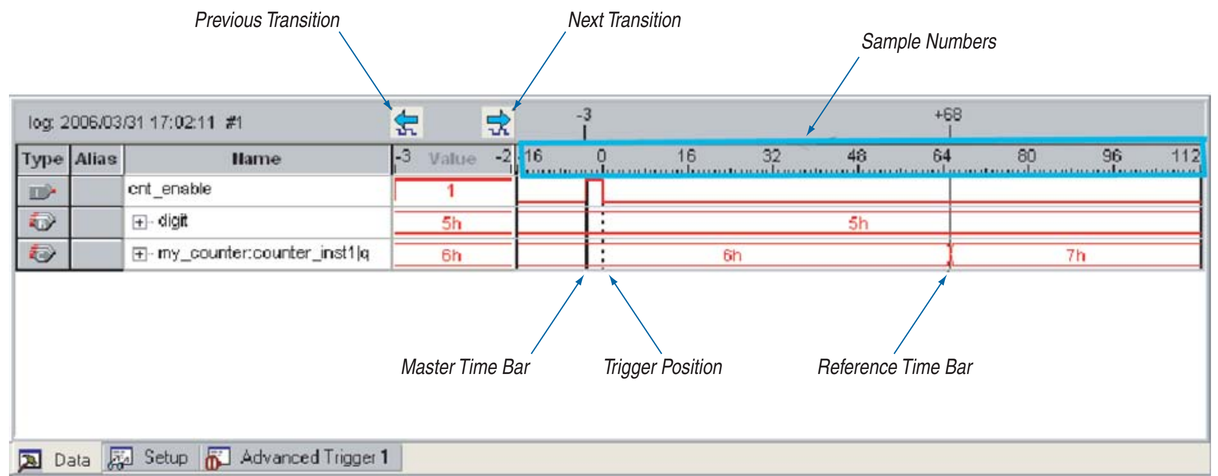
View, Analyze, and Use Captured Data

Once a trigger event has occurred or you capture data manually, you can use the SignalTap II interface to examine the data, and use your findings to help debug your design.

Viewing Captured Data

You can view captured SignalTap II data in the **Data** tab of the **.stp** file (Figure 14–47). Each row of the **Data** tab displays the captured data for one signal or bus. Buses can be expanded to show the data for each individual signal on the bus. Click on the data waveforms to zoom in on the captured data samples; right-click to zoom out.

Figure 14–47. Captured SignalTap II Data



When viewing captured data, it is often useful to know the time interval between two events. Time bars enable you to see the number of clock cycles between two samples of captured data in your system. There are two types of time bars:

- **Master Time Bar**—The master time bar's label displays the absolute time of its location in bold. The master time bar is a thick black line in the **Data** tab. The captured data has only one master time bar.
- **Reference Time Bar**—The reference time bar's label displays the time relative to the master time bar. You can create an unlimited number of reference time bars.

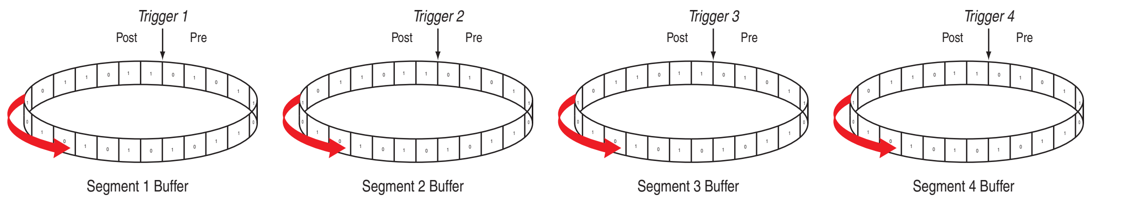
To help you find a transition of signals relative to the master time bar location, use either the **Next Transition** or the **Previous Transition** button. This aligns the master time bar with the next or previous transition of a selected signal or group of selected signals. This feature is very useful when the sample depth is very large and the rate at which signals toggle is very low.

To find bus values within the waveform quickly, use the **Find bus value** option. After you select the bus, right-click and select **Find bus value**. A dialog box appears to enter search parameters.

Capturing Data Using Segmented Buffers

Segmented Acquisition buffers allow you to perform multiple captures with a separate trigger condition for each acquisition segment. This feature allows you to capture a recurring event or sequence of events that span over a long period time efficiently. Each acquisition segment acts as a non-segmented buffer, continuously capturing data when it is activated. When you run an analysis with the **segmented buffer** option enabled, the SignalTap II Embedded Logic Analyzer performs back-to-back data captures for each acquisition segment within your data buffer. The trigger flow, or the type and order in which the trigger conditions evaluate for each buffer, is defined by either the Sequential trigger flow control or the Custom State-based trigger flow control. Figure 14–48 shows a segmented acquisition buffer with four segments represented as four separate non-segmented buffers.

Figure 14–48. Segmented Acquisition Buffer

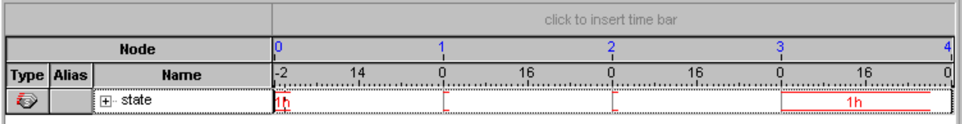


The SignalTap II Embedded Logic Analyzer finishes an acquisition with a segment, and advances to the next segment to start a new acquisition. Depending when on a trigger condition occurs, it may affect the way the data capture appears in the waveform viewer. Figure 14–48 illustrates the method data is captured. The Trigger markers in Figure 14–48—Trigger 1, Trigger 2, Trigger 3 and Trigger 4—refer to the evaluation of the `segment_trigger` and `trigger` commands in the Custom State-based trigger flow. If you are using a sequential flow, the Trigger markers refer to trigger conditions specified within the **Setup** tab.

If the Segment 1 Buffer is the active segment and Trigger 1 occurs, the SignalTap II Embedded Logic Analyzer starts evaluating Trigger 2 immediately. Data Acquisition for Segment 2 buffer starts when either Segment Buffer 1 finishes its post-fill count, or when Trigger 2 evaluates as `TRUE`, whichever condition occurs first. Thus, trigger conditions associated with the next buffer in the data capture sequence can preempt the post-fill count of the current active buffer. This is necessary so the SignalTap II Embedded Logic Analyzer can capture accurately all of the trigger conditions that have occurred. Samples that have not been used appear as a blank space in the waveform viewer.

Figure 14–49 shows an example of a capture using sequential flow control with the trigger condition for each segment set to “don’t care”. Each segment before the last captures only one sample, because the next trigger condition immediately preempts capture of the current buffer. The trigger position for all segments is set to pre-trigger (10% of the data is before the trigger condition and 90% of the data is after the trigger position). Because the last segment starts immediately with the trigger condition, the segment contains only post-trigger data. The three empty samples in the last segment is the space left over from the pre-trigger samples that the SignalTap II Embedded Logic Analyzer allocated to the buffer.

Figure 14–49. Segmented Capture with Preemption of Acquisition Segments *(Note 1)*



Note to Figure 14–49:

(1) A segmented acquisition buffer using the sequential trigger flow with a trigger condition set to “don’t care”. All segments, with the exception of the last segment, capture only one sample because the next trigger condition preempts the current buffer from filling to completion.

For the sequential trigger flow, the **Trigger Position** option applies to every segment in the buffer. For maximum flexibility on how the trigger position is defined, use the custom state-based trigger flow. By adjusting the trigger position that is specific to your debugging scenario, you can help maximize the use of the allocated buffer space.

Creating Mnemonics for Bit Patterns

The mnemonic table feature allows you to assign a meaningful name to a set of bit patterns, such as a bus. To create a mnemonic table, right-click in the **Setup** or **Data** tab of an **.stp** file and click Mnemonic Table Setup. You create a mnemonic table by entering sets of bit patterns and specifying a label to represent each pattern. Once you have created a mnemonic table, assign it to a group of signals. To assign a mnemonic table, right-click on the group, click **Bus Display Format** and select the desired mnemonic table.

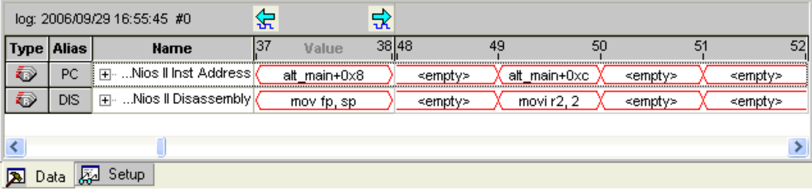
The labels you create in a table are used in different ways on the **Setup** and **Data** tabs. On the **Setup** tab, you can create basic triggers with meaningful names by right-clicking an entry in any **Trigger Conditions** column and selecting a label from the table you assigned to the signal group. On the **Data** tab, if any captured data matches a bit pattern contained in an assigned mnemonic table, the signal group data is replaced with the appropriate label, making it easy to see when expected data patterns occur.

Automatic Mnemonics with a Plug-In

When you use a plug-in to add signals to an **.stp** file, mnemonic tables for the added signals are automatically created and assigned to the signals defined in the plug-in. If you ever need to enable these mnemonic tables manually, right-click on the name of the signal or signal group. On the **Bus Display Format** submenu, click the name of the mnemonic table that matches the plug-in.

As an example, the Nios II plug-in makes it easy to monitor your design's signal activity as code is executed. If you have set up the logic analyzer to trigger on a function name in your Nios II code based on data from an **.elf** file, you can see the function name in the Instance Address signal group at the trigger sample, along with the corresponding disassembled code in the Disassembly signal group, as shown in Figure 14–50. Captured data samples around the trigger are referenced as offset addresses from the trigger function name.

Figure 14–50. Data Tab when the Nios II Plug-In is Used



Locating a Node in the Design

When you find the source of an error in your design using the SignalTap II Embedded Logic Analyzer, you can use the node locate feature to locate that signal in many of the tools found in the Quartus II software, as well as in your design files. This lets you find the source of the problem quickly so you can modify your design to correct the flaw. To locate a signal from the SignalTap II Embedded Logic Analyzer in one of the Quartus II software tools or your design files, right-click on the signal in the **.stp** file, and click **Locate in <*tool name*>**.

You can locate a signal from the node list in any of the following locations:

- Assignment Editor
- Pin Planner
- Timing Closure Floorplan
- Chip Planner
- Resource Property Editor
- Technology Map Viewer
- RTL Viewer
- Design File

For more information about using these tools, refer to each of the corresponding chapters in the *Quartus II Handbook*.

Saving Captured Data

The data log shows the history of captured data and the triggers used to capture the data. The analyzer acquires data, stores it in a log, and displays it as waveforms. When the logic analyzer is in auto-run mode and a trigger event occurs more than once, captured data for each time the trigger occurred is stored as a separate entry in the data log. This allows you to go back and review the captured data for each trigger event. The default name for a log is based on the time when the data was acquired. Altera recommends that you rename the data log with a more meaningful name.

The logs are organized in a hierarchical manner; similar logs of captured data are grouped together in trigger sets. If the **Data Log** pane is closed, on the View menu, select **Data Log** to reopen it. To enable data logging, turn on **Enable data log** in the **Data Log** (Figure 14–25). To recall a data log for a given trigger set and make it active, double-click the name of the data log in the list.

The Data Log feature is useful for organizing different sets of trigger conditions and different sets of signal configurations. For more information, refer to "Managing Multiple SignalTap II Files and Configurations" on page 14–32.

Converting Captured Data to Other File Formats

You can export captured data in the following file formats, some of which can be used with other EDA simulation tools:

- Comma Separated Values File (**.csv**)
- Table File (**.tbl**)
- Value Change Dump File (**.vcd**)
- Vector Waveform File (**.vwf**)
- Graphics format files (**.jpg**, **.bmp**)

To export the SignalTap II Embedded Logic Analyzer's captured data, on the File menu, click **Export** and specify the **File Name**, **Export Format**, and **Clock Period**.

Creating a SignalTap II List File

Captured data can also be viewed in an **.stp** list file. An **.stp** list file is a text file that lists all the data captured by the logic analyzer for a trigger event. Each row of the list file corresponds to one captured sample in the buffer. Columns correspond to the value of each of the captured signals or signal groups for that sample. If a mnemonic table was created for the captured data, the numerical values in the list are replaced with a matching entry from the table. This is especially useful with the use of a plug-in that includes instruction code disassembly. You can immediately see the order in which the instruction code was executed during the same time period of the trigger event. To create an **.stp** list file, on the File menu, select **Create/Update** and click **Create SignalTap II List File**.

Other Features

The SignalTap II Embedded Logic Analyzer has other features that do not necessarily belong to a particular task in the task flow.

Using the SignalTap II MATLAB MEX Function to Capture Data

If you use MATLAB for DSP design, you can call the MATLAB MEX function `alt_signaltap_run`, built into the Quartus II software, to acquire data from the SignalTap II Embedded Logic Analyzer directly into a matrix in the MATLAB environment. If you use the MEX function repeatedly in a loop, you can perform as many acquisitions as you can when using SignalTap II in the Quartus II software environment in the same amount of time.

The SignalTap II MATLAB MEX function is available only in the Windows version of the Quartus II software. It is compatible with MATLAB Release 14 Original Release Version 7 and later.

To set up the Quartus II software and the MATLAB environment to perform SignalTap II acquisitions, perform the following steps:

1. In the Quartus II software, create an **.stp** file (refer to "Creating and Enabling a SignalTap II File" on page 14–7).
2. In the node list in the **Data** tab of the SignalTap II Editor, organize the signals and groups of signals into the order in which you want them to appear in the MATLAB matrix. Each column of the imported matrix represents a single SignalTap II acquisition sample, while each row represents a signal or group of signals in the order they are organized in the **Data** tab.

   Signal groups acquired from the SignalTap II Embedded Logic Analyzer and transferred into the MATLAB environment with the MEX function are limited to a width of 32 signals. If you want to use the MEX function with a bus or signal group that contains more than 32 signals, split the group into smaller groups that do not exceed the 32-signal limit.

3. Save the **.stp** file and compile your design. Program your device and run the SignalTap II Embedded Logic Analyzer to ensure your trigger conditions and signal acquisition are working correctly.

4. In the MATLAB environment, add the Quartus II binary directory to your path with the following command:

```
addpath <Quartus install directory>\win ↵
```

You can view the help file for the MEX function by entering the following command in MATLAB without any operators:

```
alt_signaltap_run ↵
```

Use the MEX function in the MATLAB environment to open the JTAG connection to the device and run the SignalTap II Embedded Logic Analyzer to acquire data. When you finish acquiring data, close the connection.

To open the JTAG connection and begin acquiring captured data directly into a MATLAB matrix called `stp`, use the following command:

```
stp = alt_signaltap_run \
('<stp filename>'[,('signed'|'unsigned')[,'<instance names>'[, \
'<signalset name>'[,'<trigger name>']]]]); ↵
```

When capturing data, <*stp filename*> is the name of the **.stp** file you want to use. This is required for using the MEX function. The other MEX function options are defined in Table 14–12.

Table 14–12. SignalTap II MATLAB MEX Function Options

Option	Usage	Description
`signed` `unsigned`	`'signed'` `'unsigned'`	The **signed** option turns signal group data into 32-bit two's-complement signed integers. The MSB of the group as defined in the SignalTap II **Data** tab is the sign bit. The **unsigned** option keeps the data as an unsigned integer. The default is **signed**.
<*instance name*>	`'auto_signaltap_0'`	Specify a SignalTap II instance if more than one instance is defined. The default is the first instance in the **.stp** file, `auto_signaltap_0`.
<*signal set name*> <*trigger name*>	`'my_signalset'` `'my_trigger'`	Specify the signal set and trigger from the SignalTap II data log if multiple configurations are present in the **.stp** file. The default is the active signal set and trigger in the file.

You can enable or disable verbose mode to see the status of the logic analyzer while it is acquiring data. To enable or disable verbose mode, use the following commands:

```
alt_signaltap_run('VERBOSE_ON'); ↵
alt_signaltap_run('VERBOSE_OFF'); ↵
```

When you finish acquiring data, close the JTAG connection. Use the following command to close the connection:

```
alt_signaltap_run('END_CONNECTION'); ↵
```

For more information about the use of MEX functions in MATLAB, refer to the MATLAB Help.

Using SignalTap II in a Lab Environment

You can install a stand-alone version of the SignalTap II Embedded Logic Analyzer. This version is particularly useful in a lab environment in which you do not have a workstation that meets the requirements for a complete Quartus II installation, or if you do not have a license for a full installation of the Quartus II software. The stand-alone version of the SignalTap II Embedded Logic Analyzer is included with the Quartus II stand-alone Programmer and is available from the Downloads page of the Altera website (www.altera.com).

Remote Debugging Using the SignalTap II Embedded Logic Analyzer

You can use the SignalTap II Embedded Logic Analyzer to debug a design that is running on a device attached to a PC in a remote location.

To perform a remote debugging session, you must have the following setup:

- The Quartus II software installed on the local PC
- Stand-alone SignalTap II Embedded Logic Analyzer or the full version of the Quartus II software installed on the remote PC
- Programming hardware connected to the device on the PCB at the remote location
- TCP/IP protocol connection

Equipment Setup

On the PC in the remote location, install the stand-alone version of the SignalTap II Embedded Logic Analyzer or the full version of the Quartus II software. This remote computer must have Altera programming hardware connected, such as the EthernetBlaster or USB-Blaster.

On the local PC, install the full version of the Quartus II software. This local PC must be connected to the remote PC across a LAN with the TCP/IP protocol.

Software Setup on the Remote PC

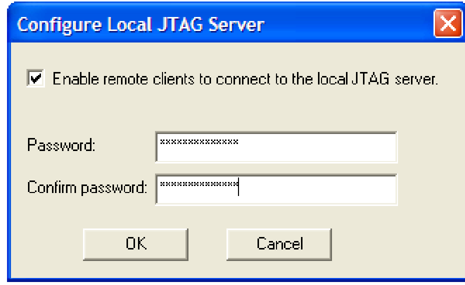
To set up the software on the remote PC, perform the following steps:

1. In the Quartus II programmer, click **Hardware Setup**.
2. Click the **JTAG Settings** tab (Figure 14–51).

Figure 14–51. Configure JTAG on Remote PC

3. Click **Configure local JTAG Server**.
4. In the **Configure Local JTAG Server** dialog box (Figure 14–52), turn on **Enable remote clients to connect to the local JTAG server** and in the password box, type your password. In the **Confirm Password** box, type your password again and click **OK**.

Figure 14–52. Configure Local JTAG Server on Remote

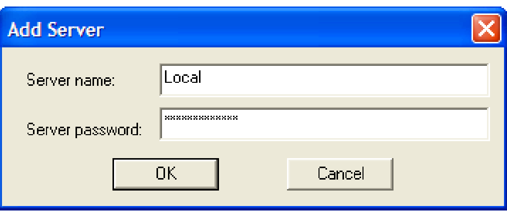


Software Setup on the Local PC

To set up your software on your local PC, perform the following steps:

1. Launch the Quartus II programmer.
2. Click **Hardware Setup**.
3. On the **JTAG** settings tab, click **Add server**.
4. In the **Add Server** dialog box (Figure 14–53), type the network name or IP address of the server you want to use and the password for the JTAG server that you created on the remote PC.

Figure 14–53. Add Server Dialog Box



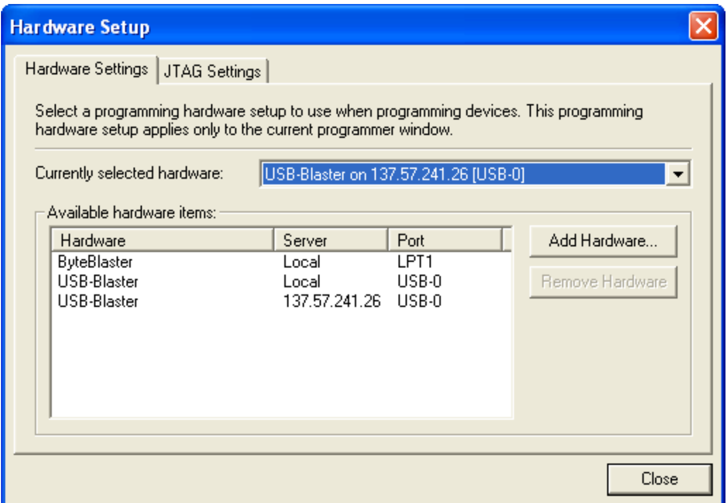
5. Click **OK**.

SignalTap II Setup on the Local PC

To connect to the hardware on the remote PC, perform the following steps:

1. Click the **Hardware Settings tab** and select the hardware on the remote PC (Figure 14–54).

Figure 14–54. Selecting Hardware on Remote PC



2. Click **Close**.

You can now control the logic analyzer on the device attached to the remote PC as if it was connected directly to the local PC.

Using the SignalTap II Embedded Logic Analyzer in Devices with Configuration Bitstream Security

Certain device families support bitstream decryption during configuration using an on-device AES decryption engine. You can still use the SignalTap II Embedded Logic Analyzer to analyze functional data within the FPGA. However, note that JTAG configuration is not possible after the security key has been programmed into the device.

Altera recommends that you use an unencrypted bitstream during the prototype and debugging phases of the design. Using an unencrypted bitstream allows you to generate new programming files and reconfigure the device over the JTAG connection during the debugging cycle.

If you must use the SignalTap II Embedded Logic Analyzer with an encrypted bitstream, first configure the device with an encrypted configuration file using Passive Serial (PS), Fast Passive Parallel (FPP), or Active Serial (AS) configuration modes. The design must contain at least one instance of the SignalTap II Embedded Logic Analyzer. After the FPGA is configured with a SignalTap II Embedded Logic Analyzer instance in the design, when you open the SignalTap II Embedded Logic Analyzer window/GUI in the Quartus II software, you then scan the chain and it will be ready to acquire data over JTAG.

Backward Compatibility with Previous Versions of Quartus II Software

You can open an old STP file in a current version of the Quartus II software. However, opening an STP file modifies it so that it cannot be opened in a previous version of the Quartus II software.

If you have a Quartus project file from a previous version of the software, you may have to update the STP configuration file if you wish to recompile the project. You can update the configuration file by invoking the SignalTap II GUI. If any updates to your configuration are necessary, a prompt will appear asking if you would like to update the **.stp** file to match the current version of the Quartus II software.

SignalTap II Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ↵
```

The *Quartus II Scripting Reference Manual* includes the same information in PDF format.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*.

For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

SignalTap II Command-Line Options

To compile your design with the SignalTap II Embedded Logic Analyzer using the command prompt, use the `quartus_stp` command. Table 14–13 shows the options that help you better understand how to use the `quartus_stp` executable.

Table 14–13. SignalTap II Command-Line Options

Option	Usage	Description
`stp_file`	`quartus_stp --stp_file <stp_filename>`	Assigns the specified **.stp** file to the `USE_SIGNALTAP_FILE` in the **.qsf** file.
`enable`	`quartus_stp --enable`	Creates assignments to the specified **.stp** file in the **.qsf** file and changes `ENABLE_SIGNALTAP` to `ON`. The SignalTap II Embedded Logic Analyzer is included in your design the next time the project is compiled. If no **.stp** file is specified in the **.qsf** file, the `--stp_file` option must be used. If the `--enable` option is omitted, the current value of `ENABLE_SIGNALTAP` in the **.qsf** file is used.
`disable`	`quartus_stp --disable`	Removes the **.stp** file reference from the **.qsf** file and changes `ENABLE_SIGNALTAP` to `OFF`. The SignalTap II Embedded Logic Analyzer is removed from the design database the next time you compile your design. If the `--disable` option is omitted, the current value of `ENABLE_SIGNALTAP` in the **.qsf** file is used.
`create_signaltap_hdl_file`	`quartus_stp --create_signaltap_hdl_file`	Creates an **.stp** file representing the SignalTap II instance in the design generated by the SignalTap II Embedded Logic Analyzer megafunction created with the MegaWizard Plug-In Manager. The file is based on the last compilation. You must use the `--stp_file` option to create an **.stp** file properly. Analogous to the **Create SignalTap II File from Design Instance(s)** command in the Quartus II software.

Example 14–6 illustrates how to compile a design with the SignalTap II Embedded Logic Analyzer at the command line.

Example 14–6.

```
quartus_stp filtref --stp_file stp1.stp --enable ↵
quartus_map filtref --source=filtref.bdf --family=CYCLONE ↵
quartus_fit filtref --part=EP1C12Q240C6 --fmax=80MHz --tsu=8ns ↵
quartus_tan filtref ↵
quartus_asm filtref ↵
```

The `quartus_stp --stp_file stp1.stp --enable` command creates the QSF variable and instructs the Quartus II software to compile the **stp1.stp** file with your design. The `--enable` option must be applied for the SignalTap II Embedded Logic Analyzer to compile properly into your design.

Example 14–7 shows how to create a new **.stp** file after building the SignalTap II Embedded Logic Analyzer instance with the MegaWizard Plug-In Manager.

Example 14–7.

```
quartus_stp filtref --create_signaltap_hdl_file --stp_file stp1.stp ↵
```

For information about the other command line executables and options, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

SignalTap II Tcl Commands

The **quartus_stp** executable supports a Tcl interface that allows you to capture data without running the Quartus II GUI. You cannot execute SignalTap II Tcl commands from within the Tcl console in the GUI. They must be run from the command line with the **quartus_stp** executable. To run a Tcl file that has SignalTap II Tcl commands, use the following command:

```
quartus_stp -t <Tcl file> ↵
```

Table 14–14 shows the Tcl commands that you can use with SignalTap II Embedded Logic Analyzer.

Table 14–14. SignalTap II Tcl Commands

Command	Argument	Description
`open_session`	`-name <stp_filename>`	Opens the specified **.stp** file. All captured data is stored in this file.
`run`	`-instance <instance_name>` `-signal_set <signal_set>` *(optional)* `-trigger <trigger_name>` *(optional)* `-data_log <data_log_name>` *(optional)* `-timeout <seconds>` *(optional)*	Starts the analyzer. This command must be followed by all the required arguments to properly start the analyzer. You can optionally specify the name of the data log you want to create. If the Trigger condition is not met, you can specify a timeout value to stop the analyzer.
`run_multiple_start`	None	Defines the start of a set of `run` commands. Use this command when multiple instances of data acquisition are started simultaneously. Add this command before the set of run commands that specify data acquisition. You must use this command with the `run_multiple_end` command. If the `run_multiple_end` command is not included, the `run` commands do not execute.
`run_multiple_end`	None	Defines the end of a set of `run` commands. Use this command when multiple instances of data acquisition are started simultaneously. Add this command after the set of `run_commands`.
`stop`	None	Stops data acquisition.
`close_session`	None	Closes the currently open **.stp** file. You cannot run the analyzer after the **.stp** file is closed.

For more information about SignalTap II Tcl commands, refer to the Quartus II Help.

Example 14–8 is an excerpt from a script that is used to continuously capture data. Once the trigger condition is met, the data is captured and stored in the data log.

Example 14–8.

```
#opens signaltap session
open_session -name stp1.stp
#start acquisition of instance auto_signaltap_0 and
#auto_signaltap_1 at the same time
#calling run_multiple_end will start all instances
#run after run_multiple_start call
run_multiple_start
run -instance auto_signaltap_0 -signal_set signal_set_1 -trigger /
trigger_1 -data_log log_1 -timeout 5
run -instance auto_signaltap_1 -signal_set signal_set_1 -trigger /
trigger_1 -data_log log_1 -timeout 5
run_multiple_end
#close signaltap session
close_session
```

When the script is completed, open the **.stp** file that you used to capture data to examine the contents of the Data Log.

Design Example: Using SignalTap II Embedded Logic Analyzers in SOPC Builder Systems

The system in this example contains many components, including a Nios processor, a direct memory access (DMA) controller, on-chip memory, and an interface to external SDRAM memory. In this example, the Nios processor executes a simple C program from on-chip memory and waits for a button push. After a button is pushed, the processor initiates a DMA transfer, which you analyze using the SignalTap II Embedded Logic Analyzer.

For more information about this example and using the SignalTap II Embedded Logic Analyzer with SOPC builder systems, refer to *AN 323: Using SignalTap II Embedded Logic Analyzers in SOPC Builder Systems* and *AN 446: Debugging Nios II Systems with the SignalTap II Logic Analyzer*.

Custom Triggering Flow Application Examples

The custom triggering flow in the SignalTap II Embedded Logic Analyzer is most useful for organizing a number of triggering conditions and for precise control over the acquisition buffer. This section provides two application examples for defining a custom triggering flow within the SignalTap II Embedded Logic Analyzer. Both examples can be easily copied and pasted directly into the state machine description box by using the state display mode **All states in one window**.

For additional triggering flow design examples, refer to the Quartus II On-Chip Debugging Design Examples page for on-chip debugging.

Design Example 1: Specifying a Custom Trigger Position

Actions to the acquisition buffer can accept an optional post-count argument. This post-count argument enables you to define a custom triggering position for each segment in the acquisition buffer. Example 14–9 shows an example that applies a trigger position to all segments in the acquisition buffer. The example describes a triggering flow for an acquisition buffer split into four segments. If each acquisition segment is 64 samples in depth, the trigger position for each buffer will be at sample #34. The acquisition stops after all four segments are filled once.

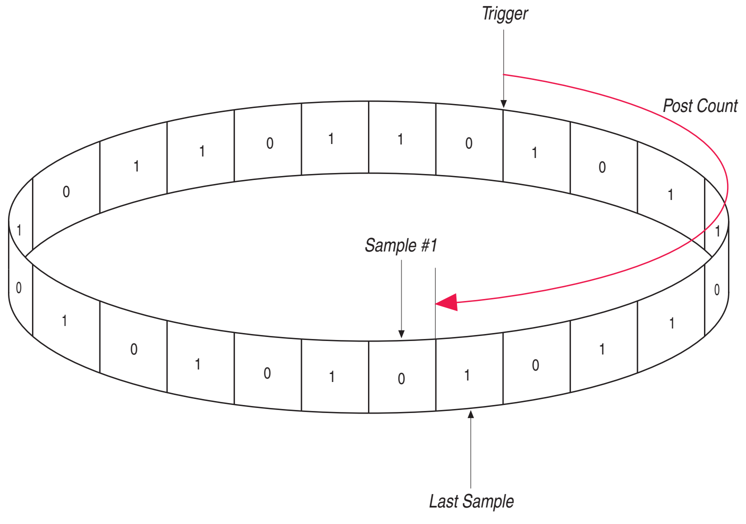
Example 14–9.

```
if (c1 == 3 && condition1)
   trigger 30;
else if ( condition1 )
begin
   segment_trigger 30;
   increment c1;

end
```

Each segment acts as a non-segmented buffer that continuously updates the memory contents with the signal values. The last acquisition before stopping the buffer is displayed on the **Data** tab as the last sample number in the affected segment. The trigger position in the affected segment is then defined by *N – post count fill*, where *N* is the number of samples per segment. Figure 14–55 illustrates the triggering position.

Figure 14–55. Specifying a Custom Trigger Position



Design Example 2: Trigger When triggercond1 Occurs Ten Times between triggercond2 and triggercond3

The custom trigger flow description is often useful to count a sequence of events before triggering the acquisition buffer. Example 14–10 shows such a sample flow. This example uses three basic triggering conditions configured in the SignalTap II **Setup** tab.

This example triggers the acquisition buffer when `condition1` occurs after `condition3` and occurs ten times prior to `condition3`. If `condition3` occurs prior to ten repetitions of `condition1`, the state machine transitions to a permanent wait state.

Example 14–10.

```
state ST1:

if ( condition2  )
begin
   reset c1;
   goto ST2;
end

State ST2 :
if ( condition1 )
    increment c1;

else if (condition3 && c1 < 10)
    goto ST3;

else if ( condition3 && c1 >= 10)
    trigger;

ST3:
goto ST3;
```

Conclusion

As the FPGA industry continues to make technological advancements, outdated methodologies need to be replaced with new technologies that maximize productivity. The SignalTap II Embedded Logic Analyzer gives you the same benefits as a traditional logic analyzer, without the many shortcomings of a piece of dedicated test equipment. This version of the SignalTap II Embedded Logic Analyzer provides many new and innovative features that allow you to capture and analyze internal signals in your FPGA, allowing you to find the source of a design flaw in the shortest amount of time.

15. In-System Debugging Using External Logic Analyzers

QII53016-9.0.0

Introduction

The Quartus II Logic Analyzer Interface (LAI) allows you to examine the behavior of internal signals using an external logic analyzer and using a minimal number of FPGA I/O pins, while your design is running at full speed on your FPGA.

This chapter's use of the term "logic analyzer" includes both logic analyzers and oscilloscopes equipped with digital channels, commonly referred to as mixed signal analyzers or MSOs.

The LAI connects a large set of internal device signals to a small number of output pins. You can connect these output pins to an external logic analyzer for debugging purposes. In the Quartus II LAI, the internal signals are grouped together, distributed to a user-configurable multiplexer, and then output to available I/O pins on your FPGA. Instead of having a one-to-one relationship between internal signals to output pins, the Quartus II LAI enables you map many internal signals to a smaller number of output pins. The exact number of internal signals that you can map to an output pin varies based on the multiplexer settings in the Quartus II LAI.

This chapter details the following topics:

- "Choosing a Logic Analyzer"
- "Debugging Your Design Using the Logic Analyzer Interface" on page 15–3
- "Advanced Features" on page 15–11

Choosing a Logic Analyzer

The Quartus II software offers the following two general purpose on-chip debugging tools for debugging a large set of RTL signals from your design:

- The embedded SignalTap® II logic analyzer
- An external logic analyzer, which connects to internal signals in your FPGA, by using the Quartus II LAI

Table 15–1 describes the advantages to each debugging technologies.

Table 15–1. Comparing the SignalTap II Embedded Logic Analyzer with the Logic Analyzer Interface

Feature and Description	Logic Analyzer Interface	SignalTap II Embedded Logic Analyzer
Sample Depth You have access to a wider sample depth with an external logic analyzer. In the SignalTap II Embedded Logic Analyzer, the maximum sample depth is set to 128 Kb, which is a device constraint. However, with an external logic analyzer, there are no device constraints, providing you a wider sample depth.	✓	—
Debugging Timing Issues Using an external logic analyzer provides you with access to a “timing” mode, which enables you to debug combined streams of data.	✓	—
Performance You frequently have limited routing resources available to place-and-route when you use SignalTap II with your design. An external logic analyzer adds minimal logic, which removes resource limits on place-and-route.	✓	—
Triggering Capability SignalTap II offers triggering capabilities that is comparable with external logic analyzers.	✓	✓
Use of Output Pins Using the SignalTap II Logic Analyzer, no additional output pins are required. Using an external logic analyzer requires the use of additional output pins.	—	✓
Acquisition Speed With the SignalTap II Logic Analyzer, you can acquire data at speeds of over 200 MHz. You can achieve the same acquisition speeds with an external logic analyzer; however, you must consider signal integrity issues.	—	✓

The Quartus II software offers a portfolio of on-chip debugging tools. For an overview and comparison of all tools available in the Quartus II software on-chip debugging tool suite, refer to *Section V. In-System Debugging* in volume 3 of the *Quartus II Handbook*.

Required Components

You must have the following components to perform analysis using the Quartus II LAI:

- The Quartus II software starting with version 5.1 and later
- The device under test
- An external logic analyzer
- An Altera® communications cable
- A cable to connect the FPGA to the external logic analyzer

Figure 15–1 shows the LAI and the hardware setup.

Figure 15–1. Logic Analyzer Interface and Hardware Setup

Notes to Figure 15–1:

(1) Configuration and control of the LAI using a computer loaded with the Quartus II software via the JTAG port.
(2) Configuration and control of the LAI using a third-party vendor logic analyzer via the JTAG port. Support varies by vendor.

FPGA Device Support

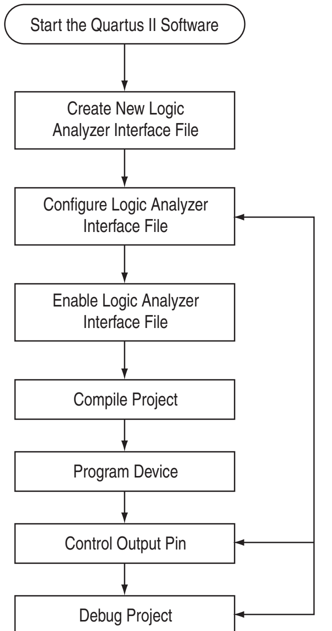
You can use the Quartus II Logic Analyzer Interface (LAI) with the following FPGA device families:

- Arria® GX
- Stratix® series
- Cyclone® series
- MAX® II
- APEX™ 20K
- APEX II

Debugging Your Design Using the Logic Analyzer Interface

Figure 15–2 shows the steps you must follow to debug your design with the Quartus II LAI.

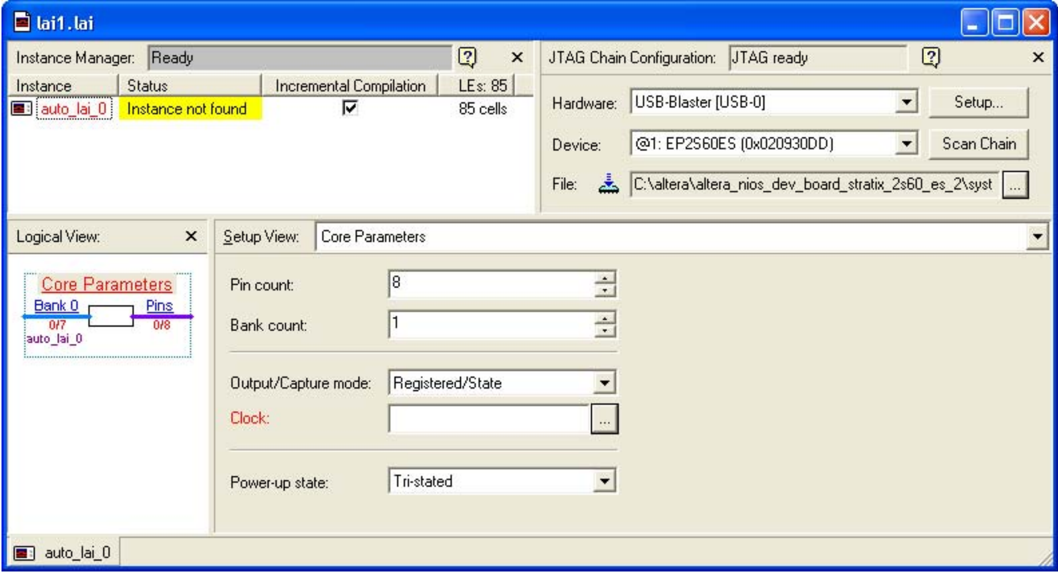
Figure 15–2. LAI Process Flow



Creating an LAI File

The Logic Analyzer Interface (**.lai**) file defines the interface that builds a connection between internal FPGA signals and your external logic analyzer. Figure 15–3 shows an example of an **.lai** editor.

Figure 15–3. The LAI Editor



To define the Quartus II LAI, you can create a new **.lai** file or use an existing **.lai** file.

Creating a New Logic Analyzer Interface File

To create a new **.lai** file, perform the following steps:

1. In the Quartus II software, on the File menu, click **New**. The **New** dialog box opens.
2. Click the **Other Files** tab.
3. Select **Logic Analyzer Interface File**.
4. Click **OK**. The LAI editor opens. The file name is assigned by the Quartus II software (refer to Figure 15–3 on page 15–4). When you save the file, you will be prompted for a file name. Refer to "Saving the External Analyzer Interface File" on page 15–5.

Opening an Existing External Analyzer Interface File

To open an existing **.lai** file, on the Tools menu, click **Logic Analyzer Interface Editor**. If no **.lai** file is enabled for the current project, the editor automatically creates a new **.lai** file. If an **.lai** file is currently enabled for the project, that file opens when you select the **Logic Analyzer Interface Editor**.

Alternatively, on the File menu, click **Open**, and select the **.lai** file you want to open.

Saving the External Analyzer Interface File

To save your **.lai** file, perform the following steps:

1. In the Quartus II software, on the File menu, click **Save As**. The **Save As** dialog box opens.
2. In the **File name** box, enter the desired file name.
3. Click **Save**.

Configuring the Logic Analyzer Interface File Core Parameters

After you have created the **.lai** file, you must configure the **.lai** file core parameters.

To configure the **.lai** file core parameters, from the **Setup View** list, select **Core Parameters**. Refer to Figure 15–4.

Figure 15–4. Logic Analyzer Interface File Core Parameters

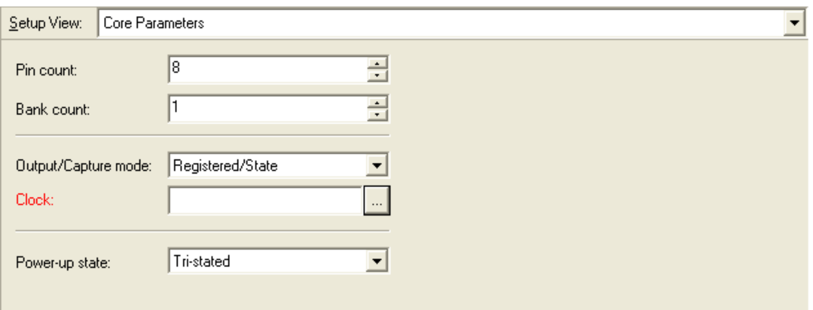


Table 15–2 lists the **.lai** file core parameters.

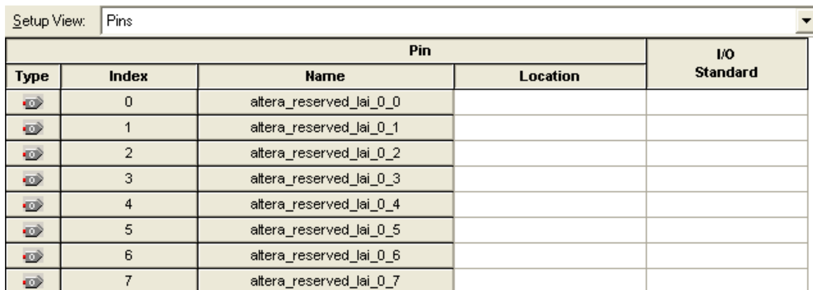
Table 15–2. Logic Analyzer Interface File Core Parameters

Parameter	Description
Pin Count	The Pin Count parameter signifies the number of pins you want dedicated to your LAI. The pins must be connected to a debug header on your board. Within the FPGA, each pin is mapped to a user-configurable number of internal signals. The Pin Count parameter can range from 1 to 255 pins.
Bank Count	The Bank Count parameter signifies the number of internal signals that you want to map to each pin. For example, a Bank Count of 8 implies that you will connect eight internal signals to each pin. The Bank Count parameter can range from 1 to 255 banks.
Output/Capture Mode	The Output/Capture Mode parameter signifies the type of acquisition you perform. There are two options that you can select: **Combinational/Timing**—This acquisition uses your external logic analyzer's internal clock to determine when to sample data. Because Combinational/Timing acquisition samples data asynchronously to your FPGA, you must determine the sample frequency you should use to debug and verify your system. This mode is effective if you want to measure timing information, such as channel-to-channel skew. For more information about the sampling frequency and the speeds at which it can run, refer to the data sheet for your external logic analyzer. **Registered/State**—This acquisition uses a signal from your system under test to determine when to sample. Because Registered/State acquisition samples data synchronously with your FPGA, it provides you with a functional view of your FPGA while it is running. This mode is effective when you verify the functionality of your design.
Clock	The clock parameter is available only when Output/Capture Mode is set to Registered State. You must specify the sample clock in the Core Parameters view. The sample clock can be any signal in your design. However, for best results, Altera recommends that you use a clock with an operating frequency fast enough to sample the data you would like to acquire.
Power-Up State	The Power-Up State parameter specifies the power-up state of the pins you have designated for use with the LAI. You have the option of selecting tri-stated for all pins, or selecting a particular bank that you have enabled.

Mapping the Logic Analyzer Interface File Pins to Available I/O Pins

To configure the **.lai** file I/O pins parameters, select Pins from the Setup View list (Figure 15–5).

Figure 15–5. Logic Analyzer Interface File Pins Parameters



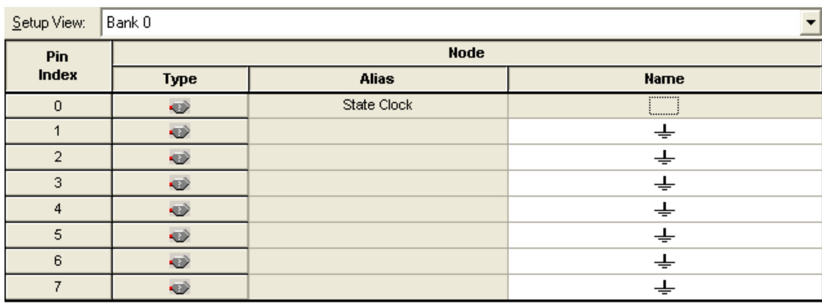
To assign pin locations for the LAI, double-click the **Location** column next to the reserved pins in the **Name** column. This opens the Pin Planner.

For information about how to use the Pin Planner, refer to the *Pin Planner* section in the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

Mapping Internal Signals to the Logic Analyzer Interface Banks

After you have specified the number of banks to use in the **Core Parameters** settings page, you must assign internal signals for each bank in the LAI. Click the **Setup View** arrow and select **Bank n** or **All Banks** (Figure 15–6).

Figure 15–6. Logic Analyzer Interface Bank Parameters



Setup View: Bank 0

	5			
	6			
	7			

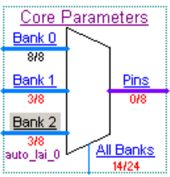
Using the Node Finder

Before making bank assignments, on the View menu, point to **Utility Windows** and click Node Finder. Find the signals that you want to acquire, then drag and drop the signals from the **Node Finder** dialog box into the bank **Setup View**. When adding signals, use **SignalTap II: pre-synthesis** for non-incrementally routed instances and **SignalTap II: post-fitting** for incrementally routed instances.

As you continue to make assignments in the bank **Setup View**, the schematic of your LAI in the **Logical View** of your **.lai** file begins to reflect your assignments (Figure 15–8).

Figure 15–8. A Logical View of the Logic Analyzer Interface Schematic



Continue making assignments for each bank in the **Setup View** until you have added all of the internal signals for which you wish to acquire data.

You can right-click to switch between the LAI schematic and the LAI **Setup** view.

Enabling the Logic Analyzer Interface Before Compiling Your Quartus II Project

Compile your project after you have completed the following steps:

- Configure your LAI parameters
- Map the LAI pins to available I/O pins
- Map the internal signals to the LAI banks

Compiling Your Quartus II Project

Before compiling your project, you must enable the LAI.

1. On the Assignments menu, click **Settings**. The **Settings** dialog box opens.
2. Under Category, click **Logic Analyzer Interface**. The **Logic Analyzer Interface** displays.
3. Turn on **Enable Logic Analyzer Interface**.
4. Click **Logic Analyzer Interface file name** and specify the full path name to your **.lai** file.

After you have specified the name of your **.lai** file, you must compile your project. To compile your project, on the Processing menu, click **Start Compilation**.

To ensure that the LAI is properly compiled with your project, expand the entity hierarchy in the Project Navigator. (To display the Project Navigator, on the View menu, point to **Utility Windows** and click **Project Navigator**.) If the LAI is compiled with your design, the `sld_hub` and `sld_multitap` entities are shown in the project navigator (Figure 15–9).

Figure 15–9. Project Navigator

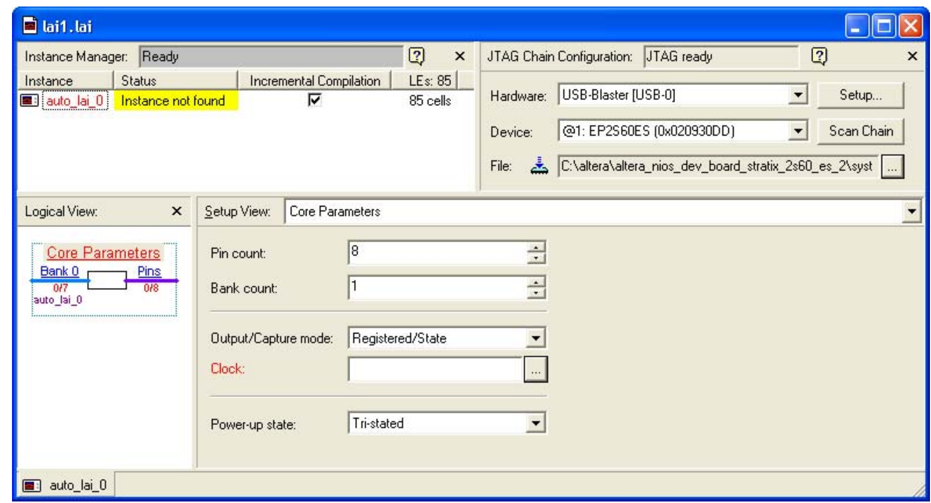
Entity	Logic Cells	LC Registers
Stratix: EP1S10B672C7		
test	136 (1)	81
sld_multitap:auto_lai_0	35 (11)	15
sld_hub:sld_hub_inst	100 (25)	65

Programming Your FPGA Using the Logic Analyzer Interface

After compilation completes, you must configure your FPGA before using the LAI. To configure a device for use with the LAI, perform the following steps:

1. Open the **.lai** file Editor (Figure 15–10).
2. Under **JTAG Chain Configuration**, click **Hardware** and select your hardware communications device. You may have to click **Settings** to configure your hardware.
3. Click **Device** and select the FPGA device to which you want to download the design (it may be automatically detected). You may have to click **Scan Chain** to configure your device.
4. Click **File** and select the SRAM Object File (**.sof**) that includes the **.lai** file (it may be automatically detected).
5. If desired, turn on **Incremental Compilation**.
6. Save the **.lai** file.
7. Click the **Program Device** icon to program the device.

Figure 15–10. The JTAG Section of the Logic Analyzer Interface File



Using the Logic Analyzer Interface with Multiple Devices

You can use the LAI with multiple devices in your JTAG chain. Your JTAG chain can also consist of devices that do not support the LAI or non-Altera, JTAG-compliant devices. To use the LAI in more than one FPGA, create an LAI and configure an **.lai** file for each FPGA that you want to analyze. To perform multi-FPGA analysis, perform the following steps:

1. Open the Quartus II software.
2. Create, configure, and compile an **.lai** file for each design.
3. Open one **.lai** file at a time.

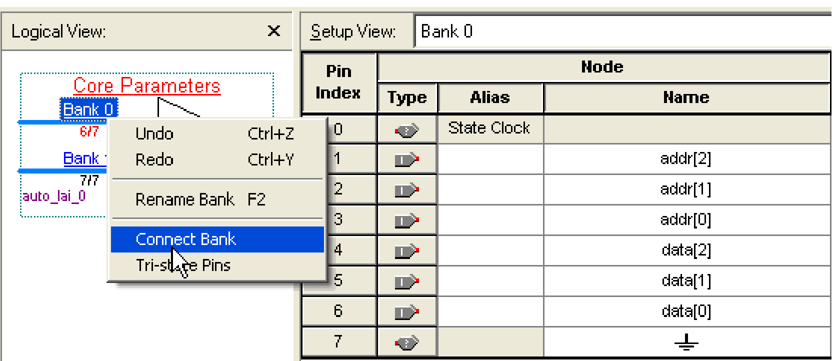
   You do not have to open a Quartus II project to open an **.lai** file.

4. Follow Steps 2 through 6 under "Programming Your FPGA Using the Logic Analyzer Interface" on page 15–9.
5. Click the **Program Device** icon to program the device.
6. Control each **.lai** file independently.

Configuring Banks in the Logic Analyzer Interface File

When you have programmed your FPGA, you can control which bank is mapped to the reserved **.lai** file output pins. To control which bank is mapped, in the schematic in the logical view, right-click the bank and click **Connect Bank** (Figure 15–11).

Figure 15–11. Configuring Banks



Acquiring Data on Your Logic Analyzer

To acquire data on your logic analyzer, you must establish a connection between your device and the external logic analyzer.

For more information about this process and for guidelines on how to establish connections between debugging headers and logic analyzers, refer to the documentation for your logic analyzer.

Advanced Features

This section describes the following advanced features:

- Using the Logic Analyzer Interface with Incremental Compilation
- Creating Multiple Logic Analyzer Interface Instances in One FPGA

Using the Logic Analyzer Interface with Incremental Compilation

Using the LAI with Incremental Compilation enables you to preserve the synthesis and fitting of your original design, and add the LAI to your design without recompiling your original source code.

To use the LAI with Incremental Compilation, perform the following steps:

1. Start the Quartus II software.
2. Enable Design Partitions. To enable Partitions, perform the following steps:
   a. On the Assignments menu, click **Design Partitions**.
   b. In the **Incremental Compilation** list, select **Full Incremental Compilation**.
   c. Create Design Partitions for the entities in your design, and set the Netlist Type to **Post-fit**.
   d. On the Processing menu, click **Start Compilation**.
3. Enable LAI Incremental Compilation by performing these steps:
   a. In your **.lai** file, under **Instance Manager**, click **Incremental Compilation**.

When you enable **Incremental Compilation**, all existing presynthesis signals are converted into post-fitting signals. Only post-fitting signals can be used with the LAI with Incremental Compilation.

   b. Add Post-Fitting nodes to your **.lai** file.
   c. On the Processing menu, click **Start Compilation**.

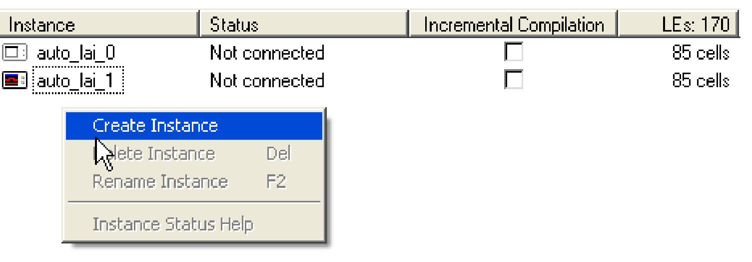
Creating Multiple Logic Analyzer Interface Instances in One FPGA

The LAI includes support for multiple interfaces in one FPGA. This feature is particularly useful when you want to build LAI configurations that contain different settings. For example, you can build one LAI instance to perform Registered/State analysis and build another instance that performs Combinational/Timing analysis on the same set of signals.

Another example would be performing Registered/State analysis on portions of your design that are in different clock domains.

To create multiple LAIs, on the Edit menu, click **Create Instance**. Alternatively, you can right-click the **Instance Manager** window, and click **Create Instance** (Figure 15–12).

Figure 15–12. Creating Multiple Logic Analyzer Interface Instances in One FPGA



Conclusion

As the FPGA industry continues to make technological advancements, outdated debugging methodologies must be replaced with new technologies that maximize productivity. The LAI feature enables you to connect many internal signals within your FPGA to an external logic analyzer with the use of a small number of I/O pins. This new technology in the Quartus II software enables you to use feature-rich external logic analyzers to debug your FPGA design, ultimately enabling you to delver your product in the shortest amount of time.

16. In-System Updating of Memory and Constants

QII53012-9.0.0

Introduction

The In-System Memory Content Editor allows you to view and update memories and constants using the JTAG port connection. This chapter explains how to use the Quartus II In-System Memory Content Editor as part of your FPGA design and verification flow.

FPGA designs are growing larger in density and are becoming more complex. Designers and verification engineers require more access to the design that is programmed in the device to quickly identify, test, and resolve issues. The in-system updating of memory and constants capability of the Quartus® II software provides read and write access to in-system FPGA memories and constants through the Joint Test Action Group (JTAG) interface, making it easier to test changes to memory contents in the FPGA while the FPGA is functioning in the end system.

This chapter contains the following sections:

- "Device Megafunction Support" on page 16–2
- "Using In-System Updating of Memory and Constants with Your Design" on page 16–2
- "Creating In-System Modifiable Memories and Constants" on page 16–3
- "Running the In-System Memory Content Editor" on page 16–3

Overview

The ability to read and update memories and constants in a programmed device provides more insight into and control over your design. The Quartus II In-System Memory Content Editor gives you access to device memories and constants. When used in conjunction with the SignalTap® II Embedded Logic Analyzer, this feature provides the visibility required to debug your design in the hardware lab.

For more information about the SignalTap II Embedded Logic Analyzer, refer to the *Design Debugging Using the SignalTap II Embedded Logic Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

The ability to read data from memories and constants allows you to quickly identify the source of problems. In addition, the write capabilities allow you to bypass functional issues by writing expected data. For example, if a parity bit in your memory is incorrect, you can use the In-System Content Editor to write the correct parity bit values into your RAM, allowing your system to continue functioning. You can also intentionally write incorrect parity bit values into your RAM to check your design's error handling functionality.

The Quartus II software offers a portfolio of on-chip debugging tools. For an overview and comparison of all tools available in the Quartus II software on-chip debugging tool suite, refer to *Section V. In-System Debugging* in volume 3 of the *Quartus II Handbook*.

Device Megafunction Support

The following tables list the devices and types of memories and constants that are currently supported by the Quartus II software. Table 16–1 lists the types of memory supported by the MegaWizard™ Plug-In Manager and the In-System Memory Content Editor.

Table 16–1. MegaWizard Plug-In Manager Support

Installed Plug-Ins Category	Megafunction Name
Gates	LPM_CONSTANT
Memory Compiler	RAM: 1-PORT, ROM: 1-PORT
Storage	ALTSYNCRAM, LPM_RAM_DQ, LPM_ROM

Table 16–2 lists support for in-system updating of memory and constants for the Stratix® series, Arria® GX, Cyclone® series, APEX™ II, and APEX 20K device families.

Table 16–2. Supported Megafunctions

Megafunction	Arria GX / Stratix Series			Cyclone Series	APEX II	APEX 20K
	M512 Blocks	M4K Blocks	MegaRAM Blocks			
LPM_CONSTANT	Read/ Write	Read/ Write	Read/ Write	Read/ Write	Read/ Write	Read/ Write
LPM_ROM	Write	Read/ Write	N/A	Read/ Write	Read/ Write	Write
LPM_RAM_DQ	N/A	Read/ Write	Read/ Write	Read/ Write	Read/ Write	N/A *(1)*
ALTSYNCRAM (ROM)	Write	Read/ Write	N/A	Read/ Write	N/A	N/A
ALTSYNCRAM (Single-Port RAM Mode)	N/A	Read/ Write	Read/ Write	Read/ Write	N/A	N/A

Note to Table 16–2:

(1) Only write-only mode is applicable for this single-port RAM. In read-only mode, use LPM_ROM instead of LPM_RAM_DQ.

Using In-System Updating of Memory and Constants with Your Design

Using the In-System Updating of Memory and Constants feature requires the following steps:

1. Identify the memories and constants that you want to access.
2. Edit the memories and constants to be run-time modifiable.
3. Perform a full compilation.
4. Program your device.
5. Launch the In-System Memory Content Editor.

Creating In-System Modifiable Memories and Constants

When you specify that a memory or constant is run-time modifiable, the Quartus II software changes the default implementation. A single-port RAM is converted to dual-port RAM, and a constant is implemented in registers instead of look-up tables (LUTs). These changes enable run-time modification without changing the functionality of your design. For a list of run-time modifiable megafunctions, refer to Table 16–1.

To enable your memory or constant to be modifiable, perform the following steps:

1. On the Tools menu, click **MegaWizard Plug-In Manager**.
2. If you are creating a new megafunction, select **Create a new custom megafunction variation**. If you have an existing megafunction, select **Edit an existing custom megafunction variation**.
3. Make the necessary changes to the megafunction based on the characteristics required by your design, turn on **Allow In-System Memory Content Editor to capture and update content independently of the system clock**, and type a value in the **Instance ID** text box. These parameters can be found on the last page of the wizard for megafunctions that support in-system updating.

   The Instance ID is a four-character string used to distinguish the megafunction from other in-system memories and constants.

4. Click **Finish**.
5. On the Processing menu, click **Start Compilation**.

If you instantiate a memory or constant megafunction directly using ports and parameters in VHDL or Verilog HDL, add or modify the `lpm_hint` parameter as follows:

In VHDL code, add the following:

```
lpm_hint => "ENABLE_RUNTIME_MOD = YES,
  INSTANCE_NAME = <instantiation name>";
```

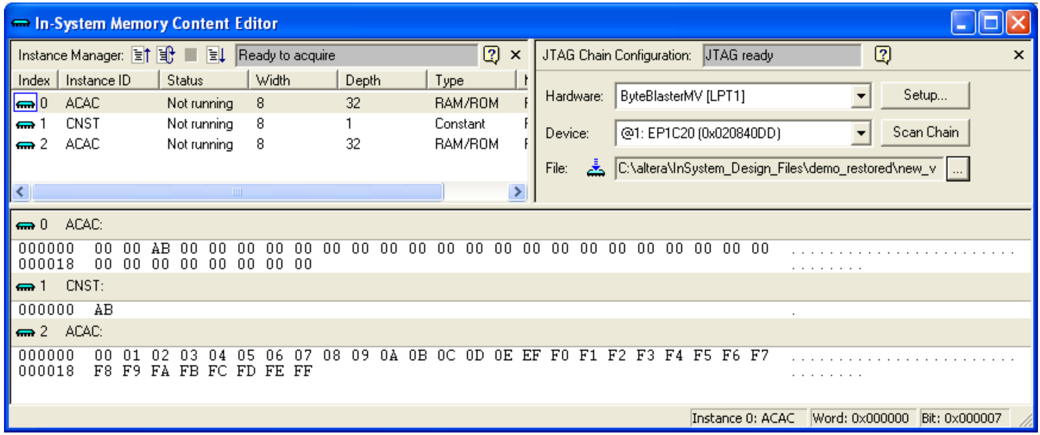
In Verilog HDL code, add the following:

```
defparam <megafunction instance name>.lpm_hint =
  "ENABLE_RUNTIME_MOD = YES,
  INSTANCE_NAME = <instantiation name>";
```

Running the In-System Memory Content Editor

The In-System Memory Content Editor is separated into the Instance Manager, JTAG Chain Configuration, and the Hex Editor (Figure 16–1).

Figure 16–1. In-System Memory Content Editor



The Instance Manager displays all available run-time modifiable memories and constants in your FPGA device. The JTAG Chain Configuration section allows you to program your FPGA and select the Altera® device in the chain to update.

Using the In-System Memory Content Editor does not require that you open a project. The In-System Memory Content Editor retrieves all instances of run-time configurable memories and constants by scanning the JTAG chain and sending a query to the specific device selected in the JTAG Chain Configuration section.

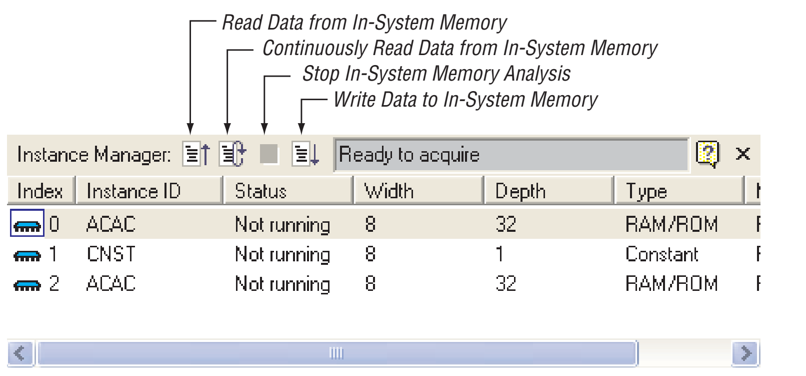
Each In-System Memory Content Editor can access the in-system memories and constants in a single device. If you have more than one device containing in-system configurable memories or constants in a JTAG chain, you can launch multiple In-System Memory Content Editors within the Quartus II software to access the memories and constants in each of the devices.

Instance Manager

Scan the JTAG chain to update the Instance Manager with a list of all run-time modifiable memories and constants in the design. The Instance Manager displays the Index, Instance, Status, Width, Depth, Type, and Mode of each element in the list.

You can read and write to in-system memory using the Instance Manager, as shown in Figure 16–2.

Figure 16–2. Instance Manager Controls



© March 2009 Altera Corporation

The following buttons are provided in the Instance Manager:

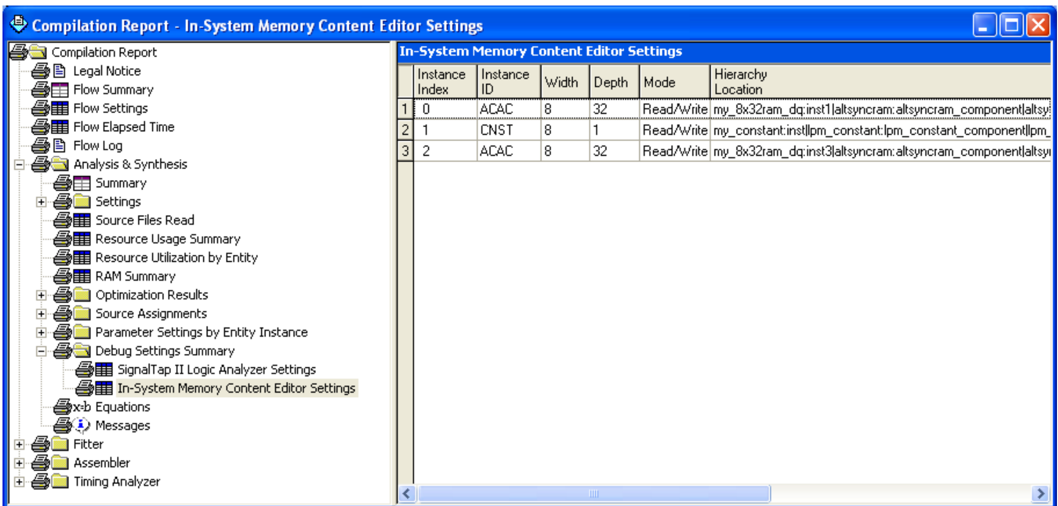
- **Read data from In-System Memory**—Reads the data from the device independently of the system clock and displays it in the Hex Editor
- **Continuously Read Data from In-System Memory**—Continuously reads the data asynchronously from the device and displays it in the Hex Editor
- **Stop In-System Memory Analysis**—Stops the current read or write operation
- **Write Data to In-System Memory**—Asynchronously writes data present in the Hex Editor to the device

In addition to the buttons available in the Instance Manager, you can also read and write data by selecting the command from the Processing menu, or the right button pop-up menu in the Instance Manager or Hex Editor.

The status of each instance is also displayed beside each entry in the Instance Manager. The status indicates if the instance is **Not running**, **Offloading data**, or **Updating data**. The health monitor provides useful information about the status of the editor.

The Quartus II software assigns a different index number to each in-system memory and constant to distinguish between multiple instances of the same memory or constant function. View the **In-System Memory Content Editor Settings** section of the compilation report to match an index with the corresponding instance ID (Figure 16–3).

Figure 16–3. Compilation Report In-System Memory Content Editor Settings Section



Editing Data Displayed in the Hex Editor

You can edit the data read from your in-system memories and constants displayed in the Hex Editor by typing values directly into the editor or by importing memory files.

To modify the data displayed in the Hex Editor, click a location in the editor and type or paste in the new data. The new data appears in blue, indicating modified data that has not been written into the FPGA. On the Edit menu, choose **Value**, and click **Fill with 0's**, **Fill with 1's**, **Fill with Random Values**, or **Custom Fills to** update a block of data by selecting a block of data.

Importing and Exporting Memory Files

The In-System Memory Content editor allows you specify a file to import and export data values to and from memories that have the In-System Updating feature enabled. Importing from a data files enables you to quickly load an entire memory image. Exporting to a data file enables you to save the contents of the memory for future use and analysis.

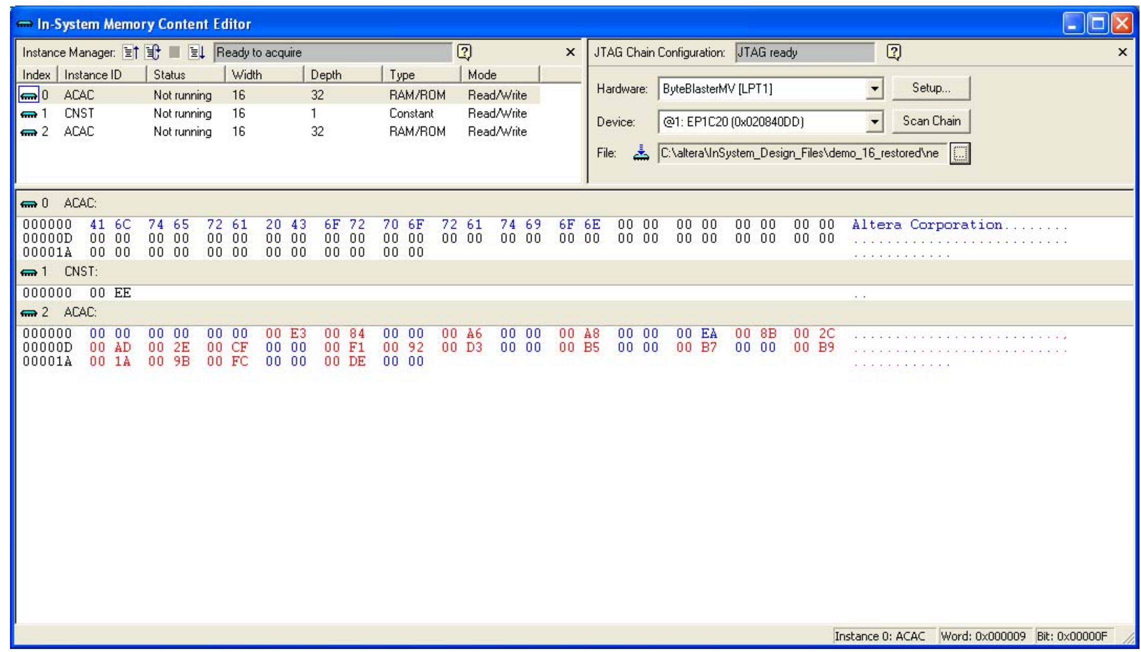
To import a file to memory using the In-System Memory Content Editor, select the memory or constant that you want to target from the instance manager. From the Edit menu, click **Import Data from File**, and specify the data file that you want to load to the targeted memory or constant. You can only import a memory file that is in either a Hexadecimal (Intel-Format) file (**.hex**) or memory initialization file (**.mif**) format.

Similarly, to export the contents of memory to a file using the In-System Memory Content Editor, select the memory or constant that you want to target from the instance manager. From the Edit menu, click **Export Data from File**, and specify the file name to which you want to save the data. You can export data to a **.hex**, **.mif**, Verilog Value Change Dump file (**.vcd**), or RAM Initialization file (**.rif**) format.

Viewing Memories and Constants in the Hex Editor

For each instance of an in-system memory or constant, the Hex Editor displays data in hexadecimal representation and ASCII characters (if the word size is a multiple of 8 bits). The arrangement of the hexadecimal numbers depends on the dimensions of the memory. For example, if the word width is 16 bits, the Hex Editor displays data in columns of words that contain columns of bytes (Figure 16–4).

Figure 16–4. Editing 16-Bit Memory Words Using the Hex Editor



Unprintable ASCII characters are represented by a period (.). The color of the data changes as you perform reads and writes. Data displayed in black indicates the data in the Hex Editor was the same as the data read from the device. If the data in the Hex Editor changes color to red, the data previously shown in the Hex Editor was different from the data read from the device.

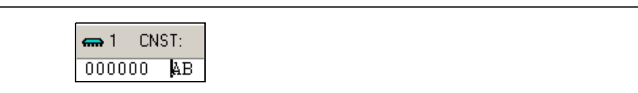
As you analyze the data, you can use the cursor and the status bar to quickly identify the exact location in memory. The status bar is located at the bottom of the In-System Memory Content Editor and displays the selected instance name, word position, and bit offset (Figure 16–5).

Figure 16–5. Status Bar in the In-System Memory Content Editor

The bit offset is the bit position of the cursor within the word. In the following example, a word is set to be 8-bits wide.

With the cursor in the position shown in Figure 16–6, the word location is 0x0000 and the bit position is 0x0007.

Figure 16–6. Hex Editor Cursor Positioned at Bit 0×0007



With the cursor in the position shown in Figure 16–7, the word location remains 0x0000 but the bit position is 0x0003.

Figure 16–7. Hex Editor Cursor Positioned at Bit 0×0003

Scripting Support

The In-System Memory Content Editor supports reading and writing of memory contents via a Tcl script or Tcl commands entered at a command prompt. For detailed information about scripting command options, refer to the Quartus II command-line and Tcl API Help browser.

To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ↵
```

The *Quartus II Scripting Reference Manual* includes the same information.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

The commonly used commands for the In-System Memory Content Editor are as follows:

- Reading from memory:

```
read_content_from_memory
[-content_in_hex]
-instance_index <instance index>
-start_address <starting address>
-word_count <word count>
```

- Writing to memory:

```
write_content_to_memory
```

- Save memory contents to file:

```
save_content_from_memory_to_file
```

- Update memory contents from File:

```
update_content_to_memory_from_file
```

For descriptions about the command options and scripting examples, refer to the Tcl API Help Browser and the *Quartus II Scripting Reference Manual*.

Programming the Device Using the In-System Memory Content Editor

If you make changes to your design, you can program the device from within the In-System Memory Content Editor. To program the device, follow these steps:

1. On the Tools menu, click **In-System Memory Content Editor.**
2. In the **JTAG Chain Configuration** panel of the In-System Memory Content Editor, select the SRAM object file (**.sof**) that includes the modifiable memories and constants.

3. Click **Scan Chain**.
4. In the **Device** list, select the device you want to program.
5. Click **Program Device**.

Example: Using the In-System Memory Content Editor with the SignalTap II Embedded Logic Analyzer

The following scenario describes how you can use the In-System Updating of Memory and Constants feature with the SignalTap II Embedded Logic Analyzer to efficiently debug your design in-system. Although both the In-System Content Editor and the SignalTap II Embedded Logic Analyzer use the JTAG communication interface, you are able to use them simultaneously.

After completing your FPGA design, you find that the characteristics of your FIR filter design are not as expected.

1. To locate the source of the problem, change all your FIR filter coefficients to be in-system modifiable and instantiate the SignalTap II Embedded Logic Analyzer.
2. Using the SignalTap II Embedded Logic Analyzer to tap and trigger on internal design nodes, you find the FIR filter to be functioning outside of the expected cut-off frequency.
3. Using the **In-System Memory Content Editor**, you check the correctness of the FIR filter coefficients. Upon reading each coefficient, you discover that one of the coefficients is incorrect.
4. Because your coefficients are in-system modifiable, you update the coefficients with the correct data using the **In-System Memory Content Editor**.

In this scenario, you are able to quickly locate the source of the problem using both the In-System Memory Content Editor and the SignalTap II Embedded Logic Analyzer. You are also able to verify the functionality of your device by changing the coefficient values before modifying the design source files.

An extension to this example would be to modify the coefficients with the In-System Memory Content Editor to vary the characteristics of the FIR filter (for example, filter attenuation, transition bandwidth, cut-off frequency, and windowing function).

Conclusion

The In-System Updating of Memory and Constants feature provides access into a device for efficient debug in a hardware lab. You can use In-System Updating of Memory and Constants with the SignalTap II Embedded Logic Analyzer to maximize the visibility into an Altera FPGA. By increasing visibility and access to internal logic of the device, you can identify and resolve problems with your design more easily.

Document Revision History

Table 16–3 shows the revision history of this chapter.

Table 16–3. Document Revision History

Date and Version	Changes Made	Summary of Changes
March 2009 v9.0.0	No change to content.	Updated for the Quartus II software version 9.0 release.
November 2008 v8.1.0	Changed to 8-1/2 x 11 page size. No change to content.	Updated for the Quartus II software version 8.1 release.
May 2008 v8.0.0	■ Added reference to Section V. In-System Debugging in volume 3 of the Quartus II Handbook on page 16-1. ■ Removed references to the Mercury device, as it is now considered to be a “Mature” device ■ Added links to referenced documents throughout document ■ Minor editorial updates	Updated for the Quartus II software version 8.0 release.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

17. Design Debugging Using In-System Sources and Probes

QII53021-9.0.0

Introduction

Traditional debugging techniques often involve using an external pattern generator to exercise the logic and a logic analyzer to study the output waveforms during run-time. The SignalTap® II Logic Analyzer and SignalProbe allow you to read or "tap" internal logic signals during run-time as a way to debug your logic on-chip. While this is useful, you can enhance the debugging cycle efficiency with the ability to drive any internal signal manually within your design. By doing this you can perform the following activities:

- Force the occurrence of trigger conditions setup in the SignalTap II Logic Analyzer
- Create simple test vectors to exercise your design without using external test equipment
- Dynamically control run-time control signals with the JTAG chain

With the introduction of the In-System Sources and Probes feature in the Quartus® II software beginning with version 7.1, Altera extends the portfolio of verification tools. The In-System Sources and Probes feature allows you to easily control any internal signal, providing you with a completely dynamic debugging environment. Coupled with either the SignalTap II Logic Analyzer or SignalProbe, the In-System Sources and Probes feature gives you a powerful debugging environment in which to generate stimuli and solicit responses from your logic design.

The Virtual JTAG Megafunction and the In-System Memory Content Editor also give you the capability to drive virtual inputs into your design. The Quartus II software offers a portfolio of on-chip debugging tools. For an overview and comparison of all the tools available in the Quartus II software on-chip debugging tool suite, refer to *Section V. In-System Debugging* in volume 3 of the *Quartus II Handbook*.

This chapter addresses the following topics:

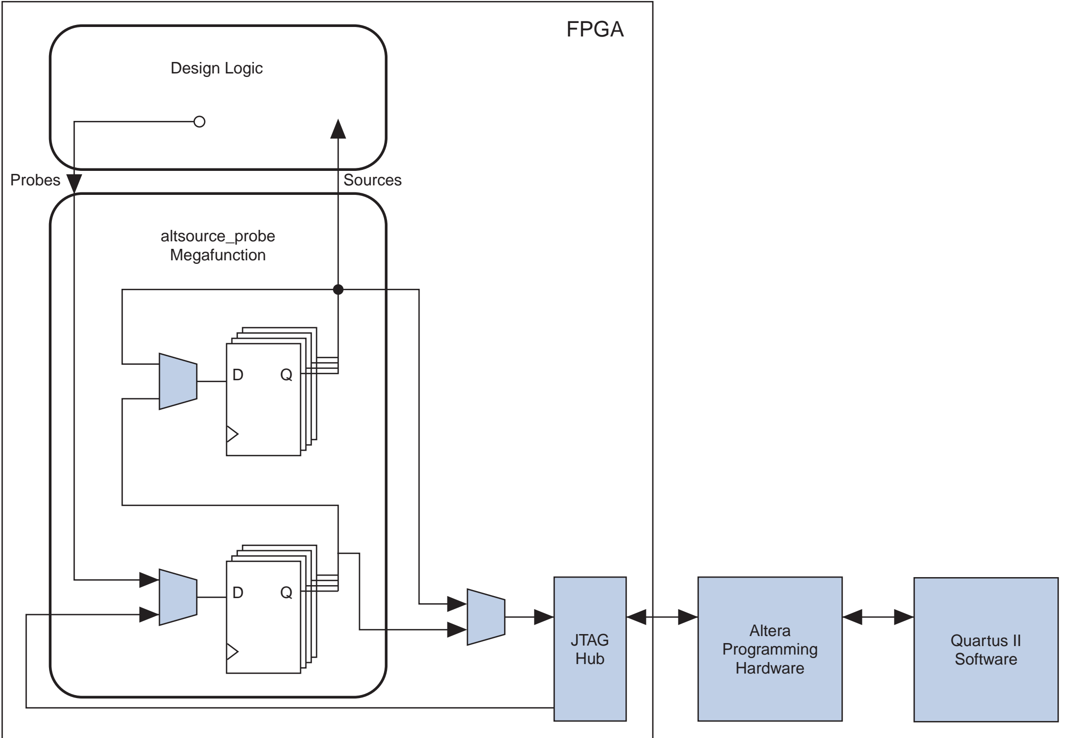
- "Design Flow Using In-System Sources and Probes" on page 17–3
- "Running the In-System Sources and Probes Editor" on page 17–7
- "Tcl Support" on page 17–11
- "Design Example: Dynamic PLL Reconfiguration" on page 17–14

Overview

The In-System Sources and Probes feature consists of the altsource_probe megafunction and an interface to control the altsource_probe megafunction instances during run-time. Each altsource_probe megafunction instance provides you with source output ports and probe input ports, where source ports drive selected signals and probe ports sample selected signals. Upon compilation, the altsource_probe

megafunction sets up a register chain to either drive or sample the selected nodes in your logic design. During runtime, the In-System Sources and Probes interface uses a JTAG connection to shift data to and from the altsource_probe megafunction instances. Figure 17–1 shows a block diagram of the components that make up the In-System Sources and Probes feature.

Figure 17–1. In-System Sources and Probes Block Diagram



The altsource_probe megafunction hides the detailed transactions between the JTAG Hub and the registers instrumented in your design to give you a basic building block for stimulating and probing your design. Moreover, the In-System Sources and Probes feature provides single-cycle samples and single-cycle writes to the selected logic nodes. This provides an easy way to input simple virtual stimuli and an easy way to capture the current value on instrumented nodes. Because In-System Sources and Probes gives you access to logic nodes within your design, this feature can be used during the debugging process to toggle the inputs of low-level components. If used in conjunction with the SignalTap II Logic Analyzer, you can force trigger conditions to help isolate your problem and shorten your debugging process.

Additionally, the ease of use of the In-System Sources and Probes feature makes it ideal for implementing control signals as virtual stimuli. This feature can be especially helpful for prototyping your design. Examples of such applications could include the ability to do the following:

- Create virtual push buttons
- Create a virtual front panel to interface with your design
- Mimic external sensor data
- Monitor and change run-time constants on the fly

In-System Sources and Probes supports Tcl commands to interface with all your altsource_probe instances to increase the level of automation.

Hardware and Software Requirements

The following components are required to use In-System Sources and Probes:

- Quartus II design software

or

- Quartus II Web Edition (with TalkBack feature enabled)
- Download Cable (USB-Blaster™ download cable or ByteBlaster™ cable)
- Altera® development kit or user design board with JTAG connection to device under test

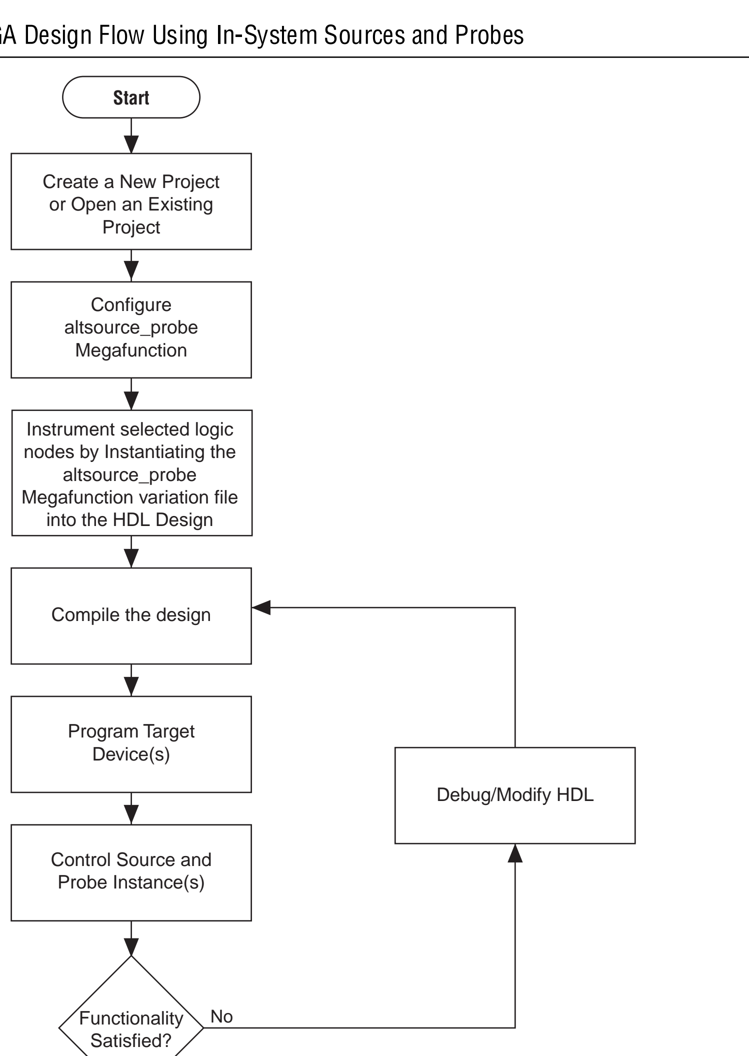
The In-System Sources and Probes feature supports the following device families:

- Arria® GX
- Stratix® series
- HardCopy® II
- HardCopy Stratix
- Cyclone® series
- MAX® II
- APEX™ II
- APEX 20KE
- APEX 20KC
- APEX 20K

Design Flow Using In-System Sources and Probes

In-System Sources and Probes supports an RTL flow in which your design nodes are instrumented in your HDL code via instantiation of the altsource_probe megafunction. After your device is compiled with the design nodes that you want instrumented, you can control your altsource_probe instances via the Sources and Probes Editor GUI or via a Tcl interface. The complete design flow is shown in Figure 17–2.

Figure 17–2. FPGA Design Flow Using In-System Sources and Probes



Configuring the altsource_probe Megafunction

To add in-system sources and probes functionality to your design, you must first instantiate the altsource_probe megafunction variation file. The altsource_probe megafunction can be easily configured using the MegaWizard™ Plug-In Manager. Each source or probe port can be up to 256 bits wide. You can have up to 128 instances of the altsource_probe megafunction in your design. The following steps will guide you through the steps necessary to configure the altsource_probe megafunction:

1. On the Tools menu, click **MegaWizard Plug-In Manager**.
2. Select **Create a new custom megafunction variation**.
3. Click **Next**.

4. On Page 2a, make the following selections:
   a. In the Installed Plug-Ins list, expand the JTAG-accessible Extensions folder. In the JTAG-accessible Extensions list, select **In-System Sources and Probes**.
   b. Make sure that the currently selected device family matches the device you are targeting.
   c. Select an output file type and enter the desired name of the altsource_probe megafunction. You can choose AHDL (**.tdf**), VHDL (**.vhd**), or Verilog HDL (**.v**) as the output file type.
5. Click **Next**.
6. On Page 3, make the following selections:
   a. Make sure that the currently selected device family matches the device that you are targeting.
   b. Under **Do you want to specify an Instance Index?**, turn on **Yes**.
   c. Specify the Instance ID of this instance.
   d. Specify the width of the probe port. The width can be from 1 bit to 256 bits wide.
   e. Specify the width of the source port. The width can be from 1 bit to 256 bits wide.
7. On Page 3, you can click **Advanced Options** and specify other parameters. The following options are included:
   - **What is the initial value of the source port, in hexadecimal?** This option allows you to specify the initial value driven on the source port at run-time.
   - **Write data to the source port synchronously to the source clock.** This allows you to synchronize your source port write transactions with the clock domain of your choice.
   - **Create an enable signal for the registered source port.** When enabled, this creates a clock enable input for the synchronization registers. This option is enabled only when the **Write data to the source port synchronously to the source clock** option is enabled.

Table 17–1 summarizes the configurable fields for the altsource_probe megafunction.

The In-System Sources and Probes feature does not support simulation. The megafunction instantiation must be removed before creating a simulation netlist.

Table 17–1. MegaWizard Plug-In Manager —altsource_probe (page 3) Options (Part 1 of 2)

Options	Description
Currently selected device family	Specifies the device family.
Do you want to specify an Instance Index?	Specifies the numeric index of the megafunction instance during run-time (from 0 to 127).
The 'Instance ID' of this Instance (optional):	Specifies the four character ID tag of the megafunction in the instance manager window of the Sources and Probes Editor.

Table 17–1. MegaWizard Plug-In Manager —altsource_probe (page 3) Options (Part 2 of 2)

Options	Description
How wide should the probe port be?	Specifies the number of signals to be read by In-System Sources and Probes.
How wide should the source port be?	Specifies the number of signals to be driven by In-System Sources and Probes.
What is the initial value of the source port? (under **Advanced Options**)	Specifies the initial value driven on the source port at run time.
Write data to the source port synchronously to the source clock. Each bit in the source port will utilize two additional registers to achieve metastability (under **Advanced Options**)	When turned on, allows you to synchronize your source port write transactions with the clock domain of your choice.
Create an enable signal for the registered source port (configured under **Advanced Options**)	Turning on this option creates a clock enable input for the synchronization registers.

Instantiating the altsource_probe Megafunction

The MegaWizard Plug-in Manager produces the necessary variation file and the instantiation template based on your inputs to the MegaWizard. Use the template to instantiate the ALTSOURCE_PROBE megafunction variation file in your design. The port information is shown in Table 17–2.

Table 17–2. altsource_probe Megafunction Port Information

Port Name	Required?	Direction	Comments
`probe[]`	No	Input	The outputs from the user's design.
`source_clk`	No	Input	Source Data is written synchronously to this clock. This input is required if the Source Clock option is turned on in the Advanced Options box in the MegaWizard Plug-in Manager.
`source_ena`	No	Input	Clock enable signal for `source_clk`. This input is required if specified in the Advanced Options box in the MegaWizard Plug-in Manager.
`source[]`	No	Output	Used to drive inputs to user design.

You can include up to 128 instances of the altsource_probe megafunction in your design, provided that there are available logic resources in your device. Each instance of the altsource_probe megafunction uses a pair of registers per signal for the width of the widest port it contains. Additionally, there will be some fixed overhead logic to accommodate communication between the altsource_probe instances and the JTAG controller. An additional pair of registers per source port is added for synchronization if it is specified.

Compiling the Design

When you compile your design with the In-System Sources and Probes megafunction instantiated, an instance of the altsource_probe instance and sld_hub megafunctions are added to your compilation hierarchy automatically. These two instances allow communication between the JTAG controller and your instrumented logic.

To modify your In-System Sources and Probes connections, you can modify the number of connections to your design by editing the altsource_probe megafunction. To open the design instance you want to modify in the MegaWizard Plug-In Manager, double-click the desired instance in the Project Navigator. You can then modify the connections in the HDL source file. You must recompile your design when you are finished editing it.

Because the design cycle is iterative in nature, you can use the Quartus II incremental compilation feature to reduce compilation time. Incremental compilation allows you to organize your design into logical partitions. During recompilation of a design, incremental compilation preserves the compilation results and performance of unchanged partitions and reduces design iteration time by compiling only modified design partitions.

For more information about Incremental Compilation, refer to the *Quartus II Incremental Compilation for Hierarchical & Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

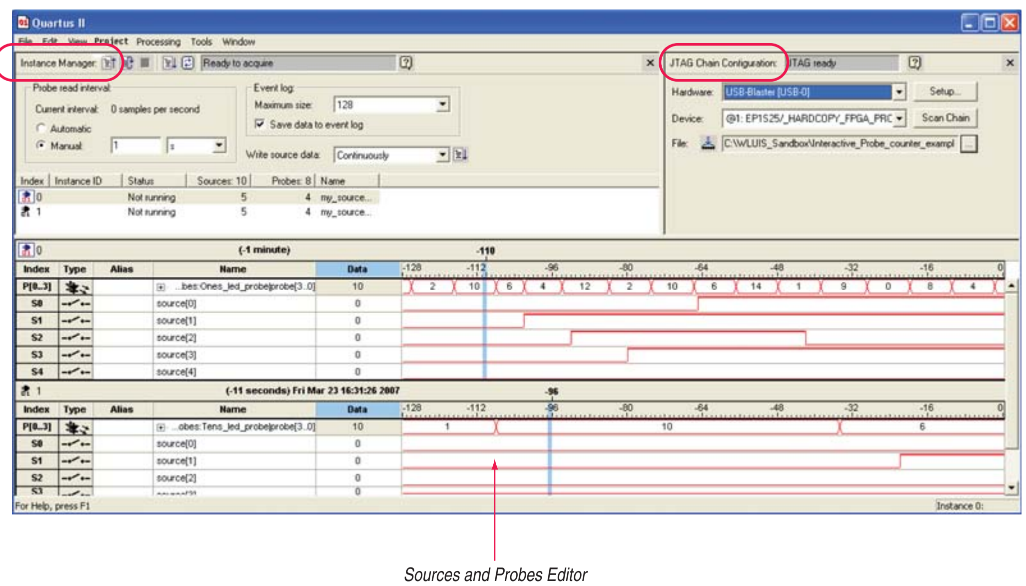
Running the In-System Sources and Probes Editor

The In-System Sources and Probes Editor is a GUI that gives you control over all of the altsource_probe megafunction instances within your design. It displays all available run-time controllable instances of the altsource_probe megafunction in your design, provides a push-button interface to drive all of your source nodes, and a logging feature to store your probe and source data.

To run the In-System Sources and Probes Editor, from the **Tools** menu, click **In-System Sources and Probes Editor.**

Figure 17–3 shows the Editor window.

Figure 17–3. In-System Sources and Probes Editor



The In-System Sources and Probes Editor is made up of three panes:

- **JTAG Chain Configuration**—Allows you to specify programming hardware, device, and file settings that the In-System Sources and Probes Editor uses to program and acquire data from a device.
- **Instance Manager**—Displays information about the instances generated when you compile a design, and allows you to control the data the In-System Sources and Probes Editor acquires.
- **Sources and Probes Editor**—Logs all the data read from the selected instance and allows you to modify source data to be written to your device.

Using the In-System Sources and Probes Editor does not require you to open a Quartus II project. The In-System Sources and Probes Editor retrieves all instances of the altsource_probe megafunction by scanning the JTAG chain and sending a query to the specific device selected in the JTAG Chain Configuration pane. Also, you can use a previously saved configuration to run the In-System Sources and Probes Editor.

Each In-System Sources and Probes Editor window can access the altsource_probe megafunction instances in a single device. If you have more than one device containing megafunction instances in a JTAG chain, you can launch multiple In-System Sources and Probes Editor windows to access the megafunction instances in each of the devices.

Programming Your Device Using the JTAG Chain Configuration Window

After compilation is complete, you must configure your FPGA before using In-System Sources and Probes. To configure a device for use with the In-System Sources and Probes, perform the following steps:

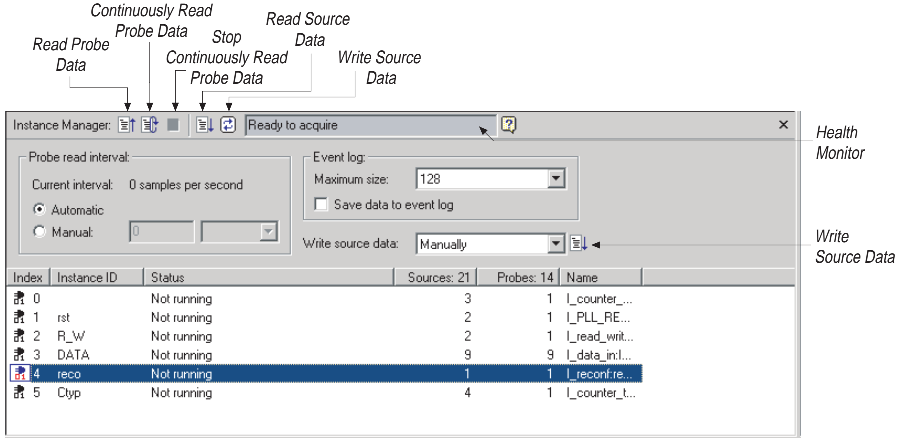
1. Open the In-System Sources and Probes Editor.
2. Under JTAG Chain Configuration, point to **Hardware** and select the desired hardware communications device. You may be prompted to configure your hardware; in this case, click **Setup**.
3. From the **Device** list, select the FPGA device to which you want to download the design (it may be automatically detected). You may have to click **Scan Chain** to detect your target device.
4. In the JTAG Configuration window, click **Browse** and select the SRAM Object File (**.sof**) that includes the In-System Sources and Probes instance or instances. (Note that it may be automatically detected).
5. Click **Program Device** (next to **File:**) to program the target device.

Instance Manager

The Instance Manager provides a list of all altsource_probe instances in the design and allows you to configure how data is acquired from or written to those instances.

The Instance Manager is shown in Figure 17–4.

Figure 17–4. Instance Manager



The following buttons and sub-panes are provided in the Instance Manager:

- **Read Probe Data**—Samples the probe data in the selected instance and displays it in the Sources and Probes Editor Window
- **Continuously Read Probe Data**—Continuously samples the probe data of the selected instance and displays it in the Sources and Probes Editor Window; you can modify the sample rate via the Probe read interval setting
- **Stop Continuously Reading Probe Data**—Cancels continuous sampling of probe of selected instance
- **Write Source Data** sub-pane —Writes data to all source nodes of the selected instance
- **Probe Read Interval** sub-pane—Displays the sample interval of all the In-system Sources and Probe instances in your design; you can modify the sample interval by clicking **Manual**
- **Event Log** sub-pane—controls the event log in the Sources and Probes Editor Window
- **Write Source Data** sub-pane—Allows you to manually or continuously write data to the system

The status of each instance is also displayed beside each entry in the Instance Manager. The status indicates if the instance is **Not running Offloading data**, **Updating data**, or if an **Unexpected JTAG communication error** occurs. This status indicator provides useful information about the sources and probes instances in your design.

Sources and Probes Editor Window

The Sources and Probes Editor window organizes and displays the data from all sources and probes in your design, organized according to the index number of the instance. The editor provides an easy way to manage your signals, allowing you to rename signals or to group them into buses. All data collected from source and probe nodes is recorded in the event log and displayed as a timing diagram.

Reading Probe Data

You can read data by selecting the desired altsource_probe instance in the Instance Manager and clicking **Read Probe Data**. This produces a single sample of the probe data and updates the data column of the selected index in the Sources and Probes Editor window. You can save the data to an event log by turning on the **Save data to event log** option in the Instance Manager.

If you want to sample data from your probe instance continuously, in the Instance Manager, click the instance you want to read, and then click **Continuously read probe data**. While reading, the status of the active instance will show **Unloading**. You can read continuously from multiple instances.

You can access read data by using the right-click menus in the Instance Manager.

To adjust the probe read interval, in the Instance Manager, turn on the **Manual** option in the **Probe read interval** sub-pane, and specify the desired sample rate in the text field next to the **Manual** option. The maximum sample rate depends on your computer setup. The actual sample rate is shown in the **Current interval** box. The event log window buffer size can be adjusted in the **Maximum Size** box.

Writing Data

To modify the source data to be written into the altsource_probe instance, click in the name field of the signal you want to change. For buses of signals, you can double-click on the data field and type in the value to be driven out to the altsource_probe instance. The In-System Sources and Probes Editor stores the modified source data values in a temporary buffer. Modified values that have not been written out to the altsource_probe instances appear in red. To update the altsource_probe instance, highlight the instance in the Instance Manager and click **Write source data**. The **Write source data** function is also available via the shortcut menus in the Instance Manager.

You can choose to have the values stored in the In-System Sources and Probes Editor continuously update the altsource_probe instances. By doing so, any modifications you make to the source data buffer are written immediately to the altsource_probe instances. To continuously update the altsource_probe instances, change the **Write source data** field from **Manually** to **Continuously**.

Data Organization

The main editor window allows you to group signals into buses, and allows you to modify the display options of the data buffer.

To create a group of signals, select the node names you want to group, right-click and select **Group**. You can modify the display format in the Bus Display Format and the Bus Bit order submenus.

The Sources and Probes Editor Window allows you to rename any signal. To rename a signal, double-click the name of the desired signal and type in the new name.

The event log contains a record of the most recent samples. The buffer size is adjustable, up to 128k samples. The time stamp for each sample is logged and is displayed above the event log of the instance being examined as you move your mouse pointer over the data samples.

You can save the changes that you have made and the recorded data into a Sources and Probes File (**.spf**). To save changes, on the File menu, click **Save**. The file contains all of the modifications you made to the signal groups, as well as the current data event log.

Tcl Support

To support automation, In-system Sources and Probes supports the procedures described in this chapter in the form of Tcl commands. The Tcl package for In-System Sources and Probes is included by default when you run **quartus_stp**.

The Tcl interface for In-System Sources and Probes provides a powerful platform to help you debug your design. It is especially helpful for debugging designs that require toggling multiple sets of control inputs. You can aggregate multiple commands using a Tcl script to define your own custom command set.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. For more information about settings and constraints in the Quartus II software, refer to the *Quartus II Settings File Reference Manual*. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Table 17–3 shows the Tcl commands you can use with In-System Sources and Probes.

Table 17–3. In-System Sources and Probes Tcl Commands (Part 1 of 2)

Command	Argument	Description
start_insystem_source_probe	-device_name *<device name>* -hardware_name *<hardware name>*	Opens a handle to a device using the specified hardware. Call this command before starting any transactions.
get_insystem_source_probe_instance_info	-device_name *<device name>* -hardware_name *<hardware name>*	Returns a list of all altsource_probe instances in your design. Each record returned will be in the following format: {*<instance Index>*, *<source width>*, *<probe width>*, *<instance name>*}
read_probe_data	-instance_index *<instance_index>* -value_in_hex *(optional)*	Retrieves the current value of the probe. A string is returned specifying the status of each probe, with the MSB as the left-most bit.
read_source_data	-instance_index *<instance_index>* -value_in_hex *(optional)*	Retrieves the current value of the sources. A string is returned specifying the status of each source, with the MSB as the left-most bit.

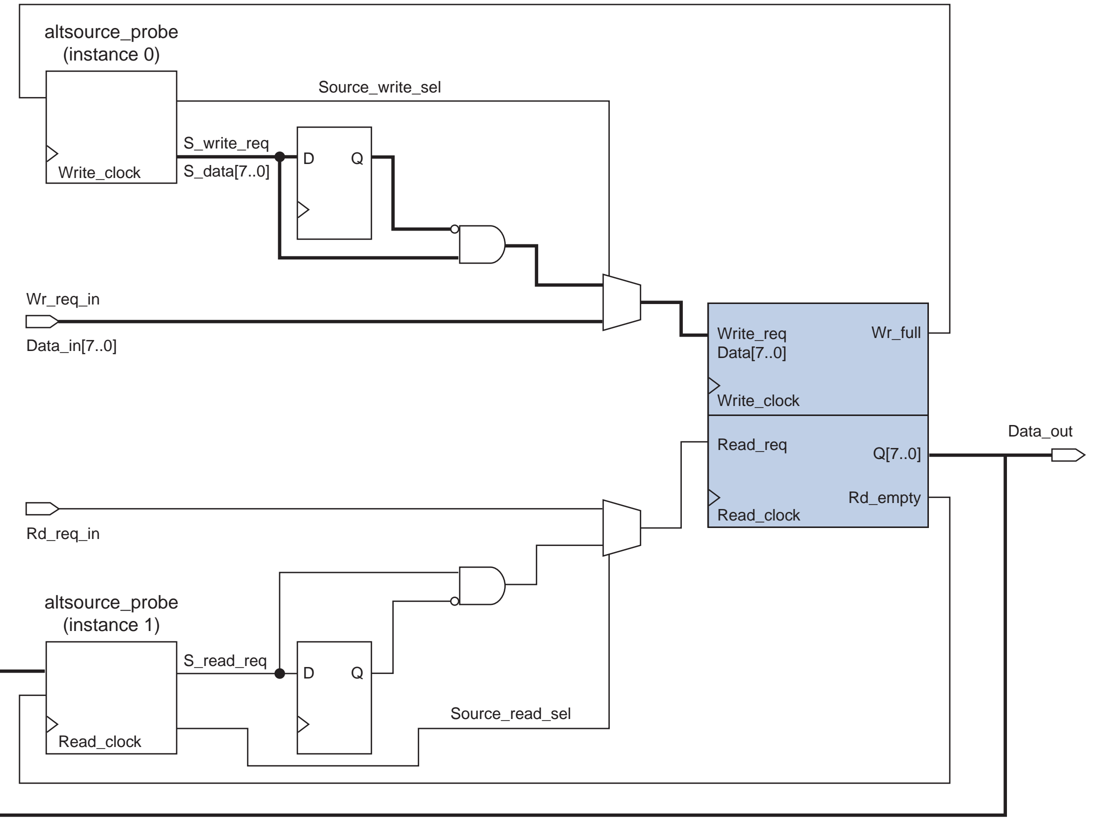
Table 17–3. In-System Sources and Probes Tcl Commands (Part 2 of 2)

Command	Argument	Description
write_source_data	`-instance_index` *`<instance_indx>`* `-value` *`<value>`* `-value_in_hex` *(optional)*	Sets the value of the sources. A binary string is sent to the source ports, with the MSB as the left-most bit.
end_interactive_probe	None	Releases the JTAG chain. Issue this command when all transactions are finished.

Example 17–1 shows an excerpt from a Tcl script with procedures that control the altsource_probe instances of the design as shown in Figure 17–5. The example design contains a DCFIFO with altsource_probe instances to read from and write to the DCFIFO. A set of control muxes are added into the design to control the flow of data to the DCFIFO between the input pins and the altsource_probe instances. A pulse generator is added to the read request and write request control lines to guarantee a single sample read or write. The altsource_probe instances, when used with the script in Example 17–1, provide visibility into the contents of the FIFO by performing single sample write and read operations and reporting the state of the full and empty status flags.

The Tcl script can be useful in debugging situations where you may want to either empty or preload the FIFO in your design. For example, you can use this feature to preload the FIFO to match a trigger condition you have set up within the SignalTap II Logic Analyzer.

Figure 17–5. A DCFIFO Example Design Controlled by the Tcl Script in Example 17–1



Example 17–1. Tcl Script Procedures for Reading and Writing to the DCFIFO in Figure 17–5 (Part 1 of 2)

```
## Setup USB hardware  - assumes only USB Blaster is installed and
## an FPGA is the only device in the JTAG chain

set usb [lindex [get_hardware_names] 0]
set device_name [lindex [get_device_names -hardware_name $usb] 0]
## write procedure :  argument value is integer

proc write {value} {

    global device_name usb
    variable full

    start_insystem_source_probe -device_name $device_name -hardware_name $usb

    #read full flag
    set full [read_probe_data -instance_index 0]

    if {$full == 1} {end_insystem_source_probe
    return "Write Buffer Full"
    }
```

Example 17–1. Tcl Script Procedures for Reading and Writing to the DCFIFO in Figure 17–5 (Part 2 of 2)

```
    ##toggle select line, drive value onto port, toggle enable
    ##bits 7:0 of instance 0 is S_data[7:0]; bit 8 = S_write_req;
    ##bit 9 = Source_write_sel

    ##int2bits is custom procedure that returns a bitstring from an integer
    ## argument

    write_source_data -instance_index 0 -value /[int2bits [expr 0x200 | $value]]
    write_source_data -instance_index 0 -value [int2bits [expr 0x300 | $value]]

    ##clear transaction

    write_source_data -instance_index 0 -value 0

    end_insystem_source_probe
}

proc read {} {

    global device_name usb
    variable empty
    start_insystem_source_probe -device_name $device_name -hardware_name $usb

    ##read empty flag : probe port[7:0] reads FIFO output; bit 8 reads empty_flag

    set empty [read_probe_data -instance_index 1]

    if {[regexp {1........} $empty]} { end_insystem_source_probe
    return "FIFO empty" }

    ## toggle select line for read transaction
    ## Source_read_sel = bit 0; s_read_reg = bit 1

    ## pulse read enable on DC FIFO
    write_source_data -instance_index 1 -value 0x1 -value_in_hex
    write_source_data -instance_index 1 -value 0x3 -value_in_hex

    set x [read_probe_data -instance_index 1 ]

    end_insystem_source_probe

    return $x
}
```

Design Example: Dynamic PLL Reconfiguration

The ease of use of the In-System Sources and Probes feature can be extremely helpful in creating a virtual front panel during the prototyping phase of your design. Relatively simple designs of high functionality can be created in a short amount of time. The following PLL reconfiguration example demonstrates how the In-System Sources and Probes feature is used to provide a GUI to dynamically reconfigure a Stratix PLL.

Stratix PLLs allows you to dynamically update PLL coefficients during run-time. Each enhanced PLL within the Stratix device contains a register chain that allows you to modify the pre-scale counters (*m* and *n* values), output divide counters, and delay counters. In addition, the altpll_reconfig megafunction provides an easy interface to access the register chain counters. The altpll_reconfig megafunction provides a cache containing all modifiable PLL parameters. After you have updated all of the PLL parameters in the cache, the alt_pll_reconfig megafunction drives the PLL register chain to update the PLL with the updated parameters. Figure 17–6 shows a Stratix-enhanced PLL with reconfigurable coefficients.

Stratix II and Stratix III devices also allow you to dynamically reconfigure PLL parameters. For more information about these families, refer to the appropriate data sheet. For more information about dynamic PLL reconfiguration, refer to *AN 282: Implementing PLL Reconfiguration in Stratix & Stratix GX Devices* or *AN 367: Implementing PLL Reconfiguration in Stratix II Devices*.

Figure 17–6. Stratix-Enhanced PLL with Reconfigurable Coefficients

The following design example uses an altsource_probe instance to update the PLL parameters in the altpll_reconfig megafunction cache. The altpll_reconfig megafunction connects to an enhanced PLL in a Stratix FPGA to drive the register chain containing the PLL reconfigurable coefficients. This design example uses a Tcl/Tk script to generate a GUI where you can enter in new *m* and *n* values for the enhanced PLL. The Tcl script extracts the m and n values from the GUI, shifts the

values out to the altsource_probe instances to update the values in the altpll_reconfig megafunction cache and asserts the reconfig signal on the altpll_reconfig megafunction. The reconfig signal on the altpll_reconfig megafunction starts the register chain transaction to update all PLL reconfigurable coefficients. A block diagram of a design example is shown in Figure 17–7. The Tk GUI is shown in Figure 17–8.

Figure 17–7. Block Diagram of Dynamic PLL Reconfiguration Design Example

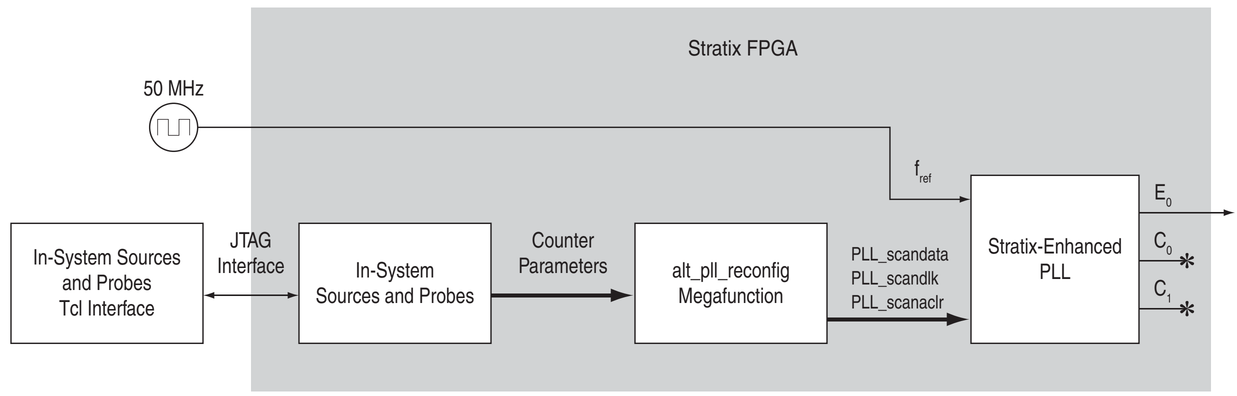


Figure 17–8. Interactive PLL Reconfiguration GUI Created with Tk and In-System Sources and Probes Tcl Package

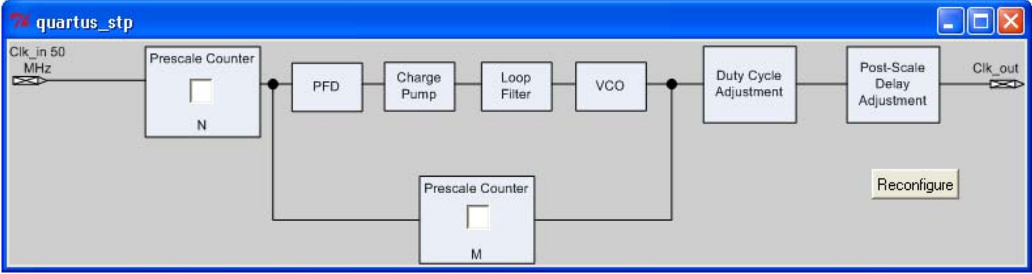

This design example was created using a Nios® II Development Kit, Stratix Edition. The file **sourceprobe_DE_dynamic_pll.zip** contains all of the necessary files for running this design example:

- **Readme.txt**—A text file that describes the files contained in the Design Example and provides instructions on running the Tk GUI shown in Figure 17–8.
- **Interactive_Reconfig.qar**—The archived Quartus II project for this Design Example

You can download the **sourceprobe_DE_dynamic_pll.zip** file associated with this chapter.

Conclusion

In-System Sources and Probes can provide stimuli and get responses from the target design during run-time. With its simple and intuitive interface, you can provide virtual inputs into your design during run-time without using external equipment. When used in conjunction with SignalTap II, you can use In-System Sources and Probes to provide greater control of the signals in your design, and thus help shorten the verification cycle. Also, with its ability to create virtual inputs into your design, you can create simple, yet powerful applications to interact with your design.

Table 17–4. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	No change to content.	—
November 2008 v8.1.0	Changed to 8-1/2 x 11 page size. No change to content.	Updated for the Quartus II software version 8.1 release.
May 2008 v8.0.0	■ Documented that this feature does not support simulation on page 17–5 ■ Updated Figure 17–8 for Interactive PLL reconfiguration manager ■ Added hyperlinks to referenced documents throughout the chapter ■ Minor editorial updates	Updated for the Quartus II software version 8.0 release.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

Section V. Formal Verification

The Quartus® II software easily interfaces with EDA formal design verification tools such as the Cadence Encounter Conformal and Synopsys Synplify software. In addition, the Quartus II software has built-in support for verifying the logical equivalence between the synthesized netlist from Synopsys Synplify and the post-fit Verilog Quartus Mapped (**.vqm**) files using Cadence Encounter Conformal software.

This section discusses formal verification, how to set-up the Quartus II software to generate the **.vqm** file and Cadence Encounter Conformal script, and how to compare designs using Cadence Encounter Conformal software.

This section includes the following chapter:

- Chapter 18, Cadence Encounter Conformal Support

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

18. Cadence Encounter Conformal Support

QII53011-9.0.0

Introduction

The Quartus® II software provides formal verification support for Altera® designs through interfaces with a formal verification EDA tool, the Cadence Encounter Conformal software.

Use the Encounter Conformal software to verify the functional equivalence of a post-synthesis Verilog Quartus Mapping (**.vqm**) netlist file from Synopsys Synplify Pro software, a post-fit Verilog Output File (**.vo**) from the Quartus II software, or both. You can also use the Encounter Conformal software to verify the functional equivalence of the register transfer level (RTL) source code and post-fit **.vo** file with the Quartus II software when using Quartus II integrated synthesis. These formal verification flows support designs for the Arria® GX, Stratix® IV, Stratix III, Stratix II, Stratix, Stratix II GX, Stratix GX, Cyclone® III, Cyclone II, Cyclone, and HardCopy® II device families.

The two types of formal verification are equivalence checking and model checking. This chapter discusses equivalence checking with the Cadence Encounter Conformal software.

This chapter contains the following sections:

- "Formal Verification Design Flow" on page 18–2
- "RTL Coding Guidelines for Quartus II Integrated Synthesis" on page 18–4
- "Black Boxes in the Encounter Conformal Flow" on page 18–8
- "Generating the Post-Fit Netlist Output File and the Encounter Conformal Setup Files" on page 18–10
- "Understanding the Formal Verification Scripts for Encounter Conformal" on page 18–15
- "Comparing Designs Using Encounter Conformal" on page 18–17
- "Known Issues and Limitations" on page 18–19
- "Black Box Models" on page 18–21
- "Conformal Dofile/Script Example" on page 18–23

Equivalence checking uses mathematical techniques to compare the logical equivalence of two versions of the same design rather than using test vectors to perform simulation. The two compared versions could be post-map design and post-fit design, or RTL design and post-fit design. Equivalence checking greatly shortens the verification cycle of the design.

Formal Verification Versus Simulation

Formal verification cannot be considered as a replacement to the vector-based simulation. Formal verification only complements the existing vector-based simulation techniques to speed up the verification cycle. Vector-based simulation techniques of gate level designs can take a considerable amount of time.

You can use Vector-based simulation techniques to perform the following functions:

- Verify design functionality
- Verify timing specifications
- Debug designs

Formal Verification: What You Need to Know

If you use formal verification techniques to verify logic equivalence of your design, you can save time by forgoing a comprehensive vector-based simulation of the gate level design. However, there might be an impact on area and performance during recompilation of your design with the Quartus II software if you choose to use formal verification flow for Cadence Conformal LEC software. The area and performance of your design might be affected by the following factors:

- Hierarchy preservation
- ROM implementation by logic elements (LEs)
- Disabled retiming is disabled

Refer to "Known Issues and Limitations" on page 18–19 before you consider using the formal verification flow in your design methodology.

Formal Verification Design Flow

Altera supports formal verification using the Encounter Conformal software for the following two synthesis tools:

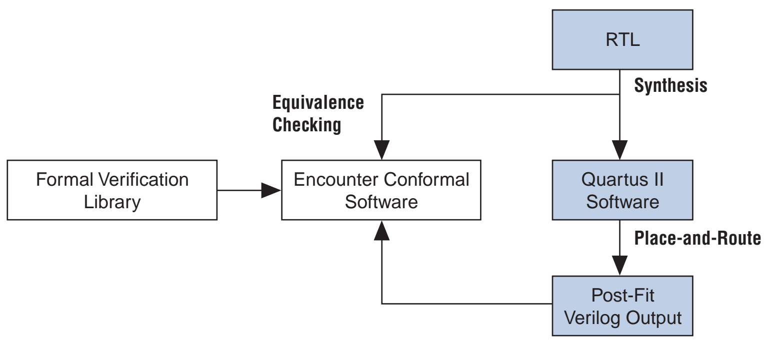
- "Quartus II Integrated Synthesis"
- "Synplify Pro" on page 18–3

The following sections describe the supported design flows for these synthesis tools.

Quartus II Integrated Synthesis

The design flow for formal verification using the Quartus II integrated synthesis is shown in Figure 18–1. This flow performs equivalency checking for the RTL source code and the post-fit netlist generated by the Quartus II software. The RTL source code can be in Verilog HDL or VHDL format. The post-fit netlist generated by the Quartus II software is always in Verilog HDL format.

Figure 18–1. Formal Verification Using Quartus II Integrated Synthesis and the Encounter Conformal Software



EDA Tool Support for Quartus II Integrated Synthesis

The formal verification flow using the Quartus II software and Cadence Encounter Conformal software supports the following software versions and operating systems:

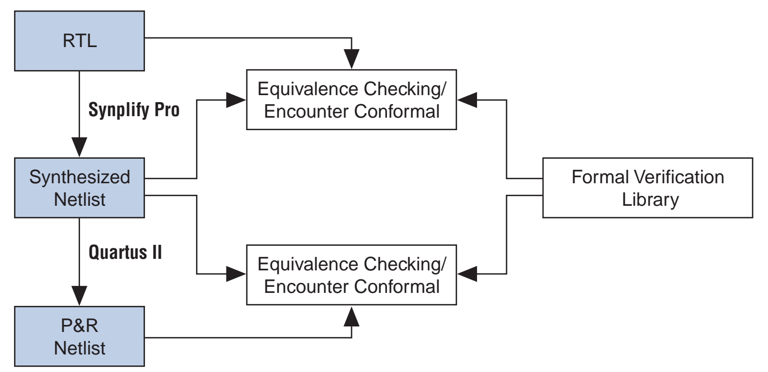
- Quartus II software beginning with version 4.2
- Cadence Encounter Conformal software beginning with 4.3.5A
- Solaris and Linux operating systems

Synplify Pro

The design flow for formal verification using Synplify Pro Synthesis performs equivalency checking for the post-synthesis netlist from Synplify Pro and the post fit netlist generated by Quartus II software, as shown in Figure 18–2.

For additional information about performing equivalency checking between RTL and post-synthesis netlist generated from Synplify Pro software, refer to the Synplify Pro documentation.

Figure 18–2. Formal Verification Flow Using Synplify Pro and the Encounter Conformal Software



EDA Tool Support for Synplify Pro

The formal verification flow using the Quartus II software, the Synopsys Synplify Pro, and the Cadence Encounter Conformal software supports the software versions and operating systems shown in Table 18–1.

Table 18–1. Compatible Software Versions

Quartus II Software Version	Cadence Conformal LEC Version	Synplify Pro Version
4.1	4.3.0.a	7.6.1
4.2	4.3.5.a	8.0
5.0	5.1	8.1
5.1	5.1	8.4
6.0	5.2	8.5
6.1	6.1	8.6.2
7.0	6.1	8.6.2
7.1	6.2	8.8.1
7.2	7.1	9.0
8.0	7.1	9.4
8.1	7.2	9.6.2
9.0	7.2	C2009.03

RTL Coding Guidelines for Quartus II Integrated Synthesis

The Cadence Encounter Conformal software can compare the RTL code against the post-fit netlist generated by the Quartus II software. The Encounter Conformal software and the Quartus II integrated synthesis parse and compile the RTL description in slightly different ways. The Quartus II software supports some RTL features that the Encounter Conformal software does not support and vice versa. The style of the RTL code is of particular concern because neither tool supports some constructs, leading to potential formal verification mismatches; for example, state machine extraction, wherein different encoding mechanisms can result in different structures. Therefore, for successful verification, both tools must interpret the RTL code in the same manner.

The following section provides information about recognizing and preventing problems that can arise in the formal verification flow.

For more details about RTL coding styles for Quartus II integrated synthesis, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

Some of the coding guidelines apply to both the Quartus II integrated synthesis and Synplify Pro flow, as indicated in each of the guidelines in the following sections.

Synthesis Directives and Attributes

Synthesis directives, also known as pragmas, play an important role in successful verification of RTL against the post-fit **.vo** netlist file from the Quartus II software.

Pragmas and trigger keywords that are supported in Quartus II integrated synthesis and Encounter Conformal are also supported in the formal verification flow. The Quartus II integrated synthesis and Encounter Conformal both support the trigger keywords "synthesis" and "synopsys." When the Quartus II software does not recognize a keyword (such as "verplex"), the keyword is disabled in the formal verification scripts produced for use with the Cadence Conformal software. Therefore, it is important to use caution with unsupported pragmas because they can lead to verification mismatches.

For example, you can use the Quartus II integrated synthesis to synthesize RTL code with the synthesis directive `read_comments_as_HDL` (Example 18–1 and Example 18–2).

Example 18–1. Verilog HDL Example of Read Comments as HDL

```
// synthesis read_comments_as_HDL on
// my_rom lpm_rom (.address (address),
// .data (data));
// synthesis read_comments_as_HDL off
```

Example 18–2. VHDL Example of Read Comments as HDL

```
-- synthesis read_comments_as_HDL on
-- my_rom : entity lpm_rom
-- port map (
-- address => address,
-- data => data, );
-- synthesis read_comments_as_HDL off
```

The Encounter Conformal software does not support the synthesis directive `read_comments_as_HDL`, and the directive has no affect on the Encounter Conformal software.

Table 18–2 lists supported pragmas and trigger keywords for formal verification.

Table 18–2. Supported Pragmas and Trigger Keywords for Formal Verification

Pragmas *(1)*	Trigger Keywords
full_case	synthesis
parallel_case	synopsys
pragma	
synthesis_off	
synthesis_on	
translate_off	
translate_on	

Note to Table 18–2:

(1) Do not use Verilog 2001-style pragma declarations. The Quartus II software and the Encounter Conformal software support this style of pragma in different manners.

Stuck-at Registers

Quartus II integrated synthesis eliminates registers that have their output stuck at a constant value. Quartus II integrated synthesis gives a warning message and adds an entry to the corresponding report panel in the formal verification folder of the Analysis & Synthesis section of the Compilation Report. If Conformal LEC does not find the same optimizations, it can lead to unmapped points in the golden netlist. Example 18–3 illustrates the issue.

Example 18–3. Verilog HDL Example Showing Stuck at Registers

```
module stuck_at_example {clk, a,b,c,d,out};
input a,b,c,d,clk;
output out;
reg e,f,g;
   always @(posedge clk) begin
      e <= a and g;// e is stuck at 0
      g <= c and e;// g is stuck at 0
      f <= e | b;
   end
assign out = f and d;
endmodule
```

In this module description, registers e and g are tied to logic 0. In this example, the Quartus II software generates the following warning message:

```
Warning: Reduced register "g" with stuck data_in port to stuck value GND
Warning: Reduced register "e" with stuck data_in port to stuck value GND
```

Quartus II integrated synthesis then adds a command to the formal verification scripts telling Conformal LEC that a register is stuck at a constant value, as shown in Example 18–4.

Example 18–4. Conformal LEC Script Showing Commands for Instance Equivalence

```
// report floating signals
// Instance-constraints commands for constant-value registers removed
// during compilation
// add instance constraints 0 e -golden
// add instance constraints 0 g -golden
```

The command is commented in the formal verification script, forcing the Encounter Conformal software to treat the register as stuck at a constant value and potentially hiding a compilation error. You must verify that input to the e and g registers is constant in the design and uncomment the command to obtain accurate results.

Altera recommends recoding your design to eliminate “stuck-at” registers.

The stuck-at register information in this section also applies to the Synplify Pro flow.

ROM, LPM_DIVIDE, and Shift Register Inference

For the purpose of formal verification, the Quartus II integrated synthesis implements both ROM and shift registers in the form of LEs instead of using dedicated on-chip memory resources. Using LEs can be less area-efficient than inferring a megafunction that can be implemented in a RAM block. However, the Quartus II software generates a warning message indicating that the megafunction was not inferred. Quartus II

integrated synthesis also reports a suggested ROM or shift register instantiation that enables you to either use the MegaWizard™ Plug-In Manager to create the appropriate megafunction explicitly, or to isolate the corresponding logic in a separate entity that you can set as a black box. By setting black box properties on a particular module or entity, you are telling the formal verification tool not to look inside the module or entity for formal verification. If the black box properties are set on the corresponding megafunction before synthesis, you can verify the megafunction with the Encounter Conformal software. For details about setting black box properties on a particular module, refer to Table 18–3 on page 18–9.

If the design contains division functionality, the Quartus II software infers an LPM_DIVIDE megafunction, which is treated as a black box for the purpose of formal verification.

RAM Inference

When the Quartus II software infers the LPM ALTSYNCRAM megafunction from the RTL code, the Quartus II software generates the following warning message:

```
Created node "<mem_block_name>" as a RAM by generating altsyncram
megafunction to implement register logic with M512 or M4K memory block
or M-RAM. Expect to get an error or a mismatch for this block in the
formal verification tool.
```

This warning is generated because the memory block (`altsyncram`) is a new instance in the post-fit netlist that is handled as a black box by the formal verification tool. However, no such instance exists in the original RTL design, resulting in mismatch or error reporting in the formal verification tool.

Latch Inference

A latch is implemented in the Quartus II integrated synthesis using a combinational feedback loop. The Encounter Conformal software infers a latch primitive in the Encounter Conformal library (DLAT) to implement a latch. This results in having a DLAT on the golden side and a combinational loop with a cut point on the revised side, leading to verification mismatches. The Quartus II software issues a warning message whenever a latch is inferred, and the Quartus II software adds an entry to the report panel in the Formal Verification folder of the Analysis & Synthesis report. Altera recommends that you avoid latches in your design; however, if latches are necessary, Altera recommends using the corresponding LPM_LATCH megafunction.

For more information about the problems related to latches, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

Combinational Loops

If the design consists of an intended combinational loop, you must define an appropriate cut point for both the RTL and the post-fit **.vo** netlist file. A warning that a combinational loop exists in the design is found in the Formal Verification subfolder of the Quartus II software Analysis & Synthesis report.

For more information on issues with combinational loops, refer to "Known Issues and Limitations" on page 18–19.

Finite State Machine Coding Styles

When a state machine is inferred by the Encounter Conformal software, it uses sequential encoding as the default encoding when no user encoding is present. The Quartus II software selects the encoding most suited for the inferred state machine if the **State Machine Processing** settings is set to the default value **Auto**. To do this, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Analysis & Synthesis Settings**. The **Analysis & Synthesis Settings** page appears.
3. Click **More Settings**. The **More Analysis & Synthesis Settings** dialog box appears.
4. Under **Option**, in the **Name** list, select **State Machine Processing**. In the **Setting** list, select **Auto**.
5. Click **OK**.
6. Click **OK**.

Use the coding style described in the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook* on RTL when writing finite state Machines (FSMs). This allows the Quartus II integrated synthesis and the Encounter Conformal software to infer a similar state machine for the same RTL code.

Black Boxes in the Encounter Conformal Flow

The Quartus II software usually generates a flattened netlist; however, you must treat some modules in the design as black boxes. The following is a list of some of these modules:

- LPMs and megafunctions without formal verification models
- Encrypted IP functions
- Entities not implemented in Verilog HDL or VHDL

To perform equivalence checking of a design between its version consisting of the modules listed above and its implemented version, the modules must be treated as black boxes by the Encounter Conformal software. To facilitate the formal verification flow, the Quartus II software reconstructs the hierarchy on the black boxes with a port interface that is identical to the module on the golden side of the design.

If your golden netlist (**.vqm** netlist file from Synplify Pro or RTL) includes any design entity not having a corresponding formal verification model, that entity is handled as a black box with its boundary interface preserved. There are three types of black boxes and required user actions, depending upon circumstances. Table 18–4 describes these three types of black boxes and the required user actions in detail.

Verilog Output netlist files written by the Quartus II software contain the black box hierarchy when you make the following assignments for a module:

- An EDA Formal Verification Hierarchy assignment with the value `BLACKBOX`
- A Preserve Hierarchical Boundary assignment with the value `Firm`

If these two assignments are not made for a module, the Quartus II software implements that module with logic cells. When this happens, the **.vo** netlist file no longer contains the black box hierarchy and does not preserve the port interface, resulting in a mismatch within the Encounter Conformal software.

Table 18–3. Black Boxes and Required User Action

Type of Black Box	Required User Action
Altera library of parameterized modules (LPMs) and megafunctions (refer to Table 18–5 on page 18–21 for a complete list).	No action required. The Quartus II software automatically creates a black box list of components and preserves the hierarchy.
Any parametrized entity other than those listed in Table 18–5 on page 18–21.	User must designate the wrapper that instantiates the parameterized entity as a black box.
Non-parameterized entities that the user wants designate as a black box.	User can designate the entity itself as a black box.

You can also use Tcl commands or Quartus II GUI to set the black box property on the entities, which the formal verification tool does not compare.

Tcl Command

Use the Tcl commands of Example 18–5 to preserve the boundary interface of a black box entity: `dram`.

Example 18–5. Tcl Command to Create a Black Box

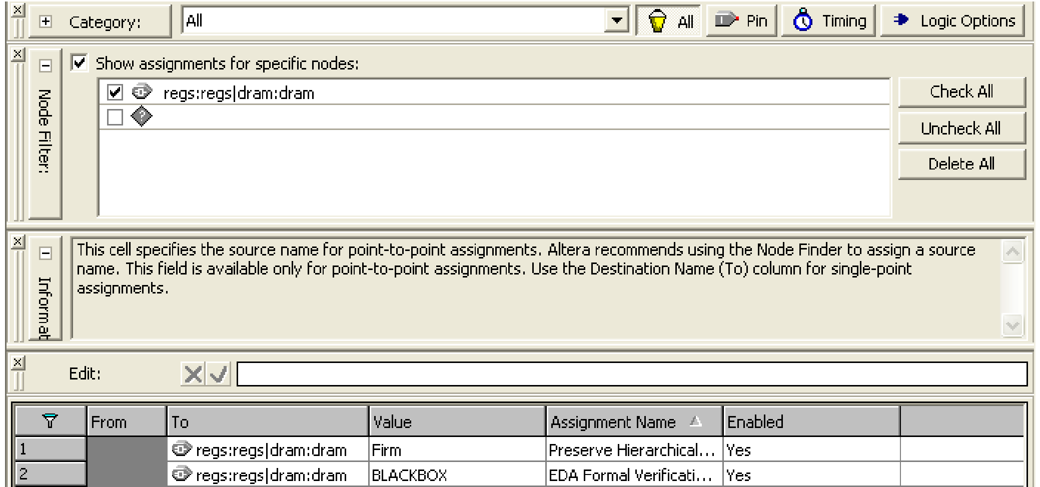
```
set_instance_assignment -name PRESERVE_HIERARCHICAL_BOUNDARY FIRM -to | -entity dram
set_instance_assignment -name EDA_FV_HIERARCHY BLACKBOX -to | -entity dram
```

GUI

To preserve the boundary interface of an entity using the GUI, perform the following steps:

1. Make an EDA Formal Verification Hierarchy assignment to the entity with the value `BLACKBOX`.
2. Make a Preserve Hierarchical Boundary assignment to the entity with the value `Firm` (Figure 18–3).

Figure 18–3. Setting the Black-Box Property on a Module



Generating the Post-Fit Netlist Output File and the Encounter Conformal Setup Files

The following steps describe how to set up the Quartus II software environment to generate the post-fit **.vo** netlist file and the Encounter Conformal script for use in formal verification. With the exception of step 2, the steps are identical for both of the Synthesis tools:

To create a new Quartus II project or open an existing project, perform the following steps:

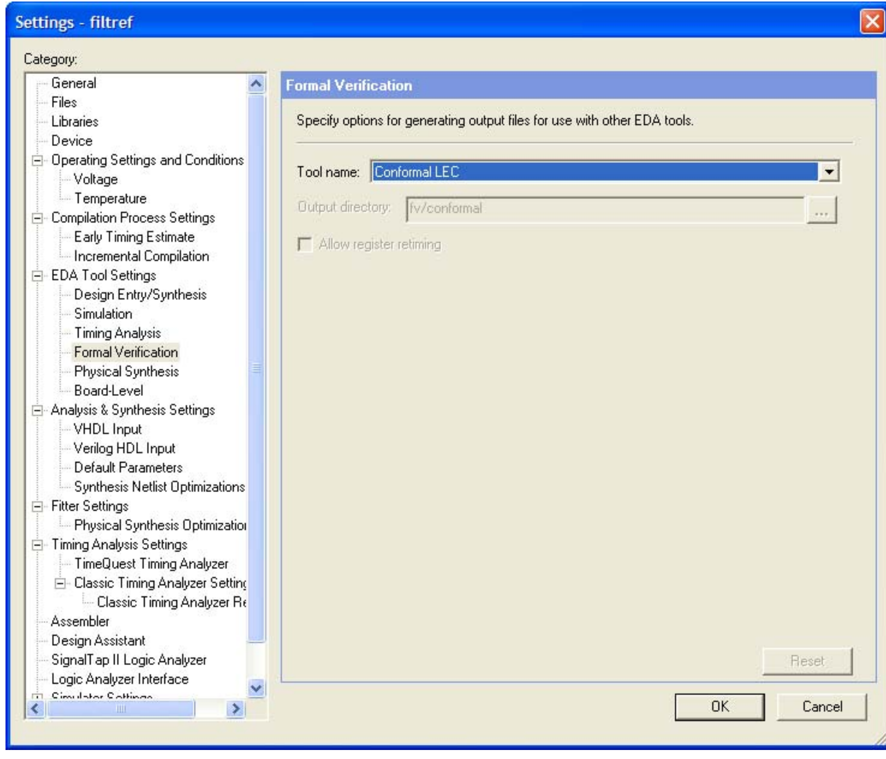
1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, click **EDA Tool Settings**.

   If you are using the Quartus II integrated synthesis, perform the following steps:

   a. In the **Category** list, under **EDA Tool Settings**, select **Design Entry/Synthesis**. Select **<None>** from the **Tool name** list.

   b. In the **Category** list, under **EDA Tool Settings**, select **Formal Verification**. Select **Conformal LEC** from the **Tool name** list (Figure 18–4).

Figure 18–4. Compilation Process Settings



If you are using Synplify Pro, perform the following steps:

a. In the **Category** list, under **EDA Tool Settings**, select **Design Entry/Synthesis**. Select **Synplify Pro** from the **Tool name** list.

b. In the **Category** list, under **EDA Tool Settings**, select **Formal Verification**. Select **Conformal LEC** from the Tool name list.

3. In the **Category** list, click the "+" icon to expand **Compilation Process Settings**, and select **Incremental Compilation**. The **Incremental Compilation** page appears.

4. Select **Full Incremental Compilation** to turn on Incremental Compilation.

or

Turn on Incremental Compilation by typing the following Tcl command in the Quartus II software Tcl console:

```
set_global_assignment -name INCREMENTAL_COMPILATION FULL_INCREMENTAL_COMPILATION
```

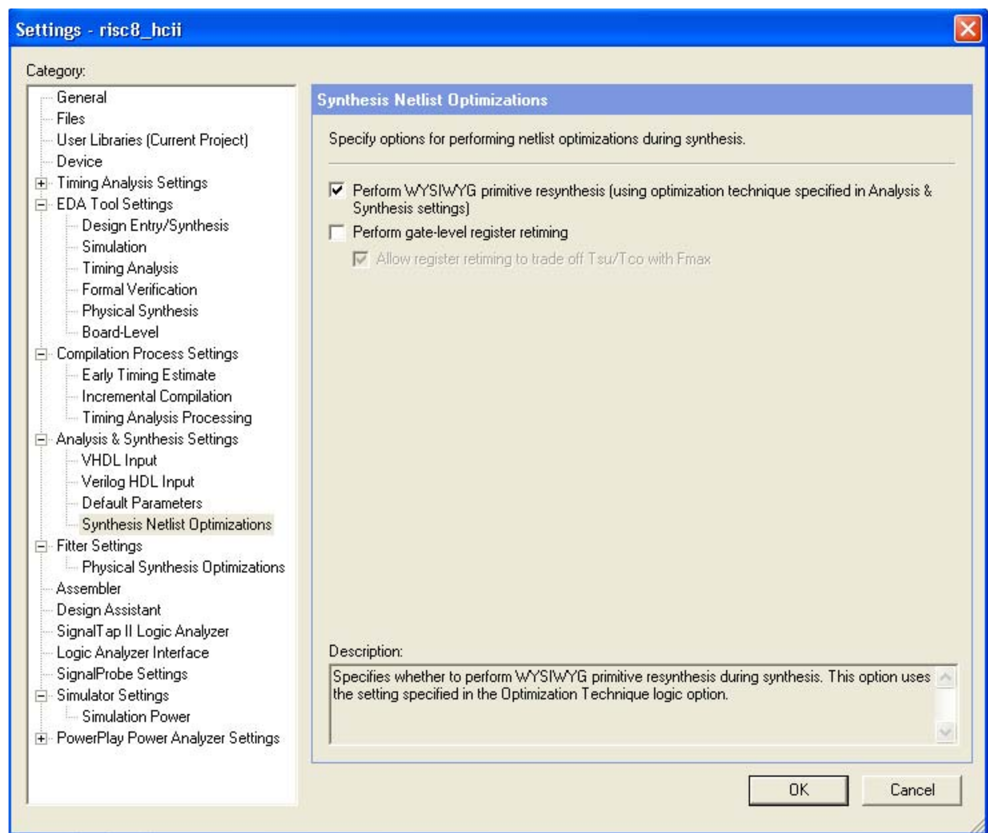
Altera requires that Incremental Compilation be turned on for Formal Verification, and that your design does not contain any user-created partitions. Starting with Quartus II software version 6.1 and later, the incremental compilation feature is on by default.

5. In the **Category** list, click the "+" icon to expand **Analysis and Synthesis Settings** and click **Synthesis Netlist Optimizations**. The **Synthesis Netlist Optimizations** page appears.

6. Turn off **Perform gate-level register retiming** (Figure 18–5).

If **Perform gate-level register retiming** is not turned off, the Encounter Conformal script can display a different set of compare points, making the resulting netlist difficult to compare against the reference netlist file.

Figure 18–5. Synthesis Netlist Optimizations

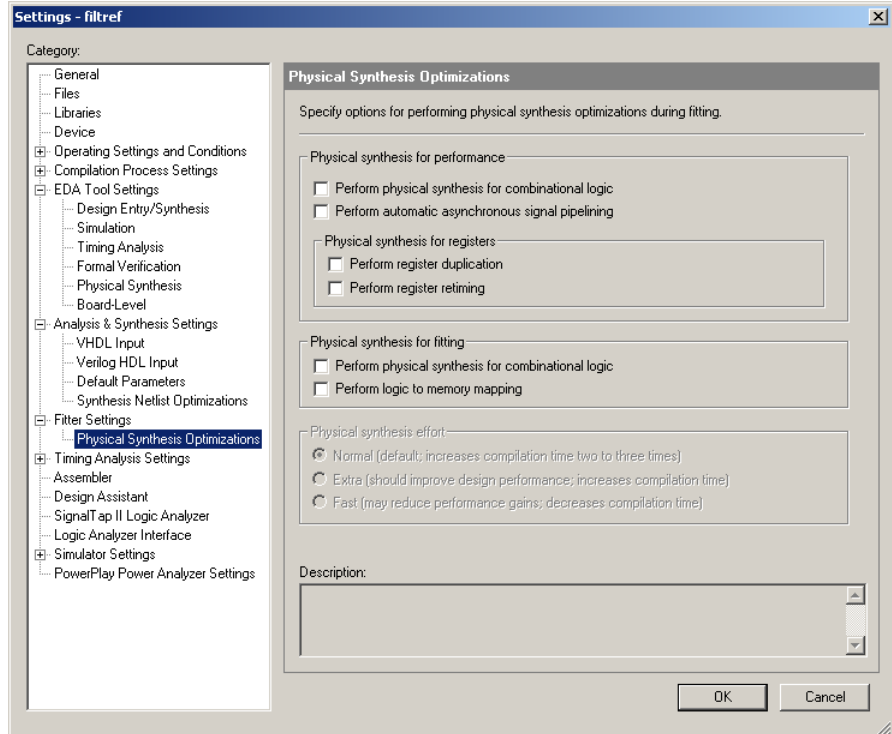


7. In the **Category** list, click the "+" icon to expand **Fitter Settings**, and select **Physical Synthesis Optimizations**. The **Physical Synthesis Optimizations** page appears.

   a. Under **Physical synthesis for registers**, turn off **Perform register retiming**.

   b. Under **Physical Synthesis for Fitting**, turn off both **Perform physical synthesis for combinational logic** and **Perform logic to memory mapping** to prevent logic from being mapped to RAMs (Figure 18–6).

Figure 18–6. Fitter Settings



Retiming a design, either during the synthesis step or during the fitting step, usually results in moving and merging registers along the critical path and is not well-supported by the equivalence checking tools. Because equivalence checkers compare the cone of logic terminating at registers, do not use retiming to move the registers during optimization in the Quartus II software.

If the **Perform gate-level register retiming** (Figure 18–5) and **Perform register retiming** options (Figure 18–6) are not turned off, the Encounter Conformal script displays a different set of compare points, making the resulting netlist difficult to compare against the reference netlist file. If you use retiming in your design during compilation, you cannot generate a netlist for formal verification.

For more information about physical synthesis, refer to the *Netlist Optimizations and Physical Synthesis* chapter in volume 2 of the *Quartus II Handbook*.

8. Perform a full compilation of the design. On the Processing menu, click **Start Compilation**, or click the **Start Compilation** icon on the Toolbar.

The Quartus II Software Generated Files, Formal Verification Scripts, and Directories

After successful compilation, the Quartus II software generates a list of files, formal verification scripts, and directories in the <*project_directory*>**/fv/conformal/** directory (Table 18–4).

Table 18–4. The Quartus II Software Compiler-Generated Files and Directories

File or Directory	Name	Details
.vo file	<*proj rev*>**.vo**	The Quartus II software-generated netlist for formal verification.
Script file	<*proj rev*>**.ctc**	The <*proj rev*>**.ctc** file references <*proj rev*>**.clg** and <*proj rev*>**.clr** that read the library files and black box descriptions. The <*proj rev*>**.ctc** file also references the <*proj rev*>**.cmc** file containing information about the mapped points. *(1)*
	<*proj rev*>**.cec**	The <*proj rev*>**.cec** file contains the information for instance equivalences.
	<*proj rev*>**.cep**	The <*proj rev*>**.cep** file contains the information for black box pin equivalences in the design.
	<*proj rev*>**.cmp**	The <*proj rev*>**.cmp** file contains the information for the black box pin mapping between the golden and revised sides. *(2)*
	<*proj rev*>**.cmc**	The <*proj rev*>**.cmc** file contains information about the additional points to be mapped in addition to the points selected by the tool.
	<*proj rev*>**_trivial.cmc**	This <*proj rev*>**_trivial.cmc** file contains mapping information for all the key points in the design. *(3)*
	<*proj rev*>**.clr**	The <*proj rev*>**.clr** file contains information about the macros and libraries for the revised design.
	<*proj rev*>**.clg**	The <*proj rev*>**.clg** file contains information about the macros and libraries for the golden design.
blackboxes directory	<*project directory*>**/fv/conformal/**<*project rev*>**_blackboxes**	This directory contains top-level module descriptions for all the user-defined black box entities and contains modules with definitions other than Verilog HDL or VHDL, for example, Block Design File (**.bdf**) in the design directory <*project directory*>**/fv/conformal/**<*project rev*>**_blackboxes**

Notes to Table 18–4:

(1) This file is used with the Encounter Conformal software.

(2) This file is called from the <*proj rev*>**.ctc** script file. By default, the line where this file is called is commented out. These files are only useful for HardCopy II device families.

(3) In some cases, Encounter Conformal software performs incorrect key point mapping, resulting in formal verification mismatches. To overcome the verification mismatches, the Quartus II software writes out the <*proj rev*>**_trivial.cmc** file that contains mapping information for all the key points in the design. Reading this file during the formal verification setup can result in increased run time. Therefore, the Quartus II software writes out the top-level script file <*proj rev*>**.ctc** with the command to read the <*proj rev*>**_trivial.cmc** file commented out. If the formal verification results are not acceptable, the user can uncomment the command and read the <*proj rev*>**_trivial.cmc** file. The command in the <*proj rev*>**.ctc** file is:

```
//Trivial mappings with same name registers
//read mapped points $PROJECT/fv/conformal/<proj rev>_trivial.cmc
```

The script file contains the setup and constraints information to use with the formal verification tool. The file <*entity*>**.v** in the **blackboxes** directory contains the module description of entities that are not defined in the formal verification library. The file also contains entities that you specify as black boxes. For example, if there is a reference to a black box for an instance of the ALTDPRAM megafunction in the design, the **blackboxes** directory does not contain a module description for the ALTDPRAM megafunction because it is defined in the **altdpram.v** file of the formal verification library. When a module does not have an RTL description, or the

description exists only in the formal verification library and you do not want to compare the module using formal verification, a file containing only the top-level module description with port declaration is written out to the **blackboxes** directory and read into the Encounter Conformal software. To learn more about black boxes, refer to "Black Boxes in the Encounter Conformal Flow" on page 18–8.

Understanding the Formal Verification Scripts for Encounter Conformal

The Quartus II software generates scripts to use with the Encounter Conformal Logic Equivalence Check (LEC) software. This section elaborates on the details of the Encounter Conformal commands used within the scripts to help you compare the revised netlist with the golden netlist. In most cases, you do not have to add any more Encounter Conformal constraints to verify your netlists.

A sample script generated by the Quartus II software is provided in "Conformal Dofile/Script Example" on page 18–23.

The Encounter Conformal Commands within the Quartus II Software-Generated Scripts

The value for the variable `QUARTUS` is the path to the Quartus II software installation directory:

```
setenv QUARTUS <Quartus Installation Directory>
```

The Quartus II software assigns the current working directory of the project to the `PROJECT` variable. Use this variable to change the project directory to the directory where the design files are installed when moving from a UNIX to a Windows environment, or vice versa:

```
setenv PROJECT <Quartus Project Directory>
```

The following command reads both the golden and the revised netlists, along with the appropriate library models:

```
read design <design files>
```

You must update the project location when the files are moved from the Windows environment to the UNIX environment.

The post place-and-route netlist from the Quartus II software might contain net and instance names that are slightly different from those of the golden netlist. By using the following command, the Quartus II software defines temporary substitute string patterns enabling the Encounter Conformal software to automatically map key points when the names are not the same:

```
add renaming rule <rule>
```

The Encounter Conformal LEC software employs three name-based methods to map key points to compare the revised netlist with the golden netlist. Scripts set the correct method to get the best results.

```
set mapping method <mapping_rule>
```

The Quartus II software performs several optimizations, including optimizing the registers whose input is driven by a constant. Under these circumstances, for the formal verification software to compare the netlists properly, the command `set flatten model` is used with the option `seq_constant`.

```
set flatten model <flattening_rule>
```

When you use the command `report black box`, verify that the following modules are listed as black boxes, along with any of the modules black boxed by the user, in both the golden and revised netlists:

- LPMs and megafunctions without the formal verification models
- Encrypted IP functions
- Entities not implemented in Verilog HDL or VHDL

Use the following command to set the same implementation on multipliers for both the golden and revised netlists:

```
set multiplier implementation <implementation_name>
```

If there are any combinational loops or instances of `LPM_LATCH`, the Quartus II software cuts the loop at the same point using the following command on both the golden and revised netlists:

```
add cut point
```

The Encounter Conformal software does not always automatically map all of the keypoints, or can incorrectly map some keypoints. To help the Encounter Conformal software successfully complete the mapping process, the Quartus II software records optimizations performed on the netlist as a series of `add mapped points` in the Encounter Conformal <*file_name*>**.cmc** script.

```
add mapped points <key_points>
```

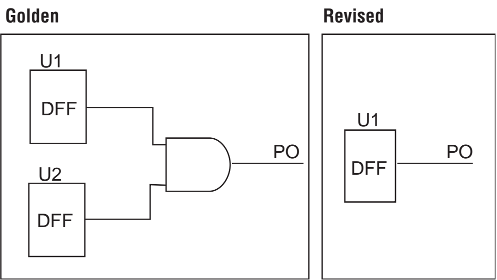
There are situations in which the inverter in front of the register is moved after the register. In this situation, the following command is used:

```
add mapped points <key_points> -invert
```

The following command reads in the mapped point information from the specified file:

```
read mapped points <file_name>.cmc
```

Figure 18–7. Instance Equivalence



During the process of optimization, the Quartus II software might merge two registers into one (Figure 18–7). The Quartus II software informs the formal verification tool that the U1 and U2 registers are equivalent to each other using the following command:

```
add instance equivalence <instance_pathname ..> [-Golden]
```

If the register duplication takes place, the following command is used:

```
add instance equivalence <instance_pathname ..> [-revised]
```

The following command is used when the inverter is moved beyond the register along with either register duplication or merging:

```
add instance equivalences <instance_pathname>
[-invert <instance_pathname>]
```

At times, the register output is driven to a constant, either `logic 0` or `logic 1`. The Quartus II software sets the value of the register to a constraint using the `add instance constraint` command. For more information about this command, refer to "Stuck-at Registers" on page 18–6.

```
add instance constraint <constraint_value>
```

Comparing Designs Using Encounter Conformal

This section addresses using the Encounter Conformal software to compare designs; that is, how to prove logical equivalence between two versions of the design.

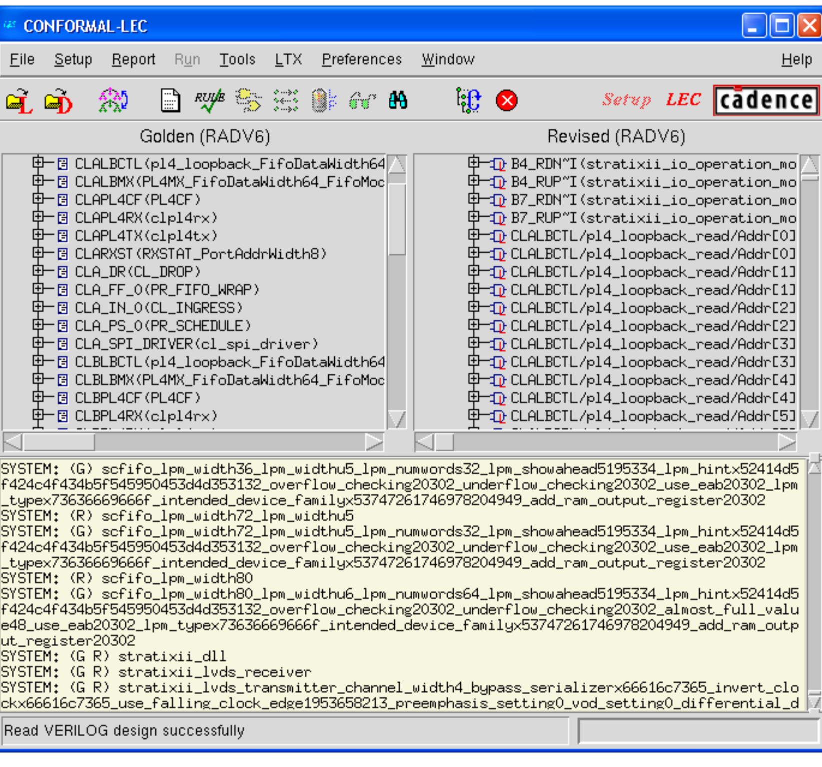
Running the Encounter Conformal Software from the GUI

To run the Encounter Conformal software from the GUI, follow these steps:

1. Open the Encounter Conformal software.
2. On the File menu, click **Do Dofile**.
3. Select the file <*path to project directory*>**/fv/conformal/**<*proj rev*>**.ctc**.

The Encounter Conformal software GUI displays the comparison results (Figure 18–8). The Golden window displays the original RTL description or the post synthesis **.vqm** netlist file from Synplify Pro, and the Revised window displays the information of the post-fit netlist generated by the Quartus II software. The message section at the bottom of the window reports the verification results and the number of unmapped and non-equivalent points found in the design.

Figure 18–8. Encounter Conformal Software GUI Display of Functional Comparisons



To investigate the verification results, click the **Mapping Manager** icon in the toolbar, or on the Tools menu, click **Mapping Manager**. The Encounter Conformal software reports the mapped, unmapped, and compared points in the **Mapped Points**, **Unmapped Points**, and **Compared Points** windows, respectively.

For more information about how to diagnose non-equivalent points, refer to the Encounter Conformal software user documentation.

Running the Encounter Conformal Software From a System Command Prompt

To run the Encounter Conformal Software without using the GUI, type the command shown in Example 18–6 at a system command prompt.

Example 18–6. Conformal LEC Command to Run Formal Verification

```
lec -dofile /<path to project directory>/fv/conformal/<proj rev>.ctc -nogui
```

To get a downloadable design example showing the formal verification flow with Quartus II software, go to www.altera.com/support/examples/quartus/exm-formal-verification.html.

For more information about the latest debugging tips and solutions for formal verification flow between Cadence Conformal LEC tool and Quartus II software, go to www.altera.com and perform an advanced search with keywords “formal verification”.

Known Issues and Limitations

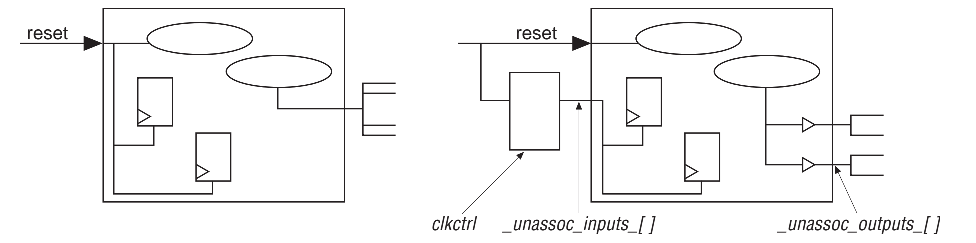
The following known issues and limitations can occur when using the formal verification flow described in this chapter:

- When a port on a black box entity drives two or more signals within the black box, the Quartus II software pushes the connections outside of the black box, and creates that many ports on the black box. This problem is only associated with Stratix II and HardCopy II designs.

  The additional ports on the black box are named `_unassoc_inputs_[]` and `_unassoc_outputs_[]` (Figure 18–9). This issue is generally associated with reset and enable signals. Figure 18–9 shows an example in which the reset pin is split into two ports outside of the black box and the `_unassoc_inputs_[]` port is driven by the `clkctrl` block. In such situations, the **.vo** netlist file generated by the Quartus II software has signals driving these black box ports, but golden RTL does not contain any signals to drive the `_unassoc_inputs_[]` port, resulting in a formal verification mismatch of the black box. The black box module definition generated by the Quartus II software in the directory <*Quartus_project*>**\fv\conformal*_blackboxes** contains these additional `_unassoc_inputs_[]` and `_unassoc_outputs_[]` ports. This black box module is read on both the golden and revised sides of the design, which results in unconnected ports on the golden side and formal verification mismatches.

  Figure 18–9 shows the creation of the `_unassoc_inputs_[]` and `_unassoc_outputs_[]` ports for the reset signal.

Figure 18–9. Creation of _unassoc_inputs_[] and _unassoc_outputs_[]

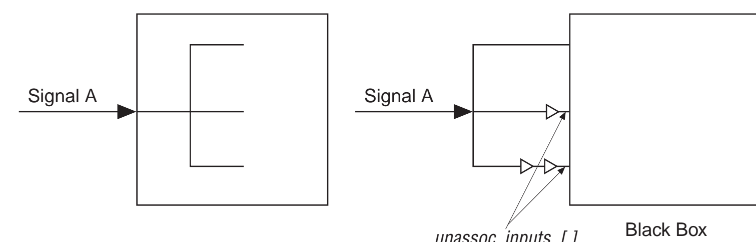


Another common occurrence of this issue is in HardCopy II designs. Whenever a port drives large fan-out within the black box, the Quartus II software inserts a buffer on the net and moves the logic outside of the black box (Figure 18–10).

To fix the problem of `_unassoc_input_[]` ports causing black box mismatches, use Cadence Conformal commands to change the type of the black box `_unassoc_input_[]` keypoint to a primary output keypoint, and then marking the appropriate pin equivalences. Similarly, to fix the problem of register mismatches due to `_unassoc_output_[]` pins from black boxes, use Conformal commands to change the type of the blackbox `_unassoc_output_[]` keypoint to a primary input, and then marking equivalent pins as such. The commands to perform these actions are written in the <*proj rev*>**.cep** file.

Figure 18–10 shows the creation of `_unassoc_inputs_[]` for a signal with large fan-out.

Figure 18–10. Creation of _unassoc_inputs_[] for a Signal with Large Fan-out



- In designs with combinational feedback loops, the Encounter Conformal software can insert extra cut points in the revised netlist, causing unmapped points and ultimately verification mismatches.
- For Cyclone II designs, Conformal LEC might report non-equivalent flipflops and extra cut points for the revised (post-fit) design when your HDL source code instantiates the `lpm_ff` primitive with an asynchronous load signal `aload` (with or without any other asynchronous control signals) and when the asynchronous clear signal `aclr` and asynchronous set signal `aset` are used together. To avoid this problem, ensure that there is a wrapper module or entity around the `lpm_ff` instantiation, and black box the module or entity that instantiates the `lpm_ff` primitive.
- For Stratix III designs, the Cadence Conformal LEC software creates cut points for the combinational loops on the golden side and might fail equivalence checking due to improper mapping. The combinational loops are due to logic around the registers emulating multiple set, resets, or both. These cut points are also reported during the mapping step in Quartus II software with warning messages. You can add Cadence Conformal commands manually to add cut points, which can result in proper mapping and formal verification.
- To perform formal verification, certain synthesis optimization options (such as register retiming, optimization through black box hierarchy boundaries, and disabling the ROM and shift register inference) are turned off, which can have an impact on the area resource and performance.
- RAM and ROM instantiations, inferences, or both are not verified using formal verification.
- Incremental Compilation for the purpose of formal verification does not support user-created design partitions.
- Formal verification does not support clear box netlists due to unconnected ports on its WYSIWYG instances.
- Formal verification does not support VHDL megafunction variations due to undriven ports on the megafunctions.
- When a black box contains bidirectional ports, the Quartus II software fails to reconstruct the hierarchy. For this reason, the black box is represented by a flat netlist, resulting in formal verification mismatches.
- ROMs in the design must be black boxed before compilation using Quartus II integrated synthesis, because the Quartus II software might perform some optimizations on the ROM, resulting in Formal Verification mismatches.

- The Conformal software might report mismatches or abort comparison of some key points when a DSP megafunction is implemented in LEs by the Quartus II software, due to implicit optimizations within the DSP and the complexity of the multiplier logic in terms of LEs.
- Unused logic optimized within and around a black box by the Quartus II software can result in a black-box interface different from the interface in the synthesized **.vqm** netlist file.

Black Box Models

The black box models are interface definitions of entities, such as primitives, atoms, LPMs, and megafunctions. These models have a parameterized interface, and do not contain any definition of behavior. They are designed and tested specifically to work with the Encounter Conformal software, which uses these models along with your design to generate black boxes for instances of the entity with varying sets of parameters in the design. Table 18–5 describes the supported black box models. Besides these black box models, you can set a black box property on a specific module or entity as explained earlier in this chapter.

Table 18–5. Supported Black Box Models (Part 1 of 3)

Entity Type	Entity Names
Megafunctions	ALT3PRAM, ALTACCUMULATE, ALTFP_MULT, ALTSQRT, ALTLVDS_RX, ALTLVDS_TX, ALTSHIFT_TAPS, SLD_VIRTUAL_JTAG, SLD_VIRTUAL_JTAG_BASIC, DCFIFO, SCFIFO, ALTSYNCRAM, ALTSQRT
LPMs	lpm_add_sub, lpm_divide

Table 18–5. Supported Black Box Models (Part 2 of 3)

Entity Type	Entity Names
Atoms *(1)*	Cyclone: cyclone_crcblock, cyclone_jtag, cyclone_pll, cyclone_ram_block, cyclone_asmiblock, cyclone_dll

```
// Trivial mappings with same name registers
// read mapped points $PROJECT/fv/conformal/mfs_3prm_1a_trivial.cmc
// dofile $PROJECT/fv/conformal/mfs_3prm_1a.cmp
map key points
remodel -seq_constant -repeat
add compare points -all
compare
usage
// exit -f
```

Conclusion

Formal verification software enables verification of the design during all stages from RTL to placement and routing. Verifying designs takes more time as designs increase in size. Formal verification is a technique that helps reduce the time needed for your design verification cycle.

- *Netlist Optimizations and Physical Synthesis* chapter in volume 2 of the *Quartus II Handbook*

Document Revision History

Table 18–6 shows the revision history for this chapter.

Table 18–6. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	Updated Table 18–1 on page 18–4.	Updated for the Quartus II software version 9.0 release.
November 2008 v8.1.0	■ Changed to 8-1/2 x 11 page size. ■ Added support for Stratix IV devices. ■ Added support for Cadence Conformal LEC version 7.2 and Synplify Pro version 9.6.2.	Updated for the Quartus II software version 8.1 release.
May 2008 v8.0.0	■ Added support for Cyclone III devices. ■ Updated “Black Boxes in the Encounter Conformal Flow” on page 18–8. ■ Updated Table 18–1 and Table 18–5.	Updated for the Quartus II software version 8.0.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

Section VI. Device Programming

The Quartus® II software offers a complete software solution for system designers who design with Altera® FPGA and CPLD devices. The Quartus II Programmer is part of the Quartus II software package that allows you to program Altera CPLD and configuration devices, and configure Altera FPGA devices. This section describes how you can use the Quartus II Programmer to program or configure your device after you successfully compile your design.

This section includes the following chapter:

- Chapter 19, Quartus II Programmer

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

19. Quartus II Programmer

QII53022-9.0.0

Introduction

The Quartus® II software offers a complete software solution for system designers who design with Altera® FPGA and CPLD devices. The Quartus II Programmer is part of the Quartus II software package that allows you to program Altera CPLD and configuration devices and configure Altera FPGA devices. After your design successfully compiles, you can use the Quartus II Programmer to program or configure your device.

This chapter contains the following sections:

- "Programming Flow"
- "Programming and Configuration Modes" on page 19–4
- "Programmer Overview" on page 19–6
- "Hardware Setup" on page 19–11
- "Device Programming and Configuration" on page 19–12
- "Optional Programming Files" on page 19–17
- "Flash Loaders" on page 19–19
- "JTAG Chain Debugger Tool" on page 19–20
- "Other Programming Tools" on page 19–30
- "Scripting Support" on page 19–30

Programming Flow

The programming flow begins with design compilation, in which the Quartus II Assembler generates the programming or configuration file, then proceeds with the programming or configuration file conversion for different configuration devices, or optional programming and configuration file creation. The flow ends with the configuration or programming of the FPGA, CPLD, or configuration devices with the programming or configuration file using the Quartus II Programmer.

Figure 19–1 shows the programming file generation flow. This flow covers the types of configuration and programming files that are used by the Quartus II Programmer. Refer to "Optional Programming Files" on page 19–17 for information on other optional programming files.

Figure 19–1. Programming File Generation Flow

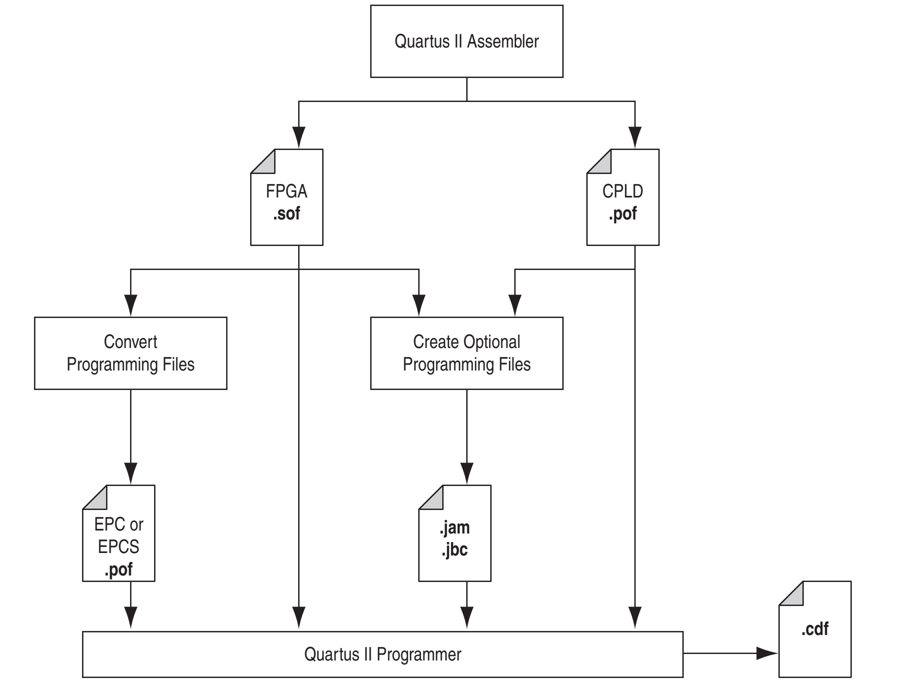

Table 19–1 shows the programming and configuration file formats supported by Altera FPGAs, CPLDs, configuration devices, enhanced configuration devices, and serial configuration devices. Chain description files (**.cdf**) are described in "Chain Description File" on page 19–16.

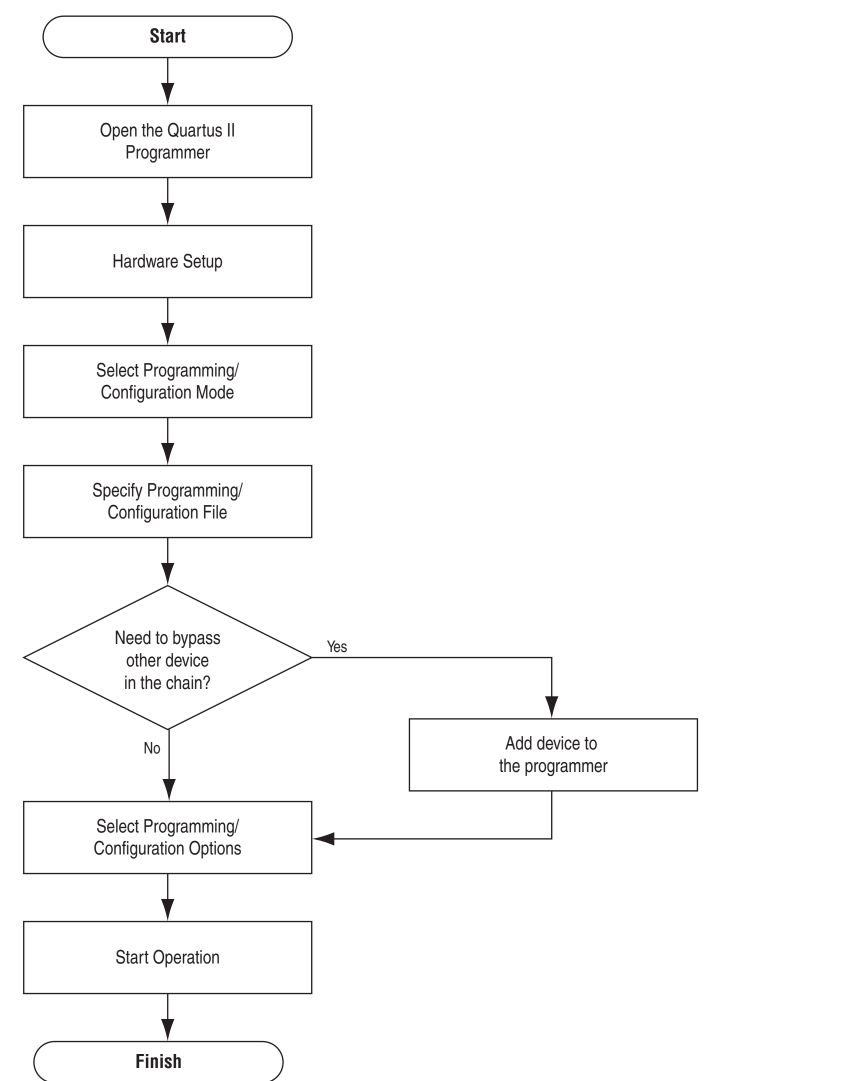
Table 19–1. Programming and Configuration File Format

File Format	FPGA	CPLD	Configuration Device and Enhanced Configuration Device	Serial Configuration Device
SRAM Object File (**.sof**)	✓	—	—	—
Programmer Object File (**.pof**)	—	✓	✓	✓
Jam File (**.jam**)	✓	✓	✓	—
Jam Byte-Code File (**.jbc**)	✓	✓	✓	—

Figure 19–2 shows the programming flow using the Quartus II Programmer. Refer to "Generating Optional Programming Files" on page 19–19 for detailed information about converting or creating different programming files. Refer to "Device Programming and Configuration" on page 19–12 for information about programming or configuring the device.

Figure 19–2. Programming Flow



Programming and Configuration Modes

The Quartus II Programmer supports the following four programming or configuration modes: JTAG, passive serial, active serial, and in-socket programming.

JTAG Mode

You can use the Joint Test Action Group (JTAG) mode to configure FPGA devices and program CPLDs, configuration devices, or enhanced configuration devices. The JTAG mode allows multiple FPGAs, CPLDs, and configuration devices connected in a JTAG chain to be configured or programmed at the same time. JTAG programming or configuration uses four JTAG pins: TCK, TDI, TMS, and TDO. The JTAG interface also allows you to perform boundary-scan test using third-party boundary scan tools.

.pof files are used for programming CPLDs, and configuration or enhanced configuration devices, while **.sof** files are used for configuring FPGA devices. **.jam** and **.jbc** files are used for both programming and configuration. Serial configuration devices do not support JTAG programming.

For more information about JTAG configuration or programming mode and JTAG pin connections, refer to the *Configuration Handbook*, or the device handbook or data sheet for the respective FPGA, CPLD, or configuration device.

Passive Serial Mode

You can use the passive serial (PS) mode to configure Altera FPGAs. PS configuration uses the DCLK, CONF_DONE, nCONFIG, nSTATUS, and DATA0 configuration pins. Unlike the JTAG scheme, the PS configuration scheme is used to configure the FPGA with a configuration device or enhanced configuration device, not necessarily through a download cable. If you use the configuration device or enhanced configuration device to configure the FPGA through PS mode, you can route the configuration signals out to a header so that you can also configure the FPGA through the download cable with the Quartus II Programmer. Configuration through PS mode with a download cable is useful in the design stage. This configuration method allows you to configure your FPGA device directly from the Quartus II Programmer as you make changes to your design for debugging and testing.

PS mode supports configuration of an FPGA chain. **.sof** files are used for configuration through PS mode. Every FPGA device in the chain requires an **.sof** file, so the number of **.sof** files used depends on the number of FPGA devices in the chain.

For more information about PS configuration mode and PS pin connection, refer to the *Configuration Handbook* or the chapter on configuration in the appropriate FPGA device handbook.

© March 2009 Altera Corporation

Active Serial Mode

You can use the active serial (AS) mode to program serial configuration devices. After programming is completed, the serial configuration device configures the FPGA. AS programming uses the DATA, DCLK, nCS, and ASDI pins. If the download cable is connected to the nCONFIG and nCE pins of the FPGA, the download cable disables the FPGA's access to the AS interface by holding the nCE pin high and the nCONFIG pin low. Upon completion of the programming, the nCE and nCONFIG pins are released and the FPGA configuration begins.

For more information about programming the serial configuration device, configuring the FPGA with the serial configuration device through AS mode, or the AS pin connections, refer to the *Serial Configuration Data Sheet* in the *Configuration Handbook* or the chapter on configuration in the appropriate FPGA device handbook.

In-Socket Programming Mode

The in-socket programming mode is used for programming a single device. This programming mode supports programming the MAX® 7000 and MAX 3000 CPLD families, configuration devices, enhanced configuration devices, and serial configuration devices. Instead of using a download cable, in-socket programming mode uses the Altera Programming Unit (APU) hardware together with the programming adapter for the corresponding device to program the device. The programming unit with the programming adapter has a socket for the device and the hardware powers the device for programming. In-socket programming is normally used in the production environment to pre-program devices before they are mounted on the printed circuit boards on the assembly line.

Refer to www.altera.com or the Quartus II Help for a list of programming adapters available for Altera devices.

Table 19–2 shows the programming and configuration modes supported by Altera devices.

Table 19–2. Programming and Configuration Modes

Mode	FPGA	CPLD	Configuration Device and Enhanced Configuration Device	Serial Configuration Device
JTAG	✓	✓	✓	—
PS	✓	—	—	—
AS	—	—	—	✓
In-Socket Programming	—	✓ *(1)*	✓	✓

Note to Table 19–2:

(1) MAX II CPLDs do not support in-socket programming mode.

Programmer Overview

The Quartus II Programmer GUI is a window in which you can add your programming and configuration files, specify the programming options and hardware, and then proceed with the programming or configuration of the device.

To open the Programmer window, on the Tools menu, click **Programmer**. Figure 19–3 shows the programmer GUI. The status of each operation, whether programming is successful or not, is reported in the Quartus II message window. Figure 19–4 shows a typical programming message after the programmer has successfully programmed a device.

Figure 19–3. The Programmer Window

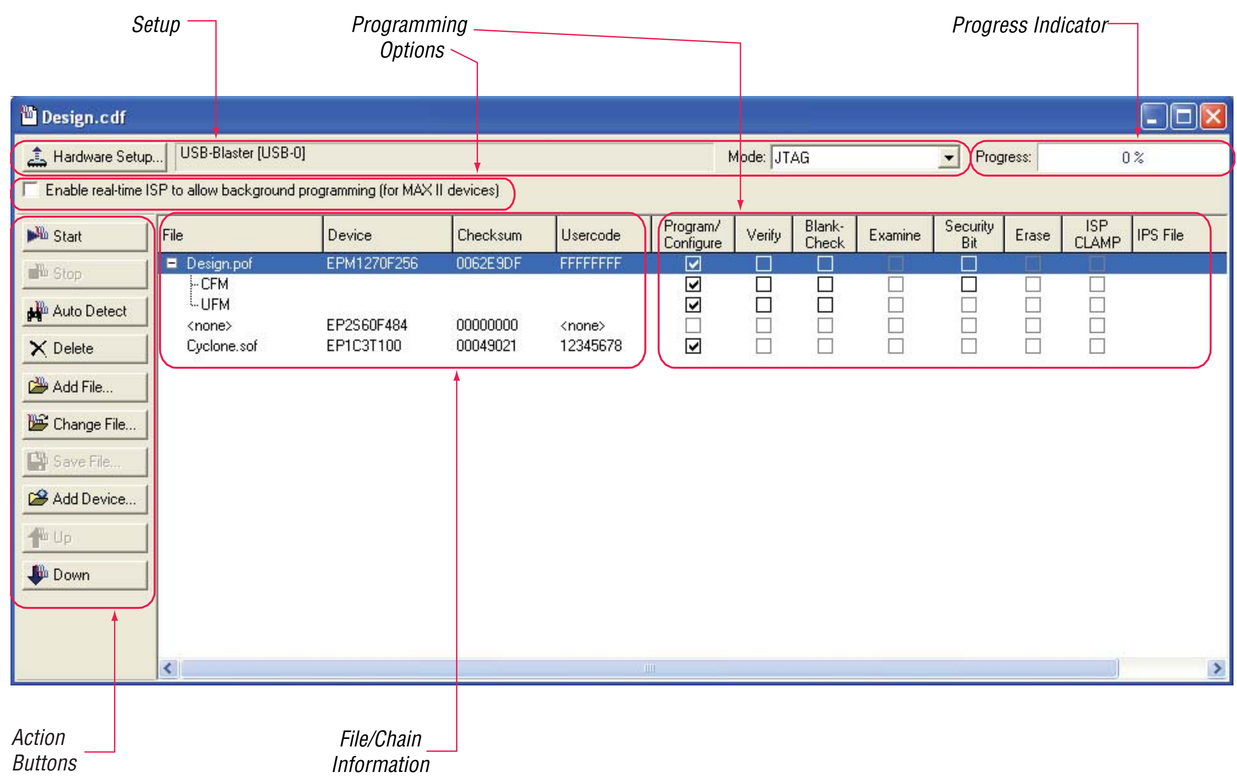


Figure 19–4. Status Report in the Message Window

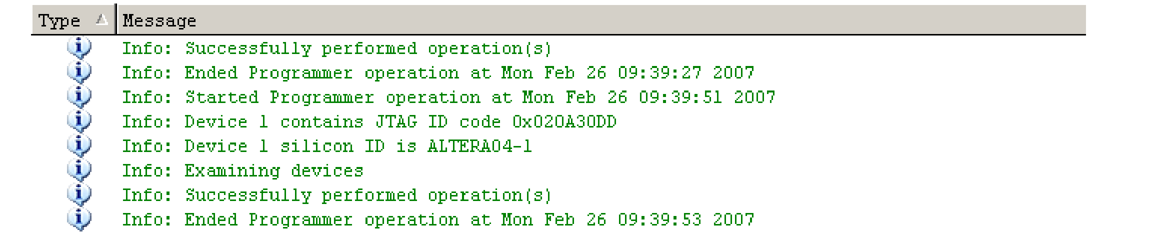


© March 2009 Altera Corporation

Table 19–3 describes the items available in the programmer window.

Table 19–3. Programmer Window Items (Part 1 of 2)

Items	Description
Hardware Setup	Opens the **Hardware Setup** dialog box in the programmer and enables you to perform the following functions: ■ Add and remove hardware items from the **Hardware** list ■ Add and remove JTAG servers from the **JTAG Servers** list ■ Configure your local JTAG server ■ Specify a programming hardware or download cable for device programming and configuration
Mode	Specifies the programming or configuration mode (either JTAG, In-Socket Programming, Passive Serial, or Active Serial Programming).
Progress	Shows the progress of a specific operation.
Action Buttons	
Start	Starts the operations of the specified programming options.
Stop	Stops all operations in progress.
Auto Detect	Scans the JTAG chain to check for devices in the chain and the chain connection.
Delete	Removes the selected programming or configuration files from the programmer.
Add File	Adds programming or configuration files to the programmer.
Change File	Replaces the selected programming or configuration file with another file.
Save File	Allows you to save the data read out from CPLD or configuration devices using the “examine” process into a **.pof** file.
Add Device	Adds a device into the JTAG device chain in the programmer. If no programming or configuration file is specified, the programmer bypasses this device during programming or configuration. You can also add your user-defined device into the chain.
Up	Moves the selected programming/configuration file or device up in the programmer window.
Down	Moves the selected programming/configuration file or device down in the programmer window.
File or Device Chain Information	
File	Displays the programming or configuration file name.
Device	The **Device** column shows the following items: ■ The target device of the file, if you add a programming or configuration file into the programmer ■ The devices in the JTAG chain detected by the programmer, if you click **Auto Detect** in JTAG mode ■ The device added to the programmer, if you manually add a device into the programmer
Checksum	The **Checksum** column shows the following items: ■ The checksum of the file, if you add a programming or configuration file into the programmer ■ The checksum for the data read out, if you examine a device The checksum is calculated by the Quartus II software. The programmer does not display the checksum for the **.jam** or **.jbc** files generated for a multi-device JTAG chain.

Table 19–3. Programmer Window Items (Part 2 of 2)

Items	Description
Usercode	The **Usercode** column shows the following items: ■ The usercode of the file, if you add a programming or configuration file into the programmer ■ The usercode read out from the device, if you examine a device You can specify the usercode before design compilation, or use the Auto usercode feature that uses the checksum as the usercode. The programmer does not show the usercode information in PS configuration mode or for the Jam or **.jbc** files generated for a multi-device JTAG chain.
Programming Options	
Enable real-time ISP to allow background programming	Can only be turned on if you are targeting a MAX II device, and is turned off for all other device families. When this option is turned on, you can do the real-time in-system programming (ISP) for the MAX II device. The existing design in the MAX II device functions normally during and after the real-time ISP is completed. The new design starts to function after a power cycle to the device occurs.
Program or Configure	Can be used for programming CPLDs, configuration devices, or configuring FPGA devices.
Verify	Verifies the content of the CPLD and all configuration devices against the respective programming files. This option is not available for FPGAs. Verification fails if the data in the file is different from the data in the device. Stand-alone verification for the CPLD with the programming file used for the programming fails if the security bit is set when the device is programmed initially.
Blank-Check	Checks whether the CPLD or configuration device is blank.
Examine	Reads back the contents of the CPLD or configuration device. You can then save the examined data as a **.pof** file. Examining a CPLD with the security bit set does not produce a usable **.pof** file. This option is not available for MAX 7000S devices.
Security Bit	Protects the design in the CPLD from being examined. If the security bit is set when the CPLD is programmed, you cannot read the correct data out using the examine process. Security bits cannot be set for the configuration devices or FPGAs.
Erase	Erases the contents of the CPLD and all configuration devices. You can also erase the user flash memory (UFM) of the MAX II CPLD. This option is not available for MAX 7000S devices.
ISP Clamp	Allows the MAX II or MAX 7000B CPLD's I/O pins to be clamped to certain states during normal programming. ISP Clamp can only be turned on if certain pins of the device have the ISP Clamp State assignment enabled, or you have added an I/O Pin State (**.ips**) file in the programmer.
IPS File	Shows the IPS file used for ISP Clamp of the MAX II or MAX 7000B CPLDs. The **IPS File** column only appears if your programmer window has a MAX II or MAX 7000B **.pof** file. To add the **.ips** file, click once on the row of the programming file and on the Edit menu, click **Add IPS File**.

Table 19–4 shows the programming and configuration options supported by Altera devices.

Table 19–4. Programming and Configuration Options

Option	FPGA	CPLD	Configuration Device and Enhanced Configuration Device	Serial Configuration Device
Program or Configure	✓	✓	✓	✓
Verify	—	✓	✓	✓
Blank-Check	—	✓	✓	✓
Examine	—	✓	✓	✓
Security Bit	—	✓	—	—
Erase	—	✓	✓	✓
ISP Clamp	—	✓ *(1)*	—	—
IPS File *(2)*	—	✓	—	—
Real-time ISP	—	✓ *(3)*	—	—

Notes to Table 19–4:

(1) Only MAX II and MAX 7000B CPLDs support the ISP Clamp feature.

(2) **.ips** file is used for ISP Clamp.

(3) Only MAX II CPLDs support the real-time ISP feature.

Tools Menu

More programmer options are available from the Tools menu. On the Tools menu, click **Options**. In the **Category** list, click **Programmer**. For descriptions of these options, refer to Table 19–5.

Table 19–5. Programmer Options (Part 1 of 2)

Option	Description
Show checksum without usercode	Determines whether the checksum values displayed in the programmer are calculated with or without JTAG user codes. This option allows you to have multiple versions of a programming or configuration file with different user codes, but share the same checksum.
Initiate configuration after programming	Specifies that configuration devices configure attached FPGA devices automatically after the programmer completes programming the configuration devices.
Display message when programming finishes	Displays a message when programming or other operation such as examining or blank-checking is complete.
Enable real-time ISP to allow background programming (for MAX II devices)	Can only be turned on if you are targeting a MAX II device. This option is turned off for all other device families. When this option is turned on, you can do the real-time in-system programming (ISP) for the MAX II device. The existing design in the MAX II device functions normally during and after the real-time ISP is completed. The new design starts to function after a power cycle to the device occurs. This option is also available in the programmer window.

Table 19–5. Programmer Options (Part 2 of 2)

Option	Description
Halt on-chip configuration controller	Halts the on-chip auto-configuration controller of the FPGA device for AS configuration, or the configuration device for PS or Fast Passive Parallel (FPP) configuration to allow JTAG configuration through a download cable. If you want to configure your FPGA through JTAG while the FPGA `MSEL` pins are set to AS mode, you should halt the on-chip configuration controller if any of the following circumstances occur: ■ The active serial configuration device connected to your FPGA is blank ■ The active serial configuration device is not present ■ An error occurs during AS configuration prior to JTAG configuration If the `MSEL` pins are set to PS or FPP mode, halt the configuration controller of the configuration device if an error occurs during PS or FPP configuration prior to JTAG configuration. The FPGA pulls the `nSTATUS` pin (which is connected to the `OE` pin of the configuration device) low to disable the configuration device.
Automatically check the Program/Configure checkbox when adding SOF	Automatically enables the program or configuration operation when adding an **.sof** file to the file list in the programmer window.
Configure volatile design security key (for Stratix III/IV devices)	Stratix III and Stratix IV GX devices support both volatile and nonvolatile design security keys. Checking this box before programming the key allows the volatile key to be programmed into the device.
Use bitstream compression to configure devices when available	Some Altera FPGAs support bitstream compression for PS configuration mode. To reduce configuration time, this option allows the devices to be configured with compressed configuration data from the Quartus II Programmer through PS mode.
Automatically open as detached window	Allows the Quartus II Programmer window to be detached from the Quartus II GUI when launched.
Use the enhanced mode Serial Flash Loader (SFL) IP for the factory default helper image	Allows the Quartus II Programmer to increase the speed of the programming and verification by filtering the extra paddings that are introduced by third-party programmer tools. In addition, this option increases the speed of programming and verification.
Check block CRCs to accelerate PFL/SFL verification when available	Reduces the time required to verify the data programmed into a flash device through the PFL. This option allows the Quartus II Programmer to verify the flash data by checking the cyclic redundancy code (CRC) generated from the data of the programming file, as well as of the flash device. This option can be used only with PFL designs created with the Quartus II software version 8.1 and later.

© March 2009 Altera Corporation

Hardware Setup

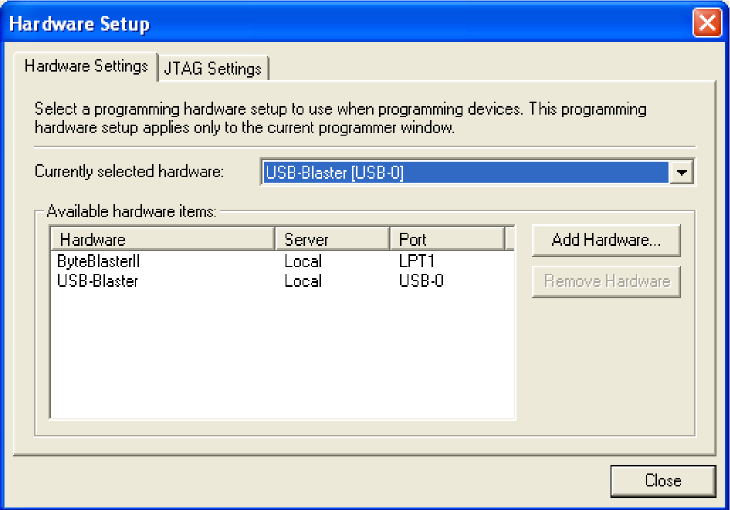
The Quartus II Programmer provides the flexibility to choose a download cable or the programming hardware. Before you can program or configure your device, you must have the correct hardware setup.

Hardware Settings

Click **Hardware Setup** to bring up the **Hardware Setup** dialog box. On the **Hardware Settings** tab (Figure 19–5), you can select a download cable or programming hardware available from the **Currently selected hardware** list. If the download cable or programming hardware you require is not displayed, click **Add Hardware** and specify the download cable or programming hardware. Make sure that you have installed the download cable driver before adding the hardware.

You do not have to manually add the USB-Blaster™ download cable to the list. After installing the driver, simply connect the download cable to the PC before opening the **Hardware Setup** dialog box. The USB-Blaster appears automatically in the list when the dialog box is opened.

Figure 19–5. Hardware Settings



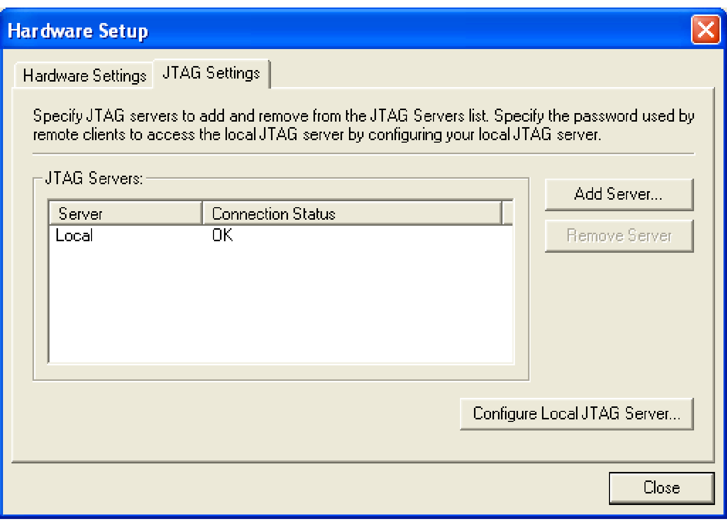
More information about programming hardware driver installation is available in the Design Software Support page on the Altera website.

JTAG Settings

The JTAG server allows programs such as the Quartus II Programmer to access the JTAG hardware. This application software is installed together with the Quartus II software. You can also access the JTAG download cable or programming hardware connected to a remote computer through the JTAG server of that computer. With the JTAG server, you can control the programming or configuration of devices from a single computer through other computers at remote locations. The JTAG server uses the TCP/IP communications protocol.

To view the **Hardware Setup** dialog box, click **Hardware Setup**. On the **JTAG Settings** tab (Figure 19–6), you can add or remove JTAG servers from the list. By default, you have only the local JTAG server (which is on your computer) in the list. By adding a remote JTAG server, you can access the JTAG hardware in that remote computer from your computer. You must have the password of the remote JTAG server to add the server to your list. Click **Add Server**, then enter the IP address of that computer in the **Server name** box and the password in the **Server password** box.

Figure 19–6. JTAG Settings



You can also allow remote clients to access the JTAG server on your computer and program or configure devices connected to your computer through the JTAG interface of your computer. Click **Configure Local JTAG Server** to enable the server and then enter the password that the remote clients require to access your JTAG server.

Device Programming and Configuration

The Quartus II Programmer supports single- or multi-device programming and configuration. This section describes the steps required to program or configure Altera devices, as well as how to bypass Altera and non-Altera devices in a JTAG chain.

Single Device Programming and Configuration

To program or configure a single device with the Quartus II Programmer, perform the following steps:

1. On the Tools menu, click **Programmer** to open the Programmer window.
2. Click **Hardware Setup** and select the programming hardware or download cable. If you are using JTAG mode, you can specify the correct JTAG settings for programming or configuration involving remote JTAG servers.
3. Click **Close**.
4. From the **Mode** list, select the programming or configuration mode.

5. Click **Add File** to add the **.pof** or **.sof** file to the programmer (you can omit this step if the file is already displayed). To change the file, select it and click **Change File**. To remove the file from the programmer, select it and click **Delete**.

If you use JTAG, AS, or in-socket programming mode, after the file has been added to the programmer, select the programming or configuration option by turning on the corresponding check box in the programmer.

6. Click **Start**.

Multi-Device Programming and Configuration

JTAG and PS modes allow you to program or configure a device chain. A JTAG chain can consist of a combination of FPGA, CPLD, and configuration devices that support JTAG mode. A PS chain consists of FPGAs that support PS mode. The steps for programming or configuring a device chain are similar to the steps for programming or configuring a single device. One exception is that in a device chain you must specify all the programming or configuration files for the devices you want to program or configure. JTAG mode allows you to bypass some of the devices in the JTAG chain while programming or configuring the rest of the devices. PS mode does not allow you to bypass devices in the FPGA chain.

Bypassing an Altera Device

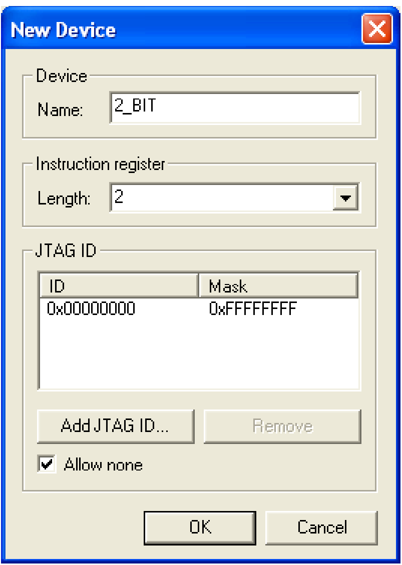
If you do not want to program an Altera device in the chain, turn off all the options in the row of that device. If you do not have the programming or configuration file for that device, click **Add Device** to specify the device.

Bypassing a Non-Altera Device

The JTAG chain you want to program or configure may contain non-Altera devices. To program or configure your Altera device in the JTAG chain, you must bypass those non-Altera devices. If the non-Altera devices are not in the list of devices that you can select, click **Add Device** in the programmer.

To bypass the devices, you must manually enter each device name and its JTAG instruction register length and JTAG ID code. Click **Add Device** to open the **Select Device** dialog box. Click **New** to define a device. In the **New Device** dialog box (Figure 19–7), enter the name of the device and the JTAG instruction register length of the device. You can find the JTAG instruction register length in the device's data sheet. You can also specify the JTAG ID code for the device by clicking **Add JTAG ID**. This is optional and you can turn on **Allow none** to set the ID code to all zeros. If you do not specify the JTAG ID code, the default value is all zeros.

Figure 19–7. New Device Dialog Box



After defining the device, the device appears in the device list (Figure 19–8). Click **Export** to save the information in a Quartus User-Defined Device (**.qud**) file. This file saves the information for the user-defined devices that appear under **Device name** in the dialog box and can be used by other Quartus II projects as well. To obtain information on the user-defined devices from the **.qud** file, click **Import** and the devices are listed under **Device name**.

Figure 19–8. Select Devices

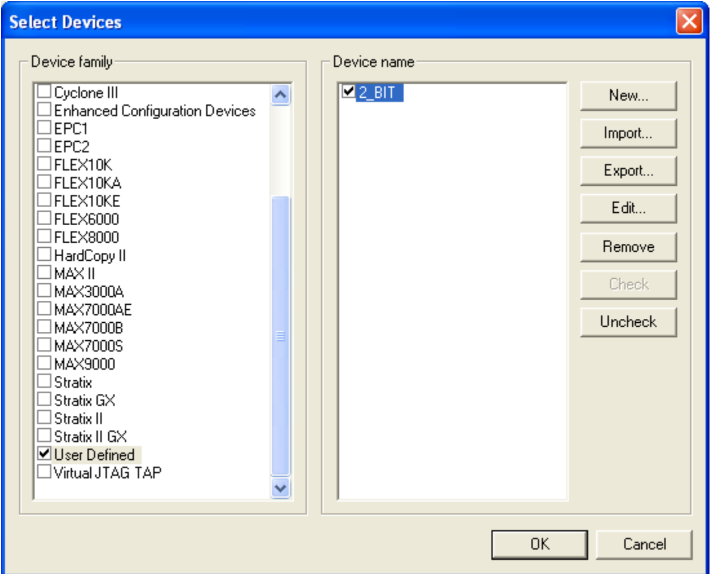


Figure 19–9 shows the programmer window for a JTAG chain.

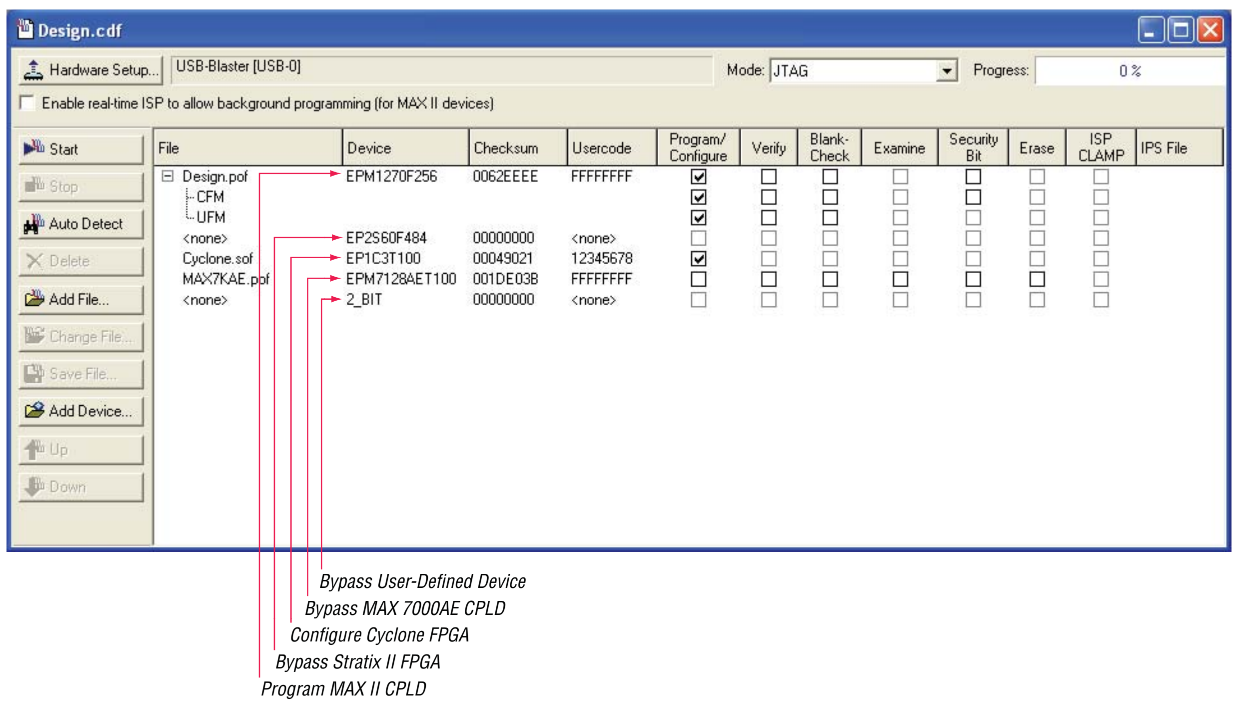
Figure 19–9. Multi-Device JTAG Chain



Chain Description File

All the information in the Quartus II Programmer, including the programming or configuration mode, programming or configuration files used, device chain information, and the programming options specified can be saved in a chain description file (**.cdf**). You do not have to specify the information each time you program the device chain. Simply open the **.cdf** file in the Quartus II software and the information appears in the Quartus II Programmer GUI.

Design Security Key Programming

The Quartus II Programmer supports the generation of encryption key programming files and encrypted configuration files for Altera FPGAs that support the design security feature. You can also use the Quartus II Programmer to program the encryption key into the FPGA.

For more information about using the design security feature with the Quartus II software, refer to *AN 341: Using the Design Security Feature in Stratix II and Stratix II GX Devices* and *AN 512: Using the Design Security Feature in Stratix III Devices*.

Optional Programming Files

The Quartus II software can generate optional programming or configuration files in various formats to be used with programming tools other than the Quartus II Programmer. In addition, you can convert the FPGA configuration files to programming files for configuration devices.

Types of Programming and Configuration Files

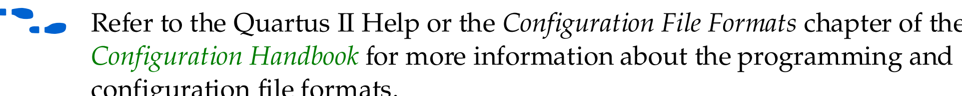
The Quartus II software generates programming files of various formats for use with different programming tools. Table 19–6 shows the programming and configuration files generated by the Quartus II software.

Table 19–6. Types of Programming and Configuration Files (Part 1 of 2)

File Format	Generated by the Quartus II Software	Supported by the Quartus II Programmer	Description
.sof	✓	✓	This configuration data file is used for configuring FPGA devices. The Quartus II Assembler generates this file when you compile your FPGA design.
.pof	✓	✓	This programming data file is used for programming CPLDs and configuration devices. The Quartus II Assembler generates the CPLD **.pof** file when you compile your CPLD design. The configuration device **.pof** file is converted from the FPGA **.sof** file.
.jam	✓	✓	This ASCII-format file is used for configuring or programming one or more FPGAs, CPLDs, and configuration devices in a JTAG chain. The **.jam** file includes both programming algorithm and data. Apart from the Quartus II Programmer, you can use Altera's Jam Standard Test and Programming Language (STAPL) player, the `quartus_jli` executable, or other third-party programming tools together with the **.jam** file. The **.jam** file is also suitable for embedded processor-type programming environments.
.jbc	✓	✓	Similar to the **.jam** file, this binary-format file is used for configuring or programming one or more FPGAs, CPLDs, and configuration devices in a JTAG chain. The **.jbc** file includes both the programming algorithm and data, and the size is smaller than the **.jam** file. In addition to the Quartus II Programmer, you can use Altera's Jam Byte-Code player, the `quartus_jli` executable, or other third-party programming tools together with the **.jbc** file. The **.jbc** file is also suitable for embedded processor-type programming environments.
Serial Vector Format File (**.svf**)	✓	—	This ASCII-format file is used for configuring, programming, blank-checking, and verifying one or more FPGAs, CPLDs, and configuration devices in a JTAG chain. The **.svf** file, which includes programming algorithm and data, is suitable for an automated test equipment (ATE) environment that requires a fixed programming algorithm.

Table 19–6. Types of Programming and Configuration Files (Part 2 of 2)

File Format	Generated by the Quartus II Software	Supported by the Quartus II Programmer	Description
In-System Configuration File (**.isc**)	✓	—	This data file is used with the IEEE 1532 BSDL file for programming a single device that supports IEEE 1532 programming. The Quartus II software supports the **.isc** file for MAX 7000AE, MAX 7000B, and MAX 3000A CPLDs.
Hexadecimal Intel-Format Output File (**.hexout**)	✓	—	The **.hexout** file is used for programming FPGA configuration data into enhanced configuration devices or other storage devices. For enhanced configuration devices, use the enhanced configuration device **.pof** file to generate the **.hexout** file. Use the FPGA **.sof** file to generate the **.hexout** file for other storage devices (for example, the flash or EEPROM devices). You can use a microcontroller to read back the data from the storage device and configure the FPGA. To program the enhanced configuration device or other storage devices with the **.hexout** file, you can use other third-party programming tools.
Raw Binary File (**.rbf**)	✓	—	This binary file contains configuration data for one or more FPGAs. You can use Microblaster or Altera's JRunner software to configure your FPGA device with the **.rbf** file. The **.rbf** file is also suitable for embedded processor configuration environments.
Tabular Text File (**.ttf**)	✓	—	This ASCII file contains configuration data for one or more FPGAs. The **.ttf** file is used for embedded processor-type configuration.
Raw Programming Data (**.rpd**)	✓	—	This binary file is used for programming serial configuration devices. Use the serial configuration device **.pof** file to generate this file. You can use Altera's SRunner software to program your serial configuration device with the **.rpd** file.
JTAG Indirect Configuration File (**.jic**)	✓	✓	The **.jic** file is used for programming serial configuration devices through JTAG with the Quartus II Programmer and Altera FPGAs that support AS configuration mode.



Refer to the Quartus II Help or the *Configuration File Formats* chapter of the *Configuration Handbook* for more information about the programming and configuration file formats.

For more information about using the **.jam** and **.jbc** programming files with the Jam STAPL Player, Jam STAPL Byte-Code Player, and the `quartus_jli` command-line executable, refer to *AN 425: Using Command-Line Jam STAPL Solution for Device Programming*.

Generating Optional Programming Files

When you compile your design, the Quartus II Assembler generates the **.sof** file for an FPGA or a **.pof** file for a CPLD. With the **.sof** or **.pof** file for your design, you can then create other optional programming or configuration files, or convert the **.sof** file to target a particular configuration device.

Create Programming Files

The Quartus II software allows you to create **.jam**, **.jbc, .svf**, or **.isc** programming or configuration files. In addition, you can create **.jam**, **.jbc**, and **.svf** files for a JTAG chain that consists of more than one device.

To create the files, open the Quartus II Programmer, set the programming or configuration mode to JTAG, and then add the programming or configuration files or devices to the programmer. On the File menu, click **Create/Update** and then click **Create JAM, SVF, or ISC File**. Select the file format and name the file accordingly.

An **.svf** file can only be created for programming or verification. In addition, you can specify whether or not to do the optional blank-check operation with the **.svf** file.

Convert Programming Files

To store the FPGA data into configuration devices, you can convert the **.sof** data to another format and program the configuration device. The Quartus II software supports converting the data into **.pof**, **.hexout**, **.rbf**, **.ttf**, **.rpd**, or **.jic** format.

For more information about converting programming files with the Quartus II software, refer to the *Configuration File Formats* chapter of the *Configuration Handbook*.

Generating Optional Programming or Configuration Files During Compilation

The Quartus II software can generate optional programming or configuration files automatically when you compile your design. To select the format of the optional programming or configuration files to be generated during compilation, on the Assignments menu, click **Settings**. Under **Device**, click **Device and Pin Options**.

You can select the configuration device from the **Configuration** tab for the **.pof** file generation. For other optional programming and configuration file generation, you can select the file format under the **Programming Files** tab.

Flash Loaders

Serial configuration devices and the common flash interface (CFI) flash devices do not support the JTAG interface and cannot be programmed directly through the normal JTAG programming. Flash loaders allow the programming of the serial configuration device and the CFI flash from the Quartus II Programmer through JTAG.

Parallel Flash Loader

The parallel flash loader (PFL) performs two functions:

- Allows the programming of the CFI flash through the JTAG interface
- Acts as the configuration controller that reads the configuration data from the CFI flash and configures the FPGA

To program the CFI flash, the PFL uses the MAX II device as a bridge between the JTAG interface of the Quartus II Programmer and the CFI of the CFI flash device. You can program FPGA configuration data and user data into the flash with a flash **.pof** file generated by the Quartus II software. After the flash is programmed with the FPGA configuration data, the PFL is then used to read the configuration data back from the CFI flash to configure the FPGA.

For more information about the PFL, refer to *AN 386: Using the MAX II Parallel Flash Loader with the Quartus II Software*.

Serial Flash Loader

The serial flash loader (SFL) allows programming of the serial configuration devices through JTAG. The SFL uses the FPGA device that supports AS configuration mode as a bridge between the active serial memory interface (ASMI) of the serial configuration device and the JTAG interface of the programmer. The Quartus II Programmer uses the **.jic** file converted from the FPGA **.sof** file to program the serial configuration device though JTAG.

For more information about the SFL, refer to *AN 370: Using the Serial Flash Loader with the Quartus II Software*.

JTAG Chain Debugger Tool

The JTAG Chain Debugger tool is a Quartus II Programmer feature that allows you to test the JTAG chain integrity and detect intermittent failures of the JTAG chain. In addition, the tool allows you to shift in JTAG instructions and data through the JTAG interface as well as stepping through the test access port (TAP) controller state machine for debugging purpose.

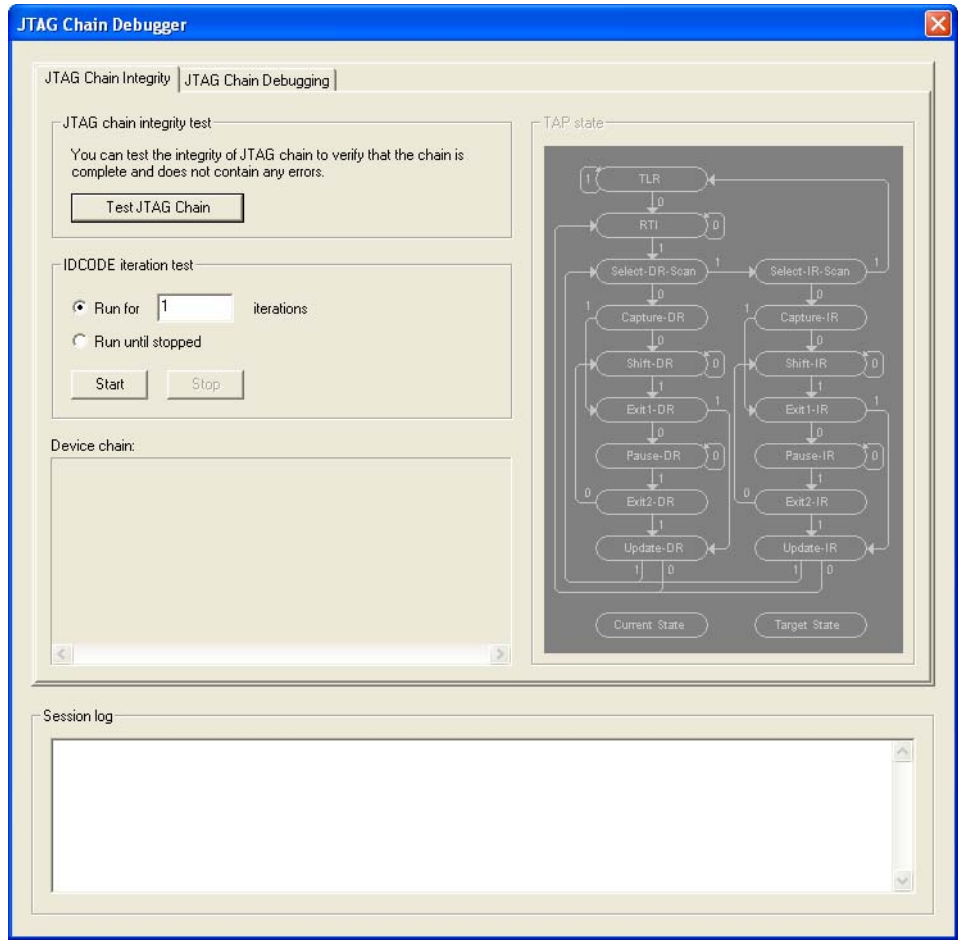
To launch the JTAG Chain Debugger, open the Quartus II Programmer. From the Processing menu, click **JTAG Chain Debugger**. The Quartus II programmer also prompts you to launch the JTAG Chain Debugger if the **Auto Detect** operation fails to detect the device chain.

The JTAG Chain Debugger GUI is divided into two sections: the JTAG Chain Integrity section and the JTAG Chain Debugging section.

JTAG Chain Integrity

From the **JTAG Chain Integrity** tab in the JTAG Chain Debugger tool, you can perform the JTAG chain integrity test and the IDCODE iteration test. Figure 19–10 shows the **JTAG Chain Integrity** tab in the JTAG Chain Debugger tool.

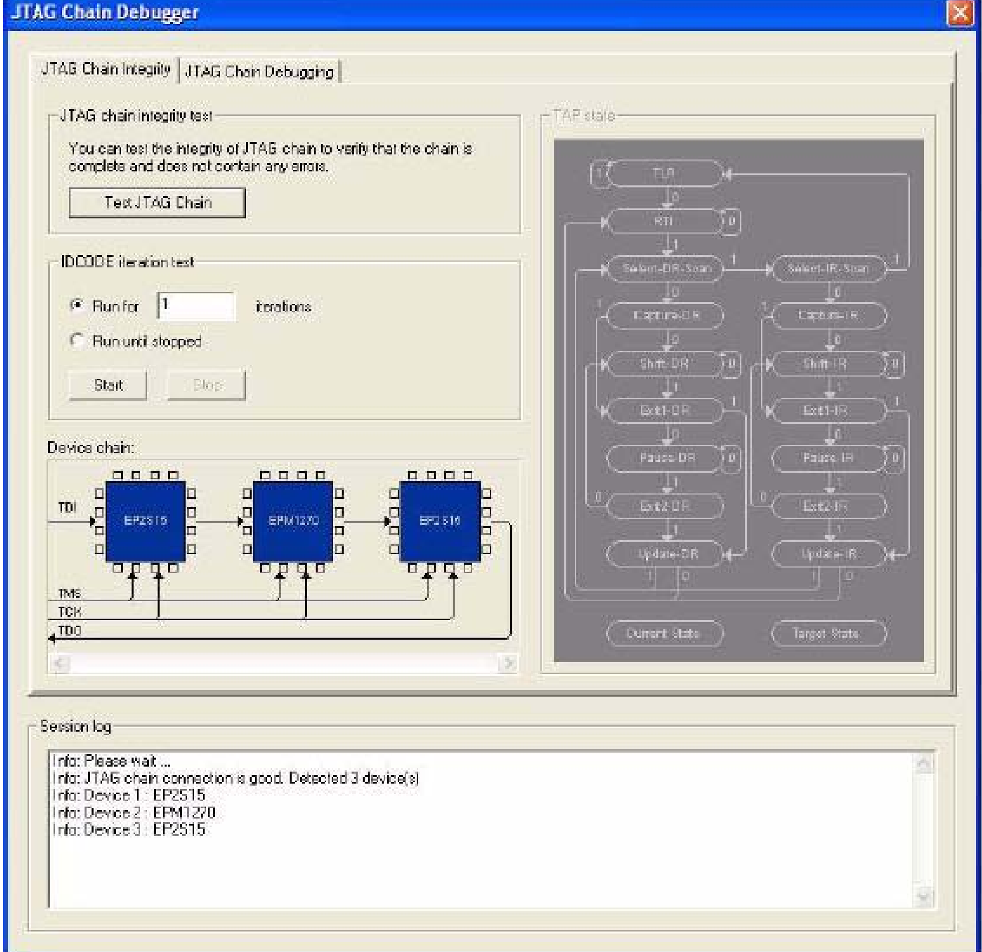
Figure 19–10. JTAG Chain Integrity Tab



JTAG Chain Integrity Test

The JTAG chain integrity test performs a simple test to ensure that there is t_{DO}-to-t_{CO} connectivity for the JTAG chain under test. When you click the **Test JTAG Chain** button, the tool attempts to read out the 32-bit IDCODE of the device or devices in the chain. If the JTAG chain connection is good, the device IDCODEs are shifted out from the chain through the `TDO` output. The **Device chain** box displays the device or devices detected in the chain based on the IDCODEs shifted out, and the **Session log** message box reports the test result. Figure 19–11 shows that the tool has detected three devices in the JTAG chain and the connection is good.

Figure 19–11. Good JTAG Chain Connection

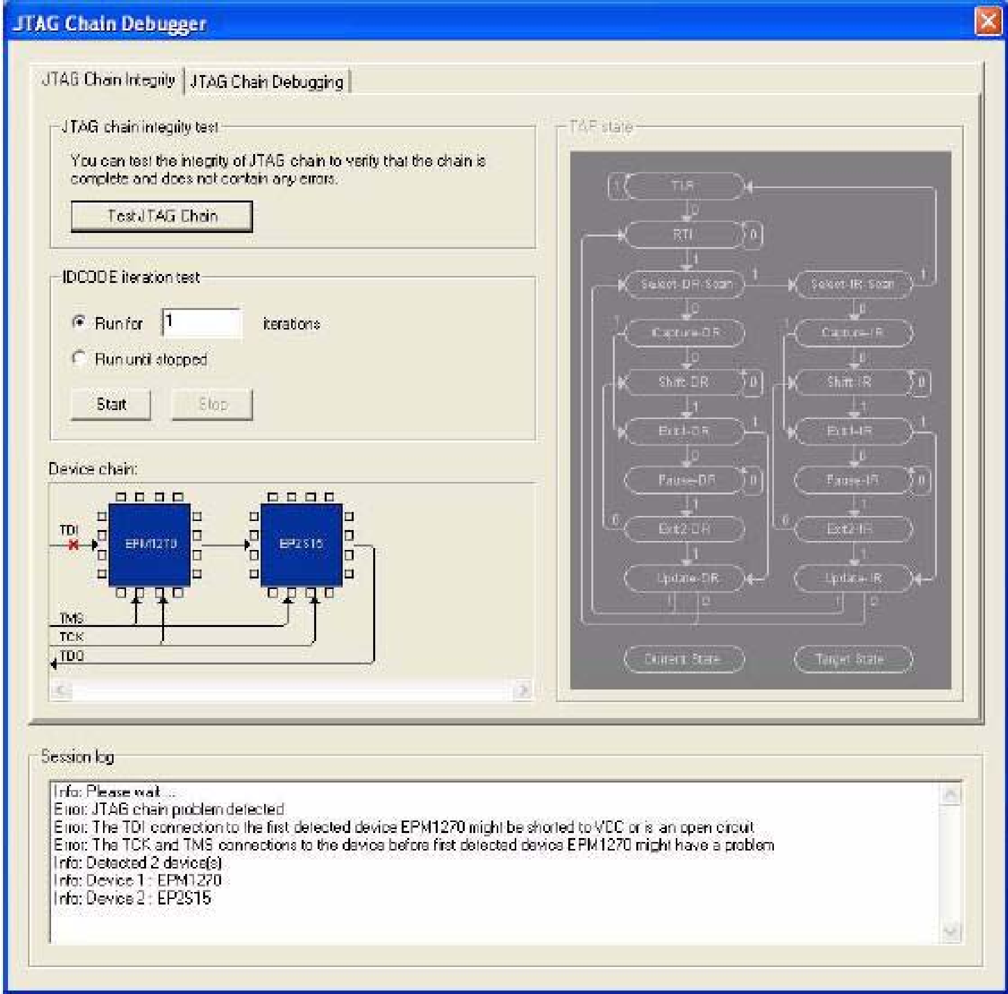


The IDCODE of the device cannot be shifted out through the chain if one or both of the following two circumstances exist:

- There is a connection problem between the `TDO` pin of a device in the chain and the `TDI` pin of the subsequent device in the chain (in which case the connection might be open)
- The device has `TCK` or `TMS` connection problems

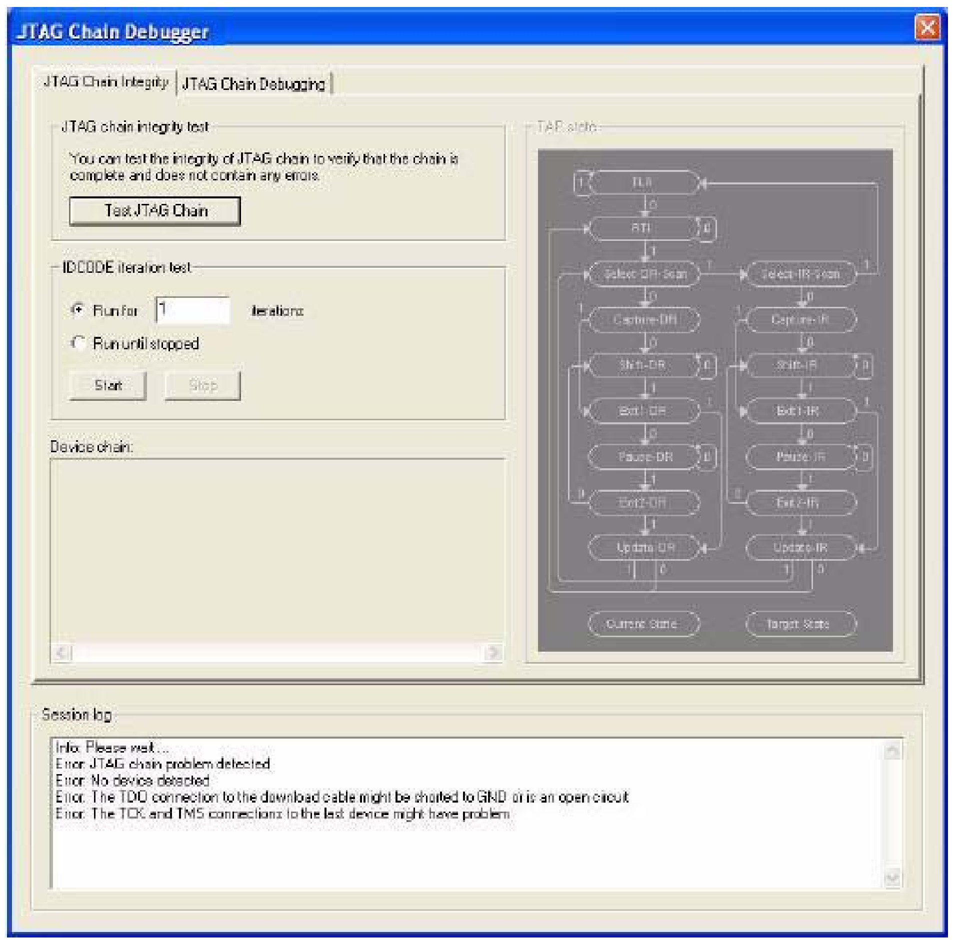
The tool can detect only the subsequent devices in the chain and report the potential problems in the chain. Figure 19–12 shows that the tool detects only two devices in the chain, and the first device in the chain has a connection problem.

Figure 19–12. Incomplete JTAG Chain Detected



If there is a connection problem between the `TDO` pin of the last device in the chain and the download cable, the JTAG Chain Debugger is not able to capture any data from the chain. The tool reports the error, as shown in Figure 19–13. In addition to the `TDO` connection problem, the tool also reports this problem if the devices in the chain are not powered up or the download cable is not connected to the JTAG chain.

Figure 19–13. No Devices Detected



IDCODE Iteration Test

You can perform the IDCODE iteration test to check the consistency of the JTAG chain. The operation is similar to the JTAG chain integrity test, except that the test can be repeated a number of times. The IDCODE test is able to detect intermittent failures that might happen in the chain based on the number of tests done. The tool reports whether the chain is consistent by checking for chain intermittent discontinuity, apart from showing the device detected.

You can specify the number of iterations to run (up to 9999 iterations) or manually stop the test by selecting **Run until stopped**. Press the **Stop** button to stop the test if the **Run until stopped** option is selected.

The **Auto Detect**, **JTAG chain integrity test**, and **IDCODE iteration test** features are used for checking the JTAG chain connection and detecting the devices in the chain. However, there are some differences between the three features. Table 19–7 shows the differences between the **Auto Detect**, **JTAG chain integrity test**, and **IDCODE iteration test** features.

Table 19–7. Differences between Auto Detect, JTAG Chain Integrity Test, and IDCODE Iteration Test

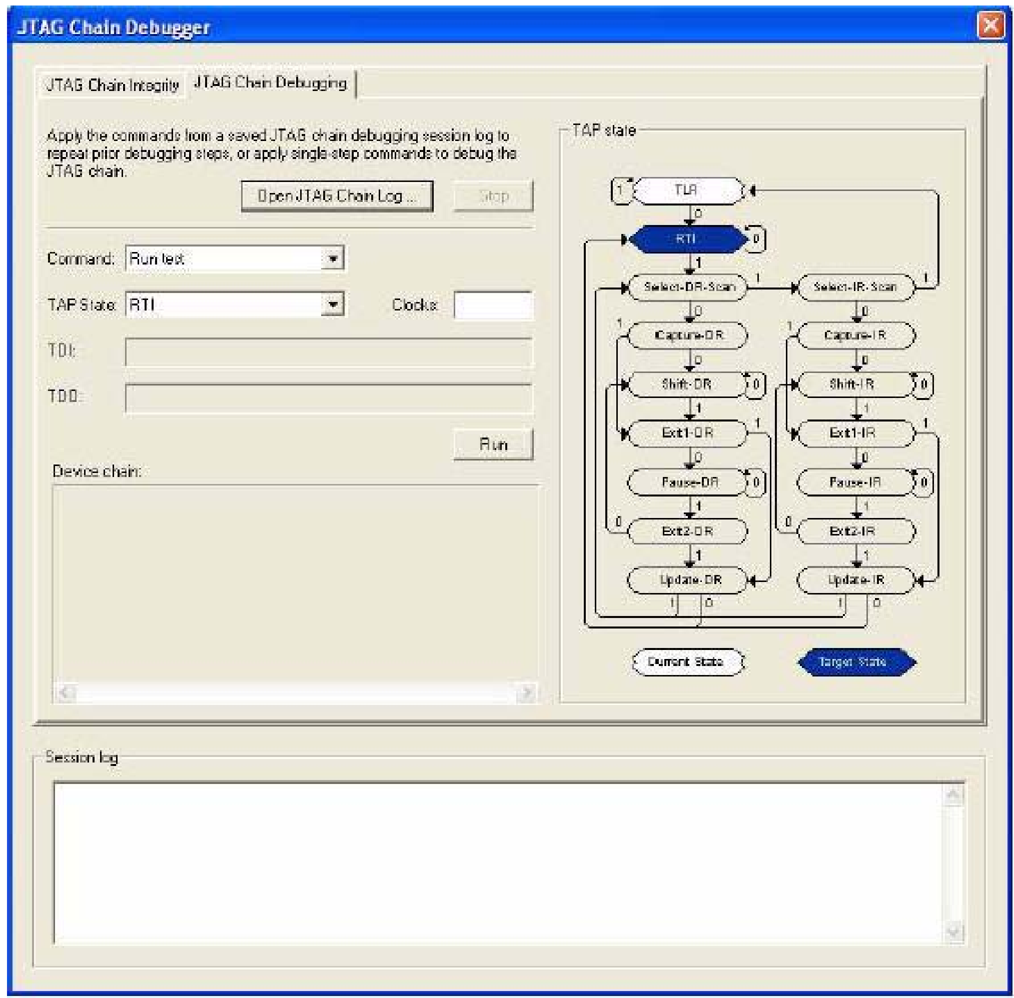
Auto Detect	JTAG Chain Integrity Test	IDCODE Iteration Test
Does not list any device detected in the chain if there is any connection problem in the chain	Lists device or devices detected in the chain, regardless of whether any of the following circumstances exist: ■ Connection problem between the download cable and the `TDI` input of the first device in the chain ■ `TDO` and `TDI` connection problem between the devices in the chain ■ `TCK` or `TMS` connection problem of devices in the chain other than the last device in the chain.	Lists device(s) detected in the chain, regardless of whether any of the following circumstances exist: ■ Connection problem between the download cable and the `TDI` input of the first device in the chain ■ `TDO` and `TDI` connection problem between the devices in the chain ■ `TCK` or `TMS` connection problem of devices in the chain other than the last device in the chain.
Error reporting more general; does not report what problem in the chain is	Error reporting more specific; reports the potential problem in the chain	Error reporting more specific; reports the potential problem in the chain
Test is only performed once	Test is only performed once	Test can be repeated based on the number specified, or until stopped by the user
Not for detecting intermittent chain connection problem	Not for detecting intermittent chain connection problem	For detecting intermittent chain connection problem

JTAG Chain Debugging

The **JTAG Chain Debugging** tab allows you to shift the JTAG instructions and data manually into the JTAG chain, as well as control the test access port (TAP) state machine of the device or devices in the JTAG chain.

Figure 19–14 shows the **JTAG Chain Debugging** tab.

Figure 19–14. JTAG Chain Debugging Tab



There are four JTAG chain debugging commands. Table 19–8 lists the commands and the descriptions.

Table 19–8. JTAG Chain Debugging Commands

Command	Description
Run Test	Forces the TAP state machine to run for a specific number of TCK cycles in one of the following states. ■ TLR (Test-Logic-Reset) ■ RTI (Run-Test-Idle) ■ Pause-DR ■ Pause-IR You must specify the number of TCK cycles the TAP state machine needs to run in the specified state.
Scan Instruction Register	Allows you to shift the JTAG instruction(s) into the instruction register(s) of the device(s) in the chain. You can specify one of the following states in which the TAP state machine stops when finished shifting in the instructions: ■ RTI ■ Pause-IR ■ TLR You must specify the instruction to be shifted in through TDI, and the number of TCK cycles
Scan Data Register	Allows you to shift the data into the device(s) in the chain. You can specify one of the following states in which the TAP state machine stops when it has completed shifting in the data: ■ RTI ■ Pause-DR ■ TLR You must specify the data to be shifted in through TDI, and the number of TCK cycles.
Goto State	Forces the TAP state machine to any one of the specified states.

To perform JTAG chain debugging with the tool, perform the following steps:

1. In the **Command** pull-down list, select the appropriate JTAG command (Figure 19–14).
2. Depending on the command you selected, make the following specifications:
   - The TAP state that is related to the JTAG command
   - The number of `TCK` cycles
   - The value to be scanned into the chain, through `TDI`, expressed as a hex value
3. To execute the command selected, click **Run**.

When you shift the instructions or data into the JTAG chain, the scanned-out value is displayed in hex by the tool.

The tool shows the current and target TAP state in the TAP state diagram. The target TAP state shown in the TAP state diagram depends on the state specified in the **TAP State** pull-down list. This is where the TAP state machine stops upon the successful execution of the JTAG command.

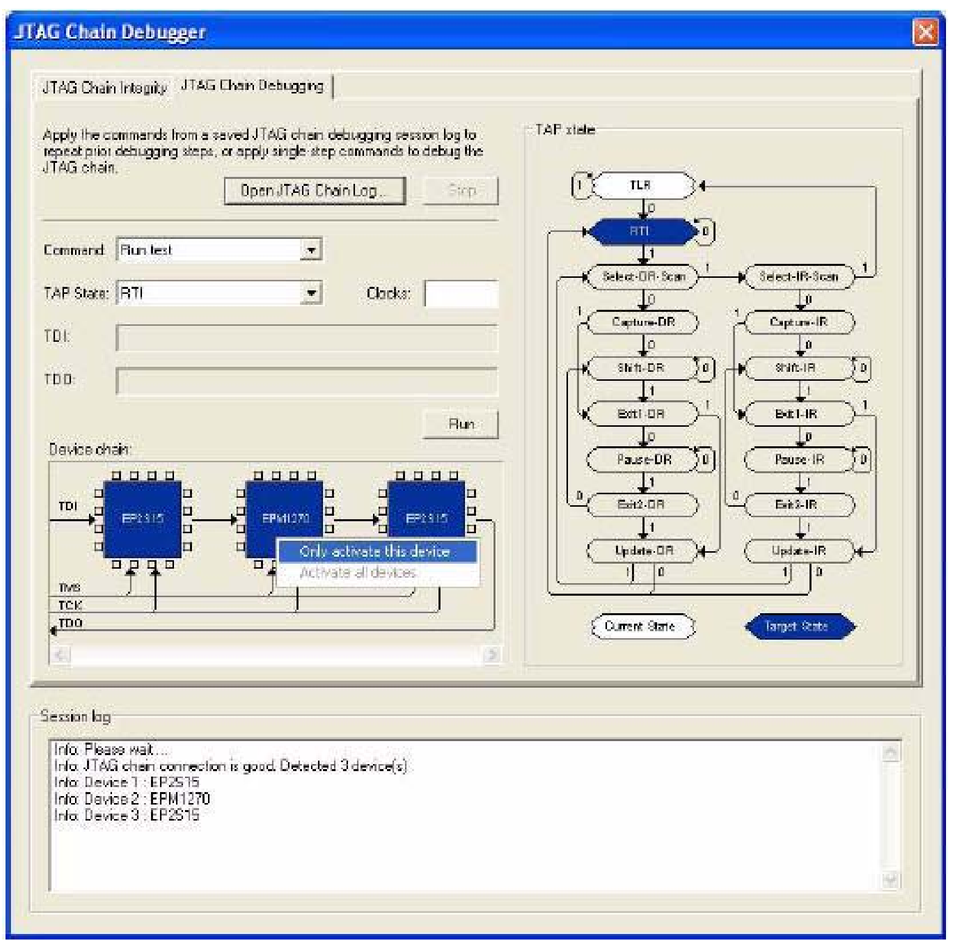
You can also double-click on a specific state in the state diagram, causing the TAP state machine to go to that state. This is similar to selecting **Goto State** from the **Command** pull-down list and clicking **Run**.

Bypassing Devices in the Chain

For a multi-device JTAG chain, you can isolate one device on the chain and perform your debugging on that device only.

1. Perform the JTAG chain integrity test before initiating the debug session. The tool displays the devices detected in the chain.
2. In the **JTAG Chain Debugging** tab, right-click the one device in the **Device chain** box that you do *not* want to bypass.
3. Select **Only activate this device**, as shown in Figure 19–15. Only the active device is in dark blue. All other devices are in bypass mode.

Figure 19–15. Activating Only One Device in the JTAG Chain

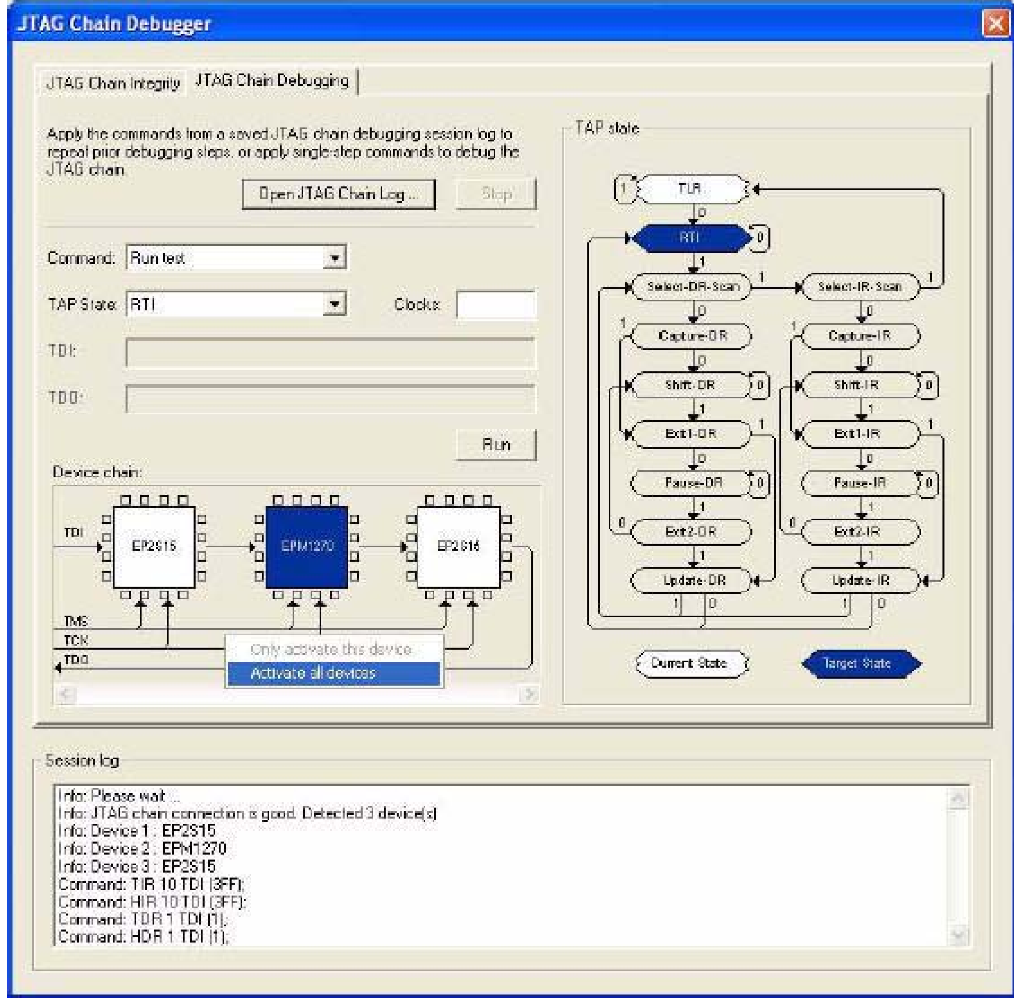


When only one device is enabled in the chain, the JTAG Chain Debugger automatically pads the additional bits for the bypassed devices when scanning the value into the chain. You can debug the chain as if this was the only one device in the chain.

© March 2009 Altera Corporation

To enable all of the bypassed devices in the chain, right-click the area inside the **Device chain** box (other than on the devices), and select **Activate all devices**, as shown in Figure 19–16.

Figure 19–16. Activating All Devices in the Chain



JTAG Chain Log

In addition to the test results and messages, all of the JTAG chain debugging operations you performed are listed in the Session log window. You can save the session log so you can play back the debugging sequences later. The commands, messages, and test results are saved in the session log file.

To save the session log, right-click the session log and select **Save Session Log**. Name the file accordingly. To clear the session log, right-click the session log and select **Clear Session Log**.

To play back the previously saved session log, click the **Open JTAG Chain Log** button and open the saved file. The JTAG Chain Debugger then executes the debug sequence commands in the file. Click the **Stop** button to stop the execution of the file.

Other Programming Tools

This section covers other programming tools that are related to the Quartus II Programmer and can be used for programming or debugging programming problems.

Quartus II Stand-Alone Programmer

If you do not have the full version of the Quartus II software, Altera offers the free Quartus II Stand-Alone Programmer. This stand-alone programmer has the full function of the normal Quartus II Programmer, and enables you to create or convert programming files from the **.sof** or **.pof** file of your design. You can download the Quartus II Stand-Alone Programmer from the Download Center on the Altera website.

jtagconfig Debugging Tool

The `jtagconfig` command-line utility is included with the Quartus II software. You can use this utility (which is similar to the auto detect operation in the Quartus II Programmer) to check the devices in a JTAG chain and the user-defined devices.

For more information about the `jtagconfig` utility, type one of the following commands at the command prompt:

```
jtagconfig -h ↵
jtagconfig --help ↵
```

Scripting Support

In addition to the Quartus II Programmer GUI, you can use the Quartus II command-line programmer (`quartus_pgm`) to enter commands. The `quartus_pgm` command-line programmer comes with the Quartus II Programmer. You can run this programmer separately from the Quartus II software. You can also run the procedures for the programmer in a Tcl script. The programmer accepts the **.pof**, **.sof**, and **.jic** programming or configuration files. You can also use the **.cdf** file.

For more information about the command-line syntax, type one of the following commands at the command prompt:

```
quartus_pgm -h ↵
quartus_pgm --help ↵
```

For more information about a specific programmer option or topic, type the following command at the command prompt:

```
quartus_pgm --help=<option|topic> ↵
```

Example 19–1 shows a command that programs a device:

Example 19–1. Programming a Device

```
quartus_pgm -c byteblasterII -m jtag -o bpv;design.pof ↵
```

Where:

`-c byteblasterII` specifies the ByteBlaster II download cable
`-m jtag` specifies the JTAG programming mode
`-o bpv` represents the blank-check, program, and verify operations
`design.pof` represents the **.pof** file used for the programming

The programmer automatically executes the erase operation before programming the device.

For detailed information about scripting command options, you can also refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ↵
```

The *Quartus II Scripting Reference Manual* includes the same information in PDF format.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. For information about all settings and constraints in the Quartus II software, refer to the *Quartus II Settings File Manual*. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Conclusion

The Quartus II Programmer offers you a wide variety of options to program and configure your Altera devices. With the Quartus II Programmer, the Quartus II software provides you with a complete solution for your FPGA or CPLD design prototyping, which can even be performed in the production environment.

Document Revision History

Table 19–9 shows the revision history for this chapter.

Table 19–9. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Added a row to Table 19–5 on page 19–9 ■ Changed references from “JTAG Chain Debug” to “JTAG Chain Debugger” ■ Updated Figure 19–10 through Figure 19–16	Updated for the Quartus II software version 9.0 release.
November 2008 v8.1.0	Added the new section “JTAG Chain Debug Tool” on page 19–20 and associated sub-headings, including: ■ “JTAG Chain Integrity” on page 19–21 ■ “JTAG Chain Integrity Test” on page 19–22 ■ “IDCODE Iteration Test” on page 19–24 ■ “JTAG Chain Debugging” on page 19–25 ■ “Bypassing Devices in the Chain” on page 19–28 ■ “JTAG Chain Log” on page 19–29 Minor editorial updates Updated entire chapter using 8½” × 11” chapter template	Updated according to Quartus II software version 8.1 release, including the JTAG Chain Debugging Tool, which is new with the current release.
May 2008 v8.0.0	Updated date and part number and added hypertext links. Also updated file format naming conventions.	—

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

About this Handbook

This handbook provides comprehensive information about the Altera® Quartus® II design software, version 9.0.

How to Contact Altera

For the most up-to-date information about Altera products, see the following table.

Contact (Note 1)	Contact Method	Address
Technical support	Website	www.altera.com/support
Technical training	Website	www.altera.com/training
	Email	custrain@altera.com
Altera literature services	Email	literature@altera.com
Non-technical support (General)	Email	nacomp@altera.com
(Software Licensing)	Email	authorization@altera.com

Note:

(1) You can also contact your local Altera sales office or sales representative.

Third-Party Software Product Information

Third-party software products described in this handbook are not Altera products, are licensed by Altera from third parties, and are subject to change without notice. Updates to these third-party software products may not be concurrent with Quartus II software releases. Altera has assumed responsibility for the selection of such third-party software products and its use in the Quartus II 9.0 software release. To the extent that the software products described in this handbook are derived from third-party software, no third party warrants the software, assumes any liability regarding use of the software, or undertakes to furnish you any support or information relating to the software. EXCEPT AS EXPRESSLY SET FORTH IN THE APPLICABLE ALTERA PROGRAM LICENSE SUBSCRIPTION AGREEMENT UNDER WHICH THIS SOFTWARE WAS PROVDED TO YOU, ALTERA AND THIRD-PARTY LICENSORS DISCLAIM ALL WARRANTIES WITH RESPECT TO THE USE OF SUCH THIRD-PARTY SOFTWARE CODE OR DOCUMENTATION IN THE SOFTWARE, INCLUDING, WITHOUT LIMITATION, ANY WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, TITLE, AND NONINFRINGEMENT. For more information, including the latest available version of specific third-party software products, refer to the documentation for the software in question.

Typographic Conventions

The following table shows the typographic conventions that this document uses.

Visual Cue	Meaning
Bold Type with Initial Capital Letters	Command names, dialog box titles, checkbox options, and dialog box options are shown in bold, initial capital letters. Example: **Save As** dialog box.
bold type	External timing parameters, directory names, project names, disk drive names, file names, file name extensions, and software utility names are shown in bold type. Examples: $\mathbf{f_{MAX}}$, **\qdesigns** directory, **d:** drive, **chiptrip.gdf** file.
Italic Type with Initial Capital Letters	Document titles are shown in italic type with initial capital letters. Example: *AN 75: High-Speed Board Design.*
Italic type	Internal timing parameters and variables are shown in italic type. Examples: t_{PIA}, $n + 1$. Variable names are enclosed in angle brackets (< >) and shown in italic type. Example: *<file name>*, *<project name>***.pof** file.
Initial Capital Letters	Keyboard keys and menu names are shown with initial capital letters. Examples: Delete key, the Options menu.
“Subheading Title”	References to sections within a document and titles of on-line help topics are shown in quotation marks. Example: “Typographic Conventions.”
`Courier type`	Signal and port names are shown in lowercase Courier type. Examples: `data1`, `tdi`, `input`. Active-low signals are denoted by suffix `n`, e.g., `resetn`. Anything that must be typed exactly as it appears is shown in Courier type. For example: `c:\qdesigns\tutorial\chiptrip.gdf`. Also, sections of an actual file, such as a Report File, references to parts of files (e.g., the AHDL keyword `SUBDESIGN`), as well as logic function names (e.g., `TRI`) are shown in Courier.
1., 2., 3., and a., b., c., etc.	Numbered steps are used in a list of items when the sequence of the items is important, such as the steps listed in a procedure.
■ ■	Bullets are used in a list of items when the sequence of the items is not important.
✓	The checkmark indicates a procedure that consists of one step only.
☞	The hand points to information that requires special attention.
CAUTION	A caution calls attention to a condition or possible situation that can damage or destroy the product or the user’s work.
WARNING	A warning calls attention to a condition or possible situation that can cause injury to the user.
↵	The angled arrow indicates you should press the Enter key.
(feet)	The feet direct you to more information on a particular topic.

Chapter Revision Dates

The chapters in this book, *Quartus II Handbook Version 9.0 Volume 4: SOPC Builder*, were revised on the following dates. Where chapters or groups of chapters are available separately, part numbers are listed.

Chapter 1 Introduction to SOPC Builder
Revised: *March 2009*
Part Number: *QII54001-9.0.0*

Chapter 2 System Interconnect Fabric for Memory-Mapped Interfaces
Revised: *March 2009*
Part Number: *QII54003-9.0.0*

Chapter 3 System Interconnect Fabric for Streaming Interfaces
Revised: *March 2009*
Part Number: *QII54019-9.0.0*

Chapter 4 SOPC Builder Components
Revised: *March 2009*
Part Number: *QII54004-9.0.0*

Chapter 5 Using SOPC Builder with the Quartus II Software
Revised: *March 2009*
Part Number: *QII54023-9.0.0*

Chapter 6 Component Editor
Revised: *March 2009*
Part Number: *QII54005-9.0.0*

Chapter 7 Component Interface Tcl Reference
Revised: *March 2009*
Part Number: *QII54022-9.0.0*

Chapter 8 Archiving SOPC Builder Projects
Revised: *March 2009*
Part Number: *QII54017-9.0.0*

Chapter 9 SOPC Builder Memory Subsystem Development Walkthrough
Revised: *March 2009*
Part Number: *QII54006-9.0.0*

Chapter 10 SOPC Builder Component Development Walkthrough
Revised: *March 2009*
Part Number: *QII54007-9.0.0*

Chapter 11 Avalon Memory-Mapped Bridges
Revised: *March 2009*
Part Number: *QII54020-9.0.0*

Chapter 12 Avalon Streaming Interconnect Components
Revised: *March 2009*
Part Number: *QII54021-9.0.0*

Section I. SOPC Builder Features

This section introduces the SOPC Builder system integration tool. Chapters in this section answer the following questions:

- What is SOPC Builder?
- What features does SOPC Builder provide?

This section includes the following chapters:

- Chapter 1, Introduction to SOPC Builder
- Chapter 2, System Interconnect Fabric for Memory-Mapped Interfaces
- Chapter 3, System Interconnect Fabric for Streaming Interfaces
- Chapter 4, SOPC Builder Components
- Chapter 5, Using SOPC Builder with the Quartus II Software
- Chapter 6, Component Editor
- Chapter 7, Component Interface Tcl Reference
- Chapter 8, Archiving SOPC Builder Projects

☞ For information about the revision history for chapters in this section, refer to each individual chapter's revision history.

1. Introduction to SOPC Builder

QII54001-9.0.0

Quick Start Guide

For a quick introduction on how to use SOPC Builder, follow these general steps:

- Install the Quartus® II software, which includes SOPC Builder. This is available at www.altera.com.
- Take advantage of the one-hour online course, *Using SOPC Builder*.
- Download and run the checksum sample design described in the *SOPC Builder Memory Subsystem Development Walkthrough* chapter in volume 4 of the *Quartus II Handbook*.

Overview

SOPC Builder is a powerful system development tool. SOPC Builder enables you to define and generate a complete system-on-a-programmable-chip (SOPC) in much less time than using traditional, manual integration methods. SOPC Builder is included as part of the Quartus II software.

You may have used SOPC Builder to create systems based on the Nios® II processor. However, SOPC Builder is more than a Nios II system builder; it is a general-purpose tool for creating systems that may or may not contain a processor and may include a soft processor other than the Nios II processor.

SOPC Builder automates the task of integrating hardware components. Using traditional design methods, you must manually write HDL modules to wire together the pieces of the system. Using SOPC Builder, you specify the system components in a GUI and SOPC Builder generates the interconnect logic automatically. SOPC Builder generates HDL files that define all components of the system, and a top-level HDL file that connects all the components together. SOPC Builder generates either Verilog HDL or VHDL equally.

In addition to its role as a system generation tool, SOPC Builder provides features to ease writing software and to accelerate system simulation. This chapter includes the following sections:

- “Architecture of SOPC Builder Systems” on page 1–2
- “Functions of SOPC Builder” on page 1–5
- “Operating System Support” on page 1–6
- “Talkback Support” on page 1–7

Architecture of SOPC Builder Systems

An SOPC Builder component is a design module that SOPC Builder recognizes and can automatically integrate into a system. You can also define and add custom components or select from a list of provided components. SOPC Builder connects multiple modules together to create a top-level HDL file called the SOPC Builder system. SOPC Builder generates system interconnect fabric that contains logic to manage the connectivity of all modules in the system.

SOPC Builder Modules

This document refers to *components* as the class definition for a module, while *module* is the instance of the component class.

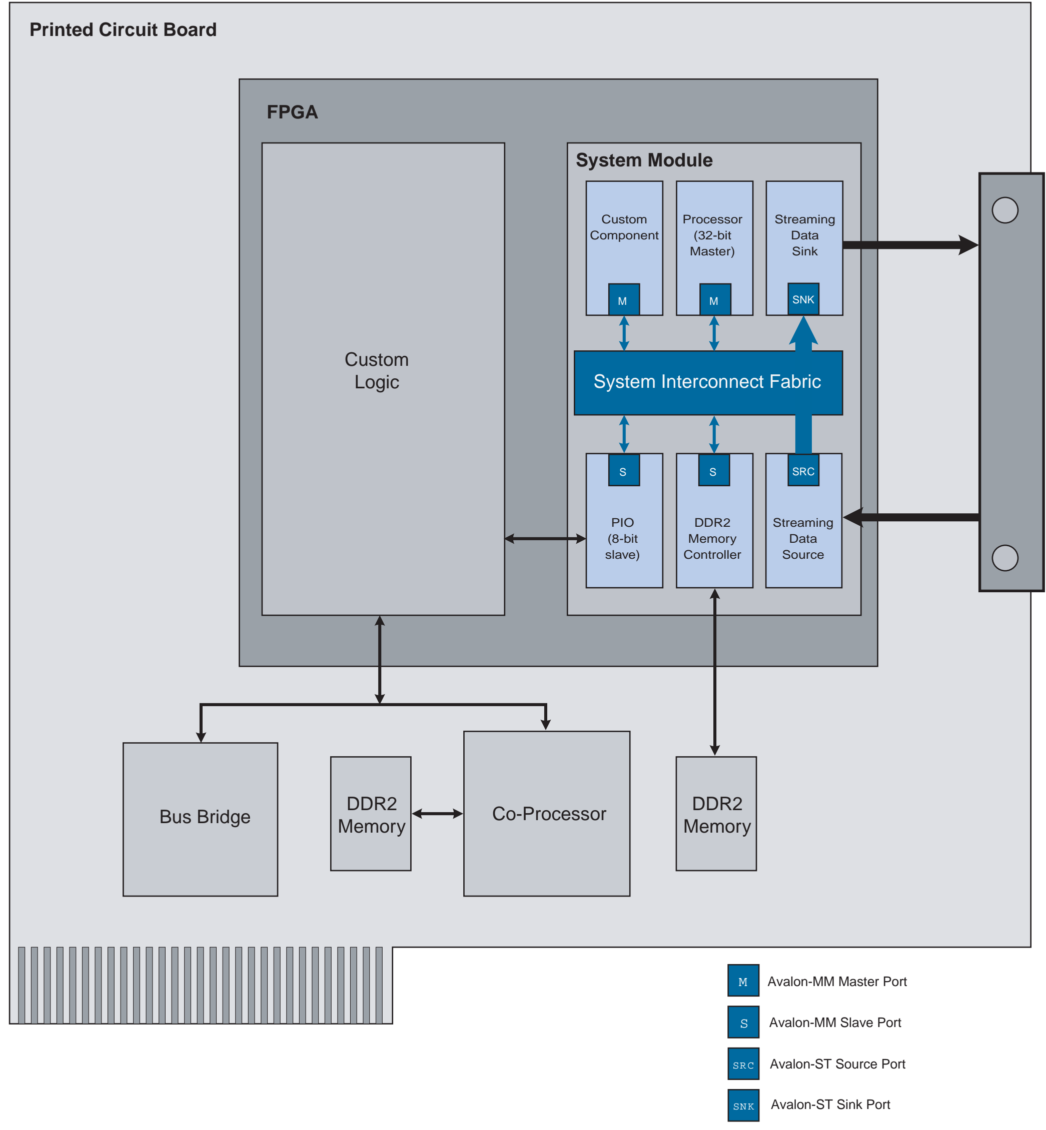
SOPC Builder modules are the building blocks for creating an SOPC Builder system. SOPC Builder modules use Avalon® interfaces, such as memory-mapped, streaming, and IRQ, for the physical connection of components. You can use SOPC Builder to connect any logical device (either on-chip or off-chip) that has an Avalon interface. There are different types of Avalon interfaces, as described in the *Avalon Interface Specifications*.

For details on the Avalon-MM interface refer to *System Interconnect Fabric for Memory-Mapped Interfaces* in chapter in volume 4 of the *Quartus II Handbook*. For details on the Avalon-ST interface, refer to the *System Interconnect Fabric for Streaming Interfaces* chapter in volume 4 of the *Quartus II Handbook*. For details about the Avalon-ST interface protocol, refer to *Avalon Interface Specifications*.

Example System

Figure 1–1 shows an FPGA design that includes an SOPC Builder system and custom logic modules. You can integrate custom logic inside or outside the SOPC Builder system. In this example, the custom component inside the SOPC Builder system communicates with other modules through an Avalon-MM master interface. The custom logic outside of the SOPC Builder system is connected to the SOPC Builder system through a PIO interface. The SOPC Builder system includes two SOPC Builder components with Avalon-ST source and sink interfaces. The system interconnect fabric connects all of the SOPC Builder components using the Avalon-MM or Avalon-ST system interconnect as appropriate.

Figure 1–1. Example of an FPGA with a SOPC Builder System Generated by SOPC Builder



A component can be a logical device that is entirely contained within the SOPC Builder system, such as the processor component shown in Figure 1–1. Alternately, a component can act as an interface to an off-chip device, such as the DDR2 interface component in Figure 1–1. In addition to the Avalon interface, a component can have other signals that connect to logic outside the SOPC Builder system. Non-Avalon signals can provide a special-purpose interface to the SOPC Builder system, such as the PIO in Figure 1–1. These non-Avalon signals are described in *Conduit Interface* chapter in the *Avalon Interface Specifications.*

Available Components

Altera and third-party developers provide ready-to-use SOPC Builder components, including:

- Microprocessors, such as the Nios II processor

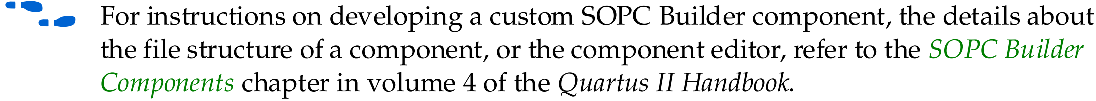
- Microcontroller peripherals, such as a Scatter-Gather DMA Controller and timer
- Serial communication interfaces, such as a UART and a serial peripheral interface (SPI)
- General purpose I/O
- Communications peripherals, such as a 10/100/1000 Ethernet MAC
- Interfaces to off-chip devices

Custom Components

You can import HDL modules and entities that you write using Verilog HDL or VHDL into SOPC builder as custom components. You use the following design flow to integrate custom logic into an SOPC Builder system:

1. Determine the interfaces used to interact with your custom component.
2. Create the component logic using either Verilog HDL or VHDL.
3. Use the SOPC Builder component editor to create an SOPC Builder component with your HDL files.
4. Instantiate your component in the system.

Once you have created an SOPC Builder component, you can use the component in other SOPC Builder systems, and share the component with other design teams.



For instructions on developing a custom SOPC Builder component, the details about the file structure of a component, or the component editor, refer to the *SOPC Builder Components* chapter in volume 4 of the *Quartus II Handbook*.

For further details, refer to the *System Interconnect Fabric for Memory-Mapped Interfaces* and *System Interconnect Fabric for Streaming Interfaces* chapters in volume 4 of the *Quartus II Handbook*.

Third-Party Components

You can also use SOPC-ready components that were developed by third-parties. Altera awards the SOPC Builder Ready certification to IP functions that are ready to integrate with the Nios II embedded processor or the system interconnect fabric via SOPC Builder. These cores support the Avalon-MM interface or the Avalon Streaming (Avalon-ST) interface and include constraints, software drivers, and simulation models when applicable.

To find third-party components that you can purchase and use in SOPC Builder systems, complete the following steps:

1. On the Tools menu in SOPC Builder, click **Download Components**.
2. On the Intellectual Property Solutions web page, type `SOPC Builder ready` ↵ in the box labeled **Search for IP, Development Kits and Reference Designs**.

Functions of SOPC Builder

This section describes the functions of SOPC Builder.

Defining and Generating the System Hardware

SOPC Builder allows you to design the structure of a hardware system. The GUI allows you to add components to a system, configure the components, and specify connectivity.

After you add and parameterize components, SOPC Builder generates the system interconnect fabric, and outputs HDL files to your project directory. During system generation, SOPC Builder creates the following items:

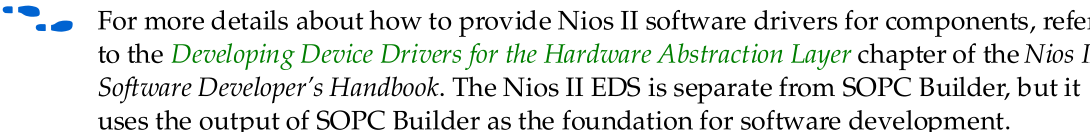
- An HDL file for the top-level SOPC Builder system and for each component in the system. The top-level HDL file is named **<*system_name*>v** for Verilog HDL designs and **<*system_name*>.vhd** for VHDL designs.
- Synopsis Design Constraints file (**.sdc**) for timing analysis.
- A Block Symbol File (**.bsf**) representation of the top-level SOPC Builder system for use in Quartus II Block Diagram Files (**.bdf**).
- An example of an instance of the top-level HDL file, **<*SOPC_project_name_inst*>.v** or **<*SOPC_project_name_inst*>.vhd**, which demonstrates how to instantiate the top-level HDL file in your code.
- A data sheet called <*system_name*>**.html** that provides a system overview including the following information:
  - All external connections for the system
  - A memory map showing the address of each Avalon-MM slave with respect to each Avalon-MM master to which it is connected
  - All parameter assignments for each component
- A functional test bench for the SOPC Builder system and ModelSim® simulation project files
- SOPC Builder information file (**.sopcinfo)** that describes all of the components and connections in your system. This file is a complete system description, and is used by downstream tools such as the Nios II tool chain. It also describes the parameterization of each component in the system; consequently, you can parse its contents to get requirements when developing software drivers for SOPC Builder components.
- A Quartus II IP File (**.qip**) that provides the Quartus II software with all required information about your SOPC Builder system. The **.qip** file includes references to the following information:
  - HDL files used in the SOPC Builder system
  - TimeQuest Timing Analyzer Synopsys Design Constraint (**.sdc**) files
  - Component definition files for archiving purposes

After you generate the SOPC Builder system, you can compile it with the Quartus II software, or you can instantiate it in a larger FPGA design.

Creating a Memory Map for Software Development

When your SOPC Builder system includes a Nios II processor, SOPC Builder generates a header file, **cpu.h**, that provides the base address of each Avalon-MM slave component. In addition, each slave component can provide software drivers and other software functions and libraries for the processor. You can create C header files for your system using the `sopc-create-header-files` utility.

For details type `sopc-create-header-files --help` in a Nios II Command shell.



For more details about how to provide Nios II software drivers for components, refer to the *Developing Device Drivers for the Hardware Abstraction Layer* chapter of the *Nios II Software Developer's Handbook*. The Nios II EDS is separate from SOPC Builder, but it uses the output of SOPC Builder as the foundation for software development.

Creating a Simulation Model and Test Bench

You can simulate your system after generating it with SOPC Builder. During system generation, SOPC Builder outputs a simulation test bench and a ModelSim setup script that eases the system simulation effort. The test bench does the following:

- Instantiates the SOPC Builder system
- Drives all clocks and resets
- Instantiates simulation models for off-chip devices when available

Visualization of Large SOPC Builder Systems

For large systems, you can use the **Filters** dialog box to customize the display of your system in the connections panel. You can filter the display of your system by interface type, module name, interface type, or using custom tags. For example, you can use filtering to view only components that include an Avalon-MM interface or components that are connected to a particular Nios II processor. For more information, refer to Quartus II online Help.

Operating System Support

SOPC Builder supports all of the operating systems that the Quartus II software supports.

For more information refer to *Quartus II Installation & Licensing for Windows and Linux Workstations.*

© March 2009 Altera Corporation

Talkback Support

Talkback is a Quartus II software feature that provides feedback to Altera on tool and IP feature usage. Altera uses the data to help guide future product planning efforts. Talkback sends Altera information on the components used, interface types, interface properties, parameter names and values, clocking, and software assignments. The Talkback file does not include information about system connectivity, interrupts or the memory map seen by each master in the system. When problems arise in the Quartus II software, Talkback data also helps Altera find and fix the cause.

The Talkback feature is enabled by default. You can disable Talkback if you do not wish to share your tool usage data with Altera.

Document Revision History

Table 1–1 shows the revision history for this chapter.

Table 1–1. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009, v9.0.0	■ Added sopc-create-header-files command ■ Added description of Generate HTML Data Sheet ■ Added instructions for downloading third-party IP. ■ Named top-level HDL system files that SOPC Builder generates. ■ Added paragraph introducing the filtering for visualization of large systems.	Updated to reflect new functionality in the 9.0 release.
November 2008, v8.1.0	■ Expanded description of **.sopcinfo** file ■ Changed page size to 8.5 x 11 inches	—
May 2008, v8.0.0	■ Updated references to Avalon Memory-Mapped and Streaming Interface Specifications and changed to Avalon Interface Specifications. ■ Add Quick Start Guide. ■ Add list of OS support.	The two specifications have been combined into one for all Avalon interfaces.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

2. System Interconnect Fabric for Memory-Mapped Interfaces

QII54003-9.0.0

Introduction

The system interconnect fabric for memory-mapped interfaces is a high-bandwidth interconnect structure for connecting components that use the Avalon® Memory-Mapped (Avalon-MM) interface. The system interconnect fabric consumes minimal logic resources, provides greater flexibility, and higher throughput than a typical shared system bus. It is a cross-connect fabric and not a tristated or time domain multiplexed bus. This chapter describes the functions of system interconnect fabric for memory-mapped interfaces and the implementation of those functions.

High-Level Description

The system interconnect fabric is the collection of interconnect and logic resources that connects Avalon-MM master and slaves on components in a system. SOPC Builder generates the system interconnect fabric to match the needs of the components in a system. The system interconnect fabric implements the connection details of a system. It guarantees that signals are routed correctly between master and slaves, as long as the ports adhere to the rules of the *Avalon Interface Specifications*. This chapter provides information on the following topics:

- "Address Decoding" on page 2–4
- "Datapath Multiplexing" on page 2–5
- "Wait State Insertion" on page 2–5
- "Pipelined Read Transfers" on page 2–6
- "Dynamic Bus Sizing and Native Address Alignment" on page 2–7
- "Arbitration for Multimaster Systems" on page 2–9
- "Burst Adapters" on page 2–13
- "Interrupts" on page 2–14
- "Reset Distribution" on page 2–16

For details about the Avalon-MM interface, refer to the *Avalon Interface Specifications*.

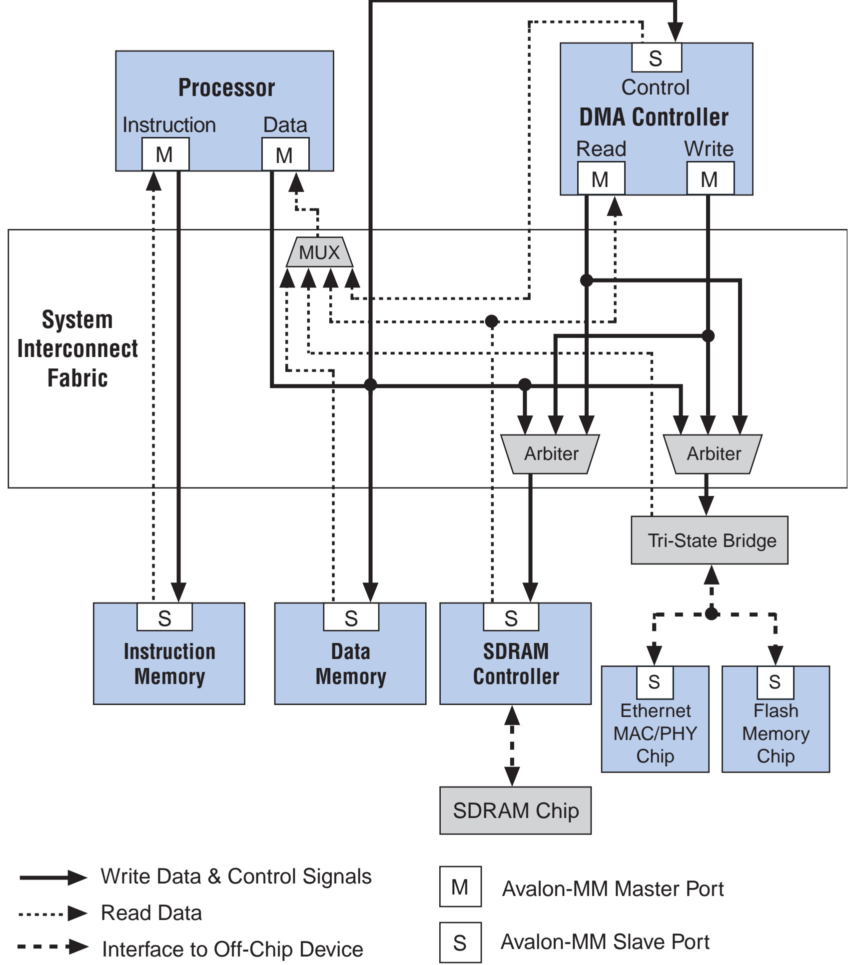
System interconnect fabric for memory-mapped interfaces supports the following items:

- Any number of master and slave components. The master-to-slave relationship can be one-to-one, one-to-many, many-to-one, or many-to-many.
- On-chip components.
- Interfaces to off-chip devices.
- Master and slaves of different data widths.
- Components operating in different clock domains.
- Components using multiple Avalon-MM ports.

Figure 2–1 shows a simplified diagram of the system interconnect fabric in an example memory-mapped system with multiple masters.

All figures in this chapter are simplified to show only the particular function being discussed. In a complete system, the system interconnect fabric might alter the address, data, and control paths beyond what is shown in any one particular figure.

Figure 2–1. System Interconnect Fabric—Example System



SOPC Builder supports components with multiple Avalon-MM interfaces, such as the processor component shown in Figure 2–1. Because SOPC Builder can create system interconnect fabric to connect components with multiple interfaces, you can create complex interfaces that provide more functionality than a single Avalon-MM interface. For example, you can create a component with two different Avalon-MM slaves, each with an associated interrupt interface.

System interconnect fabric can connect any combination of components, as long as each interface conforms to the *Avalon Interface Specifications*. It can, for example, connect a system comprised of only two components with unidirectional dataflow between them. Avalon-MM interfaces are suitable for random address transactions, such as to memories or embedded peripherals.

Generating system interconnect fabric is SOPC Builder's primary purpose. In most cases, you are not required to modify the generated HDL; however, a basic understanding of how HDL works can help you optimize your system. For example, knowledge of the arbitration algorithm can help designers of multimaster systems minimize the impact of arbitration on the system throughput.

Fundamentals of Implementation

System interconnect fabric for memory-mapped interfaces implements a partial crossbar interconnect structure that provides concurrent paths between master and slaves. System interconnect fabric consists of synchronous logic and routing resources inside the FPGA.

For each component interface, system interconnect fabric manages Avalon-MM transfers, interacting with signals on the connected component. Master and slave interfaces can contain different signals and the system interconnect fabric handle any adaptation necessary between them. In the path between master and slaves, the system interconnect fabric might introduce registers for timing synchronization, finite state machines for event sequencing, or nothing at all, depending on the services required by the specific interfaces.

For more information, refer to the *Avalon Memory-Mapped Design Optimizations* chapter in the *Embedded Design Handbook*.

Functions of System Interconnect Fabric

System interconnect fabric logic provides the following functions:

- "Address Decoding" on page 2–4
- "Datapath Multiplexing" on page 2–5
- "Wait State Insertion" on page 2–5
- "Pipelined Read Transfers" on page 2–6
- "Arbitration for Multimaster Systems" on page 2–9
- "Burst Adapters" on page 2–13
- "Interrupts" on page 2–14
- "Reset Distribution" on page 2–16

The behavior of these functions in a specific SOPC Builder system depends on the design of the components in the system and the settings made in SOPC Builder. The remaining sections of this chapter describe how SOPC Builder implements each function.

Address Decoding

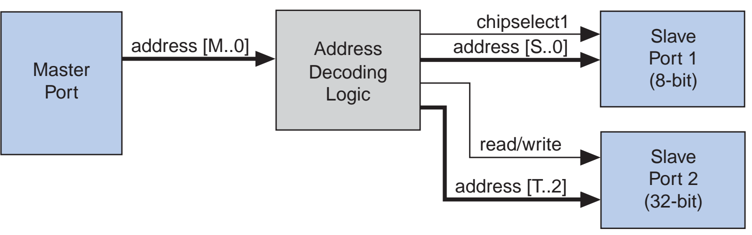
Address decoding logic in the system interconnect fabric forwards an appropriate address and produces a chipselect signal for each slave. Address decoding logic simplifies component design in the following ways:

- The system interconnect fabric selects a slave whenever it is being addressed by a master. Slave components do not need to decode the address to determine when they are selected.
- Slave addresses are properly aligned to the slave interface.
- Changing the system memory map does not involve manually editing HDL.

Figure 2–2 shows a block diagram of the address-decoding logic for one master and two slaves. Separate address-decoding logic is generated for every master in a system.

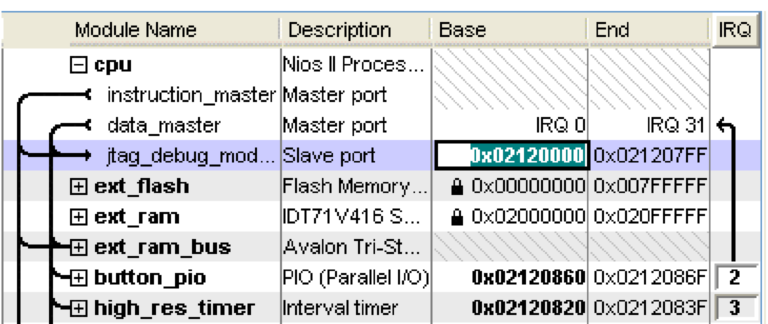
As Figure 2–2 shows, the address decoding logic handles the difference between the master address width (<*M*>) and the individual slave address widths (<*S*> and <*T*>). It also maps only the necessary master address bits to access words in each slave's address space.

Figure 2–2. Block Diagram of Address Decoding Logic



In SOPC Builder, the user-configurable aspects of address decoding logic are controlled by the **Base** setting in the list of active components on the **System Contents** tab, as shown in Figure 2–3.

Figure 2–3. Base Settings in SOPC Builder Control Address Decoding

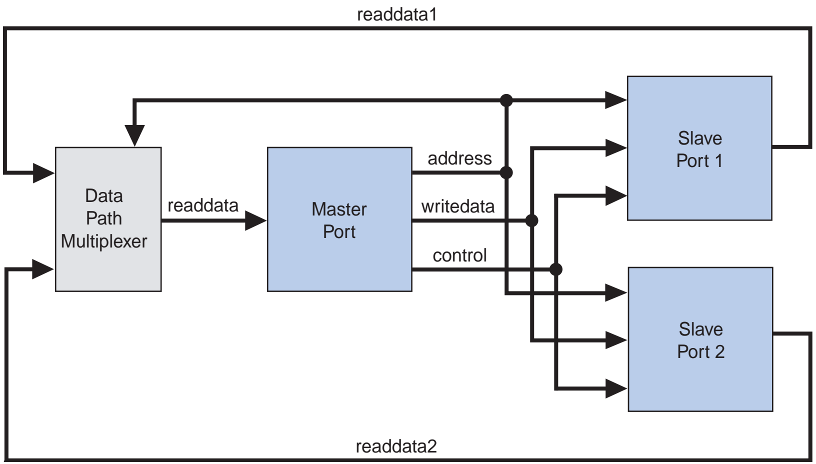


Datapath Multiplexing

Datapath multiplexing logic in the system interconnect fabric drives the `writedata` signal from the granted master to the selected slave, and the `readdata` signal from the selected slave back to the requesting master.

Figure 2–4 shows a block diagram of the datapath multiplexing logic for one master and two slaves. SOPC Builder generates separate datapath multiplexing logic for every master in the system.

Figure 2–4. Block Diagram of Datapath Multiplexing Logic



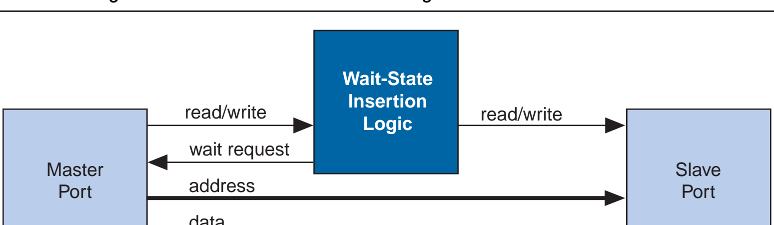
In SOPC Builder, the generation of datapath multiplexing logic is specified using the connections panel on the **System Contents** tab.

Wait State Insertion

Wait states extend the duration of a transfer by one or more cycles. Wait state insertion logic accommodates the timing needs of each slave, and causes the master to wait until the slave can proceed. System interconnect fabric inserts wait states into a transfer when the target slave cannot respond in a single clock cycle. System interconnect fabric also inserts wait states in cases when slave `read_enable` and `write_enable` signals have setup or hold time requirements.

Wait state insertion logic is a small finite-state machine that translates control signal sequencing between the slave side and the master side. Figure 2–5 shows a block diagram of the wait state insertion logic between one master and one slave.

Figure 2–5. Block Diagram of Wait State Insertion Logic



System interconnect fabric can force a master to wait for several reasons in addition to the wait state needs of a slave. For example, arbitration logic in a multimaster system can force a master to wait until it is granted access to a slave.

SOPC Builder generates wait state insertion logic based on the properties of all slaves in the system.

Pipelined Read Transfers

The Avalon-MM interface supports pipelined read transfers, allowing a pipelined master to start multiple read transfers in succession without waiting for the prior transfers to complete. Pipelined transfers allow master-slave pairs to achieve higher throughput, even though the slave requires one or more cycles of latency to return data for each transfer.

SOPC Builder generates system interconnect fabric with pipeline management logic to take advantage of pipelined components wherever possible, based on the pipeline properties of each master-slave pair in the system. Regardless of the pipeline latency of a target slave, SOPC Builder guarantees that read data arrives at each master in the order requested. Because master and slaves often have mismatched pipeline latency, system interconnect fabric often contains logic to reconcile the differences. Many cases of pipeline latency are possible, as shown in Table 2–1.

Table 2–1. Various Cases of Pipeline Latency in a Master-Slave Pair

Master	Slave	Pipeline Management Logic Structure
No pipeline	No pipeline	The system interconnect fabric does not instantiate logic to handle pipeline latency.
No pipeline	Pipelined with fixed or variable latency	The system interconnect fabric forces the master to wait through any slave-side latency cycles. This master-slave pair gains no benefits of pipelining, because the master waits for each transfer to complete before beginning a new transfer. However, while the master is waiting, the slave can accept transfers from a different master.
Pipelined	No pipeline	The system interconnect fabric carries out the transfer as if neither master nor slave were pipelined, causing the master to wait until the slave returns data.
Pipelined	Pipelined with fixed latency	The system interconnect fabric allows the master to capture data at the exact clock cycle when data from the slave is valid. This process enables the master-slave pair to achieve maximum throughput performance.
Pipelined	Pipelined with variable latency	This is the simplest pipelined case, in which the slave asserts a signal when its `readdata` is valid, and the master captures the data. This case enables this master-slave pair to achieve maximum throughput.

SOPC Builder generates logic to handle pipeline latency based on the properties of the master and slaves in the system. When configuring a system in SOPC Builder, there are no settings that directly control the pipeline management logic in the system interconnect fabric.

Dynamic Bus Sizing and Native Address Alignment

SOPC Builder generates system interconnect fabric to accommodate master and slaves with unmatched data widths. Address alignment affects how slave data is aligned in a master's address space, in the case that the master and slave data widths are different. Address alignment is a property of each slave, and can be different for each slave in a system. A slave can declare itself to use one of the following:

- Dynamic bus sizing
- Native address alignment

The following sections explain the implications of the address alignment property slave devices.

Dynamic Bus Sizing

Dynamic bus sizing hides the details of interfacing a narrow component device to a wider master, and vice versa. When an <*N*>-bit master accesses a slave with dynamic bus sizing, the master operates exclusively on full <*N*>-bit words of data, without awareness of the slave data width.

When using dynamic bus sizing, the slave data width in units of bytes must be a power of two.

Dynamic bus sizing provides the following benefits:

- Eliminates the need to create address-alignment hardware manually.
- Reduces design complexity of the master component.
- Enables any master to access any memory device, regardless of the data width.

In the case of dynamic bus sizing, the system interconnect fabric includes a small finite state machine that reconciles the difference between master and slave data widths. The behavior is different depending on whether the master data width is wider or narrower than the slave.

Wider Master

In the case of a wider master, the dynamic bus-sizing logic accepts a single, wide transfer on the master side, and then performs multiple narrow transfers on the slave side. For a data-width ratio of <*N*>:1, the dynamic bus-sizing logic generates up to <*N*> slave transfers for each master transfer. The master waits while multiple slave-side transfers complete; the master transfer ends when all slave-side transfers end.

Dynamic bus-sizing logic uses the master-side byte-enable signals to generate appropriate slave transfers. The dynamic bus-sizing logic performs as many slave-side transfers as necessary to write or read the specified byte lanes.

Narrower Master

In the case of a narrower master, one transfer on the master side generates one transfer on the slave side. In this case, multiple master word addresses map to a single offset in the slave memory space. The dynamic bus-sizing logic maps each master address to a subset of byte lanes in the appropriate slave offset. All bytes of the slave memory are accessible in the master address space.

Table 2–2 demonstrates the case of a 32-bit master accessing a 64-bit slave with dynamic bus sizing. In the table, offset refers to the offset into the slave memory space.

Table 2–2. 32-Bit Master View of 64-Bit Slave with Dynamic Bus Sizing

32-bit Address	Data
0×00000000 (word 0)	$OFFSET[0]_{31..0}$
0×00000004 (word 1)	$OFFSET[0]_{63..32}$
0×00000008 (word 2)	$OFFSET[1]_{31..0}$
0×0000000C (word 3)	$OFFSET[1]_{63..32}$

In the case of a read transfer, the dynamic bus-sizing logic multiplexes the appropriate byte lanes of the slave data to the narrow master. In the case of a write transfer, the dynamic bus-sizing logic uses slave-side byte-enable signals to write only to the appropriate byte lanes.

Altera recommends that you select dynamic bus sizing whenever possible. Dynamic bus sizing offers more flexibility when the master and slave components in your system have different widths.

Native Address Alignment

Table 2–3 demonstrates native address alignment and dynamic bus sizing for a 32-bit master connected to a 16-bit slave (a 2:1 ratio). In this example, the slave is mapped to base address <*BASE*> in the master's address space. In Table 2–3, `OFFSET` refers to the offset into the 16-bit slave address space.

Table 2–3. 32-Bit Master View of 16-Bit Slave Data

32-bit Master Address	Data with Native Alignment	Data with Dynamic Bus Sizing
BASE + 0x0 (word 0)	0×0000:OFFSET[0]	OFFSET[1]:OFFSET[0]
BASE + 0x4 (word 1)	0×0000:OFFSET[1]	OFFSET[3]:OFFSET[2]
BASE + 0x8 (word 2)	0×0000:OFFSET[2]	OFFSET[5]:OFFSET[4]
BASE + 0xC (word 3)	0×0000:OFFSET[3]	OFFSET[7]:OFFSET[6]
...	...	...
BASE + 4*N* (word *N*)	0×0000:OFFSET[N]	OFFSET[2N+1]:OFFSET[2N]

SOPC Builder generates appropriate address-alignment logic based on the properties of the master and slaves in the system. When configuring a system in SOPC Builder, there are no settings that directly control the address alignment in the system interconnect fabric.

Arbitration for Multimaster Systems

System interconnect fabric supports systems with multiple master components. In a system with multiple masters, such as the system pictured in Figure 2–1 on page 2–2, the system interconnect fabric provides shared access to slaves using a technique called slave-side arbitration. Slave-side arbitration moves the arbitration logic close to the slave, such that the algorithm that determines which master gains access to a specific slave in the event that multiple masters attempt to access the same slave at the same time.

The multimaster architecture used by system interconnect fabric offers the following benefits:

- Eliminates having to create arbitration hardware manually.
- Allows multiple masters to transfer data simultaneously. Unlike traditional host-side arbitration architectures where each master must wait until it is granted access to the shared bus, multiple Avalon-MM masters can simultaneously perform transfers with independent slaves. Arbitration logic stalls a master only when multiple masters attempt to access the same slave during the same cycle.
- Eliminates unnecessary master-slave connections. The connection between a master and a slave exists only if it is specified in SOPC Builder. If a master never initiates transfers to a specific slave, no connection is necessary, and therefore SOPC Builder does not waste logic resources to connect the two ports.
- Provides configurable arbitration settings, and arbitration for each slave is specified independently. For example, you can grant one master more arbitration shares than others, allowing it to gain more access cycles to the slave. The arbitration share settings are defined for each slave independently.
- Simplifies master component design. The details of arbitration are encapsulated inside the system interconnect fabric. Each Avalon-MM master connects to the system interconnect fabric as if it is the only master in the system. As a result, you can reuse a component in single-master and multimaster systems without requiring design changes to the component.

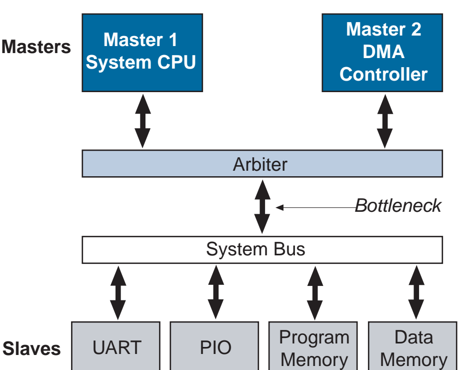
Traditional Shared Bus Architectures

This section discusses the architecture of the system interconnect fabric generated by SOPC Builder for multimaster systems. As a frame of reference for the discussion of multiple masters and arbitration, this section describes traditional bus architectures.

In traditional bus architectures, one or more bus masters and bus slaves connect to a shared bus, consisting of wires on a printed circuit board or on-chip routing. A single arbiter controls the bus (that is, the path between bus masters and bus slaves), so that multiple bus masters do not simultaneously drive the bus. Each bus master requests control of the bus from the arbiter, and the arbiter grants access to a single master at a time. Once a master has control of the bus, the master performs transfers with any bus slave. When multiple masters attempt to access the bus at the same time, the arbiter allocates the bus resources to a single master, forcing all other masters to wait.

Figure 2–6 illustrates the bus architecture for a traditional processor system. Access to the shared system bus becomes the bottleneck for throughput: only one master has access to the bus at a time, which means that other masters are forced to wait and only one slave can transfer data at a time.

Figure 2–6. Bus Architecture in a Traditional Microprocessor System



Slave-Side Arbitration

The system interconnect fabric uses multimaster architecture to eliminate the bottleneck for access to a shared bus. Multiple masters can be active at the same time, simultaneously transferring data with independent slaves. For example, Figure 2–1 on page 2–2 demonstrates a system with two masters (a CPU and a DMA controller) sharing a slave (an SDRAM controller). Arbitration is performed at the SDRAM slave; the arbiter dictates which master gains access to the slave if both masters initiate a transfer with the slave in the same cycle.

Figure 2–7 focuses on the two masters and the shared slave and shows additional detail of the data, address, and control paths. The arbiter logic multiplexes all address, data, and control signals from a master to a shared slave.

Figure 2–7. Detailed View of Multimaster Connections

Arbiter Details

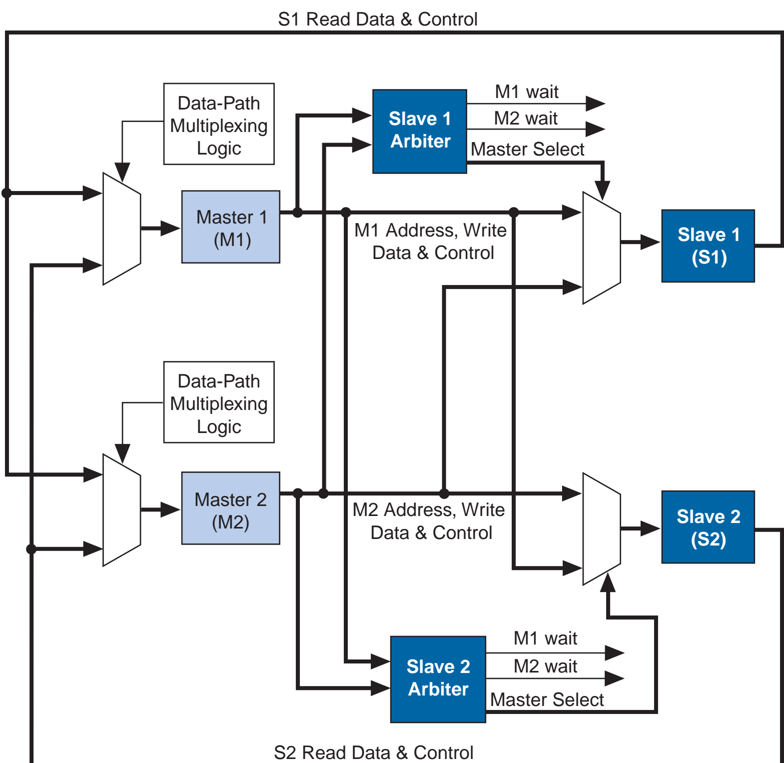
SOPC Builder generates an arbiter for every slave, based on arbitration parameters specified in SOPC Builder. The arbiter logic performs the following functions for its slave:

- Evaluates the address and control signals from each master and determines which master, if any, gains access to the slave next.

- Grants access to the chosen master and forces all other requesting masters to wait.
- Uses multiplexers to connect address, control, and datapaths between the multiple masters and the slave.

Figure 2–8 shows the arbiter logic in an example multimaster system with two masters, each connected to two slaves.

Figure 2–8. Block Diagram of Arbiter Logic



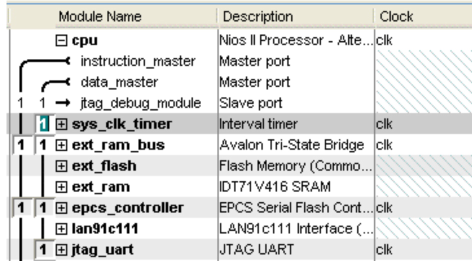
Arbitration Rules

This section describes the rules by which the arbiter grants access to masters when they contend.

Setting Arbitration Parameters in SOPC Builder

You specify the arbitration shares for each master using the connection panel on the **System Contents** tab of SOPC Builder, as shown in Figure 2–9.

Figure 2–9. Arbitration Settings on the System Contents Tab



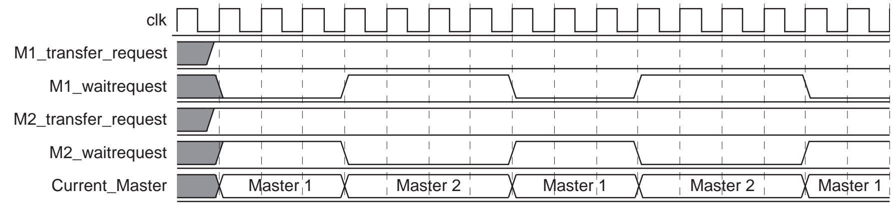
The arbitration settings are hidden by default. To see them, on the View menu, click **Show Arbitration**.

Fairness-Based Shares

Arbiter logic uses a fairness-based arbitration scheme. In a fairness-based arbitration scheme, each master pair has an integer value of transfer *shares* with respect to a slave. One share represents permission to perform one transfer.

For example, assume that two masters continuously attempt to perform back-to-back transfers to a slave. Master 1 is assigned three shares and Master 2 is assigned four shares. In this case, the arbiter grants Master 1 access for three transfers, then Master 2 for four transfers. This cycle repeats indefinitely. Figure 2–10 demonstrates this case, showing each master's transfer request output, wait request input (which is driven by the arbiter logic), and the current master with control of the slave.

Figure 2–10. Arbitration of Continuous Transfer Requests from Two Masters



If a master stops requesting transfers before it exhausts its shares, it forfeits all its remaining shares, and the arbiter grants access to another requesting master. Refer to Figure 2–11. After completing one transfer, Master 2 stops requesting for one clock cycle. As a result, the arbiter grants access back to Master 1, which gets a replenished supply of shares.

Figure 2–11. Arbitration of Two Masters with a Gap in Transfer Requests

Round-Robin Scheduling

When multiple masters contend for access to a slave, the arbiter grants shares in round-robin order. Round-robin scheduling drives a request interface according to space available and data available credit interfaces. At every slave transfer, only requesting masters are included in the arbitration.

Burst Transfers

Avalon-MM burst transfers grant a master uninterrupted access to a slave for a specified number of transfers. The master specifies the number of transfers when it initiates the burst. Once a burst begins between a master-slave pair, arbiter logic does not allow any other master to access the slave until the burst completes. For burst masters, the size of the burst determines the number of cycles that the master has access to the slave, and the selected arbitration shares have no effect.

Burst Adapters

System interconnect fabric provides burst adaptation logic to accommodate the burst capabilities of each port in the system, including ports that do not support burst transfers. Burst adaptation logic consists of a finite state machine that translates the sequencing of address and control signals between the slave side and the master side.

The maximum burst length for each port is determined by the component design and is independent of other ports in the system. Therefore, a particular master might be capable of initiating a burst longer than a slave’s maximum supported burst length. In this case, the burst management logic translates the master burst into smaller slave bursts, or into individual slave transfers if the slave does not support bursts. Until the master completes the burst, the arbiter logic prevents other masters from accessing the target slave.

For example, if a master initiates a burst of 16 transfers to a slave with maximum burst length of 8, the burst adapter logic initiates two bursts of length 8 to the slave. If the master initiates a burst of 14, the burst adapter logic segments the burst transfer into a burst of 8 words followed by a burst of 6 words, because the slave can only handle a maximum burst length of 8. If a master initiates a burst of 16 transfers to a slave that does not support bursts, the burst management logic initiates 16 separate transfers to the slave.

The burst adapter inserts one idle cycle at the start of each burst. System throughput is maximized when burst sizes are as large as possible.

In the case of a non-linewrap burst master connected to a slave with the `linewrapBursts` property set to `TRUE`, it is not always possible to issue the maximum-sized burst to the slave. In cases where a burst would cross a slave burst boundary, the burst adapter must issue the appropriate smaller bursts according to the master request. For example, if a non-linewrap burst master, data width=32 issues a burst of 8 at byte address 0xC to a linewrap burst slave, data width=32, the burst adapter issues a burst read of 5 at byte address 0xC followed by a burst read of size 3 at address 0x20. This example assumes a maximum burst size of 8 for both the master and slave. Table 2–3 provides some examples that show how bursts are handled between master and slaves with and without linewrapping. (Linewrap bursts are common for SDRAM components.) In these examples the following conditions are true:

- The master and slave have the same data width.
- Masters with the `linewrapBursts` property set to `TRUE` must also set `alwaysBurstMaxBurst` to `TRUE` due to a limitation in the burst adapter.

Table 2–4. Burst Behavior for Masters and Slaves with and without Linewrapping

Master Max Burst Size	**8**								**4**			
Slave Max Burst Size	**8**				**4**				**8**			
Master Linewrap Bursts	**True**		**False**		**True**		**False**		**True**		**False**	
Slave Linewrap Bursts	**T**	**F**	**T**	**F**	**T**	**F**	**T**	**F**	**T**	**F**	**T**	**F**
Master bursts	8@0	8@0	2@0	2@0	8@0	8@0	2@0	2@0	4@0	4@0	2@0	2@0
Slave receives	8@0	8@0	2@0	2@0	4@0, 4@4	8@0	2@0	2@0	4@0	4@0	2@0	2@0
Master bursts	8@3	8@3	6@3	6@3	8@3	4@0 4@4	6@3	6@3	4@7	4@7	4@7	4@3
Slave Receives	8@3	5@3, 3@0	5@3, 1@8	6@3	1@3, 4@4, 3@0	1@3, 4@4, 3@0	1@3, 4@4, 1@8	4@3, 2@7	1@7, 3@4	1@7, 3@4	1@7, 3@8	4@3

For more information about the `linewrapBursts` property, refer to the *Avalon Memory-Mapped Slave Interfaces* chapter in the *Avalon Interface Specifications.*

Interrupts

In systems where components have interrupt request (IRQ) sender interfaces, the system interconnect fabric includes interrupt controller logic. A separate interrupt controller is generated for each interrupt receiver. The interrupt controller aggregates IRQ signals from all interrupt senders, and maps them to user-specified values on the receiver inputs.

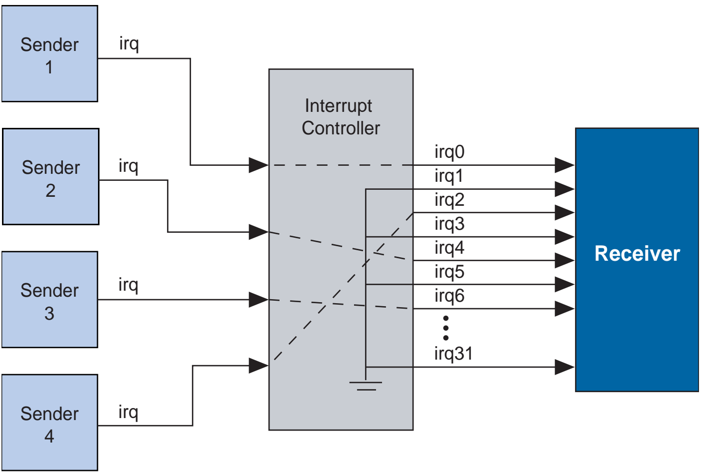
For further information, refer to the *Interrupt Interfaces* chapter in the *Avalon Interface Specifications*.

Individual Requests IRQ Scheme

In the individual requests IRQ scheme, the system interconnect fabric passes IRQs directly from the sender to the receiver, without making any assumptions about IRQ priority. In the event that multiple senders assert their IRQs simultaneously, the receiver logic (presumably under software control) determines which IRQ has highest priority, then responds appropriately.

Using individual requests, the interrupt controller can handle up to 32 IRQ inputs. The interrupt controller generates a 32-bit signal `irq[31:0]` to the receiver, and simply maps slave IRQ signals to the bits of `irq[31:0]`. Any unassigned bits of `irq[31:0]` are disabled. Figure 2–12 shows an example of the interrupt controller mapping the IRQs on four senders to `irq[31:0]` on a receiver.

Figure 2–12. IRQ Mapping Using Software Priority

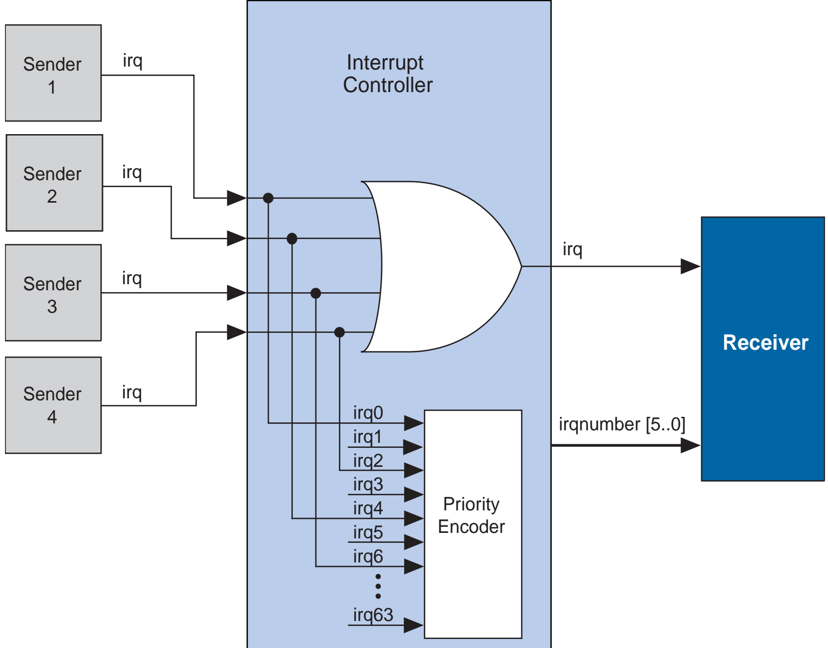


Priority Encoded Interrupt Scheme

In the priority encoded interrupt scheme, in the event that multiple slaves assert their IRQs simultaneously, the system interconnect fabric provides the interrupt receiver with a 1-bit interrupt signal, and the number of the highest priority active interrupt. An IRQ of lesser priority is undetectable until all IRQs of higher priority have been serviced.

Using priority encoded interrupts, the interrupt controller can handle up to 64 slave IRQ signals. The interrupt controller generates a 1-bit `irq` signal to the receiver, signifying that one or more senders have generated an IRQ. The controller also generates a 6-bit `irqnumber` signal, which outputs the encoded value of the highest pending IRQ. See Figure 2–13.

Figure 2–13. IRQ Mapping Using Hardware Priority



Assigning IRQs in SOPC Builder

You specify IRQ settings on the **System Contents** tab of SOPC Builder. After adding all components to the system, you make IRQ settings for all interrupt senders, with respect to each interrupt receiver. For each slave, you can either specify an IRQ number, or specify not to connect the IRQ.

Reset Distribution

SOPC Builder generates the logic used in the system interconnect fabric, which drives the reset pulse to all the logic. The system interconnect fabric distributes the reset signal conditioned for each clock domain. The duration of the reset signal is at least one clock period.

The system interconnect fabric asserts the system-wide reset in the following conditions:

- The global reset input to the SOPC Builder system is asserted.
- Any component asserts its `resetrequest` signal.

The global reset and reset requests are `OR`ed together. This signal is then synchronized to each clock domain associated to an Avalon-MM port, which causes the asynchronous resets to be de-asserted synchronously.

Document Revision History

Table 2–5 shows the revision history for this chapter.

Table 2–5. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009, v9.0.0	■ Added table showing the behavior of the burst adapter for master and slaves with and without `linewrapBursts` set to `TRUE`.	Clarification of burst behavior.
November 2008, v8.1.0	■ Added discussion of a non-bursting Avalon-MM master connected to a Avalon-MM slave with `linewrapBursts = TRUE`. Removed discussion on minimum arbitration shares; this feature is no longer supported. ■ Changed page size to 8.5 x 11 inches	Minor update to reflect software changes.
May 2008, v8.0.0	■ Updated references to Avalon Memory-Mapped and Streaming Interface Specifications and changed to Avalon Interface Specifications. ■ Moved clock-crossing bridge section from this chapter to chapter 11.	The two specifications have been combined into one for all Avalon interfaces.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

3. System Interconnect Fabric for Streaming Interfaces

QII54019-9.0.0

Introduction

Avalon® Streaming interconnect fabric connects high-bandwidth, low latency components that use the Avalon Streaming (Avalon-ST) interface. This interconnect fabric creates datapaths for unidirectional traffic including multichannel streams, packets, and DSP data. This chapter describes the Avalon-ST interconnect fabric and its use in connecting components with Avalon-ST interfaces. Descriptions of specific adapters and their use in streaming systems can be found in the following sections:

- "Adapters" on page 3–3
- "Multiplexer Examples" on page 3–5

High-Level Description

Avalon-ST interconnect fabric is logic generated by SOPC Builder. Using SOPC Builder, you specify how Avalon-ST source and sink ports connect. SOPC Builder then creates a high performance point-to-point interconnect between the two components. The Avalon-ST interconnect is flexible and can be used to implement on-chip interfaces for industry standard telecommunications and data communications cores, such as Ethernet IEEE 802.3 MAC and SPI 4.2. In all cases, bus widths, packets, and error conditions are custom-defined.

Figure 3–1 illustrates the simplest system example that generates an interconnect between the source and sink. This source-sink pair includes only the `data` and `valid` signals.

Figure 3–1. Interconnect for a Simple Avalon Streaming Source-Sink Pair

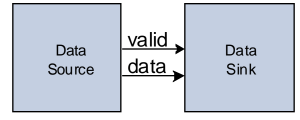

Figure 3–2 illustrates a more extensive interface that includes signals indicating the start and end of packets, channel numbers, error conditions, and back pressure.

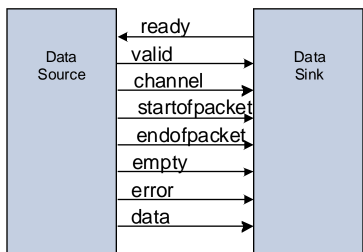
Figure 3–2. Avalon Streaming Interface for Packet Data



All data transfers using Avalon-ST interconnect occur synchronously to the rising edge of the associated clock interface. All outputs from the source interface, including the data, channel, and error signals, must be registered on the rising edge of the clock. Registers are not required for inputs at the sink interface. Registering signals only at the source provides for high frequency operation while eliminating back-to-back registration with no intervening logic. There is no inherent maximum performance of the interconnect. Throughput for a system depends on the components and how they are connected.

For details about the Avalon-ST interface protocol, refer to the *Avalon Interface Specifications*.

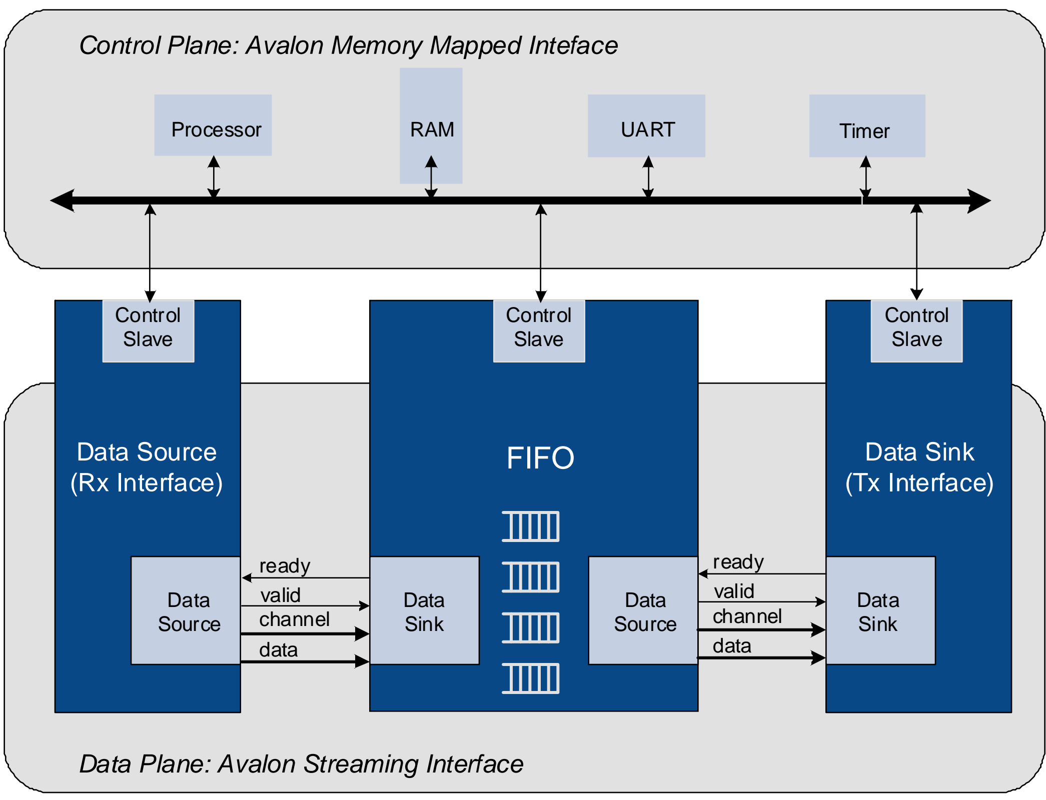
Avalon Streaming and Avalon Memory-Mapped Interfaces

The Avalon-ST and Avalon Memory-Mapped (Avalon-MM) interfaces are complementary. High bandwidth components with streaming data typically use Avalon-ST interfaces for the high throughput datapath. These components can also use Avalon-MM connection interfaces to provide an access point for control. In contrast to the Avalon-MM interconnect, which can be used to create a wide variety of topologies, the Avalon-ST interconnect fabric always creates a point-to-point between a single data source and data sink, as Figure 3–3 illustrates. There are two connection pairs in this figure:

- The data source in the Rx Interface transfers data to the data sink in the FIFO.
- The data source in the FIFO transfers data to the Tx Interface data sink.

In Figure 3–3, the Avalon-MM interface allows a processor to access the data source, FIFO or data sink to provide system control.

Figure 3–3. Use of the Avalon Memory-Mapped and Streaming Interfaces



Adapters

Adapters are configurable SOPC Builder components that are part of the streaming interconnect fabric. They are used to connect source and sink interfaces that are not exactly the same without affecting the semantics of the data. SOPC Builder includes the following four adapters:

- Data Format Adapter
- Timing Adapter
- Channel Adapter
- Error Adapter

You can add Avalon-ST adapters between two components with mismatched interfaces. The adapter allows you to connect a data source to a data sink of differing byte sizes. If you connect mismatched Avalon-ST sources and sinks in SOPC Builder without inserting adapters, SOPC Builder generates error messages. Inserting adapters into the system does not change the types of components that SOPC Builder allows you to connect. The **Insert Avalon-ST Adapters** command on the System menu attempts to correct these errors automatically, if possible, by inserting the appropriate adapter types.

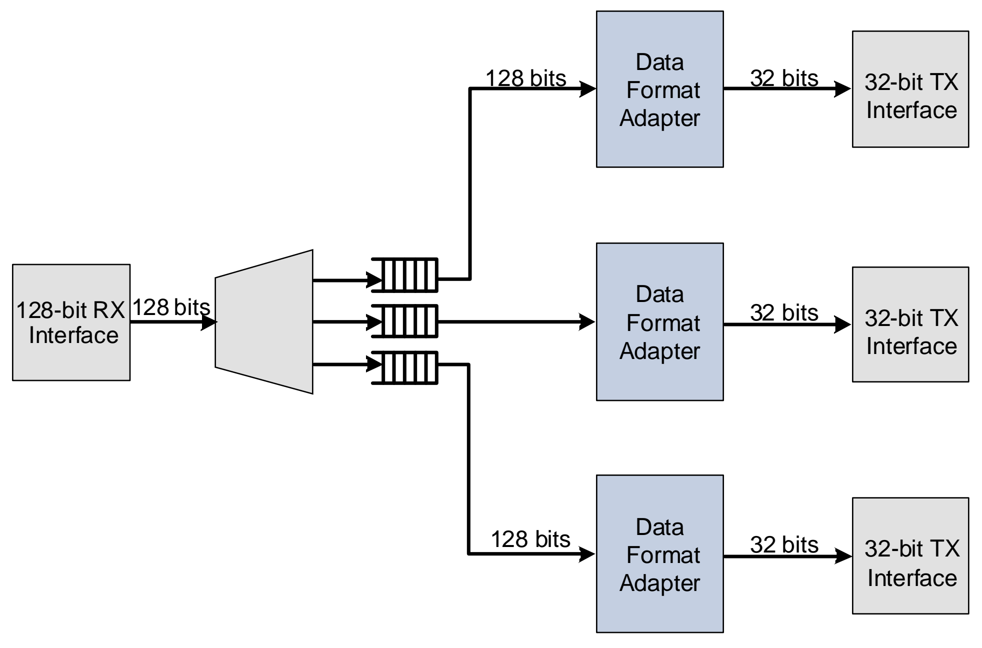
For complete information about these adapters, refer to the *Avalon Streaming Interconnect Components* chapter in volume 4 of the *Quartus II Handbook*.

The following sections provide an overview of these adapters.

Data Format Adapter

The data format adapter allows you to connect interfaces that have different values for the parameters defining the data signal. One of the most common uses of this adapter is to convert data streams of different widths. Figure 3–4 shows an adapter that allows a connection between a 128-bit input data stream and three 32-bit output data streams.

Figure 3–4. Avalon Streaming Interconnect Fabric with Data Format Adapter



Timing Adapter

The timing adapter allows you to connect component interfaces that require a different number of cycles before driving or receiving data. This adapter inserts a FIFO between the source and sink to buffer data or pipeline stages to delay the back pressure signals. The timing adapter can also be used to connect interfaces that support the `ready` signal and those that do not.

Channel Adapter

The channel adapter provides adaptations between interfaces that have different support for the channel signal or channel-related parameters. For example, if the source channel is narrower than the sink channel, you can use this adapter to connect them. The high-order bits of the sink channel are connected to zero. You can also use this adapter to connect a source with a wider channel to a sink with a narrower channel. If the source provides data for a channel that the sink cannot receive, the data is not transferred.

Error Adapter

The error adapter ensures that per-bit error information provided by the source interface is correctly connected to the sink interface's input error signal. Matching error conditions handled by the source and sink are connected. If the source has an error condition that is not supported by the sink, the signal is left unconnected; the adapter provides a simulation error message and an error indication if this error is ever asserted. If the sink has an error condition that is not supported by the source, the sink's input is tied to zero.

Multiplexer Examples

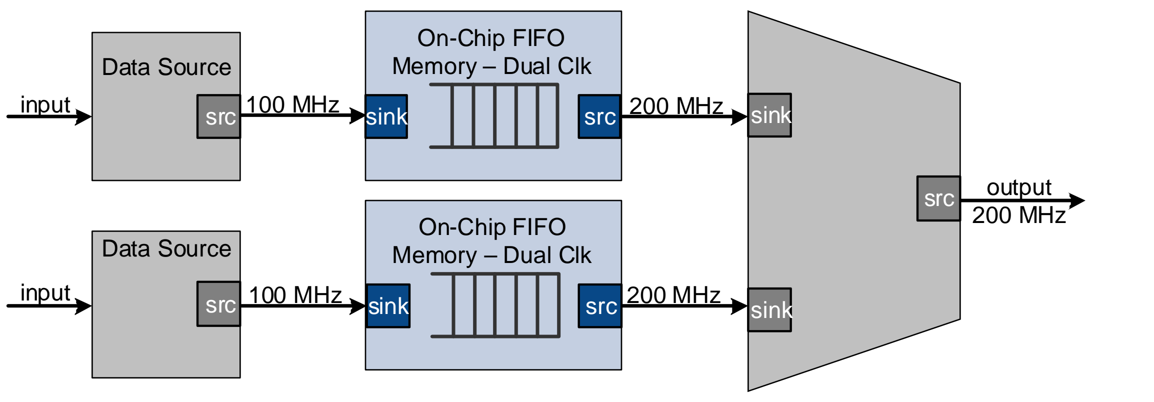
You can combine these adapters with streaming components to create datapaths whose input and output streams have different properties. The following sections provide examples of datapaths constructed using SOPC Builder in which the output stream is higher performance than the input stream:

- The first example shows an output with double the throughput of each interface with a corresponding doubling of the clock frequency.
- The second example doubles the data width.
- The third example boosts the frequency of a stream by 10% by multiplexing input data from two sources.

Example to Double Clock Frequency

Figure 3–5 illustrates a datapath that uses the dual clock version of the on-chip FIFO memory and Avalon-ST channel multiplexer to merge the 100 MHz input from two streaming data sources into a single 200 MHz streaming output. As Figure 3–5 illustrates, this example increases throughput by increasing the frequency and combining inputs.

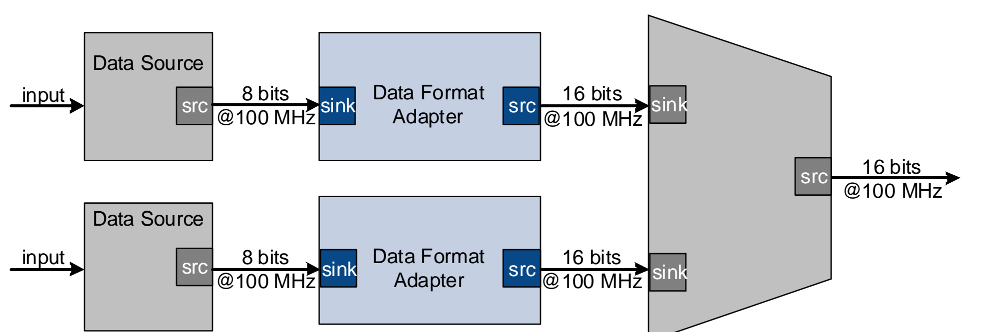
Figure 3–5. Datapath that Doubles the Clock Frequency



Example to Double Data Width and Maintain Frequency

Figure 3–6 illustrates a datapath that uses the data format adapter and Avalon-ST channel multiplexer to convert two, 8-bit inputs running at 100 MHz to a single 16-bit output at 100 MHz.

Figure 3–6. Datapath to Double Data Width and Maintain Original Frequency



Example to Boost the Frequency

Figure 3–7 illustrates a datapath that uses the dual clock version of the on-chip FIFO memory to boost the frequency of input data from 100 MHz to 110 MHz by sampling two input streams at differential rates. In this example, the on-chip FIFO memory has an input clock frequency of 100 MHz and an output clock frequency of 110 MHz. The channel multiplexer runs at 110 MHz and samples one input stream 27.3 percent of the time and the second 72.7 percent of the time.

You do not need to know what the typical and maximum input channel utilizations are before attempting this. For example, if the first channel hits 50% utilization, the output stream exceeds 100% utilization.

Figure 3–7. Datapath to Boost the Clock Frequency

4. SOPC Builder Components

QII54004-9.0.0

An SOPC Builder *component* is a hardware design block available within SOPC Builder that can be instantiated in an SOPC Builder system. This chapter defines SOPC Builder components, with emphasis on the structure of custom components.

A component includes the following:

- The HDL description of the component's hardware.
- A description of the interface to the component hardware, such as the names and types of I/O signals.
- A description of any parameters that specify the structure of the component logic and component.
- A GUI for configuring an instance of the component in SOPC Builder.
- Scripts and other information SOPC Builder requires to generate the HDL files for the component and integrate the component instance into the SOPC Builder system.
- Other component-related information, such as reference to software drivers, necessary for development steps downstream of SOPC Builder.

This chapter discusses the design flow for new and classic custom-defined SOPC Builder components, in the following sections:

- "Component Providers" on page 4–1
- "Component Hardware Structure" on page 4–2
- "Exported Connection Points—Conduit Interfaces" on page 4–4
- "SOPC Builder Component Search Path" on page 4–4
- "Component Structure" on page 4–7
- "Classic Components in SOPC Builder" on page 4–8

Component Providers

SOPC Builder components can be obtained from many providers, including the following:

- The components automatically installed with the Quartus® II software.
- Third-party IP developers can provide IP blocks as SOPC Builder-ready components, including software drivers and documentation. A list of third-party components can be found in SOPC Builder by clicking **IP MegaStore** on the Tools menu.
- Altera development kits, such as the Nios® II Development Kit, can provide SOPC Builder components as features.
- You can use the SOPC Builder component editor to convert your own HDL files into custom components.

The GUI interfaces for classic components run slower in newer versions of SOPC Builder when you add or modify your component settings. These components are marked by a gray dot in the **System Contents** tab. You have better performance when you upgrade to the Hardware Component Description File (**_hw.tcl**) component format in newer versions of SOPC Builder. These components are marked by a green dot.

For more information about the **_hw.tcl** file, refer to the *Component Editor* chapter in volume 4 of the *Quartus II Handbook*.

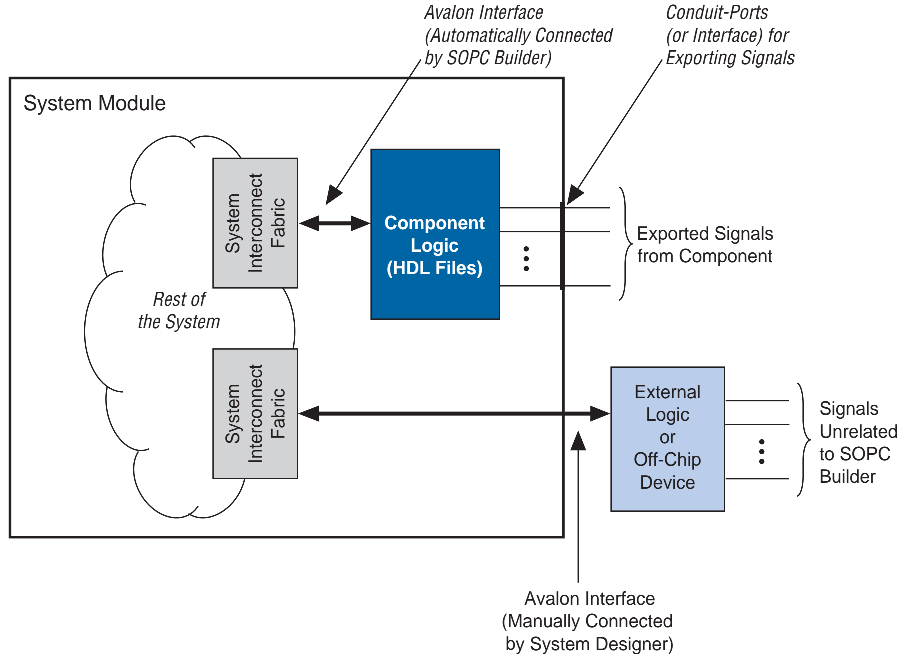
Component Hardware Structure

There are the following types of components in an SOPC Builder system, based on where the associated component logic resides:

- Components that include their associated logic inside the SOPC Builder system
- Components that interface to logic outside the SOPC Builder system

Figure 4–1 shows an example of both types of components.

Figure 4–1. Component Logic Inside and Outside the SOPC Builder System



© March 2009 Altera Corporation

Components Inside the SOPC Builder System

For components that are instantiated inside the SOPC Builder system, the component defines its logic in an associated HDL file. During system generation, SOPC Builder instantiates the component and connects it to the rest of the system. The component can include exported signals in conduit interfaces. Conduit interfaces become ports on the system, so they can be connected to logic outside the SOPC Builder system in the board-level schematic.

For more information about conduit interfaces, refer to the *Conduit Interfaces* chapter in the *Avalon Interface Specifications*.

In general, components connect to the system interconnect fabric using the Avalon® Memory-Mapped (Avalon-MM) interface or the Avalon Streaming (Avalon-ST) interface. A single component can provide more than one Avalon port. For example, a component might provide an Avalon-ST source port for high-throughput data, in addition to an Avalon-MM slave for control.

Static HDL Components

You can define SOPC Builder components whose parameters are all assigned values during the initial editing session. Examples of parameters whose values are typically known at instantiation time are address and data widths and FIFO depths. If all of a component's parameters are assigned when it is instantiated, the HDL for the component is *static*. SOPC Builder automatically generates the top-level HDL wrapper file to apply parameter values to your component.

Dynamic HDL Components

You can also create SOPC Builder components whose parameters are defined by a generation callback. Examples of parameters that might be assigned during generation callback are baud rate and output directory. When you create components that include parameters defined using a generation callback, you must provide a custom generation callback routine to create the top-level wrapper for your component.

For more information about defining your own generation program, refer to the *Generation Callback* section in the *Component Interface Tcl Reference* chapter in volume 4 of the *Quartus II Handbook.*

Components Outside the SOPC Builder System

For components that interface to external logic or off-chip devices with Avalon-compatible signals outside the SOPC Builder system, the component files describe only the interface to the external logic. During system generation, SOPC Builder exports an interface for the component in the top-level SOPC Builder system. You must manually connect the signals at the top-level of SOPC Builder to pins or logic defined outside the system that already has Avalon-compatible signals.

Exported Connection Points—Conduit Interfaces

Conduit interfaces are brought to the top level of the system as additional ports. Exported signals are usually either application-specific signals or the Avalon interface signals.

Application-specific signals are exported to the top level of the system by the conduit interface(s) defined in the **_hw.tcl** file. These are I/O signals in a component's HDL logic that are not part of any Avalon interfaces and connect to an external device, for example DDR SDRAM memory, or logic defined outside of the SOPC Builder system. You use conduit interfaces to connect application-specific signals of the external device and the SOPC Builder system.

You can also export the Avalon interfaces to manually connect them to external devices or logic defined outside a system with Avalon-compatible signals. This method allows a direct connection to the Avalon interface from any device that has Avalon-compatible signals. You can also export the Avalon interface in either an HDL file using conduit interfaces, or in the **_hw.tcl** file without an HDL file.

You export the Avalon interface signals as an HDL file with simple wire connections in the HDL description. The Avalon interface port signals are directly connected to external I/O signals in the HDL description. The conduit interface in the **_hw.tcl** file exports the external I/O signals to the top level of the system.

In the **_hw.tcl** file, no HDL files are specified and only the Avalon signals and interface ports are declared in the file.

SOPC Builder Component Search Path

Each time SOPC Builder starts, it searches for component files. The components that SOPC Builder finds are displayed in the list of available components on the SOPC Builder **System Contents** tab. When you launch SOPC Builder certain directories are searched for two kinds of files:

- **_hw.tcl** files. Each **_hw.tcl** file defines a single component.
- IP Index (**.ipx**) files. Each file indexes a collection of available components.

In general, **.ipx** files facilitate faster startup for SOPC Builder and other tools because fewer files need to be read and analyzed.

Some directories are searched recursively; others only to a specific depth. In the following list of search locations, a recursive descent is annotated by **. The * signifies any file. When a directory is recursively searched, the search stops at any directory containing a **_hw.tcl** or **.ipx** file; subdirectories are not searched.

- `$$PROJECT_DIR/*`
- `$$PROJECT_DIR/ip/**/*`
- `$QUARTUS_ROOTDIR/../ip/**/*`

In SOPC Builder, you can extend the default search path by including additional directories by clicking **Options**, then clicking **IP Search Path** and **Add**. These additional paths apply to all projects; that is, the paths are global to the current version of SOPC Builder.

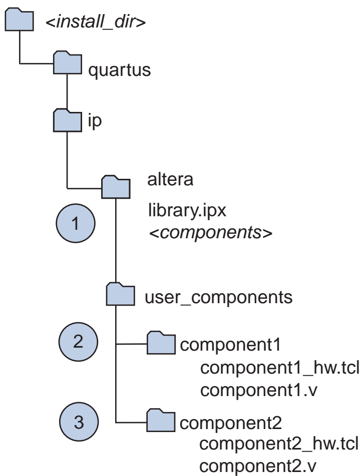
Installing Additional Components

There are two additional ways to make your components available to SOPC Builder projects. The following sections describe these methods.

Copy to the IP Root Directory

The simplest strategy is to copy your components into the standard IP directory provided by Altera. Figure 4–2 illustrates this approach.

Figure 4–2. User Library Included In Subdirectory of $IP_ROOTDIR



In Figure 4–2, the circled numbers identify three steps of the algorithm that SOPC follows during initialization. These steps are explained in the following paragraphs.

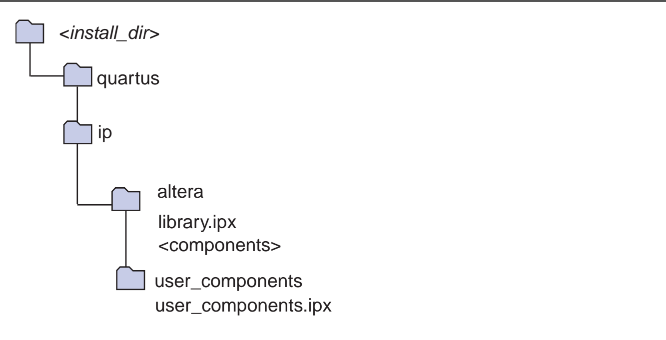
1. SOPC Builder recursively searches the *<install_dir>***/ip/** directory by default. It finds the file in the `altera` subdirectory, which tells it about all of the Altera components. **library.ipx** includes listings for all components found in its subdirectories. The recursive search stops when SOPC Builder finds this **.ipx** file.
2. As part of its recursive search, SOPC Builder also looks in the adjacent **user_components** directory. One level down SOPC Builder finds the **component1** directory, which contains **component1_hw.tcl**. SOPC Builder finds that component stops the recursive descent.
3. SOPC Builder then searches in the adjacent **component2** directory, which includes **component2_hw.tcl**. If SOPC Builder finds that component, the recursive descent stops.

If you save your **.ipx** file in the *<install_dir>***/ip/** directory, SOPC Builder finds your **.ipx** file and stops. SOPC Builder does not conduct the search just described.

Reference Components in an .ipx File

A second approach is to specify your IP directory in a **user_components.ipx** file under *<install_dir>***/ip** path. Figure 4–3 illustrates this approach.

Figure 4–3. Specifying A User .ipx directory



The **user_components.ipx** file includes a single line of code redirecting SOPC Builder to the location of the user library. Example 4–1 shows the code for this redirection.

Example 4–1. Redirect to User Library

```
<library>
  <path path="c:/<user_install_dir>/user_ip/**/*" />
<library>
```

For both of these approaches, if you install a new version of the Quartus II software, you must also update the installation to include your libraries.

Understanding IPX File Syntax

An **.ipx** file is an XML file whose top-level element is *<library>* with a *<path>* subelements are *<path>* and *<component>*. Altera recommends that you only add or edit the *<path>* subelement.

A *<path>* element contains a single attribute, also called `path` and may reference a directory with a wildcard, (*), or reference a single file. Two asterisks designate any number of subdirectories. A single asterisk designates a match to a single file or directory. In searching down the designated path, the following three types of files are identified:

- **.ipx**—additional index files
- **_hw.tcl**—SOPC Builder component definitions
- **_sw.tcl**—Nios II board support package (BSP) software component definitions

A *<component>* element contains several attributes to define a component. If you provide all the required details for each component in an **.ipx** file, the start-up time for SOPC Builder is less than if SOPC Builder must discover the files in a directory. Example 4–2 shows two *<component>* elements. Note that the paths for file names are specified relative to the **.ipx** file.

Example 4–2. Component Elements

```
<library>
  <component
    name="An SOPC Component"
    displayName="SOPC Component"
    version="2.1"
    file="./components/sopc_component/sc_hw.tcl"
   />
  <component
    name="legacy_component"
    displayName="Legacy Component (Classic Edition!)"
    version="0.9"
    file="./components/legacy/old_component/class.ptf"
   />
<library>
```

Upgrading from Earlier Versions

If you specified a custom search path in SOPC Builder prior to v8.1 using the **IP Search Path** option, or by adding it to the `$SOPC_BUILDER_PATH`, SOPC Builder automatically adds those directories to the **user_components.ipx** file in your home directory. This file is saved in *<home_dir>***/altera.quartus/ip/8.1/ip_search_path/user_components.ipx.** Go to the **IP Search Path** option in the **Options** dialog box to see the directories listed here**.**

Component Structure

Most components are defined with a **_hw.tcl** file, a text file written in the Tcl scripting language that describes the components in to SOPC Builder. You can add a component to SOPC Builder by either writing a Tcl description or you can use the component editor to generate an automatic Tcl description of it. This section describes the structure of Tcl components and how they are stored.

For details about the SOPC Builder component editor, refer to the *Component Editor* chapter in volume 4 of the *Quartus II Handbook*. For details about the SOPC Builder Tcl commands, refer to the *Component Interface Tcl Reference* chapter in volume 4 of the *Quartus II Handbook*.

Component Description File (_hw.tcl)

A Tcl component consists of:

- A component description file, which is a Tcl file with file name of the form *<entity name>***_hw.tcl.**
- Verilog HDL or VHDL files that define the top-level module of the custom component (optional).

The **_hw.tcl** file defines everything that SOPC Builder requires about the name and location of component design files.

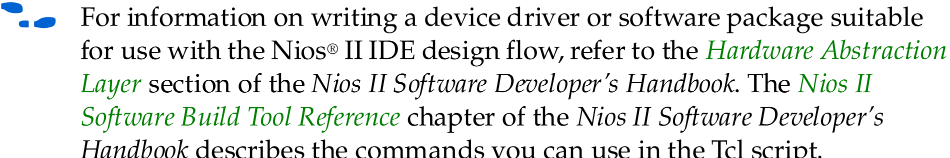
The SOPC Builder component editor saves components in the **_hw.tcl** format. You can use these Tcl files as a template for editing components by hand. When you edit a previously saved **_hw.tcl** file, SOPC Builder automatically saves the earlier version as **_hw.tcl~**.

For more information about the information that you can include in the **_hw.tcl** file, refer to the *Component Interface Tcl Reference* chapter in volume 4 of the *Quartus II Handbook*.

Component File Organization

A typical component uses the following directory structure. The precise names of the directories are not significant.

- *<component_directory>***/**
  - *<hdl>***/**— a directory that contains the component HDL design files and the **_hw.tcl** file
  - *<component name>***_hw.tcl**—the component description file
  - *<component name>***.v or .vhd**—the HDL file that contains the top-level module
  - *<component_name>***_sw.tcl**—the software driver configuration file. This file specifies the paths for the **.c** and **.h** files associated with the component.
- You are not required to create a special sub-directory for component HDL files. However, you are required to follow the naming conventions given here.
  - *<component_dir>* /
  - *<name>***_hw.tcl**
  - *<name>***.v** or **.vhd**
  - *<name>***_sw.tcl**
- *<software>***/**—a directory that contains software drivers or libraries related to the component, if any. Altera recommends that the software directory be subdirectory of the directory that contains the **_hw.tcl** file.



For information on writing a device driver or software package suitable for use with the Nios® II IDE design flow, refer to the *Hardware Abstraction Layer* section of the *Nios II Software Developer's Handbook*. The *Nios II Software Build Tool Reference* chapter of the *Nios II Software Developer's Handbook* describes the commands you can use in the Tcl script.

Classic Components in SOPC Builder

If you use classic components created with an earlier version of SOPC Builder, read through this section to familiarize yourself with the differences. This document uses the term *classic components* to refer to class.ptf-based components created with a previous version of the Quartus II software. If you do not use classic components, skip this section.

Classic components are compatible with newer versions of SOPC Builder, but be aware of the following caveats:

- Classic components configured with the **More Options** tab in SOPC Builder, such as complex IP components provided by third-party IP developers, are not supported in the Quartus II software in version 7.1 and beyond. If your component has a bind program, you cannot use the component without recreating it with the component editor or with Tcl scripting.
- To make changes to a classic component with the component editor, you must first upgrade the component by editing the classic component and saving it in the **_hw.tcl** component format in the component editor.

Document Revision History

Table 4–1 shows the revision history for this chapter.

Table 4–1. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009, v9.0.0	■ Added 2 paragraphs introducing custom generations for dynamic components.	Updated component descriptions.
November 2008, v8.1.0	■ Revised section on component search paths. ■ Added meaning of green and gray dots next to components on the **System Contents** tab. ■ Changed page size to 8.5 x 11 inches	Revised to reflect changes to the component search path in 8.1.
May 2008, v8.0.0	■ Added paragraph about IP Search Path.	—

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

5. Using SOPC Builder with the Quartus II Software

QII54023-9.0.0

Introduction

This chapter describes the Quartus® II software tools that interface with SOPC Builder, including the following:

- "Quartus II IP File"
- "Quartus II Incremental Compilation" on page 5–1
- "TimeQuest Timing Analyzer" on page 5–2

Quartus II IP File

The Quartus II IP File (**.qip**) generated by SOPC Builder provides the Quartus II software with all required information about your SOPC Builder system. SOPC Builder creates the **.qip** during system generation and adds a reference to it in the Quartus II Settings File (**.qsf)**.

The **.qip** file includes references to the following information:

- HDL files used in the SOPC Builder system
- TimeQuest Timing Analyzer Synopsys Design Constraint (**.sdc**) files
- Component definition files for archiving purposes

The **.qip** file is based on Tcl scripting syntax and is similar to the **.qsf** file. The information required to process most components is included in the system's single **.qip** file. Some complex components provide their own **.qip** file, in which case the system's **.qip** file references the component **.qip** file.

The **.qip** file is normally added to your project automatically by SOPC Builder. If it does not get added automatically you can add the file in the same way that you add other source files to your project. You can also have a **.qip** file for each component in your design. When you generate a design, each **.qip** is pulled into the main **.qip** file for your system by reference.

Quartus II Incremental Compilation

SOPC Builder supports the Quartus II incremental compilation feature, which allows you to separately compile isolated portions, or partitions, of a design. From within the Quartus II software, you can designate an entire SOPC Builder system as a design partition, or you can designate individual SOPC Builder components as design partitions.

Changing the parameters of a component and regenerating your system only prompts other partitions within the same system to recompile if the HDL in that partition depends on the changed parameters. The HDL you generate for the Nios® II processor is optimized as related to components to which the Nios II processor is connected.

For more information about incremental compilation, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

TimeQuest Timing Analyzer

Altera recommends the TimeQuest Timing Analyzer in the Quartus II software for analysis of all new designs. SOPC Builder automatically generates a TimeQuest **.sdc** constraints file for SOPC Builder systems and components. In most cases, you use the TimeQuest constraints to declare false paths for signals that cross clock domains within a component, so that the TimeQuest Timing Analyzer does not perform normal setup and hold analysis for them. You can add **.sdc** files for custom components, using **Add Files** command on **HDL Files** tab in the Component Editor. Turn on the **Synth** option and turn off the **Synth** option.

The Classic Timing Analyzer was primary in earlier versions of the Quartus II software. However, Altera now recommends that you constrain designs before compilation, because the TimeQuest Timing Analyzer reports any unconstrained paths by default during the compilation process.

Refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook* for further description of the TimeQuest Timing Analyzer. Refer to the *Switching to the Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook* for a description of the benefits of using the TimeQuest Timing Analyzer rather than the Classic Timing Analyzer. Refer to *TimeQuest Example: Basic SDC Example* on www.altera.com for a working example of using the TimeQuest Timing Analyzer. Refer to *TimeQuest Design Examples* on www.altera.com for further details about how to constrain different types of circuits for the TimeQuest Timing Analyzer.

Analyzing PLLs

You must constrain PLL clocks for proper analysis by the TimeQuest Timing Analyzer. You can define clocks generated by PLLs using one of the following methods:

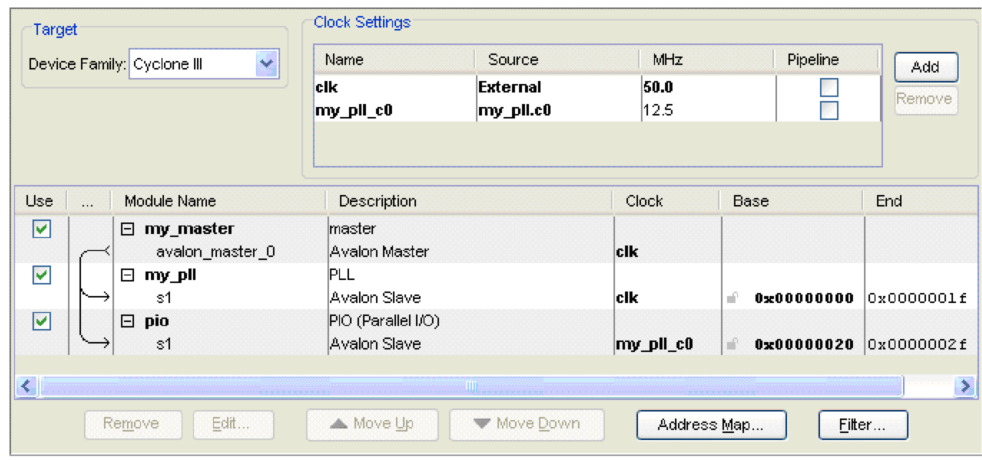
- Use the `derive_pll_clocks` command to derive clocks for all PLL outputs in the design. This is the best method.
- Use the `create_generated_clock` command to designate each clock output.
- Use the `-create_base_clocks` option of the `derive_pll_clock` assignments to designate the base clock feeding the PLL.

The following example focuses on the use of the `derive_pll_clocks` assignment, because this method automatically defines clock frequencies and phase shifts.

`derive_pll_clocks` generates clocks for all PLLs in the Quartus II hardware project, not just for the PLLs in the SOPC Builder system.

The SOPC system shown in Figure 5–1 illustrates the use of the `derive_pll_clocks` assignment in the case of a single clock input and one PLL using a single output.

Figure 5–1. Example SOPC System

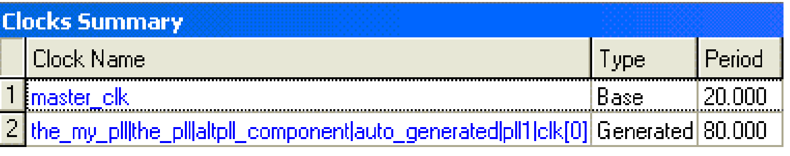


After running the following commands in the TimeQuest Timing Analyzer, two clocks are generated:

```
create_clock -name master_clk -period 20 [get_ports {clk}]
derive_pll_clocks
```

The TimeQuest Timing Analyzer analyzes and reports performance of the constrained clocks in the Clocks Summary report. This displays a report as shown in Figure 5–2.

Figure 5–2. Clocks Summary Report



Clocks Summary

	Clock Name	Type	Period
1	master_clk	Base	20.000
2	the_my_pll|the_pll|altpll_component|auto_generated|pll1|clk[0]	Generated	80.000

`master_clk` is defined by the `create_clock` command, and `the_my_pll` clock is derived from the `derive_pll_clocks` command.

Analyzing Slow Asynchronous I/O Paths

If you use slow asynchronous I/O in an SOPC Builder system, such as PIO and UART peripherals, you do not have to analyze these paths because they are asynchronous to the clock that is used to capture or output data. In this case you must designate false paths to produce an accurate analysis.

For outputs, set a false path between the launch clock and the output. For inputs, a false path should be set between the input and the latching clock. For bidirectional signals, set a false path from the launching clock to the bidirectional pin and also from the bidirectional pin to the latching clock. Launch and latch clocks are typically the clocks associated with the SOPC Builder module that includes the I/O.

For the system described in the PLL section, the following command sets false paths for the PLL outputs:

```
set_false_path -to [get_ports {*_pio[*]}]
```

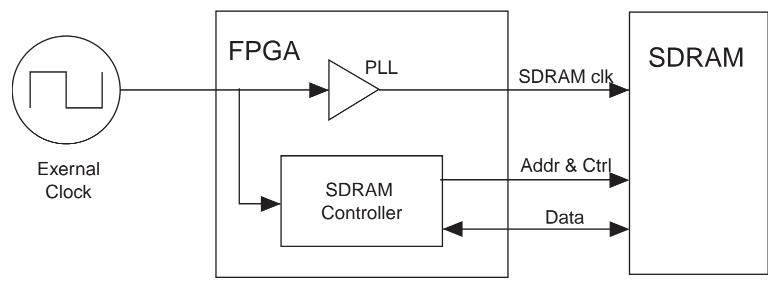
Because design contains a 4-bit PIO, `filter *_pio[*]` includes the following I/O pins.

- `out_port_from_the_pio[0]`
- `out_port_from_the_pio[1]`
- `out_port_from_the_pio[2]`
- `out_port_from_the_pio[3]`

Analyzing Single Data Rate SDRAM and SSRAM

Single data SDRAM interfaces in SOPC Builder typically use the type of circuit shown in Figure 5–3. You can use a PLL to fine tune the phase shift to the external memory to meet I/O timing requirements.

Figure 5–3. Typical Single Data Rate SDRAM Circuit



To constrain this interface, you must create a clock that is recognized by the external SDRAM; then you must set the I/O timing relative to that clock.

Example 5–1 shows how to constrain a PLL output clock and set a Tcl variable for that clock.

Example 5–1. Constraining PLL Output Clock

```
create_clock -period 20.000 -name ext_clk [get_ports {clk}]
derive_pll_clocks
set sdram_clk\my_pll_inst|altpll_component|auto_generated|pll1|clk[0]
```

You can then use the `create_generated_clock` command to define a clock as recognized by the external memory. This generated clock automatically adds delays associated with routing to the clock output pin and the delay of the pin itself. You must also account for some board delay due to the PCB trace between the FPGA and SDRAM by using the `offset` option.

The following command shows the creation of the `sdram_clk_pin` generated clock derived from the output pin `sdram_clk` clock. A 0.5 ns offset accounts for PCB routing delay.

```
create_generated_clock -name sdram_clk_pin -source $sdram_clk \
-offset 0.5 [get_ports {sdram_clk}]
```

There may be some uncertainty associated with the PCB delay not accounted for in this command. The uncertainty can be included in the I/O constraints that are specific to input or output and minimum or maximum delays.

The I/O constraints must be defined in relation to the data sheet for the external memory. Figure 5–4 shows part of a data sheet for an SDRAM device with the worst case input and output timing highlighted for a CAS latency of 3.

Figure 5–4. AC Characteristics from SDRAM Device Data sheet

AC Characteristics Parameter		Symbol	-6		-7		Units	Notes
			Min	Max	Min	Max		
Access time from CLK (pos. edge)	CL = 3	^{t}AC (3)		5.5		5.5	ns	
	CL = 2	^{t}AC (2)		7.5		8	ns	
	CL = 1	^{t}AC (1)		17		17	ns	
Address hold time		^{t}AH	1		1		ns	
Address setup time		^{t}AS	1.5		2		ns	
CLK high-level width		^{t}CH	2.5		2.75		ns	
CLK low-level width		^{t}CL	2.5		2.75		ns	
Clock cycle time	CL = 3	^{t}CK (3)	6		7		ns	23
	CL = 2	^{t}CK (2)	10		10		ns	23
	CL = 1	^{t}CK (1)	20		20		ns	23
CKE hold time		^{t}CKH	1		1		ns	
CKE setup time		^{t}CKS	1.5		2		ns	
CS#, RAS#, CAS#, WE#, DQM hold time		^{t}CMH	1		1		ns	
CS#, RAS#, CAS#, WE#, DQM setup time		^{t}CMS	1.5		2		ns	
Data-in hold time		^{t}DH	1		1		ns	
Data-in setup time		^{t}DS	1.5		2		ns	
Data-out High-Z time	CL = 3	^{t}HZ (3)		5.5		5.5	ns	10
	CL = 2	^{t}HZ (2)		7.5		8	ns	10
	CL = 1	^{t}HZ (1)		17		17	ns	10
Data-out Low-Z time		^{t}LZ	1		1		ns	
Data-out hold time		^{t}OH	2		2.5		ns	

The mapping of external memory timing to FPGA I/O delays is shown in Table 5–1. This also shows whether the minimum or maximum PCB routing delay should be used, which must be added to the FPGA delay constraints.

Table 5–1. External Memory Timing

Memory Timing	FPGA Timing	PCB Routing
Max clock to out	Max input delay	Max
Min clock to out	Min input delay	Min
Min setup	Max output delay	Max
Min hold	Min output delay (-ve)	Min

Note to Table 5–1:

(1) The constraint for minimum output delay is actually 0 – Min hold.

You can use the set_input_delay and set_output_delay commands to set the I/O constraints. In the following examples, a common PCB routing delay of 0.5ns ± 0.1 ns is used, which adds a 0.4 ns or 0.6 ns delay to the paths. Example 5–2 illustrates the use of these commands.

Example 5–2. set_input_delay and set_output_delay commands

```
set_input_delay -clock sdram_clk_pin -max [expr 5.5 + 0.6] <ports>
set_input_delay -clock sdram_clk_pin -min [expr 2.5 + 0.4] <ports>
set_output_delay -clock sdram_clk_pin -max [expr 2.0 + 0.6] <ports>
set_output_delay -clock sdram_clk_pin -min [expr 1 – (1.0 + 0.4)]<ports>
```

In this example, <*ports*> represent a list of I/O ports for the relevant constraints as shown in Example 5–3.

Example 5–3. <ports>

```
set_output_delay -clock sdram_clk_pin -max [expr 2.0 + 1.2] \
[get_ports {cas_n ras_n cs_n we_n addr[*]}]
```

You can use multiple set_input_delay and set_output_delay commands to set different delays for different I/O.

Analyzing Tristate Bridges and Asynchronous Devices

This section discusses the timing constraints associated with the Avalon tristate bridge and asynchronous external devices, such as the CFI Flash and user tristate components. These components typically have slower performance requirements compared with the FPGA, and SOPC Builder generates logic within the interface to control timing across multiple clock cycles. You define the tristate component's timing parameters by entering data for setup, wait, and hold times.

For the interface types previously discussed, the timing is controlled by a state machine that is generated based on setup, wait, and hold settings you specify in the component editor. Because data sheet values for the FPGA are used in calculating the timing, the constraints simply ensure the data sheet timing is met. Adding these constraints ensures that issues associated with data sheet misinterpretation and fitting problems that affect I/O timing are captured.

The TimeQuest Timing Analyzer uses constraints that are based upon the timing of the external device.

For further information on how to convert older FPGA-centric constraints into system-centric constraints, refer to *Switching to the Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Analyzing DDR and DDR2 Memories

When using DDR, DDR2, or DDR3 memory with Cyclone® III, Stratix® III, and Stratix IV families, you must use the corresponding High-Performance Controller MegaCore® function. You can use the MegaWizard™ Plug-In Manager interface to parameterize these functions and generate timing constraints in the form of **.sdc** files. You must ensure that the constraints file associated with the MegaCore function is included in the project for timing analysis. You can add an **.sdc** file to the project by clicking **Add/Remove Files in Project** on the Project menu in the Quartus II software.

As these MegaCore functions make use of the `derive_pll_clocks` command, conflicts may occur if your **.sdc** file also uses these constraints.

For more design examples, refer to TimeQuest Design Examples on www.altera.com. Also, *AN: 433 Constraining and Analyzing Source-Synchronous Interfaces* describes source synchronous constraints for the TimeQuest Timing Analyzer.

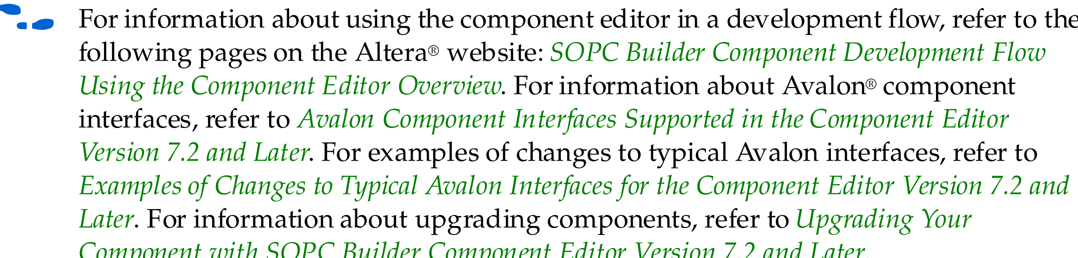
6. Component Editor

QII54005-9.0.0

Introduction

This chapter describes the SOPC Builder component editor. The component editor provides a GUI to support the creation and editing of the Hardware Component Description File (**_hw.tcl**) file that describes a component to SOPC Builder. You use the component editor to do the following:

- Specify the Verilog HDL or VHDL files that describe the modules in your component hardware.
- Conversely, create an HDL template for a component by first defining its interface using the **HDL Files** tab of the component editor.
- Specify the signals for each of the component's interfaces, and define the behavior of each interface signal.
- Specify relationships between interfaces, such as determining which clock interface is used by a slave interface.
- Declare any parameters that alter the component structure or functionality, and define a user interface to let users parameterize instances of the component.



For information about using the component editor in a development flow, refer to the following pages on the Altera® website: *SOPC Builder Component Development Flow Using the Component Editor Overview*. For information about Avalon® component interfaces, refer to *Avalon Component Interfaces Supported in the Component Editor Version 7.2 and Later*. For examples of changes to typical Avalon interfaces, refer to *Examples of Changes to Typical Avalon Interfaces for the Component Editor Version 7.2 and Later*. For information about upgrading components, refer to *Upgrading Your Component with SOPC Builder Component Editor Version 7.2 and Later*.

For information about the use of the component editor, see the following sections:

- "Starting the Component Editor" on page 6–2.
- "HDL Files Tab" on page 6–2.
- "Signals Tab" on page 6–3.
- "Interfaces Tab" on page 6–6.
- "Component Wizard Tab" on page 6–6.
- "Saving a Component" on page 6–8.
- "Editing a Component" on page 6–8.
- "Component GUI" on page 6–8.

For more information about components, refer to the *Component Interface Tcl Reference* chapter in volume 4 of the *Quartus II Handbook*, For more information about the Avalon-MM interface, refer to the *Avalon Interface Specifications*.

Component Hardware Structure

The component editor creates components with the following characteristics:

- A component has one or more interfaces. Typically, an *interface* means an Avalon® Memory-Mapped (Avalon-MM) master or slave or an Avalon Streaming (Avalon-ST) source or sink. You can also specify exported component signals that appear at the top-level of the SOPC Builder system, which can be connected to logic outside the SOPC Builder system. The component editor lets you build a component with any combination of Avalon interfaces, which include:
  - Avalon-MM master and slave
  - Avalon-ST source and sink
  - Avalon-MM tristate slave
  - Interrupt sender and receiver
  - Clock input and output
  - Nios II custom instruction master and slave interfaces
  - Conduit (for exporting signals to the top level)
- Each interface is comprised of one or more signals.
- The component can represent logic that is instantiated inside the SOPC Builder system, or can represent logic outside the system with an interface to it on the generated system.

Starting the Component Editor

To start the component editor in SOPC Builder, on the File menu, click **New Component.** When the component editor starts, the **Introduction** tab displays, which describes how to use the component editor.

The component editor presents several tabs that group related settings. A message window at the bottom of the component editor displays warning and error messages.

Each tab in the component editor provides on-screen information that describes how to use the tab. Click the triangle labeled **About** at the top-left of each tab to view these instructions. You can also refer to Quartus® II online Help for additional information about the component editor.

You navigate through the tabs from left to right as you progress through the component creation process.

HDL Files Tab

The **HDL Files** tab allows you to create an SOPC Builder component from existing Verilog HDL or VHDL files, or to create an HDL template in either Verilog HDL or VHDL for a SOPC Builder component by first specifying its interfaces. The following sections describe both the bottom-up and top-down approaches to component design.

Bottom-Up Design

You can use the **HDL Files** tab to specify Verilog HDL or VHDL files that describe the component logic. Files are provided to downstream tools such as the Quartus II software and ModelSim® in the same order as they appear in the table.

You can also use the component editor to define the interface to components outside the SOPC Builder system. In this case, you do not provide HDL files. Instead, you use the component editor to interactively define the hardware interface.

After you specify an HDL file, the component editor analyzes the file by invoking the Quartus II Analysis and Elaboration module. The component editor analyzes signals and parameters declared for all modules in the top-level file. If the file is successfully analyzed, the component editor's **Signals** tab lists all design modules in the **Top Level Module** list. If your HDL contains more than one module, you must select the appropriate top-level module from the **Top Level Module** list.

All files are managed in a single table, with options for **Synth** and **Sim**. You can select the **Top** option to select the top-level file for synthesis. When the top-level module is changed, the component editor performs best-effort signal matching against the existing port definitions. If a port is absent from the module, it is removed from the port list. You can use the up and down arrows to specify the HDL file analysis order.

By default, all files are added with both **Synth** and **Sim** options turned on. To add a simulation-only file, turn off the **Synth** option for that file. Files that turn on the **Sim** option are passed to ModelSim® for simulation. To add a synthesis-only file, turn off the **Sim** file option. You can add the **.sdc** file for your component using the **Synth** option. Only files that you mark for **Synth** are added to the **.qip** file for your project.

The component editor determines the signals on the component when only the top-level module or entity is added to the table, but all of the files required for the component must be added for the component to compile in Quartus II software or work in simulation.

Top-Down Design

The **Create HDL Template** button on the **HDL Files** tab allows you to create an HDL template for a component if you have not provided a HDL description for it. Clicking the **Create HDL Template** button shows you the component HDL and lets you choose between Verilog HDL and VHDL. Altera recommends that you define your signals, interfaces, parameters and basic component information, including the component name, before creating the HDL template by clicking **Save**. The component editor writes <***component_name***>**.v** or <***component_name***>**.vhd** to your project directory.

After you have component the component's HDL code, you can add other files that are required to define your component, including the **_hw.tcl** file, and synthesis and simulation files using the **Add** button on the **HDL Files** tab.

Signals Tab

You use the **Signals** tab to specify the purpose of each signal on the top-level component module. If you specified a file on the **HDL Files** tab, the signals on the top-level module appear on the **Signals** tab.

The **Interface** list also allows creation of a new interface so that you can assign a signal to a different interface without first switching to the **Interfaces** tab. Each signal must belong to an interface and be assigned a legal signal type for that interface. In addition to Avalon Memory-Mapped and Streaming interfaces, components typically have clock interfaces, interrupt interfaces, and perhaps a conduit interface for exported signals.

Naming Signals for Automatic Type and Interface Recognition

The component editor recognizes signal types and interfaces based on the names of signals in the source HDL file, if they conform to the following naming conventions:

Signal associated with a specific interface—<*interface type*>_<*interface name*>_<*signal type*>[_n]

For any value of <*interface_name*> the component editor automatically creates an interface by that name, if necessary, and assigns the signal to it. The <*signal_type*> must match one of the valid signal types for the type of interface. Refer to the *Avalon Interface Specifications* for the signal types available for each interface type. You can *append* _n to indicate an active-low signal. Table 6–1 lists the valid values for <*interface_type*>.

Table 6–1. Valid Values for <Interface Type>

Value	Meaning
avs	Avalon-MM slave
avm	Avalon-MM master
ats	Avalon-MM tristate slave
aso	Avalon-ST source
asi	Avalon-ST sink
cso	Clock output
csi	Clock input
coe	Conduit
inr	Interrupt receiver
ins	Interrupt sender
ncm	Nios II custom instruction master
ncs	Nios II custom instruction slave

Example 6–1 shows a Verilog HDL module declaration with signal names that infer two Avalon-MM slaves.

Example 6–1. Verilog HDL Module With Automatically Recognized Signal Names

```
module my_slave_irq_component (

   // Signals for Avalon-MM slave port "s1" with irq

   csi_clockreset_clk; //clockreset clock interface
   csi_clockreset_reset_n;//clockreset clock interface

   avs_s1_address;//s1 slave interface
   avs_s1_read; //s1 slave interface
   avs_s1_write;  //s1 slave interface
   avs_s1_writedata; //s1 slave interface
   avs_s1_readdata; //s1 slave interface
   ins_irq0_irq; //irq0 interrupt sender interface
   );

   input csi_clockreset_clk;
   input csi_clockreset_reset_n;
   input [7:0]avs_s1_address;
   input avs_s1_read;
   input avs_s1_write;
   input [31:0]avs_s1_writedata;
   output [31:0]avs_s1_readdata;
   output ins_irq0_irq;

/* Insert your logic here */

endmodule
```

Templates for Interfaces to External Logic

If the component does not use an HDL file to interface to external logic that is Avalon compatible, you can manually add the signals that comprise the interface to the external logic or use the **Create HDL Template** to generate an HDL template for the component. You connect these signals outside of the SOPC Builder system. If your component uses an Avalon interface to interface outside of SOPC Builder, you can use the Templates menu in the component editor to add typical interface signals to your signal list. There are templates for the following interfaces:

- Avalon-MM Slave
- Avalon-MM Slave with Interrupt
- Avalon-MM Master
- Avalon-MM Master with Interrupt
- Avalon-ST Source
- Avalon-ST Sink

After adding a typical Avalon interface using a template, you can add or delete signals to customize the interface.

Interfaces Tab

The **Interfaces** tab allows you to configure the interfaces on your component and specify a name for each interface. The interface name identifies the interface and appears in the SOPC Builder connection panel. The interface name is also used to uniquely identify any signals that are ports on the top-level SOPC Builder system.

The **Interfaces** tab allows you to configure the type and properties of each interface. For example, an Avalon-MM slave interface has timing parameters that you must set appropriately. The **Interfaces** tab displays waveforms that illustrate the timing that you specified. If you update the timing parameters, the waveforms automatically update to illustrate the new timing. The waveforms are available for the following interface types:

- Avalon Memory-Mapped
- Avalon Memory-Mapped tristate
- Avalon Streaming
- Interrupts

If you convert a component from a **class.ptf** to a **_hw.tcl** file, you may require three interfaces: a clock input, the Avalon slave, and an interrupt sender. A parameter in the interrupt sender must be set to reference the Avalon slave.

Component Wizard Tab

The **Component Wizard** tab provides options that affect the presentation of your new component.

Identifying Information

You can specify information that identifies the component as follows:

- Folder—Specifies the location of the component, determined by the location of the top-level HDL file.
- Class Name—Specifies the name used internally to store the component in the component library. The class name is stored in the **.sopc** file. Use the class name when saving a system that contains an instance of this component. It is also the name you use for the component type when you create a system using a **.tcl** script. If you change the class name of a component, existing **.sopc** files that use the component may break.

  SOPC builder uses the class name and version to find components. If two components with the same class name and version are available to SOPC builder at the same time, the behavior of SOPC builder is undefined.

- Display Name—Specifies the user-visible name for this component in SOPC Builder.
- Version—Specifies the version number of the component.
- Group—Specifies which group in SOPC Builder displays your component in the list of available components. If you enter a previously unused group name, SOPC Builder creates a new group by that name.

- Description—Allows you to describe the component.
- Created By—Allows you to specify the author of the component.
- Icon—Allows you to place an image in the title bar of your component, in place of the MegaCore logo. The icon can be a **.jpg**, **.gif**, or **.png** file. The directory for the icon is relative to the directory that contains the **_hw.tcl** file.
- Data sheet URL—Allows you to specify a URL for the datasheet. You can use this property to specify a file on the internet or in your company's file system. The specified file can be in either **.html** or **.pdf** format. To specify an internet file, begin your path with **http://**, for example: **http://mydomain.com/datasheets/my_memory_controller.html**. To specify a file in your company's file system, you begin you path with **file:///** for Linux and **file:////** for Windows, for example: **file:////company_server/datasheets/my_memory_controller.pdf**. For handwritten **_hw.tcl** files, you can specify a relative path using the following Tcl command: `set_module_property DATASHEET_URL [get_module_property MODULE_DIRECTORY]/<relative_path_to_hw.tcl>`
- Parameters—Allows you to specify the parameters for creating the component, as described in the next section.

Parameters

The **Parameters** table allows you to specify the user-configurable parameters for the component.

If the top-level module of the component HDL declares any parameters (*parameters* for Verilog HD or *generics* for VHDL), those parameters appear in the **Parameters** table. The parameters are presented to you when you create or edit an instance of your component. Using the **Parameters** table, you can specify whether or not each parameter is user-editable.

The following rules apply to HDL parameters exposed via the component GUI:

- Editable parameters cannot contain computed expressions.
- If a parameter <*N*> defines the width of a signal, the signal width must be of the form <*N*-1>:0.
- When a VHDL component is used in a Verilog HDL SOPC Builder system, or vice versa, numeric parameters must be 32-bit decimal integers. When passing other numeric parameter types, unpredictable results occur.

Click **Preview the Wizard** at any time to see how the component GUI appears.

Refer to *Component Interface Tcl Reference* chapter in the *Quartus II Handbook* for detailed information about creating and displaying parameters using Tcl scripts.

Saving a Component

You can save the component by clicking **Finish** on any of the tabs, or by clicking **Save** on the File menu. Based on the settings you specify in the component editor, the component editor creates a component description file with the file name *<class-name>***_hw.tcl**. The component editor saves the file in the same directory as the HDL file that describes the component's hardware interface. If you did not specify an HDL file, you can save the component description file to any location you choose.

You can relocate component files later. For example, you could move component files into a subdirectory and store it in a central network location so that other users can instantiate the component in their systems. The **_hw.tcl** file contains relative paths to the other files, so if you move the **_hw.tcl** file you should move all the HDL and other files associated with it.

Altera recommends that you store **_hw.tcl** files for a project is in the **ip/<*class-name*>** directory for the project. You should store the HDL and other files in the same directory as the **_hw.tcl** file.

Editing a Component

After you save a component and exit the component editor, you can edit it in SOPC Builder. To edit a component, right-click it in the list of available components on the **System Contents** tab and click **Edit Component**.

You cannot edit components that were created outside of the component editor, such as Altera-provided components.

If you edit the HDL for a component and change the interface to the top-level module, you need to edit the component to reflect the changes you made to the HDL.

Software Assignments

You can use Tcl commands to create software assignments.You can register any software assignment that you want, as arbitrary key-value pairs. Example 6–2 shows a typical Tcl API script:

Example 6–2. Typical Software Assignment with Tcl API Scripting

```
set_module_assignment name value
set_interface_assignment name value
```

The result is that the assignments go into the **.sopcinfo** file, available for use for downstream components.

Component GUI

To edit component instance parameters, select a component in the **System Contents** tab of the SOPC Builder window and click **Edit**.

Document Revision History

Table 6–2 shows the revision history for this chapter.

Table 6–2. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009, v9.0.0	■ Revised description of the **Create HDL Template** functionality and the Templates menu. ■ Interfaces tab now includes waveforms that illustrate timing parameters. ■ Added reference to *Component Interface Tcl Reference* chapter for detailed information about defining and displaying GUI parameters. ■ Added data sheet URL to Component Wizard tab.	Updated to reflect new functionality.
November 2008, v8.1.0	■ Added information about new HDL template feature ■ Changed page size to 8.5 x 11 inches	—
May 2008, v8.0.0	Extensive edits to this chapter, including: ■ Chapter renumbered. ■ Added new section on software assignments.	—

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

7. Component Interface Tcl Reference

QII54022-9.0.0

Introduction

You define SOPC Builder components by declaring their properties and behaviors in a Hardware Component Description File (**_hw.tcl**). Each **_hw.tcl** file represents one component instance which you can add to an SOPC Builder system. You can also share the components that you design with other designers. For your component to have maximum flexibility, you should consider what aspects of its behavior can be parameterized so that other users can change the default parameterization to address different design requirements.

An SOPC Builder component is usually composed of the following four types of files:

- **_hw.tcl** file—describes the SOPC Builder related characteristics, such as interface behaviors. This file is required.
- HDL files—define the component's functionality as hardware. These files are optional.
- **_sw.tcl**—used by the software build tools to compile the component driver code. This file is optional.
- Component driver files—defines the component register map and driver software to allow software to control the component. These files are optional.

This chapter discusses the following topics:

- "Information in a Hardware Component Description File" on page 7–1
- "Component Phases" on page 7–2
- "Writing a Hardware Component Description File" on page 7–2
- "Overriding Default Behaviors" on page 7–9
- "Hardware Tcl Command Reference" on page 7–12

Information in a Hardware Component Description File

A typical **_hw.tcl** file contains the following information:

- Basic component information—includes the component's name, version, and description, a link to its documentation, and pointers to HDL implementation files for synthesis and simulation.
- Parameter Declarations—Parameters are values that the user of your component can set that affect how the component is implemented, such as the size of a memory. Properties of each parameter include the parameter's name, whether or not it is visible, and, if visible, the text to display when describing it. When the SOPC Builder system is generated, the parameters can be applied to the component as Verilog HDL parameters or VHDL generics.

- Interface Properties—The interfaces of a component define how to connect it to the rest of the system and determine how other components in the system interact with it. When you add interfaces to a component, you declare which signals make up each interface. You also define interface properties, such as wait states for an Avalon® Memory-Mapped (Avalon-MM) interface.

Component Phases

The following section describes the distinct phases in the development of an SOPC Builder component.

- Main Program—SOPC Builder first discovers a component and adds it to the component library. The **_hw.tcl** file is executed and the Tcl statements provide non-instance-specific information to SOPC Builder. During this phase, some component interfaces may be incompletely described and ports may have a width of 0 or -1 to indicate that they are variable.
- Validation—Validation allows the component to generate error, warning, or informational messages. Validation occurs when an instance of a component is created, when its parameters are changed, or when some other property of the system is changed.
- Elaboration—Elaboration occurs as SOPC Builder queries a component for its interface information. Elaboration typically occurs immediately after validation and before generation. Interfaces defined in the main program can be enabled or disabled during elaboration. Depending on the validation callback code, elaboration and validation may alternate a few times. Elaboration and validation always occur before generation. Once elaboration is complete, the component must be completely described. For example, all port widths must have positive values.
- Generation—Generation creates all the information that the Quartus® II software and HDL simulator require. The required files typically include VHDL or Verilog HDL files, simulation models, timing constraints, and other information.
- Editor—After an instance of your component has been added to an SOPC Builder system, allows the user of your component to edit the GUI that displays the parameterization. You can change the appearance of the default editor to make it easier to use.

Writing a Hardware Component Description File

This section provides detailed information about **_hw.tcl** files and describes the default behavior of a component in all five phases. The following example uses a simple UART with some simple parameterization.

Providing Basic Information

A typical **_hw.tcl** file first declares basic information, such as the name, location, and the files it includes. Example 7–1 provides sample Tcl code for basic component information.

The Tcl scripts shown in each example are each part of the single **_hw.tcl** that defines a component. `String` arguments must only be enclosed in quotes if they include embedded spaces.

An excellent source of information about Tcl syntax is the Tcl Developer Xchange website.

Example 7–1. Basic Information for _hw.tcl File

```
# The name and version of the component
set_module_property NAME example_uart
set_module_property VERSION 1.0

# The name of the component to display in the library
set_module_property DISPLAY_NAME "Example Component"

# The component's description.
set_module_property DESCRIPTION "An Example Component"

# The component library group that component belongs to
set_module_property GROUP Examples
```

Declaring Parameters

By including configuration parameters in your **_hw.tcl** file, you allow other users of your component to parameterize it differently. Component users can enter integer parameters as decimal, binary, or hexadecimal values. You can specify binary values using the `b'` notation, for example: `b'1111`. You can specify hexadecimal values with either the `0x` or `'h` prefix, for example: `0x100` or `'h100`. Example 7–2 illustrates the use of parameters that can be configured by other users of your component.

Example 7–2. Declaring Parameters

```
# Declare Baud Rate parameter as an integer with a default value of 9600.
add_parameter BAUD_RATE int 9600
# Display this parameter as "Baud Rate" in the Parameter Editor.
set_parameter_property BAUD_RATE DISPLAY_NAME "Baud Rate (bps)"
# We only support three baud rates
set_parameter_property BAUD_RATE ALLOWED_RANGES {9600 19200 38400}
```

You can use the `SYSTEM_INFO` parameter property in conjunction with the `set_parameter_property` command to introduce custom parameters that are part of your component definition. `SYSTEM_INFO` requires the *`<info-type>`* argument that can take on many different values. In some cases, `SYSTEM_INFO` requires more than one argument. For example, when the *`<info-type>`* is `ADDRESS_MAP`, you must specify the Avalon-MM master whose address map you need. Example 7–3 illustrates the use of the `SYSTEM_INFO` parameter.

Example 7–3. Syntax of Tcl Command using the SYSTEM_INFO Parameter

```
set_parameter_property my_parameter SYSTEM_INFO {<info-type> [<arg>]}
```

The following types of system information are defined:

- `CLOCK_RATE` (`Integer` or `String`)—Assigns a positive number which is the clock frequency in Hz to the clock input interface you specify. Assigns 0 if the clock rate is not known.

```
set_parameter_property <my_parameter> SYSTEM_INFO {CLOCK_RATE
<my_clk>}
```

- `CLOCK_DOMAIN` (`Integer`)—Assigns an integer representing the clock domain to the parameter you specify. You can use this command to determine whether multiple interfaces in your module are on the same clock domain. The absolute value of the integer value is arbitrary, but if two interfaces are on the same clock domain, the `CLOCK_DOMAIN` value is guaranteed to be the same and greater than zero.

```
set_parameter_property <my_parameter> SYSTEM_INFO {CLOCK_DOMAIN
<my_clk>}
```

- `RESET_DOMAIN` (`Integer`)—Assigns an integer representing the reset domain to the parameter you specify. You can use this command to determine whether multiple interfaces in your module are on the same reset domain. The absolute value of the integer value is arbitrary, but if two interfaces are on the same reset domain, the `RESET_DOMAIN` value is guaranteed to be the same and greater than zero.

```
set_parameter_property <my_parameter> SYSTEM_INFO {RESET_DOMAIN
<my_reset>}
```

- `ADDRESS_WIDTH` (`Integer`)—Assigns an integer to the parameter that you specify that is the number of bits an Avalon-MM master must drive to address all of its slaves, using byte addresses.

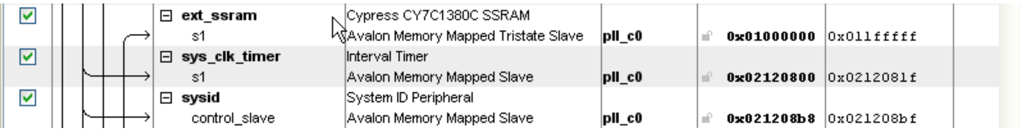
```
set_parameter_property <my_parameter> SYSTEM_INFO (ADDRESS_WIDTH
<my_avalon-mm_master>)
```

- `ADDRESS_MAP` (`String`)—Assigns an XML formatted string describing the address map to the parameter you specify.

```
set_parameter_property <my_parameter> SYSTEM_INFO {ADDRESS_MAP
<my_avalon-mm_master>}
```

  The XML code describing each slave includes, its name, start address, and end address + 1. Figure 7–1 shows a portion of an SOPC Builder system with three Avalon-MM slave devices.

Figure 7–1. SOPC Builder System with Three Avalon-MM Slaves



Example 7–4 shows the XML that describes the address map for the Avalon-MM master that accesses these slaves. The format of the XML string provided may differ from that described here, it may have different white space between the elements and could include additional attributes or elements.

Altera recommends that you use the code provided in the description of “decode_address_map” on page 7–24 to enumerate over the components within an address map, rather than writing your own parser.

Example 7–4. Address Map for an Avalon-MM Master

```
<address-map>
  <slave name='ext_ssram' start='0x01000000' end='0x01200000' />
  <slave name='sys_clk_timer' start='0x02120800' end='0x02120820' />
  <slave name='sysid' start='0x021208B8' end='0x021208C0' />
</address-map>
```

- `MAX_SLAVE_DATA_WIDTH` (`Integer`)—Assigns an integer to the parameter you specify that is the data width of the widest slave connected to the specified Avalon-MM master.

  ```
  set_parameter_property <my_parameter> SYSTEM_INFO
  {MAX_SLAVE_DATA_WIDTH <my_avalon_mm_master>}
  ```

- `INTERRUPTS_USED` (`Integer` or `String`)—Creates a mask indicating which bits of the interrupt receiver vector are connected to an interrupt sender. This mask is assigned to the parameter you specify. You can use this interrupt mask to optimize logic that handles interrupts.

  ```
  set_parameter_property <my_parameter> SYSTEM_INFO (INTERRUPTS_USED
  <my_interrupt_receiver>}
  ```

- `DEVICE_FAMILY` (`String`)—Assigns the family name (not the specific device part number) of the currently selected device to the parameter you specify.

  ```
  set_parameter_property <my_parameter> SYSTEM_INFO {DEVICE_FAMILY}
  ```

- `DEVICE_FEATURES` (`String`)—Creates a list of key/value pairs delineated by spaces indicating whether a particular device feature is available in the currently selected device family. The format of the list is suitable for passing to the Tcl `array set` command. This list is assigned to the parameter you specify. The following features are supported: M512_MEMORY, M4K_MEMORY, M9K_MEMORY, M144K_MEMORY, MRAM_MEMORY, MLAB_MEMORY, ESB, DSP, and EMUL

  ```
  set_parameter_property <my_parameter> SYSTEM_INFO {DEVICE_FEATURES}
  ```

Declaring Interfaces

Most components require a clock input interface. To declare an interface, declare its properties and indicate which signals belong to it. For components with HDL files, `quartus_map` determines each port's direction and width. The interface declaration statement includes the name of the interface, the interface direction, and the clock interface with which it is associated. For interfaces that aren't associated with clocks (such as clock interfaces themselves), omit the associated clock interface, or use the word *asynchronous*.Example 7–5 illustrates interface declaration.

Example 7–5. Declare Interfaces

```
# Declare the clock sink interface, "clock_sink", type=clock, direction=sink

add_interface clock_sink clock sink

# The clock interface has two signals, named "clk" and "reset_n" of types "clk" "reset_n"

add_interface_port clock_sink clk clk input 1
add_interface_port clock_sink reset_n reset_n input 1

# Declare the Avalon slave interface, name=avalon_slave_0, type=avalon, directon=slave,
# associated with the clock_sink clock interface.

add_interface avalon_slave_0 avalon slave clock_sink

# Set a number of properties about the Avalon Slave interface

set_interface_property avalon_slave_0 writeWaitTime 0
set_interface_property avalon_slave_0 addressAlignment DYNAMIC
set_interface_property avalon_slave_0 readWaitTime 1
set_interface_property avalon_slave_0 readLatency 0

# Declare all the signals that belong to my Avalon Slave interface

add_interface_port avalon_slave_0 my_readdata readdata output 8
add_interface_port avalon_slave_0 my_read read input 1
add_interface_port avalon_slave_0 my_write write input 1
add_interface_port avalon_slave_0 my_waitrequest waitrequest output 1
add_interface_port avalon_slave_0 my_address address input 24
add_interface_port avalon_slave_0 my_writedata writedata input 8
```

Adding Files and Guiding Generation

Component description files typically provide all of the information required for generation and downstream tools, identifying the files used by the component such as HDL files and **.sdc** constraint files. You also identify which of the added files is the top-level HDL file and specify which verilog module or VHDL entity within that file is the top-level module for the component. Example 7–6 illustrates the files that are typically required for generation and downstream tools.

Example 7–6. Add Files

```
# Add the HDL file to the component,to be used for synthesis and simulation.

add_file simple_uart.v {SYNTHESIS SIMULATION}

# Add the Timequest file with Quartus timing constraints.

add_file simple_uart.sdc SDC

# Add top-level HDL file that describes the component, name of the top-level module/entity

set_module_property TOP_LEVEL_HDL_FILE simple_uart.v
set_module_property TOP_LEVEL_HDL_MODULE simple_uart
```

Default Behaviors

The **_hw.tcl** file described in the previous section has default behaviors during the validation, elaboration, generation, and editor phases. These default behaviors apply to instances of a component. This section describes the default SOPC Builder behaviors for each of these phases. To override these default behaviors, refer to "Overriding Default Behaviors" on page 7–9.

Validation Phase Behavior

SOPC Builder's default validation checks each parameter value against its ALLOWED_RANGES property. If the values specified are outside the allowed ranges, an error message displays.

The ALLOWED_RANGES property of each parameter is a list of ranges that the parameter can take on, where each range is a single value, or a range of values defined by a start and end value separated by a colon. Table 7–1 shows some examples of values the ALLOWED_RANGES property can take.

Table 7–1. ALLOWED_RANGES Property

ALLOWED_RANGES	Meaning
{a b c}	a or b or c
{1 2 4 8 16}	1, 2, 4, 8, or 16.
1:3	1 through 3, inclusive
{1 2 3 7:10}	1, 2, 3, or 7 through 10 inclusive

Elaboration Phase Behavior

SOPC Builder's default elaboration process calls quartus_map to determine the correct port widths. Because calling quartus_map can be slow, you can set the AFFECTS_ELABORATION property to false for parameters which do not affect port widths, this will prevent re-elaboration when one of these parameters changes.

Generation Phase Behavior

SOPC Builder's default generation does one of the following:

- If the component defines the TOP_LEVEL_HDL_MODULE property, SOPC Builder creates a Verilog HDL or VHDL wrapper module to instantiate the top-level module and applies the parameters as selected by the user of your component. SOPC Builder does not apply parameters in the wrapper if they are not declared in the underlying HDL file.

  or

If the component does not define the TOP_LEVEL_HDL_MODULE property, but instead sets the INSTANTIATE_IN_SYSTEM_MODULE_module property to false, the module is not instantiated inside the SOPC Builder system and a wrapper file is not created. Rather, the interface to the module is exported to the top-level of the SOPC Builder system, and the module must be connected outside the system.

Editor Phase Behavior

SOPC Builder's default editor phase behavior is to use all of the parameter definitions to display the parameterization GUI. The properties of the parameters guide SOPC Builder when it builds the default GUI. Table 7–4 on page 7–20 lists the properties of parameters.

You can place parameters in logical groups and provide images to create a custom GUI for your component. Example 7–7 defines four parameters and illustrates the use of the add_display_item command and the DISPLAY_HINT and ALLOWED_RANGES parameters.

Example 7–7. Defining and Customizing GUI Parameters

```
# provide an icon for the sound group
add_display_item icon Speaker speaker-image speaker.png
add_parameter sound string 0 0
add_parameter volume_control boolean 0 0
add_parameter separate_control string 0 0

# Setup DISPLAY_NAMES for the parameters
set_parameter_property sound DISPLAY_NAME Audio
set_parameter_property volume_control DISPLAY_NAME "Include Volume Control Interface"
set_parameter_property separate_control DISPLAY_NAME "Treble/Bass Controls"

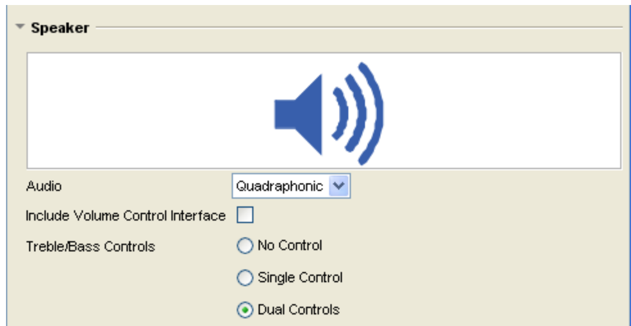
# Display all parameters in the Speaker group
add_display_item parameter Speaker sound
add_display_item parameter Speaker volume_control
add_display_item parameter Speaker separate_control

# There are 4 choices for the sound parameter.
# Strings with internal spaces require double quotes
set_parameter_property sound allowed_ranges {"0:No Audio" 1:Monophonic 2:Stereo
4:Quadraphonic}
set_parameter_property separate_control allowed_ranges {"No Control" "Single Control"
"Dual Controls"}

#Specify how parameters should be displayed
set_parameter_property volume_control DISPLAY_HINT boolean
set_parameter_property separate_control DISPLAY_HINT radio
```

Figure 7–2 shows the GUI that the Tcl commands in Example 7–4 produces.

Figure 7–2. Parameter GUI for Audio Component



Overriding Default Behaviors

You can override each of the default behaviors by using callbacks. This section explains how to write callback procedures for each phase of component development.

Validation Callback

You can use the validation callback to provide validation that extends beyond the default range checking. A validation callback is defined by setting the `VALIDATION_CALLBACK` module property to be the name of the validation callback procedure, as shown in Example 7–8. This validation procedure displays an error if you select a baud rate of 38400 and odd parity.

You can also use the validation callback to set the value of derived parameters. Derived parameters are parameters that are derived from other parameters; their values are not editable and are not saved in the system-on-a-programmable-chip (**.sopc**) file. You indicate that a parameter is derived by setting the parameter's `DERIVED` property to `true`. In Example 7–8 `BAUDRATE_PRESCALE` is a derived parameter whose value is 1/16 of the value of the BAUDRATE parameter.

Example 7–8. Custom Validation Callback Function

```
# Declare the validation callback.

# Declare the validation callback.
set_module_property VALIDATION_CALLBACK my_validation_callback

# Add the BAUDRATE_PRESCALE parameter
add_parameter BAUDRATE_PRESCALE int 600
set_parameter_property BAUDRATE_PRESCALE DERIVED true

# Add the PARITY parameter
add_parameter PARITYd string ODD
set_parameter_property PARITY ALLOWED_RANGES {EVEN ODD}

# The validation callback
proc my_validation_callback {} {
    # Get the current value of parameters we care about
    set br [get_parameter_value BAUD_RATE]
    set p [get_parameter_value PARITY]
    # Display an error for invalid combinations.
    if {($br==38400) && ($p=="ODD")} {
        send_message warning "Odd parity at 38400 bps is not supported."
    }
    # Set the value of our derived parameter
    set bp [expr $br / 16]
    set_parameter_value BAUDRATE_PRESCALE $bp
}
```

Elaboration Callback

You can use an elaboration callback to change interface properties or add new interfaces as a function of parameter values. You define an elaboration callback by setting the ELABORATION_CALLBACK module property to the name of the elaboration callback function, as shown in Example 7–9. You can enable and disable interfaces from the elaboration callback if they are only needed for some parameterizations of the component. Example 7–9 shows how an Avalon-MM slave interface can be included in an instance of the component, based on the USE_STATUS_INTERFACE parameter.

The elaboration callback is not allowed to use parameters marked as AFFECTS_ELABORATION=false. It will not be called if such a parameter is changed.

Example 7–9. Elaboration Callback

```
# Declare the callback.
set_module_property ELABORATION_CALLBACK my_elaboration_callback
# Add the USE_STATUS_INTERFACE parameter
add_parameter USE_STATUS_INTERFACE boolean
# Declare the status slave interface
add_interface status_slave avalon slave clock_sink
set_interface_property status_slave enabled false

# The elaboration callback
proc my_elaboration_callback {} {
    # Get the current value of parameters we care about
    set use_status [get_parameter_value USE_STATUS_INTERFACE]
    # Optionally add an interface
    if { $use_status } {
   set_interface_property status_slave enabled false
   # Set interface properties
   set_interface_property status_slave writeWaitTime 0
   set_interface_property status_slave readWaitTime 1
   # Declare signals
   add_interface_port status_slave st_readdata readdata output 16
   add_interface_port status_slave st_read read input 1
   add_interface_port status_slave st_write write input 1
   add_interface_port status_slave st_waitrequest waitrequest output 1
   add_interface_port status_slave st_address address input 24
   add_interface_port status_slave st_writedata writedata input 16
    }
}
```

Generation Callback

If you define a generation callback, SOPC Builder does not generate an HDL wrapper file to apply parameter values to your component. Instead, it calls the generation callback you defined during the generation phase, allowing the component to programmatically generate its HDL. A generation callback is defined by setting the GENERATION_CALLBACK module property to be the name of the generation callback function, as Example 7–10 illustrates.

Generation callbacks typically retrieve the current value of the component's parameters and the generation properties that guide the generation process, and then generate the HDL files and supporting files in Tcl or by calling an external program. The callback procedure also reports the required files to SOPC Builder with the `add_files` command. Any files added in the generation callback are in addition to the files added in the main body of the **_hw.tcl** file.

The generation callback must write <*output_name.v*> for Verilog or <*output_name.vhd*> for VHDL to the specified <*output_directory*>. This file is a parameterized instance of the component. Other supporting files, such as **.hex** files to initialize memory, may be written to <*output_directory*>. These file names must begin with <*output_name*>. If the supporting files are the same for all parameterizations of the component, you add them from the main program rather than the generation callback. If your system includes multiple instantiations of a component with different parameterizations, you must add the supporting files from the main program to prevent failures.

Example 7–10. Generation Callback Example

```
set_module_property GENERATION_CALLBACK my_generate

# My generation method

proc my_generate {} {
  send_message info "Starting Generation"

  # get generation settings

  set language [get_generation_property HDL_LANGUAGE]
  set outdir [get_generation_property OUTPUT_DIRECTORY ]
  set outputname [get_generation_property OUTPUT_NAME ]

  # get parameter values

  set p1 [get_parameter_value PARAMETER_ONE]
  set csr [get_parameter_value CSR_ENABLED]

  # Do HDL generation with perl

  # add_file creates files relative to the _hw.tcl directory; therefore specify $outdir
  # for synthesis and simulation files

  exec perl my_generate.pl lang=$language dir=$outdir name=$outputname p1=$p1 csr=$csr
  add_file ${outdir}${outputname}.v SYNTHESIS
  add_file ${outdir}${outputname}_sim.v SIMULATION
}
```

Editor Callback

You can use the editor callback procedure to override the parameterization GUI. An editor callback is defined by setting the `EDITOR_CALLBACK` module property to the name of your editor callback procedure, as shown in the Example 7–11. If the editor callback is defined, SOPC Builder calls the editor callback any time the parameterization GUI is displayed, typically when the component is added to a system or updated after it is in the system.

To display your custom GUI, the editor callback must call another program. Typically, an editor callback provides the current parameter values to your program via the command line and collects the new parameter values via `stdout`. The editor callback then uses the `set_parameter_value` command to update SOPC Builder with the new parameter values.

The editor callback returns one of the following three values:

- OK—indicates that the results of the edit should be applied.
- CANCEL—indicates that the system should revert to the state it was in before the editor callback was called.
- ERROR—indicates that the GUI was unable to launch. An appropriate error message should be displayed.

If no value is returned, OK is assumed.

Example 7–11. Editor Callback

```
set_module_property EDITOR_CALLBACK my_editor

# Define Module parameters.

add_parameter PARAMETER_ONE integer 32 "A parameter"
add_parameter CSR_ENABLED boolean true "Enable CSR interface"

# My editor method

proc my_editor {} {

# get parameter values

  set p1 [ get_parameter_value PARAMETER_ONE ]
  set csr [ get_parameter_value CSR_ENABLE ]

  # Display UI, populated with current parameter values.
  # The stdout returned by the UI program includes the new paramter values.

  set result = [exec my_component_ui.exe p1=$p1 csr=$csr]

  # Use the fictional "parse_for_new_value" procedure to parse the returned text for the
  # new parameter values.

  set p1 [parse_for_new_value $result p1]
  set csr [parse_for_new_value $result csr]

# Return the new parameter values to SOPC Builder

  set_parameter_value PARAMETER_ONE $p1
  set_parameter_value CSR_ENABLED $csr
  return OK

}
```

Hardware Tcl Command Reference

This section provides a reference for all hardware Tcl commands, as follows:

- "Module Definition" on page 7–14
- "Parameters" on page 7–19
- "Interfaces and Ports" on page 7–25
- "get_interface_assignment" on page 7–30

The description of each command indicates during which phases it is available: in the main body of the program (main), or during the validation, elaboration, generation, and editor callback phases, or any combination. Table 7–2 summarizes the commands and provides a reference to the full description.

Table 7–2. Command Summary *(Note 1)* (Part 1 of 2)

Command	Full Description
Module Definition	
get_module_properties	page 7–14
get_module_property *<propertyName>*	page 7–15
set_module_property *<propertyName> <propertyValue>*	page 7–16
get_module_ports	page 7–16
get_module_assignment *<moduleName>*	page 7–16
set_module_assignment *<moduleName> [value]*	page 7–17
add_file filename *[<fileProperties> . . .]*	page 7–17
get_files	page 7–18
get_file_property *<filename> <propertyName>*	page 7–18
set_file_property *<filename> <propertyName> <propertyValue>*	page 7–18
send_message *<messageLevel> <messageText>*	page 7–19
Parameters	
add_parameter *<parameterName> <parameterType> [<defaultValue> <description>]*	page 7–22
get_parameters	page 7–22
get_parameter_properties	page 7–19
get_parameter_property *<parameterName> <propertyName>*	page 7–23
set_parameter_property *<parameterName> <propertyName> <value>*	page 7–23
get_parameter_value *<parameterName>*	page 7–23
set_parameter_value *<parameterName> <value>*	page 7–24
decode_address_map *<address_map_XML_string>*	page 7–24
add_display_item *<groupName> <id> <type> [<additionalInfo>]*	page 7–24
Interfaces and Ports	
add_interface *<interfaceName> <interfaceType> <direction> [<associatedClock>]*	page 7–26
get_interfaces	page 7–26
get_interface_properties *<interfaceName>*	page 7–27
get_interface_property *<interfaceName> <propertyName>*	page 7–27
set_interface_property *<interfaceName> <propertyName> <value>*	page 7–27
add_interface_port *<interfaceName> <portName> <portRole> [<direction> <width>]*	page 7–28
get_interface_ports *[<interfaceName>]*	page 7–28
get_port_properties	page 7–29
get_port_property *<portName> <propertyName>*	page 7–29
set_port_property *<portName> <propertyName> [<value>]*	page 7–30
get_interface_assignment *<interfaceName> <name>*	page 7–30
set_interface_assignment *<interfaceName> <name> [<value>]*	page 7–31
Generation	

Table 7–2. Command Summary *(Note 1)* (Part 2 of 2)

Command	Full Description
`get_generation_property <propertyName>`	page 7–32
`get_generation_properties`	page 7–31
`get_project_property <propertyName>`	page 7–32

Note to Table 7–2:

(1) Arguments enclosed in []'s are optional

Module Definition

This section provides information about the commands that you use to define and query a module.

get_module_properties

This command returns the names of all the available module properties as a list of strings. You can use the `get_module_property` and `set_module_property` commands to get and set values of individual properties. The value returned by this command is always the same for a particular version of SOPC Builder.

get_module_properties	
Callback availability	Main, validation, elaboration, generation, and editor
Usage	`get_module_properties`
Returns	list of strings
Arguments	None
Example	`get_module_properties`

Table 7–3 lists the available module properties, their use, and the phases in which they can be set.

Table 7–3. Module Properties (Part 1 of 2)

Property Name	Property Type	Can Be Set	Description
`NAME`	`String`	Main program	The name of the module, such as `my_sopc_component`.
`DISPLAY_NAME`	`String`	Main program	The name to display when referencing the module, such as "My SOPC Component."
`VERSION`	`String`	Main program	The module's version, such as 8.0.
`AUTHOR`	`String`	Main program	The module's author.
`DESCRIPTION`	`String`	Main program	The description of the module, such as "Example SOPC Builder Module."
`GROUP`	`String`	Main program	The component group that the module belongs to, such as "Example Components."
`ICON_PATH`	`String`	Main program	A path to an icon to display in the module's parameter editor.

Table 7–3. Module Properties (Part 2 of 2)

Property Name	Property Type	Can Be Set	Description
DATASHEET_URL	String	Main program	A path to the module's data sheet, for example: http://www.mydomain.com/my_memory_controller.html.
EDITABLE	Boolean	Main program	Indicates if the component is editable in the component editor.
MODULE_TCL_FILE	String	Can only be read, not set	The path to the **_hw.tcl** file. When possible, all other files should be specified relative to the **_hw.tcl** file.
MODULE_DIRECTORY	String	Can only be read, not set	The directory containing the **_hw.tcl** file.
TOP_LEVEL_HDL_FILE	String	Main program	Indicates which of the files added by the `add_file` command contains the module's top-level HDL.
TOP_LEVEL_HDL_MODULE	String	Main program	Indicates the name of the top-level module which must be defined in the module's top-level HDL file.
INSTANTIATE_IN_SYSTEM_MODULE	Boolean	Main program	When `false` the instances of the module are not included in the generated system interconnect fabric. Instead, interfaces to the module are exported out of the top-level of the SOPC Builder system.
VALIDATION_CALLBACK	String	Main program	The name of the validation callback. The default validation is used if this property is not set.
EDITOR_CALLBACK	String	Main program	The name of the editor callback. The default parameterization UI is called if this property is not set.
ELABORATION_CALLBACK	String	Main program	The name of the elaboration callback. The default elaborations used if this property is not set.
GENERATION_CALLBACK	String	Main program	The name of the generation callback. The default generation is used if this property is not set.

get_module_property

This command returns the value of a single module property.

get_module_property		
Callback availability	Main, validation, elaboration, generation, and editor	
Usage	`get_module_property <propertyName>`	
Returns	`String` or `boolean`	
Arguments	`propertyName`	One of the properties listed in Table 7–3 on page 7–14
Example	`set my_name [get_module_property NAME]`	

set_module_property

This command allows you to set the values for module properties.

set_module_property		
Callback availability	Main program	
Usage	`set_module_property` <*propertyName*> <*propertyValue*>	
Returns	None	
Arguments	`propertyName`	One of the properties listed in Table 7–3 on page 7–14
	`propertyValue`	The new value of the property
Example	`set_module_property VERSION 8.0`	

get_module_ports

This command returns a list of the names of all the ports which are currently defined.

get_module_ports		
Callback availability	Main, validation, elaboration, generation, and editor	
Usage	`get_module_ports`	
Returns	List of strings	
Arguments	none	(The ports are implicitly those for the current module.)
Example	`get_module_ports`	

get_module_assignment

This command returns the value of the specified argument. You can use the `get_module_assignment` and `set_module_assignment` and the `get_interface_assignment` and `set_interface_assignment` commands to transfer information about hardware components to embedded software tools and applications.

For more information about specifying information for software tools, refer to *Publishing Component Information to Embedded Software* in the *Nios II Software Developer's Handbook - Studio Edition*.

get_module_assignment		
Callback availability	Main and validation	
Usage	`get_module_assignment` <*name*>	
Returns	`String`	
Arguments	`name`	The name whose value is being retrieved
Example	`get_module_assignment embedded.sw.CMacro.colorSpace`	

set_module_assignment

This command sets the value of the specified argument.

set_module_assignment		
Callback availability	Main and validation	
Usage	`set_module_assignment` *<name> [<value>]*	
Returns	None	
Arguments	`name`	The name whose value is being set
	`value`	The value of the *<name>* argument
Example	`set_module_assignment embedded.sw.CMacro.colorSpace CMYK`	

add_file

This command adds a synthesis, simulation, or TimeQuest constraints file to the module. Files added in the main program cannot be removed. Adding files in the generation callback allows the included files to be a function of the parameter set or to be a result of generation. Files added in callbacks are in addition to any files added in the main program.

add_file		
Callback availability *(1)*	Main, elaboration, and generation	
Usage	`add_file filename` *[<fileProperties> . . .]*	
Returns	None	
Arguments	`filename`	The file name to be added, relative to the directory containing the **_hw.tcl** file
	`fileProperties`	Files support the following 4 properties: ■ `SIMULATION`—File for simulation ■ `SYNTHESIS`—File for synthesis ■ `SDC`—TimeQuest constraints
Example	`add_file my_component.v {SIMULATION SYNTHESIS}`	

Note:

(1) Beginning in version 9.1 of SOPC Builder, the `add_file` command will be restricted to main and generation callbacks.

get_files

This command returns a list of all the files that have been added to the module.

get_files	
Callback availability	Main, validation, elaboration, generation, and editor
Usage	`get_files`
Returns	List of strings
Arguments	None
Example	`set list_of_files [get_files]`

get_file_property

This command returns the value of a single file property. The file name passed as an argument can be a partial as long as it is unique. For example, if the full file name is **/components/my_file.v**, **my_file.v** is sufficient.

get_file_property		
Callback availability	Main, validation, elaboration, generation, and editor	
Usage	`get_file_property` *`<filename> <propertyName>`*	
Returns	None	
Arguments	`filename`	The file name whose properties are being retrieved
	`propertyName`	The filename property whose value is being retrieved
Example	`set forSynthesis [get_file_property my_file.v SYNTHESIS]`	

set_file_property

This command sets the value of a single file property. The file name passed to the function can be a partial file name as long as it is unique. For example, if the full file name is **/components/my_file.v**, **my_file.v** is sufficient. The available properties are described in the `add_files` command.

set_file_property		
Callback availability	Main, elaboration, and generation	
Usage	`set_file_property` *`<filename> <propertyName> <propertyValue>`*	
Returns	None	
Arguments	`filename`	The file name whose properties are being retrieved
	`propertyName`	Name of the file property whose value is being retrieved
	`propertyValue`	Value to set for the file property
Example	`set_file_property my_file.v SYNTHESIS true`	

send_message

This command sends a message to the user of the component.

send_message		
Callback availability	Main, validation, elaboration, generation, and editor	
Usage	send_message *<messageLevel>* *<messageText>*	
Returns	None	
Arguments	messageLevel	The following 4 message levels are supported: ■ Error—provides an error message. The SOPC Builder system cannot be generated while there are error messages. ■ Warning—provides a warning message. ■ Info—provides an informational message. ■ Debug—provides messages when debug mode is enabled.
	messageText	The text of the message
Example	send_message Error "param1 must be greater than param2."	

Parameters

Parameters allow users of your component to affect its operation in the same manner as Verilog HDL parameters or VHDL generics.

get_parameter_properties

This command returns a list of all the available parameter properties as a list of strings. The get_parameter_property and set_parameter_property commands are used to get and set the values of these properties, respectively.

get_parameter_properties	
Callback availability	Main, validation, elaboration, generation, and editor
Usage	get_parameter_properties
Returns	List of parameter property names
Arguments	None
Example	set property_summary [get_parameter_properties]

Table 7–4 describes the properties available to describe the behaviors of each of the parameters you can specify, their use, and when they can be set.

Table 7–4. Parameter Properties (Part 1 of 2)

Property Name	Property Type	Can Be Set	Description
DISPLAY_NAME	String	Main program	The text string to use when displaying the parameter.
ALLOWED_RANGES	String	Main program	Indicates the range or ranges that the parameter value can have. For integers, The ALLOWED_RANGES property is a list of ranges that the parameter can take on, where each range is a single value, or a range of values defined by a start and end value separated by a colon, such as 11:15. This property can also specify legal values and display strings for integers, such as {0:None 1:Monophonic 2:Stereo 4:Quadrophonic} meaning 0,1,2,4 are the legal values. Refer to Example 7–7 and Figure 7–2 for examples illustrating the use of this property.
GROUP	String	Main program	The group in which to display the parameter. This property is deprecated. Use add_display_item instead.
IS_HDL_PARAMETER	Boolean	Main program	When true, the parameter must be passed to the HDL component description. The default value is false false if there is a generation callback. Or, its value is calculated by analyzing the HDL if you have specified a top-level HDL file.
AFFECTS_ELABORATION (1)	Boolean	Main program	Set AFFECTS_ELABORATION to false for parameters that do not affect the external interface of the module. An example of a parameter that does not affect the external interface is isNonVolatileStorage. An example of a parameter that does affect the external interface is width. When the value of a parameter changes, if that parameter has set AFFECTS_ELABORATION=false, the elaboration phase (calling the callback or hardware analysis) is not repeated, improving performance. Because the default value of AFFECTS_ELABORATION is true, the provided HDL file is normally re-analyzed to determine the new port widths and configuration every time a parameter changes.
VISIBLE	Boolean	Main program, validation callback	Indicates whether or not to display the parameter in the parameterization GUI.
ENABLED	Boolean	Main program, validation callback	When false, the parameter is disabled, meaning that it is displayed, but greyed out indicating that it is not editable, on the parameterization GUI.
DERIVED	Boolean	Main program	When true, indicates that the parameter value does not need to be stored, typically because it is set from the validation callback. The default value is false.

Table 7–4. Parameter Properties (Part 2 of 2)

Property Name	Property Type	Can Be Set	Description
DISPLAY_HINT	String	Main program	Provides a hint about how to display a property. The following values are possible: ■ boolean—for integer parameters whose value can be 0 or 1. The parameter displays as a checkbox. ■ radio—displays a parameter with a list of values as radio buttons instead of a drop-down list. ■ hexadecimal—for integer parameters, display and interpret the value as a hexadecimal number, for example: 0x00000010 instead of 16. Refer to Example 7–7 and Figure 7–2 for examples illustrating the use of this property.
SYSTEM_INFO	String	Main program	Allows you to assign information about your system to a parameter that you define. SYSTEM_INFO requires an argument specifying the type of information requested, *<info-type>*. *<info-type>* may also take an argument. The syntax of the Tcl command is: set_parameter_property my_parameter SYSTEM_INFO {*<info-type> [<arg>]*} The following values for *<info-type>* are predefined: ■ CLOCK_RATE ■ CLOCK_DOMAIN ■ RESET_DOMAIN ■ ADDRESS_WIDTH ■ ADDRESS_MAP ■ MAX_SLAVE_DATA_WIDTH ■ INTERRUPTS_USED ■ DEVICE_FAMILY ■ DEVICE_FEATURES For more information about the SYSTEM_INFO and the *<info_type>* argument refer to "Declaring Parameters" on page 7–3.

Note to Table 7–4:

(1) The AFFECTS_ELABORATION property was called AFFECTS_PORT_WIDTHS before version 9.0 of the Quartus II software.

add_parameter

This command adds a parameter to your component.

add_parameter		
Callback availability	Main program	
Usage	add_parameter *<parameterName> <parameterType> [<defaultValue> <description>]*	
Returns	None	
Arguments	parameterName	A name that you, the component author, choose for your parameter
	parameterType	The following 7 types are supported: ■ Integer ■ Natural ■ Positive ■ Boolean ■ Std_logic (VHDL based components only) ■ Std_logic_vector (VHDL based components only) ■ String
	defaultValue	The default length of the parameter is derived from its range.
	description	Explains the use of the parameter
Example	add_parameter seed integer 17 "The seed to use for data generation."	

get_parameters

This command returns the names of all parameters that have been previously defined by add_parameter as a space separated list.

get_parameters	
Callback availability	Main, validation, elaboration, generation, and editor
Usage	get_parameters
Returns	list of strings
Arguments	None
Example	set parameter_summary [get_parameters]

get_parameter_property

This command returns a single parameter property.

get_parameter_property		
Callback availability	Main, validation, elaboration, generation, and editor	
Usage	get_parameter_property *<parameterName> <propertyName>*	
Returns	string or boolean, depending on property refer to Table 7–4	
Arguments	parameterName	The name of the parameter whose property value is being retrieved
	propertyName	One of the properties listed in Table 7–4
Example	get_parameter_property parameter1 GROUP	

set_parameter_property

This command sets a single parameter property.

set_parameter_property		
Callback availability	Main and validation	
Usage	set_parameter_property *<parameterName> <propertyName> <value>*	
Returns	None	
Arguments	parameterName	Specifies the parameter that is being set
	propertyName	Specifies the property of parameterName that is being set, refer to Table 7–4 for a list of properties
	value	Provides the values
Example	set_parameter_property BAUD_RATE ALLOWED_RANGES {9600 19200 38400}	

get_parameter_value

This command returns the current value of a parameter defined previously with the add_parameter command.

get_parameter_value		
Callback availability	Validation, elaboration *(1)*, generation, and editor	
Usage	get_parameter_value *<parameterName>*	
Returns	Depends on type of the parameter	
Arguments	parameterName	Specifies the parameter that is being retrieved
Example	set fifo_width [get_parameter_value fifo_width]	

Note:

(1) If AFFECTS_ELABORATION=false for a given parameter, get_parameter_value is not available for that parameter from the elaboration callback.

set_parameter_value

This command sets a parameter value. Typically, the value of derived parameters is set during the validation callback based on the value of other parameters.

set_parameter_value		
Callback availability	Validation and editor	
Usage	`set_parameter_value <parameterName> <value>`	
Returns	None	
Arguments	`parameterName`	Specifies the parameter that is being set
	`value`	Specifies the value of `parameterName`
Example	`set_parameter_value BAUD_RATE 19200`	

decode_address_map

This is a utility function to convert an XML–formatted address map into a list of Tcl lists. Each inner list is in the correct format for conversion to an array. Using this command to decode the XML representing an Avalon-MM master's address map is easier and ensures that your code will work with future versions of the XML address map.

decode_address_map		
Callback availability	Validation, elaboration, and generation	
Usage	`decode_address_map <address_map_XML_string>`	
Returns	List of Tcl lists, each one suitable for passing to array set	
Arguments	`address_map_XML_string`	An XML string describing the address map of an Avalon-MM master (refer to the `ADDRESS_MAP` type in the "Declaring Parameters" on page 7–3 for more information.

Example	`set address_map_xml [get_parameter_value my_map_param]`
	`set address_map_dec [decode_address_map $address_map_xml]`
	
	`foreach i $address_map_dec {`
	`    array set info $i`
	`    send_message info "Connected to slave $info(name)"`
	`}`	

add_display_item

You can use this command to specify the following two aspects of component display:

- You can create logical groups for a component's parameters. For example, you might want to create separate groups for the component's timing, size, and simulation parameters. A component displays the groups and parameters in the order that you specify them in the **_hw.tcl** file.
- You can specify an image to provide a pictorial representation of a parameter or parameter group.

You create a display group by adding display items to it. You do not need to explicitly create groups before using them.

add_display_item		
Callback availability	Main	
Usage	add_display_item *<groupName> <id> <type> [<additionalInfo>]*	
Returns	None	
Arguments	groupName	Specifies the group to which a display item belongs.
	id	Specifies the parameter or icon to be displayed in a group. Each display item associated with a component must have a different ID.
	type	Specifies the category of the display item. There are currently 2 types: parameter and icon.
	additionalInfo	Provides extra information required for some display items. For icons, it provides the filename of the icon. You can use GIF, JPEG, and PNG file formats.
Examples	add_display_item timing read_latency parameter add_display_item sound speaker icon speaker.jpg	

Interfaces and Ports

You can use the interface and port commands to define interfaces and ports and retrieve their properties.

add_interface

This command adds an interface to your module. As the component author, you choose the name of the interface. By default, interfaces are enabled. You can set the interface property ENABLED to false, to disable a component interface. If an interface is disabled, it is hidden and its ports are automatically terminated to their default values. Signals that you designate as active low by appending a *_n* are terminated to 1. All other signals are terminated to 0.

The properties available for each interface type are different for every interface type. Refer to the *Avalon Interface Specifications*.

add_interface			
Callback availability	Main program and elaboration #		
Usage	add_interface *<interfaceName>* *<interfaceType>* *<direction>* [*<associatedClock>*] *(1)*		
Returns	None		
Arguments	interfaceName	A name that you choose to identify an interface.	
	interfaceType and direction	There are 7 interfaceTypes. The following directions are possible for these interfaceTypes:	
		Interface Type	Direction
		avalon	master, slave *(2)*
		avalon_tristate	slave
		avalon_streaming	source, sink
		interrupt	sender, receiver
		conduit	start
		clock	source, sink
		nios_custom_instruction	slave
	associatedClock	This defines the clock associated with the interface. It is required for all interfaces except clock interfaces.	
Example	add_interface mm_slave avalon slave clock0		

Notes:

(1) For interfaces that are not associated with clocks, such as clock interfaces themselves, the associatedClock is omitted. Another option is to specify the associatedClock argument as asynchronous.

(2) The terms *master*, *source* and *start* are interchangeable. The terms *slave*, *sink* and *end* are interchangeable.

get_interfaces

This command returns the names of all interfaces that have been previously defined by add_interface as space separated list.

get_interfaces	
Callback availability	Main, validation, elaboration, generation, and editor
Usage	get_interfaces
Returns	list of strings
Arguments	None
Example	set all_interfaces [get_interfaces]

get_interface_properties

This command returns the names of all the available interface properties for the specified interface as a space separated list.

get_interface_properties		
Callback availability	Main program and elaboration	
Usage	`get_interface_properties <interfaceName>`	
Returns	list of strings	
Arguments	interfaceName	The name of an interface that you defined
Example	`get_interface_properties mm_slave`	

The properties available for each interface type are different for every interface type. Refer to the *Avalon Interface Specifications*.

get_interface_property

This command returns the value of a single interface property from the specified interface.

get_interface_property		
Callback availability	Main program and elaboration	
Usage	`get_interface_property <interfaceName> <propertyName>`	
Returns	Depends upon the type of the property being returned	
Arguments	`interfaceName`	The name of an interface from which you want to retrieve information
	`propertyName`	The name of the property whose value you want to retrieve
Example	`get_interface_property mm_slave readWaitTime`	

set_interface_property

This command sets a single interface property for an interface.

set_interface_property		
Callback availability	Main, validation, elaboration, generation, and editor	
Usage	`set_interface_property <interfaceName> <propertyName> <value>`	
Returns	Depends upon the type of the property being returned	
Arguments	`interfaceName`	The name of an interface that includes this property
	`propertyName`	The name of the property whose value you want to set
	`value`	The value to set for the specified property
Example	`set_interface_property mm_slave linewrapBursts false`	

add_interface_port

This command adds a port to an interface on your module. As the component author, you determine the name of the port. The port roles that you can set depend on the interface. The port direction and width may be omitted if either:

- If you have defined the direction and width of the port in the top-level HDL file
- If you define the direction and width by setting port properties in the elaboration callback

For ports added in the main program you can pass in a width of -1 to indicate explicitly that the port width will be defined later.

add_interface_port		
Callback availability	Main program and elaboration	
Usage	add_interface_port *<interfaceName> <portName> <portRole> [<direction> <width>]*	
Returns	None	
Arguments	interfaceName	The name of the interface to which the port belongs.
	portName	The name of the port that you, the component author, have chosen.
	portRole	The role of this port within the interfaces. Port roles are referred to as signal types in the *Avalon Specification*. Refer to the *Avalon Interface Specifications* for the signal types available for each interface type.
	direction	The direction can be input, output, bidir, and for VHDL, buffer.
	width	The width of the port in bits.
Example	add_interface_port mm_slave s0_rdata readdata output 32	

get_interface_ports

This command returns the names of all of the ports that have been added to a given interface. If the interface name is omitted, all ports for all interfaces are returned.

get_interface_ports		
Callback availability	Main, validation, elaboration, generation, and editor	
Usage	get_interface_ports *[<interfaceName>]*	
Returns	list of strings	
Arguments	interfaceName	The name of the interface whose ports you want to list. (Optional)
Example	get_interface_ports mm_slave	

get_port_properties

This command returns a list of all available port properties.

<table>
<tr><th colspan="5">get_port_properties</th></tr>
<tr><td>Callback availability</td><td colspan="4">Main, validation, elaboration, generation, and editor</td></tr>
<tr><td>Usage</td><td colspan="4"><code>get_port_properties <portName></code></td></tr>
<tr><td>Returns</td><td colspan="4">list of strings</td></tr>
<tr><td rowspan="6">Arguments</td><td><code>portName</code></td><td colspan="3">The name of the port whose properties are required. The following 4 port properties are supported:</td></tr>
<tr><td>Property</td><td>Type</td><td colspan="2">Description</td></tr>
<tr><td><code>DIRECTION</code></td><td><code>INPUT,OUTPUT</code>
<code>BIDIR,BUFFER</code></td><td colspan="2">The direction of the port from the component’s perspective.</td></tr>
<tr><td><code>WIDTH</code></td><td><code>Integer</code></td><td colspan="2">The width of the port in bits.</td></tr>
<tr><td><code>TERMINATION</code></td><td><code>Boolean</code></td><td colspan="2">When true, instead of connecting the port to the SOPC Builder system, it is left unconnected (<code>OUTPUT</code>, <code>BIDIR</code>, and <code>BUFFER</code>) or set to a fixed value (<code>INPUT</code>). Has no effect for components that implement a generation callback instead of using the default wrapper generation.</td></tr>
<tr><td><code>TERMINATION_WIDE</code></td><td>up to 63 bits</td><td colspan="2">The constant value to drive an input port.</td></tr>
<tr><td>Example</td><td colspan="4"><code>get_port_properties mm_slave</code></td></tr>
</table>

get_port_property

This command returns the value of single port property for the specified port.

<table>
<tr><th colspan="3">get_port_property<</th></tr>
<tr><td>Callback availability</td><td colspan="2">Main, validation, elaboration, generation, and editor</td></tr>
<tr><td>Usage</td><td colspan="2"><code>get_port_property <portName> <propertyName></code></td></tr>
<tr><td>Returns</td><td colspan="2">Depends on the type of the property</td></tr>
<tr><td rowspan="2">Arguments</td><td><code>portName</code></td><td>The name of the port</td></tr>
<tr><td><code>propertyName</code></td><td>One of the 4 supported properties:
■ <code>DIRECTION</code>
■ <code>WIDTH</code>
■ <code>TERMINATION</code>
■ <code>TERMINATION_VALUE</code></td></tr>
<tr><td>Example</td><td colspan="2"><code>get_port_property rdata WIDTH</code></td></tr>
</table>

set_port_property

This command sets a single port property.

set_port_property		
Callback availability	Main program, elaboration, and custom generation	
Usage	`set_port_property <portName> <propertyName> [<value>]`	
Returns	None	
Arguments	`portName`	The name of the port
	`propertyName`	■ One of the 4 supported properties: ■ `DIRECTION` ■ `WIDTH` ■ `TERMINATION` ■ `TERMINATION_VALUE`
	`value`	The value to set
Example	`set_port_property rdata WIDTH 32`	

get_interface_assignment

This command returns the value of the specified name for the specified interface.

get_interface_assignment		
Callback availability	Main and validation	
Usage	`get_interface_assignment <interfaceName> <name>`	
Returns	String	
Arguments	`interfaceName`	The name of the Avalon interface whose assignment is being retrieved
	`name`	The assignment whose value is being retrieved.
Example	`get_interface_assignment s1 embeddedsw.configuration.isFlash 1`	

set_interface_assignment

This command sets the value of the specified assignment for the specified interface.

set_interface_assignment		
Callback availability	Main and validation	
Usage	set_interface_assignment *<interfaceName> <name> [<value>]*	
Returns	None	
Arguments	interfaceName	The name of the Avalon interface whose assignment is being set
	name	The assignment whose value is being set.
	value	The value to assign
Example	set_interface_assignment s1 embeddedsw.configuration.isFlash 1	

Generation

This section covers the commands that set and get generation properties.

get_generation_properties

This command returns the names of all the available generation properties as a space separated list. These properties cannot be changed by the module.

get_generation_properties			
Callback availability	Main, validation, elaboration, generation, and editor		
Usage	get_generation_properties		
Returns	list of strings. The following generation properties are supported:		
	Property	Type	Description
	HDL_LANGUAGE	ENUM	The HDL language to generate. Is either verilog or vhdl (lowercase). If the module cannot generate the specified language, generating in the other language is acceptable.
	OUTPUT_DIRECTORY	File	The location in which files must be generated. The filename components in the directory name are separated with forward slashes.
	OUTPUT_NAME	String	The top-level file name and entity to be generated. If the OUTPUT_NAME is module_0 and the HDL_LANGUAGE is verilog, the file **module_0.v** must be generated and must contain the module, module_0.
Arguments	None		
Example	get_generation_properties		

get_generation_property

This command returns the value of a single generation property.

get_generation_property		
Callback availability	Generation	
Usage	`get_generation_property <propertyName>`	
Returns	`String` or `boolean`, depending on the type	
Arguments	`propertyName`	One of the 3 generation properties: ■ `HDL_LANGUAGE` ■ `OUTPUT_DIRECTORY` ■ `OUTPUT_NAME`
Example	`get_generation_property OUTPUT_DIRECTORY`	

get_project_property

This command returns the value of a single project property.

get_project_property			
Availability	Validation, elaboration, generation, and editor		
Usage	`get_project_property <propertyName>`		
Returns	`String` or `boolean`, depending on the property		
Argument	`propertyName` The following properties are supported:		
	Property	Type	Description
	`QUARTUS_ROOTDIR`	`DIRECTORY`	Value of the `$QUARTUS_ROOTDIR` env variable
	`QUARTUS_PROJECT_DIRECTORY`	`DIRECTORY`	Path to the current project directory
	`QUARTUS_PROJECT_NAME`	`String`	Name of the current Quartus II project
	`DEVICE_FAMILY_NAME`	`Enum`	One of the following current device families: STRATIX, STRATIXII, STRATIXIIGX, ARRIAGX, STRATIXGX, STRATIXIII, STRATIXIV, CYCLONE, CYCLONEII, CYCLONEIII, HARDCOPY, HARDCOPYII,HARDCOPYIII, MAXII, APEX20KE, APEX20KC, APEXII, ACEX1K
	`DEVICE_FAMILY_FEATURES`	`Enum`	The device family supports the following features: M512_MEMORY, M4K_MEMORY, M9K_MEMORY, M144K_MEMORY, MRAM_MEMORY, MLAB_MEMORY, ESB, EPCS, DSP, EMUL, HARDCOPY, LVDS_IO, ADDRESS_STALL, TRANSCEIVER_3G_BLOCK TRANSCEIVER_6G_BLOCK,DSP_SHIFTER_BLOCK
Example	`get_project_property DEVICE_FAMILY_NAME`

Document Revision History

Table 7–6 shows the revision history for this chapter.

Table 7–6. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009, v9.0.0	■ Added `add_display_item` commands. ■ Added `DISPLAY_HINT`, `IS_HDL_PARAMETER`, `DERIVED`, and `SYSTEM_INFO` parameters to Table 7–4 on page 7–20. Described `SYSTEM_INFO` parameter in detail. ■ Added ENABLED interface property to enable or disable an interface. ■ The `AFFECTS_PORT_WIDTHS` parameter has been renamed `AFFECTS_ELABORATION` to better reflect its function. ■ Added note saying that the `add_file` command will be restricted to the main and generation callbacks starting in version 9.1 of the Quartus II software. ■ Explained that before the elaboration phase, parameters may have values of 0 or -1 that are determined during HDL analysis.	Added several new commands to increase functionality, clarified a few others, and corrected typographic errors.\
November 2008, v8.1	■ Added `get_module_ports`, `get_interface_assignment`, `set_interface_assignment`, `get_module_assignment`, and `set_module_assignment` commands ■ Corrected availability to include more callbacks for several commands ■ Added two additional types for `add_parameter` command: `natural` and `positive` ■ Added brackets for some optional parameters ■ Changed `add_file` command for simulation and synthesis in Example 7–10 to write to `$outdir` ■ `get_project_property` is available in validation callback ■ Changed page size to 8.5 x 11 inches	Added 5 new commands and corrected commands that did not define optional arguments or omitted some callback availability.
June 2008, v8.0.1	■ Reformatted command information in tables.	—
May 2008, v 8.0.0	■ Added new Editing **_hw.tcl** commands and ■ debug commands sections. ■ Changed chapter title from *Building a Component Interface with Tcl Scripting Commands* to *Component Interface Tcl Reference*.	—

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

8. Archiving SOPC Builder Projects

QII54017-9.0.0

Introduction

This chapter identifies the files you must include when archiving an SOPC Builder project. With this information, you can archive the SOPC Builder system. You may want to archive your SOPC Builder system for one of the following reasons:

- To place an SOPC Builder design under source control
- To create a backup
- To bundle a design for transfer to another location

To use this information, you must decide what source control or archiving tool to use, and you must know how to use it. This chapter describes how to find and identify the files that you must include in an archived SOPC Builder design. Refer to "Required Files" on page 8–2.

Limitations

This chapter provides information about archiving SOPC Builder systems, including Nios® II software applications, if any. If your SOPC Builder system does not contain a Nios II processor, you can disregard information about archiving Nios II software applications.

This chapter does not cover archiving SOPC Builder components, for two reasons:

- SOPC Builder components can be recovered, if necessary, from the original Quartus® II and Nios II installations.
- If your SOPC Builder system was developed with an earlier version of the Quartus II software and Nios II Embedded Design Suite (EDS), when you restore it for use with the current version, you normally use the current, installed components.

If your SOPC Builder system was developed with an earlier version of the Quartus II Complete Design Suite and you restore it for use with the current version, the regenerated system is functionally identical to the original system. However, there might be differences in details such as timing performance, component implementation, or HAL implementation.

For details of version changes, refer to the *Quartus II Reference Documentation*.

To ensure that you can regenerate your exact original design, maintain a record of the tool and IP version(s) originally used to develop the design. Retain the original installation files or media in a safe place.

The archival process addressed by this chapter is different than Quartus II project archiving. A Quartus II project archive contains the complete Quartus II project, including the SOPC Builder module. The Quartus II software adds all HDL files to the archive, including HDL files generated by SOPC Builder, although these files are not strictly necessary, if you regenerate the design files afterwards. A Quartus II project archive also archives the Quartus II IP (**.qip**) file.

This chapter is only concerned with archiving the SOPC Builder system, without the generated HDL files.

For more details about archiving Quartus II projects, refer to the *Managing Quartus II Projects* chapter in volume 2 of the *Quartus II Handbook.*

Required Files

This section describes the files required to archive an SOPC Builder system and its associated Nios II software projects (if any). This is the minimum set of files needed to completely recompile an archived system, both the SRAM Object File (**.sof**) and the executable software (**.elf**).

If you have Nios II software projects, archive them together with the SOPC Builder system on which they are based. For more details about archiving Nios II designs, refer to the *Using the Nios II Software Build Tools* chapter of the *Nios II Software Developer's Handbook*.

The files listed in Table 8–1 are located in the Quartus II project directory.

Table 8–1. Files Required for an SOPC Builder System

File Description	File Name	Write Permission Required? *(1)*
SOPC Builder system description	*<sopc_builder_system>*.**sopc**	Yes
SOPC Builder classic system description for generation *(1)*	*<sopc_builder_system>*.**ptf**	Yes
SOPC Builder report file	*<sopc_builder_system>*.**sopcinfo**	Yes
All non-generated HDL source files *(2)*	for example: **top_level_schematic.bdf**, **customlogic.v**	No
Quartus II project file	*<project_name>*.**qpf**	No
Quartus II settings file	*<project_name>*.**qsf**	Yes

Notes to Table 8–1:

(1) The *<sopc_builder_system>*.**ptf** file is only required if you intend to edit or view the system in a version of SOPC Builder prior to version 7.1 and must also be writable to generate a system.

(2) Include all HDL source files not generated by SOPC Builder, including HDL source files you create or copy from elsewhere. To identify a file generated by SOPC Builder, open the file and look for the following header: `Legal Notice: (C)<year> Altera Corporation. All rights reserved.`

Many source control tools mark local files `read-only` by default. In this case, you must override this behavior. You do not have to check the files out of source control unless you are modifying the SOPC Builder design or Nios II software project.

Section II. Building Systems with SOPC Builder

This section uses example designs to show you how to build a system or component. Chapters in this section serve to answer the question, "How do I define systems in SOPC Builder." This chapter refers to design examples that you can download free from www.altera.com. Design file hyperlinks are located with individual chapters linked from the Altera website.

This section includes the following chapters:

- Chapter 9, SOPC Builder Memory Subsystem Development Walkthrough
- Chapter 10, SOPC Builder Component Development Walkthrough

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

9. SOPC Builder Memory Subsystem Development Walkthrough

QII54006-9.0.0

Introduction

Most systems generated with SOPC Builder require memory. For example, embedded processor systems require memory for software, while digital signal processing (DSP) systems require memory for data buffers. Many systems use multiple types of memories. For example, a processor-based DSP system can use off-chip SDRAM to store software, and on-chip RAM for fast access to data buffers. You can use SOPC Builder to integrate almost any type of memory into your system.

This chapter uses design examples to describe how to build a memory subsystem as part of a larger system created with SOPC Builder. This chapter focuses on the following kinds of memory most commonly used in SOPC Builder systems:

- "On-Chip RAM and ROM" on page 9–6
- "EPCS Serial Configuration Device" on page 9–9
- "SDR SDRAM" on page 9–11
- "DDR SDRAM" on page 9–14
- "DDR2 SDRAM" on page 9–14
- "Off-Chip SRAM and Flash Memory" on page 9–15

This chapter assumes that you are familiar with the following task and concepts:

- Creating FPGA designs and making pin assignments with the Quartus® II software. For details, refer to the *Introduction to the Quartus II Software* manual.
- Building simple systems with SOPC Builder. For details, refer to the *Introduction to SOPC Builder* chapter in volume 4 of the *Quartus II Handbook.*
- SOPC Builder components. For details, refer to the *SOPC Builder Components* chapter in volume 4 of the *Quartus II Handbook*.
- Basic concepts of the Avalon® interfaces. You do not need extensive knowledge of the Avalon interfaces, such as transfer types or signal timing. However, to create your own custom memory subsystem with external memories, you need to understand the Avalon Memory-Mapped (Avalon-MM) interface. For details, refer to the *System Interconnect Fabric for Memory-Mapped Interfaces* chapter in volume 4 of the *Quartus II Handbook* and the *Avalon Interface Specifications*.

Refer to the *Memory System Design* chapter in the *Embedded Design Handbook* for additional information on the efficient use of memories in SOPC Builder systems.

Example Design

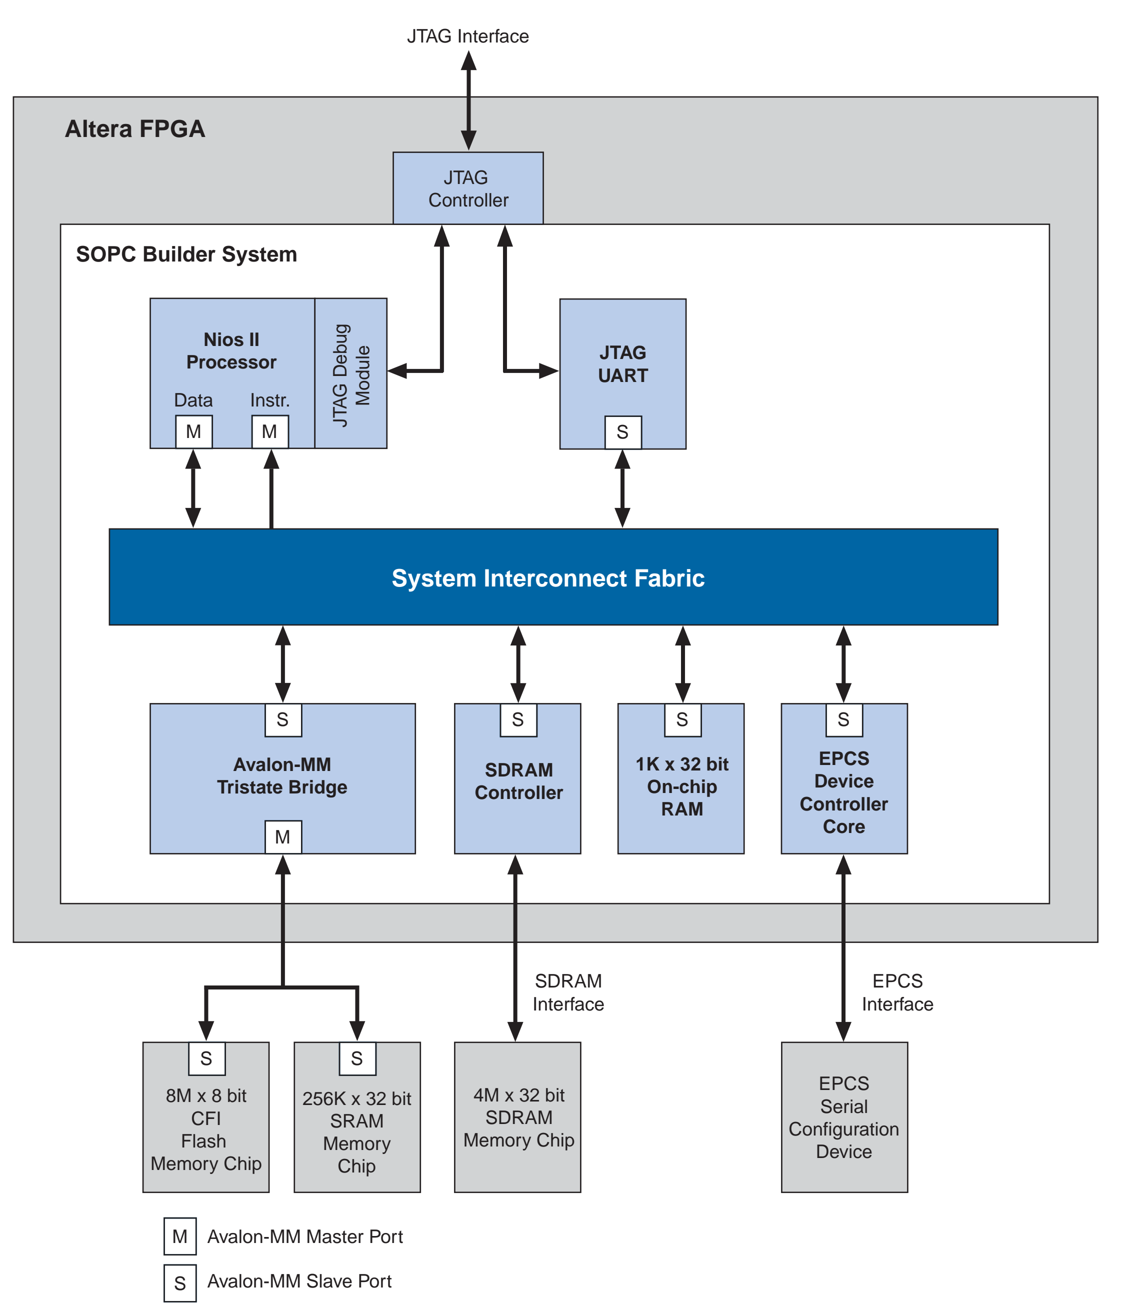
This chapter demonstrates the process for building a system that contains one of each type of memory as shown in Figure 9–1. Each section of the chapter builds on previous sections, culminating in a complete system.

By following the example design in this chapter, you learn how to create a complete customized memory subsystem for your system or design. The memory components in the example design are independent. For a custom system, you only need to instantiate the memories you need. You can also create multiple instantiations of the same type of memory, limited only by on-chip memory resources or FPGA pins to interface with off-chip memory devices.

Example Design Structure

Figure 9–1 shows a block diagram of the example system.

Figure 9–1. Example Design Block Diagram



In Figure 9–1, all blocks shown below the system interconnect fabric comprise the memory subsystem. For demonstration purposes, this system uses a Nios® II processor core to master the memory devices, and a JTAG UART core to communicate with the host PC. However, the memory subsystem could be connected to any master component, located either on-chip or off-chip.

Example Design Starting Point

The example design consists of the following elements:

- A Quartus II project named **quartus2_project**. A Block Design File (**.bdf)** named **toplevel_design**. **toplevel_design** is the top-level design file for **quartus2_project**. **toplevel_design** instantiates the SOPC Builder system, as well as other pins and modules required to complete the design.
- An SOPC Builder system named **sopc_memory_system**. **sopc_memory_system** is a subdesign of **toplevel_design**. **sopc_memory_system** instantiates the memory components and other SOPC Builder components required for a functioning SOPC Builder system.

This discussion assumes that the **quartus2_project** already exists, **sopc_memory_system** has been started in SOPC Builder, and the Nios II core and the JTAG UART core are already instantiated. This example design uses the default settings for the Nios II core and the JTAG UART core; these settings do not affect the rest of the memory subsystem.

Hardware and Software Requirements

To build a memory subsystem similar to the example design in this chapter, you need the following tools:

- Quartus II software version 5.0 or higher—Both Quartus II Web Edition and the fully licensed version support this design flow.
- Nios II Embedded Design Suite (EDS) version 5.0 or higher—Both the evaluation edition and the fully licensed version support this design flow. The Nios II EDS provides the SOPC Builder memory components described in this chapter. It also provides several complete example designs which demonstrate a variety of memory components instantiated in working systems.

The Quartus II Web Edition software and the Nios II EDS, Evaluation Edition are available free for download from the Altera® website. Visit www.altera.com/download. Also, for further reference, see the Design Examples.

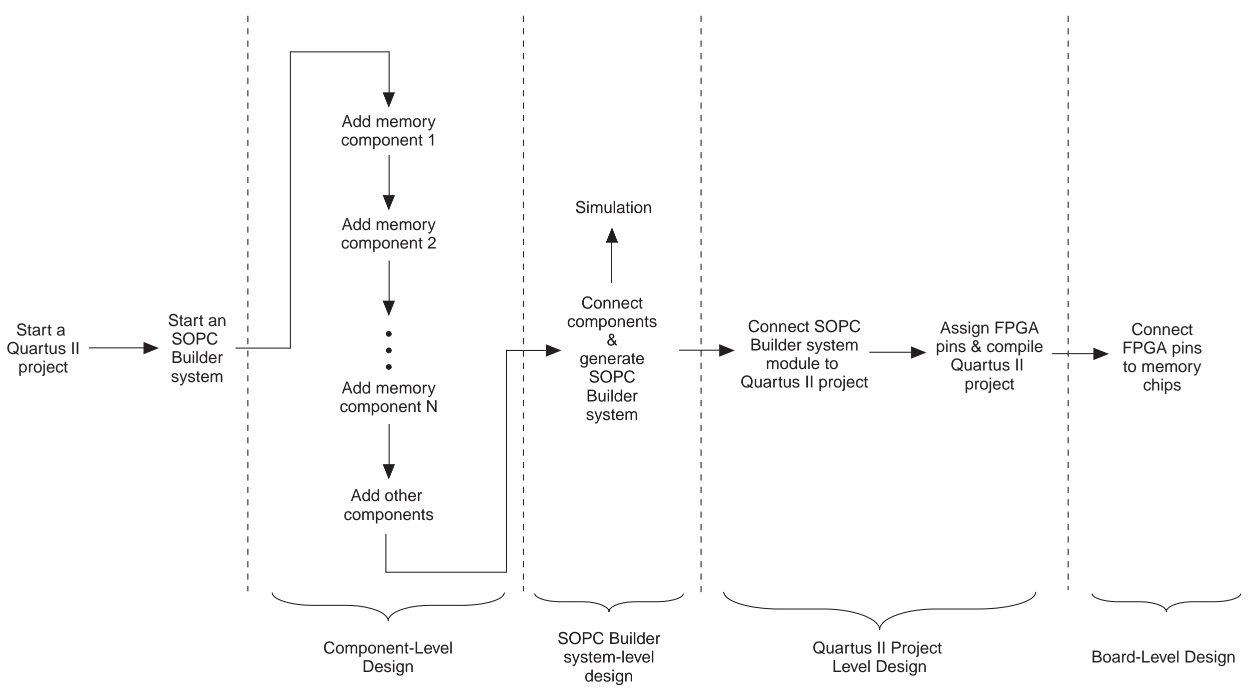
This chapter does not describe downloading and verifying a working system in hardware. Therefore, there are no hardware requirements for the completion of this chapter. However, the example memory subsystem has been tested in hardware.

Design Flow

This section describes the design flow for building memory subsystems with SOPC Builder, which is similar to other SOPC Builder designs. After starting a Quartus II project and an SOPC Builder system, there are five steps to completing the system, as shown in Figure 9–2:

1. Component-level design in SOPC Builder
2. SOPC Builder system-level design
3. Simulation
4. Quartus II project-level design
5. Board-level design

Figure 9–2. Design Flow



Component-Level Design in SOPC Builder

In this step, you specify which memory components to use and configure each component to meet the needs of the system. All memory components are available from the **Memory and Memory Controllers** category in the list of available components in SOPC Builder.

SOPC Builder System-Level Design

In this step, you connect components together and configure the SOPC Builder system as a whole. Like the process of adding non-memory SOPC Builder components, you use the **System Contents** tab to do the following:

- Rename the component instance (optional).

- Connect the memory component to masters in the system. Each memory component must be connected to at least one master.
- Assign a base address.
- Assign a clock domain. A memory component can operate on the same or different clock domain as the master(s) that access it.

Simulation

In this step, you verify the functionality of the SOPC Builder system. For systems with memories, this step depends on simulation models for each of the memory components, in addition to the system testbench generated by SOPC Builder. Refer to “Simulation Considerations” for more information.

Quartus II Project-Level Design

In this step, you integrate the SOPC Builder system with the rest of the Quartus II project, which includes connecting the SOPC Builder system to FPGA pins, connecting wiring the SOPC Builder system to other design blocks (such as other HDL modules) in the Quartus II project.

In the example design in this chapter, the SOPC Builder system comprises the entire FPGA design. There are no other design blocks in the Quartus II project.

Board-Level Design

In this step, you connect the physical FPGA pins to memory devices on the board. If the SOPC Builder system interfaces with off-chip memory devices, you must make board-level design choices.

Simulation Considerations

SOPC Builder can automatically generate a testbench for RTL simulation of the system using ModelSim®. This testbench instantiates the SOPC Builder system and can also instantiate memory models for external memory components. The testbench is plain text HDL, located at the bottom of the top-level SOPC Builder system HDL design file. To explore the contents of the auto-generated testbench, open the top-level HDL file and search on keyword `test_bench`.

Beginning in ModelSim SE 6.2, design optimization is on by default. Optimization may eliminate design nodes which are referenced in your wave display file. In this case, the you cannot display the waveforms. You can ignore this failure if you want to run an optimized simulation. However, if you want to see the simulation signals, you can disable the optimized compile by setting `VoptFlow = 0` in your **modelsim.ini** file. The **modelsim.ini** is stored in the top-level directory of the ModelSim installation.

Generic Memory Models

The memory components described in this chapter, except for the SRAM, provide generic simulation models. Therefore, it is very easy to simulate an SOPC Builder system with memory components immediately after generating the system.

The generic memory models store memory initialization files, such as Data (**.dat**) and Hexadecimal (**.hex**) files, in a directory named *<Quartus II project directory>*/*<SOPC Builder system name>***_sim**. When generating a new system, SOPC Builder creates empty initialization files. You can manually edit these files to provide custom memory initialization contents for simulation.

For designs that include a Nios II processor, you can create memory initialization files using the Nios II software build tools. For more information, refer to *Creating Memory Initialization Files* in the *Nios II Software Developer's Handbook – Studio Edition*.

Vendor-Specific Memory Models

You can also manually connect vendor-specific memory models to the SOPC Builder system. In this case, you must manually edit the testbench and connect the vendor memory model. You might also need to edit the vendor memory model slightly for time delays. The SOPC Builder testbench assumes zero delay.

On-Chip RAM and ROM

Altera FPGAs include on-chip memory blocks that can be used as RAM or ROM in SOPC Builder systems. On-chip memory has the following benefits for SOPC Builder systems:

- On-chip memory has fast access time, compared to off-chip memory.
- SOPC Builder automatically instantiates on-chip memory inside the SOPC Builder system, so you do not have to make any manual connections.
- Certain memory blocks can have initialized contents when the FPGA powers up. This feature is useful, for example, for storing data constants or processor boot code.
- On-chip memories support dual port accesses, allowing two master to access the same memory concurrently.

Component-Level Design for On-Chip Memory

In SOPC Builder you instantiate on-chip memory by clicking **On-chip Memory (RAM or ROM)** from the list of available components. The configuration wizard for the **On-chip Memory (RAM or ROM)** component has the following options: **Memory type**, **Size**, and **Read latency**.

Memory Type

The **Memory type** options define the structure of the on-chip memory:

- **RAM (writable)**—This setting creates a readable and writable memory.
- **ROM (read only)**—This setting creates a read-only memory.

- **Dual-port access—**This setting creates a memory component with two slaves, which allows two masters to access the memory simultaneously.

If two masters access the same address simultaneously in a dual-port memory undefined results will occur. (Concurrent accesses are only a problem for two writes. A read and write to the same location will read out the old data and store the new data.)

- **Block type—**This setting directs the Quartus II software to use a specific type of memory block when fitting the on-chip memory in the FPGA.

The MRAM blocks do not allow the contents to be initialized during power up. The M512s memory type does not support dual-port mode where both ports support both reads and writes.

Because of the constraints on some memory types, it is frequently best to use the **Auto** setting. **Auto** allows the Quartus II software to choose a type and the other settings direct the Quartus II software to select a particular type.

Size

The **Size** options define the size and width of the memory.

- **Data width—**This setting determines the data width of the memory. The available choices are **8**, **16**, **32**, **64**, **128**, **256**, **512**, or **1024** bits. Assign **Data width** to match the width of the master that accesses this memory the most frequently or has the most critical throughput requirements. For example, if you are connecting the on-chip memory to the data master of a Nios II processor, you should set the data width of the on-chip memory to 32 bits, the same as the data-width of the Nios II data master. Otherwise, the access latency could be longer than one cycle because the Avalon interconnect fabric performs width translation.
- **Total memory size—**This setting determines the total size of the on-chip memory block. The total memory size must be less than the available memory in the target FPGA.

Read Latency

On-chip memory components use synchronous, pipelined Avalon-MM slaves. Pipelined access improves f_{MAX} performance, but also adds latency cycles when reading the memory. The **Read latency** option allows you to specify either one or two cycles of read latency required to access data. If the **Dual-port access** setting is turned on, you can specify a different read latency for each slave. When you have dual-port memory in your system you can specify different clock frequencies for the ports. You specify this on the **System Contents** tab in SOPC Builder.

Non-Default Memory Initialization

For ROM memories, you can specify your own initialization file by selecting **Enable non-default initialization file**. This option allows the file you specify to be used to initialize the ROM in place of the default initialization file created by SOPC Builder.

Enable In-System Memory Content Editor Feature

Enables a JTAG interface used to read and write to the RAM while it is operating. You can use this interface to update or read the contents of the memory from your host PC.

For more information refer to *In-System Updating of Memory and Constants* in volume 3 of the *Quartus II Handbook*.

SOPC Builder System-Level Design for On-Chip Memory

There are few SOPC Builder system-level design considerations for on-chip memories. See “SOPC Builder System-Level Design” on page 9–4.

When generating a new system, SOPC Builder creates a blank initialization file in the Quartus II project directory for each on-chip memory that can power up with initialized contents. The name of this file is <*name of memory component*>**.hex**.

Simulation for On-Chip Memory

At system generation time, SOPC Builder generates a simulation model for the on-chip memory. This model is embedded inside the SOPC Builder system, and there are no user-configurable options for the simulation testbench.

You can provide memory initialization contents for simulation in the file <*Quartus II project directory*>/<*SOPC Builder system name*>**_sim/**<*Memory component name*>**.dat**.

Quartus II Project-Level Design for On-Chip Memory

The on-chip memory is embedded inside the SOPC Builder system, and there are no signals to connect to the Quartus II project.

To provide memory initialization contents, you must fill in the file <*name of memory component*>**.hex.** The Quartus II software recognizes this file during design compilation and incorporates the contents into the configuration files for the FPGA.

If your design includes a Nios II processor, you can create memory initialization files using the Nios II software build tools. For more information, refer to *Creating Memory Initialization Files* in the *Nios II Software Developer’s Handbook – Studio.* For the memory to be initialized, you then must compile the hardware in the Quartus II software for the SRAM Object File (**.sof**) to pick up the memory initialization files. All memory types with the exception of MRAMs support this feature.

Board-Level Design for On-Chip Memory

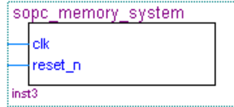
The on-chip memory is embedded inside the SOPC Builder system, and there is nothing to connect at the board level.

Example Design with On-Chip Memory

This section demonstrates adding a 4 KByte on-chip RAM to the example design. This memory uses a single slave interface with a read latency of one cycle.

For demonstration purposes, Figure 9–3 shows the result of generating the SOPC Builder system at this stage. (In a normal design flow, you generate the system only after adding all system components.)

Figure 9–3. SOPC Builder System with On-Chip Memory



Because the on-chip memory is contained entirely within the SOPC Builder system, **sopc_memory_system** has no I/O signals associated with **onchip_ram**. Therefore, you do not need to make any Quartus II project connections or assignments for the on-chip RAM, and there are no board-level considerations.

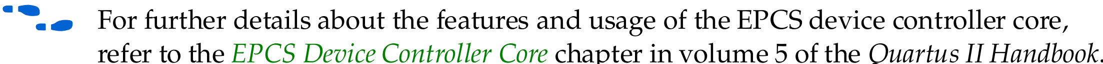
EPCS Serial Configuration Device

Many systems use an Altera EPCS serial configuration device to configure the FPGA. Altera provides the EPCS device controller core, which allows SOPC Builder systems to access the memory contents of the EPCS device.

This feature provides flexible design options:

- The FPGA design can reprogram its own configuration memory, providing a mechanism for remote upgrades.
- The FPGA design can use leftover space in the EPCS as nonvolatile storage.

Physically, the EPCS device is a serial flash memory device, which has slow access time. Altera provides software drivers to control the EPCS core for the Nios II processor only.



For further details about the features and usage of the EPCS device controller core, refer to the *EPCS Device Controller Core* chapter in volume 5 of the *Quartus II Handbook*.

Component-Level Design for an EPCS Device

In SOPC Builder you instantiate an EPCS controller core by adding an **EPCS Serial Flash Controller** component. There are no settings for this component.

For details, refer to the *Nios II Flash Programmer User Guide*.

SOPC Builder System-Level Design for an EPCS Device

There are two SOPC Builder system-level design considerations for EPCS devices:

- Assign a base address.
- Set the IRQ connection to **NC** (no connect). The EPCS controller hardware is capable of generating an IRQ. However, the Nios II driver software does not use this IRQ, and therefore you can leave the IRQ signal disconnected.

There can only be one EPCS controller core per FPGA, and the instance of the core is always named `epcs_controller`.

If you want to store Nios II code in the EPCS memory, point the Nios II reset address at the EPCS controller. Inside the EPCS controller is a bootloader, which Nios II runs after it leaves reset, that copies the code from the EPCS flash into main memory.

Simulation for an EPCS Device

The EPCS controller core provides a limited simulation model:

- Functional simulation does not include the FPGA configuration process, and therefore the EPCS controller does not model the configuration features.
- The simulation model does not support read and write operations to the flash region of the EPCS device.
- A Nios II processor can boot from the EPCS device in simulation. However, the boot loader code is different during simulation. The EPCS controller boot loader code assumes that all other memory simulation models are initialized, and therefore the boot load process is unnecessary. During simulation, the boot loader simply forces the Nios II processor to jump to start, skipping the boot load process.

Verification in the hardware is the best way to test features related to the EPCS device.

Quartus II Project-Level Design for an EPCS Device

If you use a device from Cyclone III, Stratix III, or Stratix IV families, you must connect the EPCS pins manually.

For earlier device families, however, the Quartus II software automatically connects the EPCS controller core in the SOPC Builder system to the dedicated configuration pins on the FPGA. This connection is invisible to you. Therefore, there are no EPCS-related signals to connect in the Quartus II project.

Board-Level Design for an EPCS Device

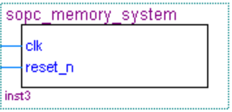
You must connect the EPCS device to the FPGA as described in the Altera *Configuration Handbook*. No other connections are necessary.

Example Design with an EPCS Device

This section demonstrates adding an EPCS device controller core to the example design.

For demonstration purposes only, Figure 9–4 shows the result of generating the SOPC Builder system at this stage.

Figure 9–4. SOPC Builder System with EPCS Device



Because the Quartus II software automatically connects the EPCS controller core to the FPGA pins, the SOPC Builder system has no I/O signals associated with **epcs_controller**. Therefore, you do not need to make any connections or assignments between the Quartus II project and the EPCS controller core.

This chapter does not cover the details of configuration using the EPCS device. For further information, refer to the Altera *Configuration Handbook*.

SDR SDRAM

Altera provides a free SDR SDRAM controller core, which allows you to use inexpensive SDRAM as bulk RAM in your FPGA designs. The SDR SDRAM controller core is necessary, because Avalon-MM signals cannot describe the complex interface on an SDRAM device. The SDR SDRAM controller acts as a bridge between the system interconnect fabric and the pins on an SDRAM device. The SDR SDRAM controller can operate in excess of 100 MHz.

SDR SDRAM is a single data rate SDR SDRAM. Synchronous design allows precise cycle control. With the use of system clock, I/O transactions are possible on every clock cycle. Operating over a range of frequencies, programmable latencies allow the same device to be useful for a variety of high bandwidth, high performance memory system applications.

For further details about the features and usage of the SDR SDRAM controller core, refer to the *SDR-SDRAM Controller Core with Avalon Interface* chapter in volume 5 of the *Quartus II Handbook*.

Component-Level Design for SDRAM

The choice of SDRAM device(s) and the configuration of the device(s) on the board heavily influence the component-level design for the SDRAM controller. Typically, the component-level design task involves parameterizing the SDRAM controller core to match the SDRAM device(s) on the board. You must specify the structure (address width, data width, number of devices, number of banks, and so on) and the timing specifications of the device(s) on the board.

For complete details about configuration options for the SDRAM controller core, refer to the *SDRAM Controller Core* chapter in volume 5 of the *Quartus II Handbook*.

SOPC Builder System-Level Design for SDRAM

You can select the SDRAM controller in the SOPC Builder **System Contents** tab. Like the on-chip memory, there are few SOPC Builder system-level design considerations for SDRAM. Refer to “SOPC Builder System-Level Design” on page 9–4.

Simulation for SDRAM

At system generation time, SOPC Builder can generate a generic SDRAM simulation model and include the model in the system testbench. To use the generic SDRAM simulation model, you must turn on a setting in the SDRAM controller configuration wizard. You can provide memory initialization contents for simulation in the file *<Quartus II project directory>*/*<SOPC Builder system name>***_sim/***<Memory component name>***.dat.**

Alternatively, you can provide a specific vendor memory model for the SDRAM. In this case, you must manually wire up the vendor memory model in the system testbench.

For further details, refer to "Simulation Considerations" on page 9–5 and the *SDRAM Controller Core* chapter in volume 5 of the *Quartus II Handbook*.

Quartus II Project-Level Design for SDRAM

SOPC Builder generates a SOPC Builder system with top-level I/O signals associated with the SDRAM controller. In the Quartus II project, you must connect these I/O signals to FPGA pins, which connect to the SDRAM device on the board. In addition, you might have to accommodate clock skew issues.

Connecting and Assigning the SDRAM-Related Pins

After generating the system with SOPC Builder, you can find the names and directions of the I/O signals in the top-level HDL file for the SOPC Builder system. The file has the name

<Quartus II project directory>/*<SOPC Builder system name>***.v** or *<Quartus II project directory>*/*<SOPC Builder system name>***.vhd**. You must connect these signals in the top-level Quartus II design file.

You must assign a pin location for each I/O signal in the top-level Quartus II design to match the target board. Depending on the performance requirements for the design, you might have to assign FPGA pins carefully to achieve the required performance.

Accommodating Clock Skew

As SDRAM frequency increases, so does the possibility that you must accommodate skew between the SDRAM clock and I/O signals. This issue affects all synchronous memory devices, including SDRAM. To accommodate clock skew, you can instantiate an ALTPLL megafunction in the top-level Quartus II design to create a phase-locked loop (PLL) clock output. You use a phase-shifted PLL output to drive the SDRAM clock and reduce clock-skew issues. The exact settings for the ALTPLL megafunction depend on your target hardware. You must experiment to tune the phase shift to match the board.

For details, refer to the *ALTPLL Megafunction User Guide*.

Board-Level Design for SDRAM

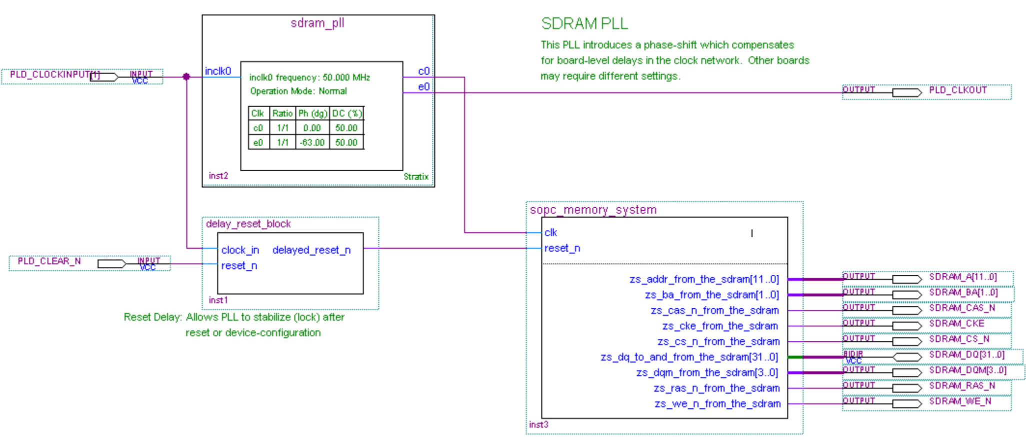
Memory requirements largely dictate the board-level configuration of the SDRAM device or devices. The SDRAM controller core can accommodate various configurations of SDRAM on the board, including multiple banks and multiple devices.

Example Design with SDR SDRAM

This section demonstrates adding a 16-Mbyte SDRAM device to the example design, using the SDRAM Controller configuration wizard. This SDRAM is a single device with 32-bit data.

For demonstration purposes, Figure 9–5 shows the result of generating the SOPC Builder system at this stage, and connecting it in **toplevel_design.bdf**.

Figure 9–5. toplevel_design.bdf with SDRAM



After generating the system, the top-level SOPC Builder system file **sopc_memory_system.v** contains the list of SDRAM-related I/O signals that must be connected to FPGA pins. Example 9–1 shows these pins.

Example 9–1. I/O Signals Connected to FPGA Pins

```
output  [ 11: 0] zs_addr_from_the_sdram;
output  [  1: 0] zs_ba_from_the_sdram;
output           zs_cas_n_from_the_sdram;
output           zs_cke_from_the_sdram;
output           zs_cs_n_from_the_sdram;
inout   [ 31: 0] zs_dq_to_and_from_the_sdram;
output  [  3: 0] zs_dqm_from_the_sdram;
output           zs_ras_n_from_the_sdram;
output           zs_we_n_from_the_sdram;
```

As shown in Figure 9–5, **toplevel_design.bdf** uses an instance of `sdram_pll` to phase shift the SDRAM clock by –63 degrees. (Degrees are relative to clock frequency. If you change the clock speed you must change the phase shift. You should parameterize the PLL with -3.5 ns, because the compensation is for the round-trip delays and clock to I/O delays.)

toplevel_design.bdf also uses a subdesign `delay_reset_block` to insert a delay on the `reset_n` signal for the SOPC Builder system. This delay is necessary to allow the PLL output to stabilize before the SOPC Builder system begins operating.

Figure 9–6 shows pin assignments in the Quartus II Assignment Editor for some of the SDRAM pins. The correct pin assignments depend on the target board.

Figure 9–6. Pin Assignments for SDRAM

	To	Location	I/O Bank	I/O Standard	General Function	Special Function	Reserved
188	SDRAM_A[0]	PIN_AE4	7	LVTTL	Column I/O

208	SDRAM_DQM[3]	PIN_AG10	7	LVTTL	Column I/O	DQS3B	

DDR SDRAM

You can use double-data rate (DDR) SDRAM devices for a broad range of applications, such as embedded processor systems, image processing, storage, communications, and networking. In addition, the universal adoption of DDR SDRAM in PCs makes DDR SDRAM memory a solution for high-bandwidth applications. DDR SDRAM is a <*2n*> prefetch architecture where the internal data bus is twice the width of the external data bus and data transfers occur on both clock edges. It uses a strobe, `DQS`, which is associated with a group of data pins (`DQ`) for read and write operations. Both the `DQS` and `DQ` ports are bidirectional. Address ports are shared for write and read operations.

Refer to the DDR SDRAM literature on the Altera website for further details on the use of DDR SDRAM memory, including *AN 517: Using High-Performance DDR, DDR2, and DDR3 SDRAM With SOPC Builder*.

DDR2 SDRAM

Double-data rate DDR2 SDRAM is the second generation of double-data rate DDR SDRAM technology, with features such as lower power consumption, higher data bandwidth, enhanced signal quality, and on-die termination. DDR2 SDRAM brings higher memory performance to a broad range of applications, such as PCs, embedded processor systems, image processing, storage, communications, and networking. It is a <*4n*> pre-fetch architecture with two data transfers per clock cycle. The memory uses a strobe (`DQS`) associated with a group of data pins (`DQ`) for read and write operations. Both the `DQ` and `DQS` ports are bidirectional. Address ports are shared for write and read operations.

For more information refer to the *DDR and DDR2 SDRAM Controller Compiler User Guide*, the *DDR2 SDRAM High-Performance Controller User Guide*, and *AN 517: Using High-Performance DDR, DDR2, and DDR3 SDRAM With SOPC Builder*.

Off-Chip SRAM and Flash Memory

SOPC Builder systems can directly access many off-chip RAM and ROM devices, without a controller core to drive the off-chip memory. Avalon-MM signals can describe the interfaces on many standard memories, such as SRAM and flash memory. I/O signals on the SOPC Builder system can connect directly to the memory device.

While off-chip memory usually has slower access time than on-chip memory, off-chip memory provides the following benefits:

- Off-chip memory cost-per-bit is less expensive than on-chip memory resources.
- The size of off-chip memory is bounded only by the 32-bit Avalon-MM address space.
- Off-chip ROM, such as flash memory, can be used for bulk storage of nonvolatile data.
- Multiple off-chip RAM and ROM memories can share address and data pins to conserve FPGA I/O resources at the expense of throughput.

Adding off-chip memories to an SOPC Builder system also requires the **Avalon-MM Tristate Bridge** component.

Component-Level Design for SRAM and Flash Memory

There are several ways to instantiate an interface to an off-chip memory device:

- For common flash interface (CFI) flash memory devices, add the **Flash Memory (Common Flash Interface)** component in SOPC Builder.
- For Altera development boards, Altera provides SOPC Builder components that interface to the specific devices on each development board. For example, the Nios II EDS includes the components **Cypress CY7C1380C SSRAM** and **IDT71V416 SRAM**, which appear on Nios II development boards.

For further details about the features and usage of the SSRAM controller core, refer to the *Nios Development Board Cyclone II Edition Reference Manual* or *Nios Development Board Stratix II Edition*.

For further details about the features and usage of the SDRAM controller core, refer to the *Building Memory Subsystems Using SOPC Builder* chapter in volume 4 of the *Quartus II Handbook*.

These components make it easy for you to create memory systems targeting Altera development boards. However, these components target only the specific memory device on the board; they do not work for different devices.

- For general memory devices, RAM or ROM, you can create a custom interface to the device with the SOPC Builder component editor. Using the component editor, you define the I/O pins on the memory device and the timing requirements of the pins.

In all cases, you must also instantiate the **Avalon-MM Tristate Bridge** component. Multiple off-chip memories can connect to a single tristate bridge, in order to share pins such as the off-chip address bus.

Avalon-MM Tristate Bridge

A tristate bridge connects off-chip devices to the system interconnect fabric. The tristate bridge creates I/O signals for the SOPC Builder system, which you must connect to FPGA pins in the top-level Quartus II project.

The tristate bridge creates address and data pins that can be shared by multiple off-chip devices. This feature lets you conserve FPGA pins when connecting the FPGA to multiple devices with mutually exclusive access.

You must use a tristate bridge in either of the following cases:

- The off-chip device has bidirectional data pins.
- Multiple off-chip devices share the address, data, or both address and data buses.

In SOPC Builder, you instantiate a tristate bridge by instantiating the **Avalon-MM Tristate Bridge** component. The Avalon-MM Tristate Bridge configuration wizard has a single option: To register incoming (to the FPGA) signals or not.

- **Registered**—This setting adds registers to all FPGA input pins associated with the tristate bridge (outputs from the memory device).
- **Not Registered**—This setting does not add registers between the memory device output pins and the system interconnect fabric.

The Avalon-MM tristate bridge automatically adds registers to output signals from the tristate bridge to off-chip devices.

Registering the input and output signals shortens the register-to-register delay from the memory device to the FPGA, resulting in higher system f_{MAX} performance. However, the registers add one additional cycle of latency for Avalon-MM masters accessing memory connected to the tristate bridge in each direction. The registers do not affect the timing (setup, hold, and wait) of the transfers from the perspective of the memory device.

For details about the Avalon-MM tristate interface, refer to the *Avalon Interface Specifications*.

Flash Memory

In SOPC Builder, you instantiate an interface to CFI flash memory by adding a **Flash Memory (Common Flash Interface)** component. If the flash memory is not CFI compliant, you must create a custom interface to the device with the SOPC Builder component editor.

The choice of flash devices and the configuration of the devices on the board help determine the component-level design for the flash memory configuration wizard. Typically, the component-level design task involves parameterizing the flash memory interface to match the devices on the board. Using the Flash Memory (Common Flash Interface) configuration wizard, you must specify the structure (address width and data width) and the timing specifications of the flash memory devices.

For details about features and usage, refer to the *Common Flash Interface Controller Core* chapter in volume 5 of the *Quartus II Handbook*.

For an example of instantiating the Flash Memory (Common Flash Interface) component in an SOPC Builder system, see "Example Design with SRAM and Flash Memory" on page 9–21.

SRAM

To instantiate an interface to off-chip SRAM:

1. Create a new component with the SOPC Builder component editor that defines the interface.
2. Instantiate the new interface component in the SOPC Builder system.

The choice of RAM devices and the configuration of the devices on the board determine how you create the interface component. The component-level design task involves entering parameters into the component editor to match the devices on the board.

For details about using the component editor, refer to the *Component Editor* chapter in volume 4 of the *Quartus II Handbook*.

SOPC Builder System-Level Design for SRAM and Flash Memory

In the SOPC Builder **System Contents** tab, the Avalon-MM tristate bridge has two ports:

- Avalon-MM slave—This port faces the on-chip logic in the SOPC Builder system. You connect this slave to on-chip masters in the system.
- Avalon-MM tristate master—This port faces the off-chip memory devices. You connect this master to the Avalon-MM tristate slaves on the interface components for off-chip memories.

You assign a clock to the Avalon-MM tristate bridge that determines the Avalon-MM clock cycle time for off-chip devices connected to the tristate bridge.

You must assign base addresses to each off-chip memory. The Avalon-MM tristate bridge does not have an address; it passes unmodified addresses from on-chip masters to off-chip slaves.

Simulation for SRAM and Flash Memory

The SOPC Builder output for simulation depends on the type of memory components in the system:

- **Flash Memory (Common Flash Interface)** component—This component provides a generic simulation model. You can provide memory initialization contents for simulation in the file *<Quartus II project directory>*/*<SOPC Builder system name>***_sim/***<Flash memory component name>***.dat**.
- Custom memory interface created with the component editor—In this case, you must manually connect the vendor simulation model to the system testbench. SOPC Builder does not automatically connect simulation models for custom memory components to the SOPC Builder system.
- Altera-provided interfaces to memory devices—Altera provides simulation models for these interface components. You can provide memory initialization contents for simulation in the file *<Quartus II project directory>*/*<SOPC Builder system name>***_sim/***<Memory component name>***.dat**. Alternately, you can provide a specific vendor simulation model for the memory. In this case, you must manually wire up the vendor memory model in the system testbench.

For further details, see "Simulation Considerations" on page 9–5.

Quartus II Project-Level Design for SRAM and Flash Memory

SOPC Builder generates an SOPC Builder system with top-level I/O signals associated with the tristate bridge and the memory interface components. In the Quartus II project, you must connect the I/O signals to FPGA pins, which connect to the memory devices on the board.

After generating the system with SOPC Builder, you can find the names and directions of the I/O signals in the top-level HDL file for the SOPC Builder system. The file has the name *<Quartus II project directory>*/*<SOPC Builder system name>***.v** or *<Quartus II project directory>*/*<SOPC Builder system name>***.vhd**. You must connect these signals in the top-level Quartus II design file.

You must assign a pin location for each I/O signal in the top-level Quartus II design to match the target board. Depending on the performance requirements for the design, you might have to assign FPGA pins carefully to achieve timing.

SOPC Builder inserts synthesis directives in the top-level SOPC Builder system HDL to assist the Quartus II fitter with signals that interface with off-chip devices. Example 9–2 illustrates a directive. Using `FAST_OUTPUT_REGISTER=ON` places the output register in the IO block, reducing the off-chip delay.

For more information about improving IO timing refer to the I/O Specifications section in *The Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook* and the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook.*

Example 9–2. Synthesis Directive

```
reg [ 22: 0] tri_state_bridge_address /* synthesis
ALTERA_ATTRIBUTE =  "FAST_OUTPUT_REGISTER=ON" */;
```

Board-Level Design for SRAM and Flash Memory

Memory requirements determine the board-level configuration of the SRAM and flash memory device or devices. You can lay out memory devices in any configuration, as long as the resulting interface can be described with Avalon-MM signals.

Special consideration is required when connecting the Avalon-MM `address` signal to the address pins on the memory devices.

The SOPC Builder system presents the smallest number of address lines required to access the largest off-chip memory, which is usually less than 32 address bits. Not all memory devices connect to all address lines.

Aligning the Least-Significant Address Bits

The Avalon-MM tristate `address` signal always presents a byte address. Each address location in many memory devices contains more than one byte of data. In this case, the memory device must ignore one or more of the least-significant Avalon-MM `address` lines. For example, a 16-bit memory device must ignore Avalon-MM `address[0]` (which is a byte address), and connect Avalon-MM `address[1]` to the least-significant address line.

Table 9–1 shows the relationship between Avalon-MM `address` lines and off-chip address pins for all possible Avalon-MM data widths.

Table 9–1. Connecting the Least-Significant Avalon-MM Address Line (Part 1 of 2)

Avalon-MM Address Line	Address Line Connecting to Memory Device				
	8-bit Memory	16-bit Memory	32-bit Memory	64-bit Memory	128-bit Memory
`address[0]`	A0	No connect	No connect	No connect	No connect
`address[1]`	A1	A0	No connect	No connect	No connect
`address[2]`	A2	A1	A0	No connect	No connect

Table 9–1. Connecting the Least-Significant Avalon-MM Address Line (Part 2 of 2)

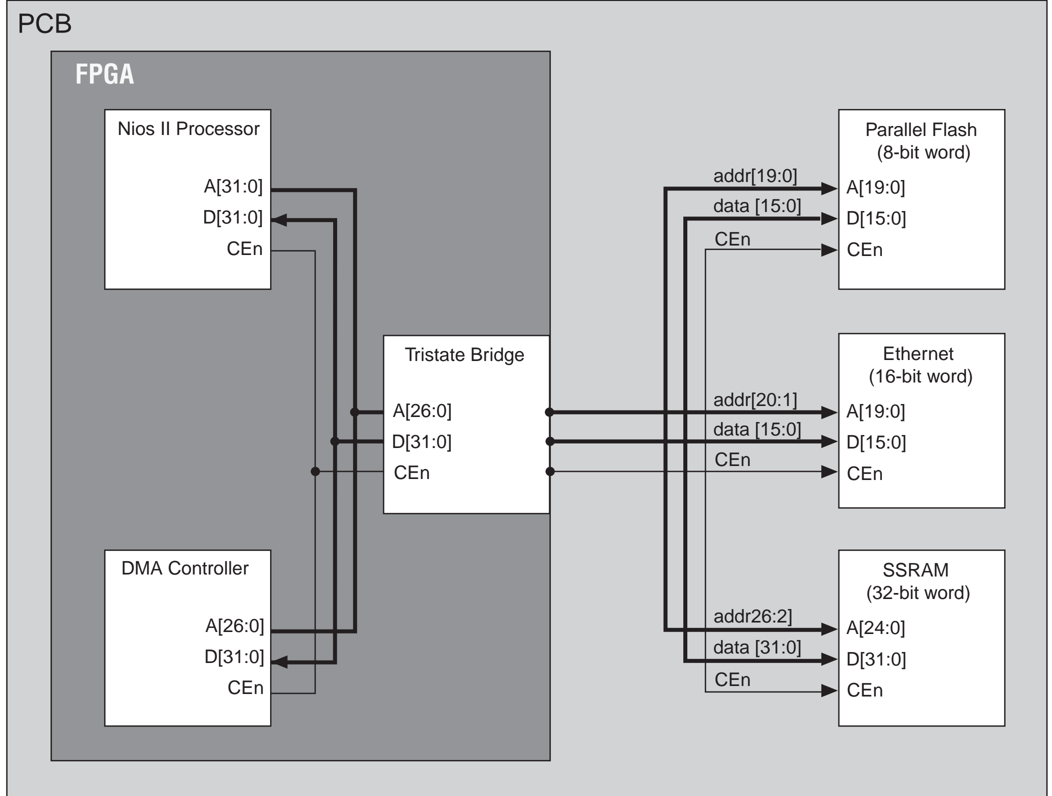
Avalon-MM Address Line	Address Line Connecting to Memory Device				
	8-bit Memory	**16-bit Memory**	**32-bit Memory**	**64-bit Memory**	**128-bit Memory**
`address[3]`	A3	A2	A1	A0	No connect
`address[4]`	A4	A3	A2	A1	A0
`address[5]`	A5	A4	A3	A2	A1
`address[6]`	A6	A5	A4	A3	A2
`address[7]`	A7	A6	A5	A4	A3
`address[8]`	A8	A7	A6	A5	A4
`address[9]`	A9	A8	A7	A6	A5
`address[10]`	A10	A9	A8	A7	A6
...	...	...	...	...	...

You must ensure that the address bits are properly assigned when mixed width components are connecting to the tristate bridge. Failing to ensure that the components are properly aligned may result in a board respin.

Aligning the Most-Significant Address Bits

The Avalon-MM `address` signal contains enough address lines for the largest memory connected to the tristate bridge. Smaller off-chip memories might not use all of the most-significant address lines as Figure 9–7 illustrates.

Figure 9–7. Connecting a Tristate Bridge to Components with Address Widths and Different Word Sizes



Example Design with SRAM and Flash Memory

This section demonstrates adding a 1-MByte SRAM and an 8-MByte flash memory to the example design. These memory devices connect to the system interconnect fabric through an Avalon-MM tristate bridge.

Adding the Avalon-MM Tristate Bridge

In the **Avalon-MM Tristate Bridge** configuration wizard, turn on the **Registered inputs and outputs** option to maximize system f_{MAX}, which increases the read latency by two for both the SRAM and flash memory.

Adding the Flash Memory Interface

The flash memory is 8M × 8-bit, which requires 23 address bits and 8 data bits. Table 9–2 gives the **Flash Memory (Common Flash Interface)** settings for the example design.

Table 9–2. Flash Memory Interface (CFI)

Parameter	Value
Attributes	
Presets	AMD29LV065D12R
Address Width (bits)	23
Data Width (bits)	8
Timing	
Setup	40
Wait	160
Hold	40
Units	ns

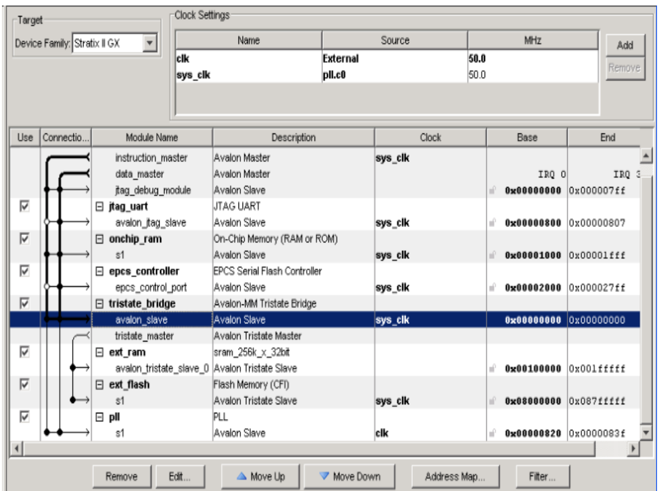
Adding the SRAM Interface

The SRAM device is 256K × 32-bit, which requires 18 word address bits and 32 data bits. The example design uses a custom memory interface created with the SOPC Builder component editor.

SOPC Builder System Contents Tab

Figure 9–8 shows the SOPC Builder system after adding the Tristate bridge and memory interface components, and configuring them appropriately on the **System Contents** tab. Figure 9–8 represents the complete example design in SOPC Builder.

Figure 9–8. SOPC Builder System with SRAM and Flash Memory



After generating the system, the top-level SOPC Builder system file **sopc_memory_system.v** contains the list of I/O signals for SRAM and flash memory that must be connected to FPGA pins, as shown in Example 9–3.

Example 9–3. I/O Signals for SRAM and Flash Memory

```
output          address_to_the_ext_flash[ 23..0];
output          address to_the_ext_ram[ 19..0];
output          be_n_to_the_ext_ram[ 3..0];
output          read_n_to_the_ext_flash;
output          read_n_to_the_ext_ram;
output          read_n_to_the_ext_ram;
output          select_n_to_the_ext_flash;
output          select_n_to_the_ext_ram;
bidirectional   tristate_bridge_data [ 31..0]
output          write_n_to_the_ext_flash;
output          write_n_to_the_ext_ram;
```

The Avalon-MM tristate bridge signals that can be shared are named after the instance of the tristate bridge component, such as `tri_state_bridge_data[31:0]`.

Connecting and Assigning Pins in the Quartus II Project

Figure 9–9 shows the result of generating the SOPC Builder system for the complete example design.

Figure 9–9. Top Level System with SRAM and Flash Memory

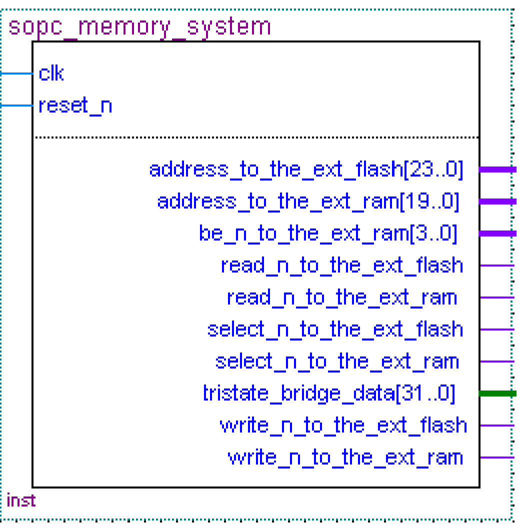


Figure 9–10 shows the pin assignments in the Quartus II Assignment Editor for some of the SRAM and flash memory pins. The correct pin assignments depend on the target board.

Figure 9–10. Pin Assignments for SRAM and Flash Memory

	To	Location	I/O Bank	I/O Standard	General Function	Special Function	Reser
243	SRAM_BE_N[0]	PIN_M18	3	LVTTL	Column I/O		
244	SRAM_BE_N[1]	PIN_F17	3	LVTTL	Column I/O		
245	SRAM_BE_N[2]	PIN_J18	3	LVTTL	Column I/O	RUP3	
246	SRAM_BE_N[3]	PIN_L17	3	LVTTL	Column I/O	CLK15n	
247	SRAM_CS_N	PIN_B24	3	LVTTL	Column I/O	DQ9T4

10. SOPC Builder Component Development Walkthrough

QII54007-9.0.0

Introduction

This chapter describes the parts of a custom SOPC Builder component and guides you through the process of creating an example custom component, integrating it into a system, and testing it in hardware.

This chapter is divided into the following sections:

- "Component Development Flow" on page 10–2.
- "Design Example: Checksum Hardware Accelerator" on page 10–4. This design example shows you how to develop a component with both Avalon® Memory-Mapped (Avalon-MM) master and slaves.
- "Sharing Components" on page 10–7. This section shows you how to use components in other systems, or share them with other designers.
- ".sopcinfo Files" on page 10–7.

SOPC Builder Components and the Component Editor

An SOPC Builder component is usually composed of the following four types of files:

- HDL files—define the component's functionality as hardware.
- Hardware Component Description File (**_hw.tcl**) —describes the SOPC Builder related characteristics, such as interface behaviors. This file is created by the component editor.
- C-language files—define the component register map and driver software to allow programs to control the component.
- Software Component Description File (**_sw.tcl**) file—used by the software build tools to use and compile the component driver code.

The component editor guides you through the creation of your component. You can then instantiate the component in an SOPC Builder system and make connections in the same manner as other SOPC Builder components. You can also share your component with other designers.

For information about creating the **_sw.tcl** file, see the *Developing Device Drivers for the Hardware Abstraction Layer* chapter in the *Nios II Software Developer's Handbook*.

Prerequisites

This chapter assumes that you are familiar with the following:

- Building systems with SOPC Builder. For details, refer to the *Introduction to SOPC Builder* chapter in volume 4 of the *Quartus II Handbook*.
- SOPC Builder components. For details, refer to the *SOPC Builder Components* chapter in volume 4 of the *Quartus II Handbook*.
- Basic concepts of the Avalon-MM interface.

Hardware and Software Requirements

To use the design example in this chapter, in addition to the current version of the Quartus II software and Nios II Embedded Design Suite, you must have the following:

- Design files for the example design—A hyperlink to the design files appears next to the chapter, *SOPC Builder Component Development Walkthrough*, on the SOPC Builder literature page.
- Nios development board and an Altera® USB-Blaster™ download cable—You can use either of the following Nios development boards:
  - Stratix® II Edition, RoHS compliant version
  - Cyclone® II Edition

If you do not have a development board, you can follow the hardware development steps. You cannot download the complete system without a working board, but you can simulate the system.

You can download the Quartus II Web Edition software and the Nios II EDS, Evaluation Edition for free from the Altera Download Center at www.altera.com.

Component Development Flow

This section provides an overview of the development process for SOPC Builder components.

Typical Design Steps

A typical development sequence for an SOPC Builder component includes the following items:

1. Specification and definition.
   a. Define the functionality of the component.
   b. Determine component interfaces, such as Avalon Memory-Mapped (Avalon-MM), Avalon Streaming (Avalon-ST), interrupt, or other interfaces.
   c. Determine the component clocking requirements; what interfaces are synchronous to what clock inputs.
   d. If you want a microprocessor to control the component, determine the interface to software, such as the register map.
2. Implement the component in VHDL or Verilog HDL.

3. Import the component into SOPC Builder.

   a. Use the component editor to create a **_hw.tcl** file that describes the component.

   b. Instantiate the component into an SOPC Builder system.

   When importing an HDL file using the component editor, any parameter definitions that are dependent upon other defined parameters cause an error. Example 10–1 illustrates the declaration of a `DEPTH` parameter which is legal Verilog HDL syntax in the Quartus II software, but causes an error in the component editor syntax checker.

Example 10–1. DEPTH Parameter

```
parameter WIDTH = 32;
parameter DEPTH = ((WIDTH == 32) ? 8 : 16);
```

   To avoid this error, use a `localparam` for the dependent parameter instead, as shown in Example 10–2.

Example 10–2. localparam Parameter

```
parameter WIDTH = 32;
localparam DEPTH = ((WIDTH == 32)?8:16);
```

4. Develop the software driver, which can occur in parallel with the hardware implementation. Create the component’s driver, including a C header file that defines the hardware-level register map for software.

   For further details, see the *Nios II Software Developer’s Handbook*.

5. Perform in-system testing, such as the following:

   a. Test register-level accesses to the component in hardware or simulation using a microprocessor, such as the Nios II processor.

   b. Performance benchmarking.

Hardware Design

As with any logic design process, the development of SOPC Builder component hardware begins after the specification phase. Creating the HDL design is often an iterative process, as you write and verify the HDL logic against the specification.

The architecture of a typical component consists of the following functional blocks:

- Task logic—Implements the component's fundamental function. The task logic is design dependent.
- Interface logic—Provides a standard way of providing data to or getting data from the components and of controlling the functioning of the components.

  For further details, refer to the *Avalon Interface Specifications*.

Figure 10–1 shows the top-level blocks of a checksum component, which includes both Avalon-MM master and slaves.

The work flow for developing SOPC Builder hardware, including how to decide upon and implement the register map, is described in the *Using the Nios II Software Build Tools* chapter in the *Nios II Software Developer's Handbook*. Also, guidelines for developing device drivers is described in the *Developing Device Drivers for the Hardware Abstraction Layer* chapter of the *Nios II Software Developer's Handbook*.

Design Example: Checksum Hardware Accelerator

Altera has provided a checksum hardware accelerator design example to demonstrate the steps to create a component and instantiate it in a system. This design example is available for download from the Altera literature website. Included in the compressed download file is a **readme.pdf** that describes how to create and compile the hardware design, and describes how to use the checksum hardware accelerator in your design.

You can use the checksum algorithm in network applications where data integrity must be inspected by the receiving device. The checksum algorithm accumulates data with end-round-carry summation, which means that the carry bit from the accumulator is added to the least significant bit of the next input. After the data is accumulated, you can use the result to verify the data integrity of the data buffer. Because the checksum algorithm operates over a data buffer, you can implement it more efficiently with a pipelined read master. A pipelined read master continuously posts read transactions minimizing the effects of the memory read latency. The checksum accelerator can read data and calculate the checksum result every clock cycle, which you cannot do with a general purpose processor.

The checksum hardware accelerator requires information from a host processor such as the buffer base address, buffer length, and various control signals. As a result, the hardware accelerator exposes an Avalon-MM slave interface so that a host processor can control the read master operation. The host processor also accesses the checksum result from the slave interface. Each piece of information sent or read by the host processor is accessed separately in the register file implemented with the slave interface. For example, the status and control signals are implemented as separate registers because they contain information used for different purposes and have different access capabilities.

Hardware accelerators can operate in parallel with a host processor; consequently, adding an interrupt sender interface to the hardware accelerator increases system performance. While the accelerator is operating on a buffer, the host processor can perform other tasks such as preparing another buffer for transmission. The interrupt is asserted after the buffer checksum is calculated. The host processor can be interrupted by the hardware accelerator to notify it that a checksum result has been calculated. The host processor can then read the checksum value and clear the interrupt by writing to the status register via the accelerator slave interface.

Figure 10–1. Checksum Component with Avalon-MM Master and Slaves

Software Design

If you want a microprocessor to control your component, you must provide software files that define the software view of the component. At a minimum, you must define the register map for each Avalon-MM slave that is accessible to a processor.

Typically, the header file declares macros to read and write each register in the component, relative to a symbolic base address assigned to the component. Table 10–1 shows the register map of the checksum component for use by the Nios II processor.

Table 10–1. Avalon-MM Slave Port Register Map (Control)

Offset	Name	Rd/Wr/clr	Bits										
			31 10	9	8	7	6	5	4	3	2	1	0
0	Status	Rd/Wclr										Busy	Done
4	Read Address *(1)*	Rd/Wr	Read Address (32-bit word aligned)										
8	N/A	—	Reserved ()										
12	Length (Bytes)	Rd/Wr	Length in Bytes (must be a multiple of 4 for word aligned)										
16	N/A	—	Reserved ()										
20	N/A	—	Reserved ()										
24	Control	Rd/Wr			RC ON				I_E N	GO		Inv	Clr
28	Checksum Results	Rd	16-Bit Checksum Result (upper 16 bits are zeros)										

Note to Table 10–1:

(1) Wr=Writable; Rd=Readable; Wclr=Write 1 to clear

In the example checksum project, you can view an example of a software driver in the directory <*projectdir*>**/ip/checksum_accelerator**, which is the top level folder of the hardware and software for the custom checksum block.

Software drivers abstract hardware details of the component so that software can access the component at a high level. The driver functions provide the software an API to access the hardware. The software requirements vary according to the needs of the component. The most common types of routines initialize the hardware, read data, and write data.

When developing software drivers, you should review the software files provided for other ready-made components. The IP installer provides many components you can use as reference. You can also view the <*Nios II EDS install path*>/**components**/ directory for examples.

For details about writing drivers for the Nios II hardware abstraction layer (HAL), refer to the *Developing Device Drivers for the Hardware Abstraction Layer* chapter of the *Nios II Software Developer's Handbook*.

Verifying the Component

You can verify the component in incremental stages, as you complete more of the design. You should first verify the hardware logic as a unit (which might consist of multiple smaller stages of verification) and later verify the component in a system.

System Console

The system console is an interactive Tcl console available from within SOPC Builder that provides you with read and write access to the debugging capabilities that are available in your FPGA logic. You can use the system console to control and query the state of the Nios II processor, issue Avalon transactions, board bring-up, and access either JTAG UARTs or system level debug (SLD) nodes.

 © March 2009 Altera Corporation

For further details, refer to the *System Console User Guide*.

System-Level Verification

After you package a **_hw.tcl** file with the component editor, you can instantiate the component in a system and verify the functionality of the overall SOPC Builder system.

SOPC Builder provides support for system-level verification for HDL simulators such as ModelSim®. SOPC Builder automatically produces a test bench for system-level verification.

You can include a Nios II processor in your system to enhance simulation capabilities during the verification phase. Even if your component has no relationship to the Nios II processor, the auto-generated ModelSim simulation environment provides an easy-to-use starting point.

Sharing Components

When you create a component, component editor saves the **_hw.tcl** file in the same directory as the top-level HDL file. Where appropriate, files referenced by the **_hw.tcl** file are specified relative to the **_hw.tcl** file itself, so the files can easily be moved and copied. To share a component, include it in your IP library.

For more information about including components in an IP library refer to *Finding Components in SOPC Builder* in *Chapter 4: SOPC Builder Components* in volume 4 of the *Quartus II Handbook*.

.sopcinfo Files

Every time SOPC Builder generates a system, a <*mysystem*>**.sopcinfo** file is also generated, which contains the following information:

- SOPC Builder project, including:
  - Name and tool version
  - HDL language
- Each module instantiated in the system, including:
  - Name and version
  - Where interface information was found on the disk, such as signal names and types, interface properties, and clock domain mapping
  - Parameter names and values
- Each connection, including:
  - Component and interface connections
  - Base address, Avalon-MM interfaces, IRQ number interfaces
  - Memory map as seen by each master in the system

The **.sopcinfo** file is a report file only, and cannot be edited with SOPC Builder.

Document Revision History

Table 10–2 shows the revision history for this chapter.

Table 10–2. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009, v9.0.0	Corrected direction of transform_data_available and transform_byte_lanes signals in Figure 10–1 on page 10–5.	One correction.
November 2008, v8.1.0	■ Added reference to new search path for IP chapter 4 of this volume. ■ Correction direction of signals in Figure 10–1. ■ Changed page size to 8.5 x 11 inches.	One correction and one change to reflect changes in underlying software.
May 2008, v8.0.0	■ Chapter renumbered from 9 to 10. ■ Removed discussion of the Checksum Design example, which will now be in a readme.pdf file and zipped with the rest of the design files. ■ Deleted references to Avalon Memory-Mapped and Streaming Interface Specifications and changed to Avalon Interface Specifications. ■ New Figure 9-1 and Table 9-1. ■ New section on **.sopcinfo** file.	Deleted example procedure.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

Section III. Interconnect Components

This section provides information on Avalon® Memory-Mapped (Avalon-MM) and Avalon Streaming (Avalon-ST) components that can be added to SOPC Builder systems. The components described in these chapters help you to create and optimize your SOPC Builder system. They are provided for free and can be used without a license in any design targeting an Altera device.

This section includes the following chapters:

- Chapter 11, Avalon Memory-Mapped Bridges
- Chapter 12, Avalon Streaming Interconnect Components

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

11. Avalon Memory-Mapped Bridges

QII54020-9.0.0

Introduction to Bridges

This chapter introduces Avalon® Memory-Mapped (Avalon-MM) bridges, and describes the Avalon-MM bridge components provided by Altera® for use in SOPC Builder systems.

You use bridges to control the topology of the generated SOPC Builder system. Bridges are not end-points for data, but rather affect the way data is transported between components. By inserting Avalon-MM bridges between masters and slaves, you control system topology, which in turn affects the interconnect that SOPC Builder generates. You can also use bridges to separate components in different clock domains and to implement clock domain crossing logic. Manual control of the interconnect can result in higher performance or lower logic utilization or both. Altera provides the following Avalon-MM bridges:

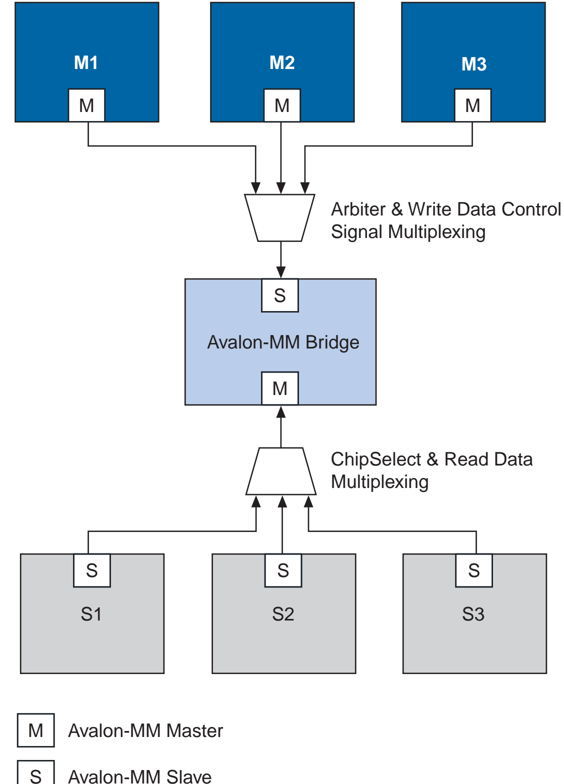
- "Avalon-MM Pipeline Bridge" on page 11–7
- "Clock Crossing Bridge" on page 11–10
- "Avalon-MM DDR Memory Half-Rate Bridge" on page 11–18

For additional information on using bridges to optimize and control the topology of SOPC Builder systems, refer to *Avalon Memory-Mapped Design Optimizations* in the *Embedded Design Handbook*.

Structure of a Bridge

A bridge has one Avalon-MM slave and one Avalon-MM master, as shown in Figure 11–1. In an SOPC Builder system, one or more masters connect to the bridge slave; in turn, the Avalon-MM bridge master connects to one or more slaves. In Figure 11–1, all three masters have logical connections to all three slaves, although physically each master only connects to the bridge.

Figure 11–1. Example of an Avalon-MM Bridge in an SOPC Builder System



Transfers initiated to the bridge's slave propagate to the master in the same order in which they are initiated on the slave.

For details on the Avalon-MM interface, refer to the *Avalon Interface Specifications*.

Reasons for Using a Bridge

When you have no bridges between master-slave pairs, SOPC Builder generates a system interconnect fabric with maximum parallelism, such that all masters can drive transactions to all slaves concurrently, as long as each master accesses a different slave. For systems that do not require a large degree of concurrency, the default behavior might not provide optimal performance. With knowledge of the system and application, you can optimize the system interconnect fabric by inserting bridges to control the system topology.

Figure 11–2 and Figure 11–3 show an SOPC system without bridges. This system includes three CPUs, a DDR SDRAM controller, a message buffer RAM, a message buffer mutex, and a tristate bridge to an external SRAM.

Figure 11–2. Example System Without Bridges—SOPC Builder View

Figure 11–3 illustrates the default system interconnect fabric for the system in Figure 11–2.

Figure 11–3. Example System without Bridges—System Interconnect View

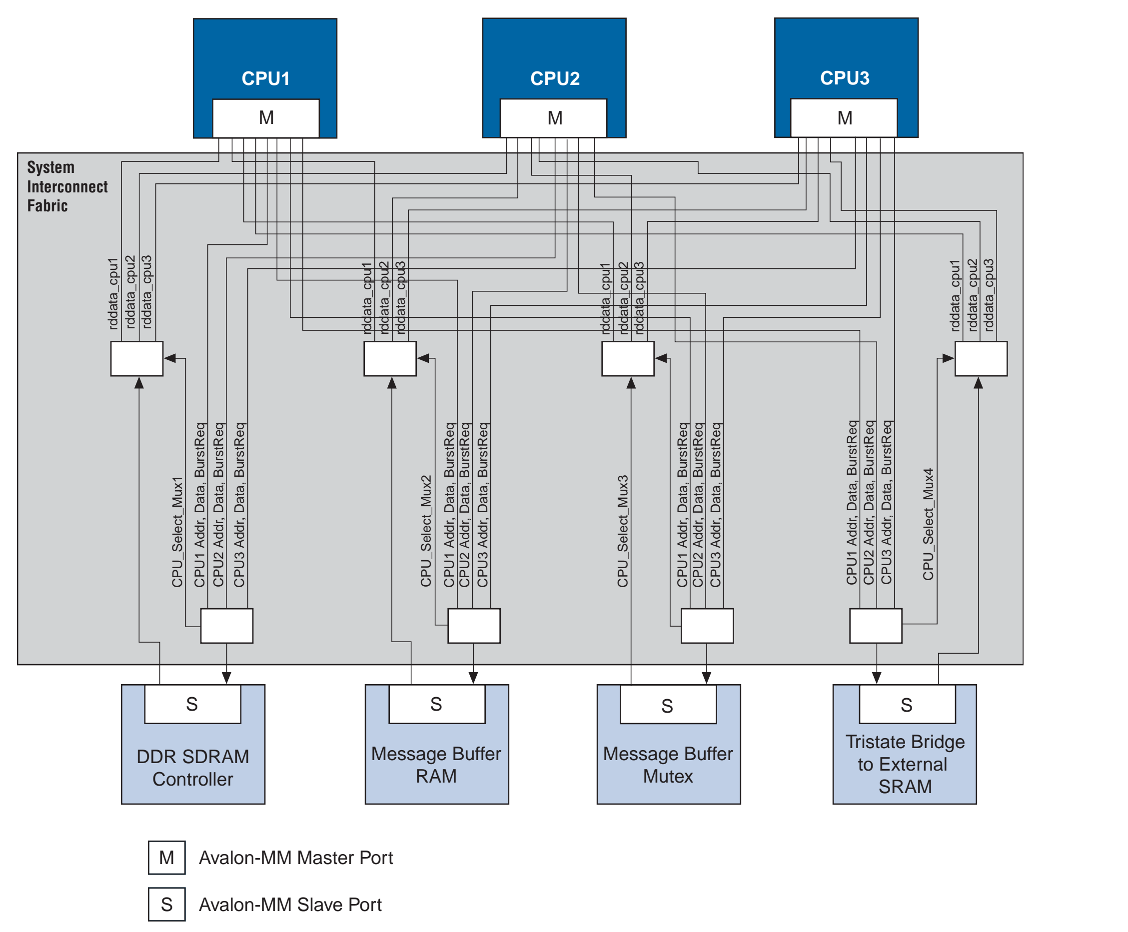

Figure 11–4 and Figure 11–5 show how inserting bridges can affect the generated logic. For example, if the DDR SDRAM controller can run at 166 MHz and the CPUs accessing it can run at 120 MHz, inserting an Avalon-MM clock-crossing bridge between the CPUs and the DDR SDRAM has the following benefits:

- Allows the CPU and DDR interfaces to run at different frequencies.
- Places system interconnect fabric for the arbitration logic and multiplexer for the DDR SDRAM controller in the slower clock domain.
- Reduces the complexity of the interconnect logic in the faster domain, allowing the system to achieve a higher f_{MAX}.

Inserting the clock-crossing bridge does increase read latency and may not be beneficial unless your system includes more devices that access the memory.

In the system illustrated in Figure 11–4, the message buffer RAM and message buffer mutex must respond quickly to the CPUs, but each response includes only a small amount of data. Placing an Avalon-MM pipeline bridge between the CPUs and the message buffers results in the following benefits:

- Eliminates separate arbiter logic for the message buffer RAM and message buffer mutex, which reduces logic utilization and propagation delay, thus increasing the f_{MAX}.
- Reduces the overall size and complexity of the system interconnect fabric.

Figure 11–4. Example SOPC System with Bridges—SOPC Builder View

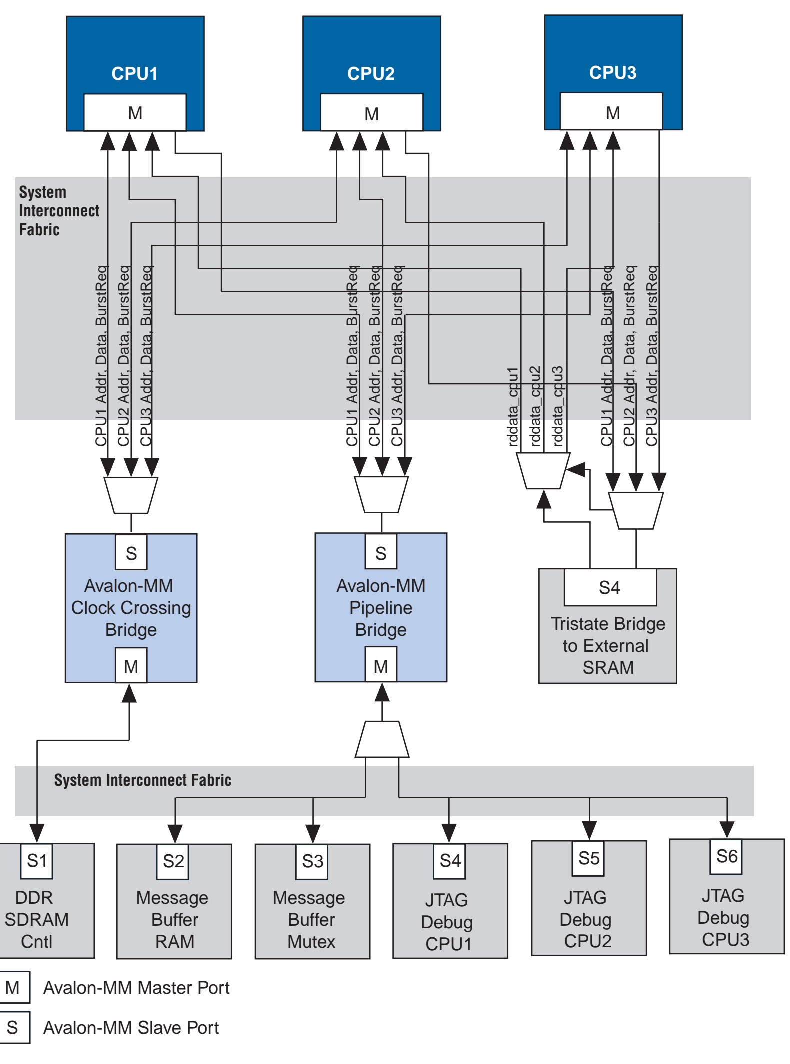
If an orange triangle appears next to an address in Figure 11–4, it indicates that the address is an offset value and is not the true value of the address in the address map.

Figure 11–5 shows the system interconnect fabric that SOPC Builder creates for the system in Figure 11–4. Figure 11–5 is the same system that is pictured in Figure 11–3 with bridges to control system topology.

Figure 11–5. Example System with a Bridge



Address Mapping for Systems with Avalon-MM Bridges

An Avalon-MM bridge has an address span and range that are defined as follows:

- The address *span* of an Avalon-MM bridge is the smallest power-of-two size that encompasses all of its slave's ranges.
- The address *range* of an Avalon-MM bridge is a numerical range from its base address to its base address plus its (span -1).

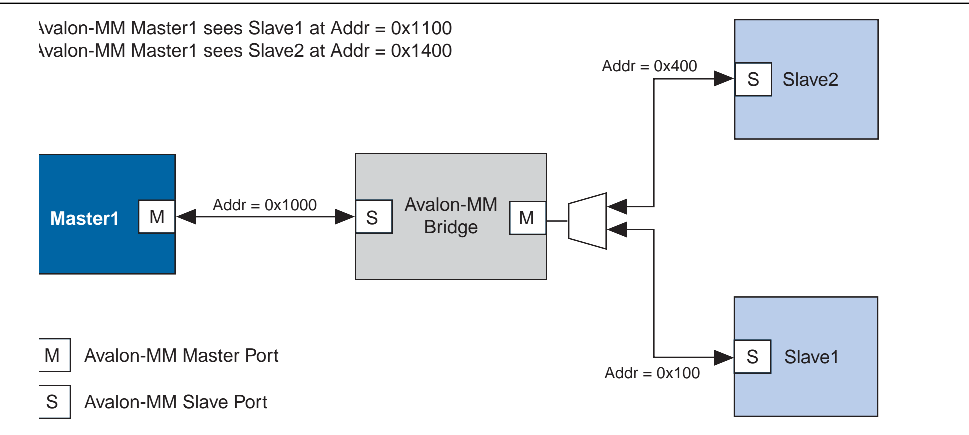
Equation 11–1.

range = [base_address .. (base_address + (span - 1)];

SOPC Builder follows several rules in constructing an address map for a system with Avalon-MM bridges:

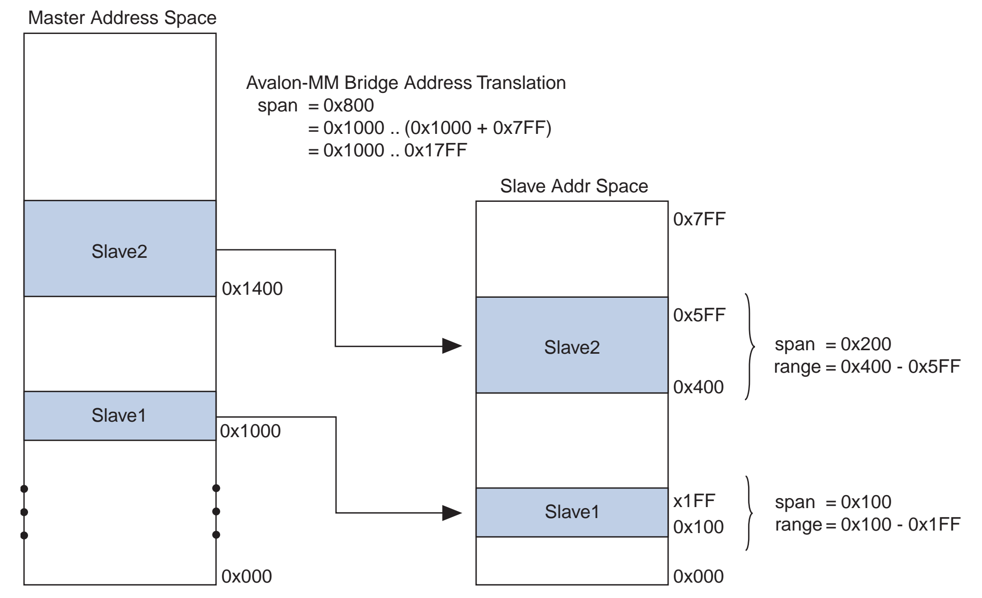
1. The address span of each Avalon-MM slave is rounded up to the nearest power of two.
2. Each Avalon-MM slave connected to a bridge has an address relative to the base address of the bridge. This address must be a multiple of its span. (See Figure 11–6.)

Figure 11–6. Avalon-MM Master and Slave Addresses



3. In the example shown in Figure 11–6, if the address span of Slave 1 is 0x100 and the address span of Slave 2 is 0x200, Figure 11–7 illustrates the address span of the Avalon-MM bridge.

Figure 11–7. The Address Span of an Avalon-MM Bridge



Tools for Visualizing the Address Map

The **Base Address** column of the **System Contents** tab displays the base address *offset* of the Avalon-MM slave relative to the base address of the Avalon-MM bridge to which it is connected. You can see the absolute address map for each master in the system by clicking **Address Map** on the **System Contents** tab.

Differences between Avalon-MM Bridges and Avalon-MM Tristate Bridges

You use Avalon-MM bridges to control topology and separate clock domains for on-chip components. You use tristate bridges to connect to off-chip components and to share pins, decreasing the overall pin count of the device. Tristate bridges are *transparent*, meaning that they do not affect the addresses of the components to which they connect.

For more information about the Avalon-MM tristate bridge, refer to the *SOPC Builder Memory Subsystem Development Walkthrough* chapter in volume 4 of the *Quartus II Handbook*.

Avalon-MM Pipeline Bridge

This section describes the hardware structure and functionality of the Avalon-MM pipeline bridge component.

Component Overview

The Avalon-MM pipeline bridge inserts registers in the path between its master and slaves. In a given SOPC Builder system, if the critical register-to-register delay occurs in the system interconnect fabric, the pipeline bridge can help reduce this delay and improve system f_{MAX}.

The bridge allows you to independently pipeline different groups of signals that can create a critical timing path in the interconnect:

- Master-to-slave signals, such as address, write data, and control signals
- Slave-to-master signals, such as read data
- The `waitrequest` signal to the master

You can also use the Avalon-MM pipeline bridge to control topology without adding a pipeline stage. To instantiate a bridge that does not add any pipeline stages, simply do not select any of the **Pipeline Options** on the parameter page. For the system illustrated in Figure 11–5, a pipeline bridge that does not add a pipeline register stage is optimal because the CPUs benefit from minimal delay from the message buffer mutex and message buffer RAM.

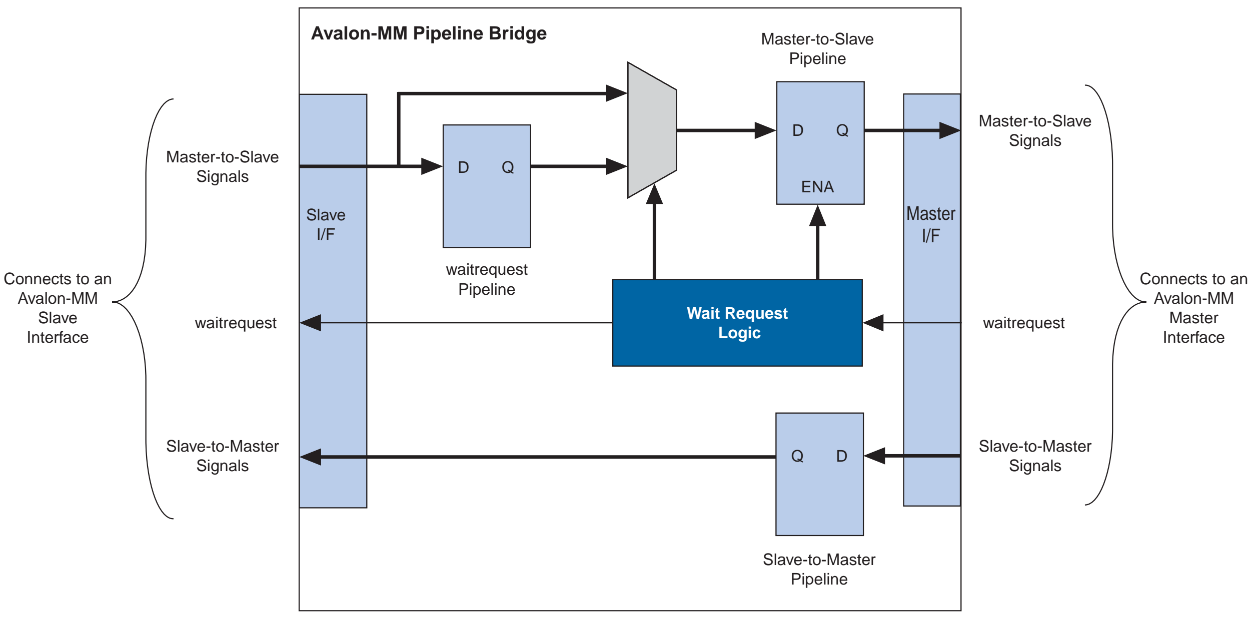
A pipeline bridge with no latency cannot be used with slaves that support pipelined reads. If a slave does not have read latency, you cannot connect it to a bridge with no pipeline stages, because the pipeline bridge slave port has a `readdatavalid` signal. Pipelined read components cannot have zero read latency. Some examples of 0 latency components available in SOPC Builder include the UART, Timer and SPI core. You you are connecting a pipeline bridge to one of these components, increase the read latency from 0 to 1.

The Avalon-MM pipeline bridge component integrates easily into any SOPC Builder system.

Functional Description

Figure 11–8 shows a block diagram of the Avalon-MM pipeline bridge component.

Figure 11–8. Avalon-MM Pipeline Bridge Block Diagram



The following sections describe the component's hardware functionality.

Interfaces

The bridge interface is composed of an Avalon-MM slave and an Avalon-MM master. The data width of the ports is configurable, which can affect how SOPC Builder generates dynamic bus sizing logic in the system interconnect fabric. Both ports support Avalon-MM pipelined transfers with variable latency. Both ports optionally support bursts of lengths that you can configure.

Pipeline Stages and Effects on Latency

The bridge provides three optional register stages to pipeline the following groups of signals.

- Master-to-slave signals, including:
  - `address`
  - `writedata`
  - `write`
  - `read`
  - `byteenable`
  - `chipselect`
  - `burstcount` (optional)
- Slave-to-master signals, including:
  - `readdata`
  - `readdatavalid`
- The `waitrequest` signal to the master

When you include a register stage, it affects the timing and latency of transfers through the bridge, as follows:

- The latency increases by one cycle in each direction.
- Write transfers on the master side of the bridge are decoupled from write transfers on the slave side of the bridge because Avalon-MM write transfers do not require an acknowledge signal from the slave.
- Including the `waitrequest` register stage increases the latency of master-to-slave signals by one additional cycle when the `waitrequest` signal is asserted.

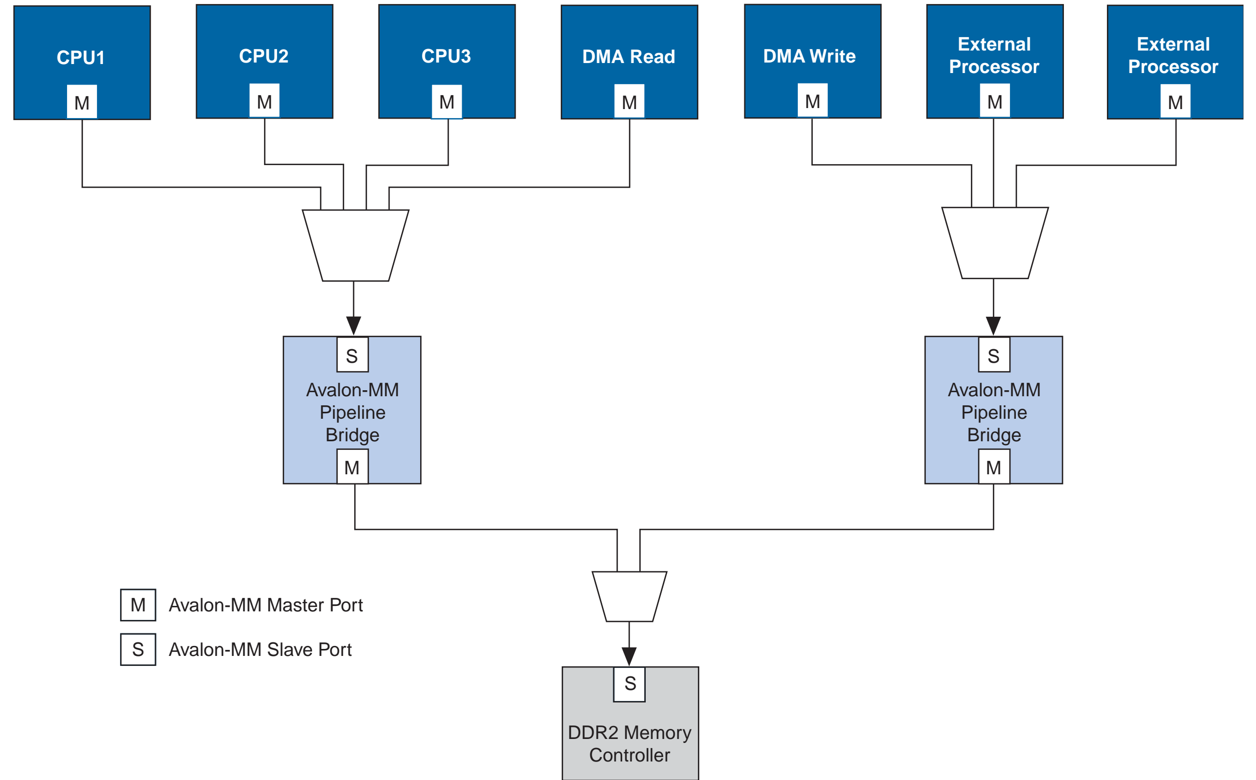
Burst Support

The bridge can support bursts with configurable maximum burst length. When configured to support bursts, the bridge propagates bursts between master-slave pairs, up to the maximum burst length. Not having burst support is equivalent to a maximum burst length of one. In this case, the system interconnect fabric automatically decomposes master-to-bridge bursts into a sequence of individual transfers.

Example System with Avalon-MM Pipeline Bridges

Figure 11–9 illustrates a system in which seven Avalon-MM masters are accessing a single DDR2 memory controller. By inserting two Avalon-MM pipeline bridges, you can limit the complexity of the multiplexer that would be required.

Figure 11–9. Seven Avalon-MM Masters Accessing One Avalon-MM Slave



Clock Crossing Bridge

The Avalon-MM clock-crossing bridge allows you to connect Avalon-MM master and slaves that operate in different clock domains. Without a bridge, SOPC Builder automatically includes generic clock domain crossing (CDC) logic in the system interconnect fabric, but it does not provide optimal performance for high-throughput applications. Because the clock-crossing bridge includes a buffering mechanism, you can pipeline multiple read and write transfers. After an initial penalty for the first read or write, there is no additional latency penalty for pending reads and writes, increasing throughput at the expense primarily of on-chip memory. The clock-crossing bridge has parameterizeable FIFOs for master-to-slave and slave-to-master signals, and allows burst transfers across clock domains.

The Avalon-MM clock-crossing bridge component is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system.

Choosing Clock Crossing Methodology

When determining clock frequencies for your components, you should also consider the impact on the latency that transferring data across clock domains can cause. Whether you use a clock-crossing bridge or rely on the clock domain adapter created automatically by SOPC Builder, additional latency occurs. You should also consider the resource usage and throughput capabilities of each solution.

If you rely on the automatically generated clock crossing adapter to connect master and slave ports driven by separate clock inputs, there is a fixed latency penalty associated to each transfer. Each transfer becomes blocking, meaning that while one transfer is underway another cannot begin until the first completes. For this reason, you should not connect high-speed, pipelined components such as SDRAM memory to a master on a different clock domain without using a clock-crossing bridge between them. The clock crossing bridge, on the other hand, can queue multiple transfers, so that even though the latency increases, the throughput does not decrease.

Because a clock crossing adapter is generated for every master and slave pair, you should use a clock crossing bridge if your design contains multiple master and slave pairs operating in different clock domains. Alternatively, if your design uses a large amount of on-chip memory, you may need to use a clock domain adapter, because the clock-crossing bridge uses on-chip memory resources for buffering.

Functional Description

Figure 11–10 shows a block diagram of the Avalon-MM clock-crossing bridge component. The following sections describe the component's hardware functionality.

Figure 11–10. Avalon-MM Clock-Crossing Bridge Block Diagram

Interfaces

The bridge interface comprises an Avalon-MM slave and an Avalon-MM master. The data width of the ports is configurable, which affects the size of the bridge hardware and how SOPC Builder generates dynamic bus sizing logic in the system interconnect fabric. Both ports support Avalon-MM pipelined transfers with variable latency. Both ports optionally support bursts of user-configurable length. Ideally, the settings for one port match the other, such that there are no mixed data widths or bursting capabilities.

Clock Crossing Bridge and FIFOs

Two FIFOs in the bridge transport address, data, and control signals across the clock domains. One FIFO captures data and controls traveling in the master-to-slave direction, and the other FIFO captures data in the slave-to-master direction. Clock crossing logic surrounding the FIFOs coordinates the details of passing data across the clock-domain boundaries and ensures that the FIFOs do not overflow or underflow.

The signals that pass through the master-to-slave FIFO include:

- `writedata`
- `address`
- `read`
- `write`
- `byteenable`
- `burstcount`, when bursting is enabled

The signals that pass through the slave-to-master FIFO include:

- `readdata`
- `readdatavalid`

You can configure the depth of each FIFO. Because there are more signals traveling in the master-to-slave direction, changing the depth of the master-to-slave FIFO has a greater impact on the memory utilization of the bridge.

For read transfers across the bridge, the FIFOs in both directions incur latency for data to return from the slave. To avoid paying a latency penalty for each transfer, the master can issue multiple reads that are queued in the FIFO. The slave of the bridge asserts `readdatavalid` when it drives valid data and asserts `waitrequest` when it is not ready to accept more reads.

For write transfers, the master-to-slave FIFO causes a delay between the master-to-bridge transfers and the corresponding bridge-to-slave transfers. Because Avalon-MM write transfers do not require an acknowledge from the slave, multiple write transfers from master-to-bridge might complete by the time the bridge initiates the corresponding bridge-to-slave transfers.

Burst Support

The bridge optionally supports bursts with configurable maximum burst length. When configured to support bursts, the bridge propagates bursts between master-slave pairs, up to the maximum burst length. Not having burst support is equivalent to a maximum burst length of one. In this case, the system interconnect fabric automatically breaks master-to-bridge bursts into a sequence of individual transfers.

When you configure the bridge to support bursts, you must configure the slave-to-master FIFO depth deeply enough to capture all burst read data without overflowing. The masters connected to the bridge could potentially fill the master-to-slave FIFO with read burst requests; therefore, the minimum slave-to-master FIFO depth is described by equation given in Example 11–1.

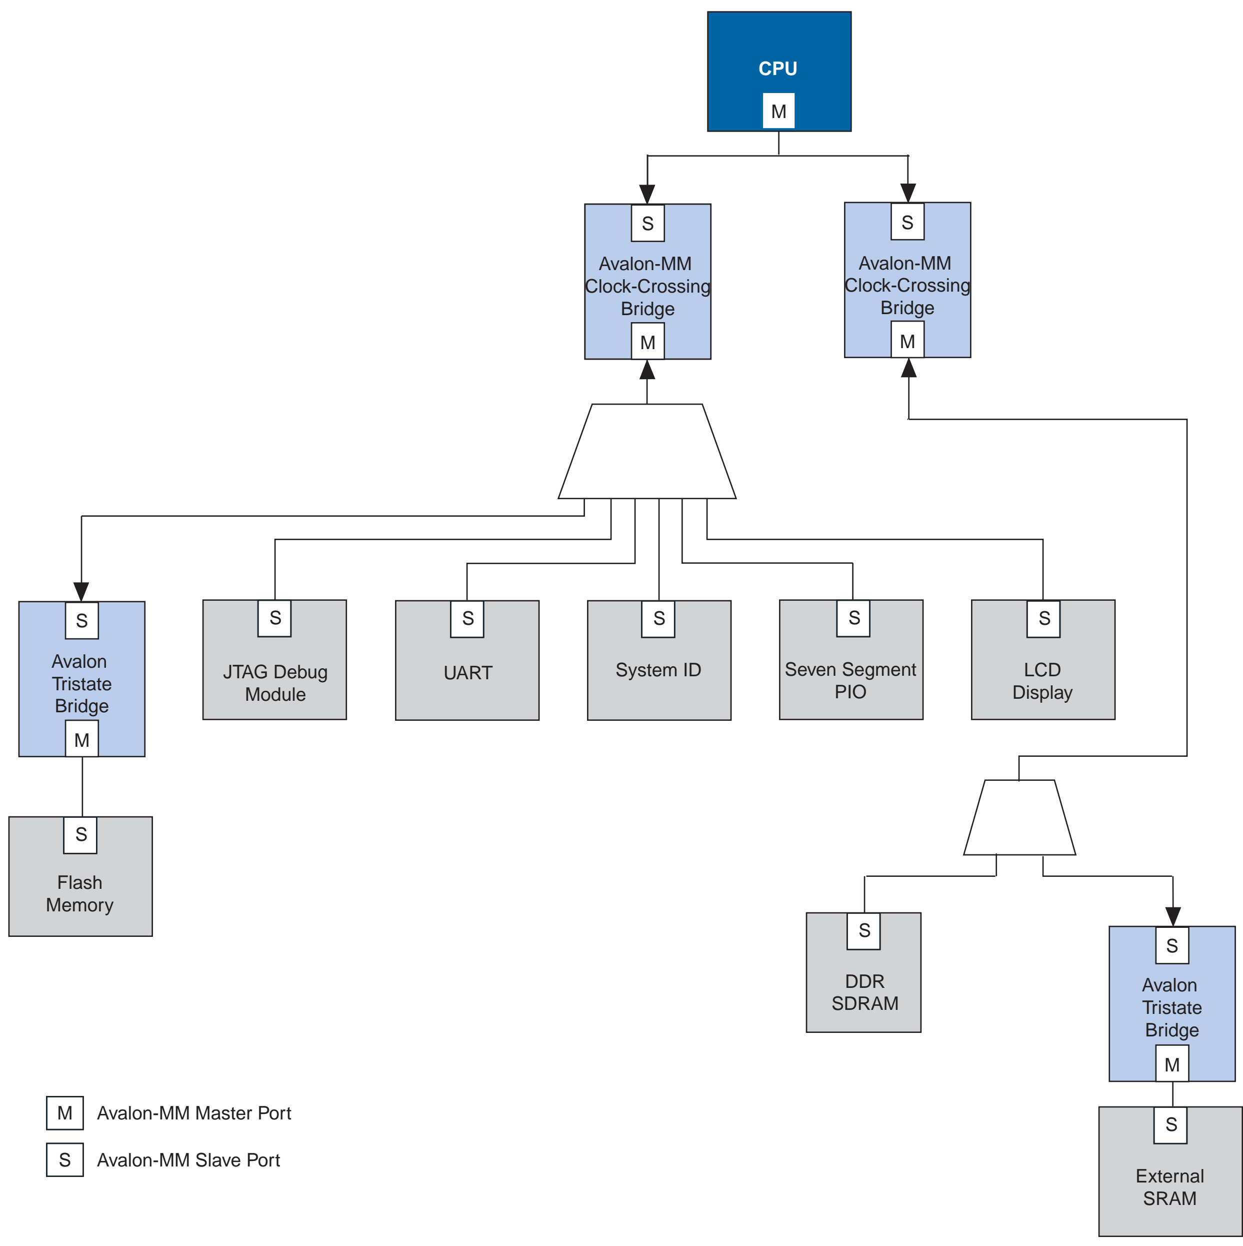
Example 11–1. Minimum Slave-To-Master FIFO Depth

```
= ((master-to-slave FIFO depth) * (max burst length)) + max slave latency/pending reads
```

Example System with Avalon-MM Clock-Crossing Bridges

Figure 11–11 uses Avalon-MM clocking crossing bridges to separate slave components into two groups. The low-performance slave components are placed behind a single bridge and clocked at a low speed. The high performance components are placed behind a second bridge and clocked at a higher speed. By inserting clock-crossing bridges in the system, you optimize the interconnect fabric and allow the Quartus® II fitter to expend effort optimizing paths that require minimal propagation delay.

Figure 11–11. One Avalon-MM Master with Two Groups of Avalon-MM Slaves



Instantiating the Avalon-MM Clock-Crossing Bridge in SOPC Builder

Table 11–1 describes the options available on the **Parameter Settings** page of the MegaWizard™ interface.

Table 11–1. Avalon-MM Clock Crossing Bridge Parameters

Master-to-slave FIFO		
Parameter	**Value**	**Description**
FIFO depth	**8, 16, 32**	Determines the depth of the FIFO.
Construct FIFO with registers instead of memory blocks	**On/Off**	When you turn on this option, the FIFO uses registers as storage instead of embedded memory blocks. This can considerably increase the size of the bridge hardware and lower the f_{MAX}.
Slave-to-master FIFO		
FIFO depth	**8, 16, 32, 64, 128, 256, 512, 1024**	Determines the depth of the FIFO.
Construct FIFO with registers instead of memory blocks	**On/Off**	When you turn on this option, the FIFO uses registers as storage instead of embedded memory blocks. This can considerably increase the size of the bridge hardware and lower the f_{MAX}.
Common options		
Data width	**8, 16, 32, 64, 128, 256,512, 1024**	Determines the data width of the interfaces on the bridge, and affects the size of both FIFOs. For the highest bandwidth, set **Data width** to be as wide as the widest master connected to the bridge.
Slave domain synchronizer length	**2–8**	The number of pipeline stages in the clock crossing logic in the issuing master to target slave direction. Increasing this value leads to a larger meantime between failures (MTBF). You can determine the MTBF for a given design can be determined by running a TimeQuest timing analysis.
Master domain synchronizer length	**2–8**	The number of pipeline stages in the clock crossing logic in the issuing master to target slave direction. Increasing this value leads to a larger meantime between failures (MTBF). You can determine the MTBF for a given design can be determined by running a TimeQuest timing analysis.
Burst settings		
Allow bursts	**On/Off**	Includes logic for the bridge's master and slaves to support bursts. You can use this option to restrict the minimum depth for the slave-to-master FIFO.
Maximum burst size	**2, 4, 8, 16, 32, 64, 128, 256, 512, 1024**	Determines the maximum length of bursts for the bridge to support, when you turn on **Allow bursts**.

Clock Domain Crossing Logic

SOPC Builder generates CDC logic that hides the details of interfacing components operating in different clock domains. The system interconnect fabric upholds the Avalon-MM protocol with each port independently, and therefore masters do not need to incorporate clock adapters in order to interface to slaves on a different domain. The system interconnect fabric logic propagates transfers across clock domain boundaries automatically.

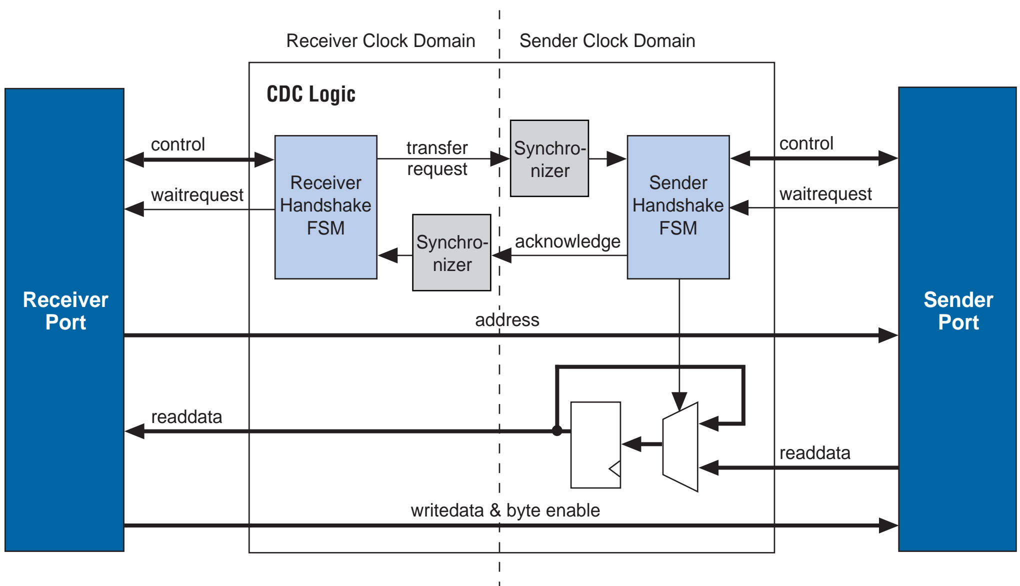
The clock-domain adapters in the system interconnect fabric provide the following benefits that simplify system design efforts:

- Allow component interfaces to operate at different clock frequencies.
- Eliminate the need to design CDC hardware.
- Allow each Avalon-MM port to operate in only one clock domain, which reduces design complexity of components.
- Enable masters to access any slave without communication with the slave clock domain.
- Allow you to focus performance optimization efforts only on components that require fast clock speed.

Description of Clock Domain Adapter

The clock domain adapter consists of two finite state machines (FSM), one in each clock domain, that use a simple hand-shaking protocol to propagate transfer control signals (`read_request`, `write_request`, and the master `waitrequest` signals) across the clock boundary. Figure 11–12 shows a block diagram of the clock domain adapter between one master and one slave.

Figure 11–12. Block Diagram of Clock Crossing Adapter



The synchronizer blocks in Figure 11–12 use multiple stages of flipflops to eliminate the propagation of metastable events on the control signals that enter the handshake FSMs.

The CDC logic works with any clock ratio. Altera tests the CDC logic extensively on a variety of system architectures, both in simulation and in hardware, to ensure that the logic functions correctly.

The typical sequence of events for a transfer across the CDC logic is described as follows:

1. Master asserts address, data, and control signals.
2. The master handshake FSM captures the control signals, and immediately forces the master to wait.

The FSM uses only the control signals, not address and data. For example, the master simply holds the address signal constant until the slave side has safely captured it.

3. Master handshake FSM initiates a transfer request to the slave handshake FSM.
4. The transfer request is synchronized to the slave clock domain.
5. The slave handshake FSM processes the request, performing the requested transfer with the slave.
6. When the slave transfer completes, the slave handshake FSM sends an acknowledge back to the master handshake FSM.
7. The acknowledge is synchronized back to the master clock domain.
8. The master handshake FSM completes the transaction by releasing the master from the wait condition.

Transfers proceed as normal on the slave and the master side, without a special protocol to handle crossing clock domains. From the perspective of a slave, there is nothing different about a transfer initiated by a master in a different clock domain. From the perspective of a master, a transfer across clock domains simply requires extra clock cycles. Similar to other transfer delay cases (for example, arbitration delay or wait states on the slave side), the system interconnect fabric simply forces the master to wait until the transfer terminates. As a result, pipeline master ports do not benefit from pipelining when performing transfers to a different clock domain.

Location of Clock Domain Adapter

You can use the clock crossing bridge described in the following paragraphs for higher throughput clock crossing, at the expense of memory resources.

SOPC Builder automatically determines where to insert the CDC logic, based on the system contents and the connections between components. SOPC Builder places CDC logic to maintain the highest transfer rate for all components. SOPC Builder evaluates the need for CDC logic for each master and slave pair independently, and generates CDC logic wherever necessary.

Duration of Transfers Crossing Clock Domains

CDC logic extends the duration of master transfers across clock domain boundaries. In the worst case which is for reads, each transfer is extended by five master clock cycles and five slave clock cycles. Assuming the default value of 2 for the **Master domain synchronizer length** and the **Slave domain synchronizer length**, the components of this delay are the following:

- Four additional master clock cycles, due to the master-side clock synchronizer
- Four additional slave clock cycles, due to the slave-side clock synchronizer
- One additional clock in each direction, due to potential metastable events as the control signals cross clock domains

Systems that require a higher performance clock should use the Avalon-MM clock crossing bridge instead of the automatically inserted CDC logic. The clock crossing bridge includes a buffering mechanism, so that multiple reads and writes can be pipelined. After paying the initial penalty for the first read or write, there is no additional latency penalty for pending reads and writes, increasing throughput by up to four times, at the expense of added logic resources.

For more information, refer to the *System Interconnect Fabric for Streaming Interfaces* chapter in volume 4 of the *Quartus II Handbook* and *Avalon Memory-Mapped Design Optimizations* in the *Embedded Design Handbook.*

Implementing Multiple Clock Domains in SOPC Builder

You specify the clock domains used by your system on the **System Contents** tab of SOPC Builder. You define the input clocks to the system with the **Clock Settings** table. Clock sources can be driven by external input signals to the SOPC Builder system or by PLLs inside the SOPC Builder system. Clock domains are differentiated based on the name of the clock. You may create multiple asynchronous clocks with the same frequency.

To specify which clock drives which components you must display the **Clock** column in the **System Contents** tab. By default, clock names are not displayed. To display clock names in the **Module Name** column and the clocks in the **Clock** column in the **System Contents** tab, right-click in the **Module Name** column and click **Show All**. To connect a clock to follow these steps.

1. Click in the **Clock** column next to the clock port. A list of available clock signals appears.
2. Select the appropriate signal from the list of available clocks. Figure 11–13 illustrates this step.

Figure 11–13. Assigning Clocks to Components

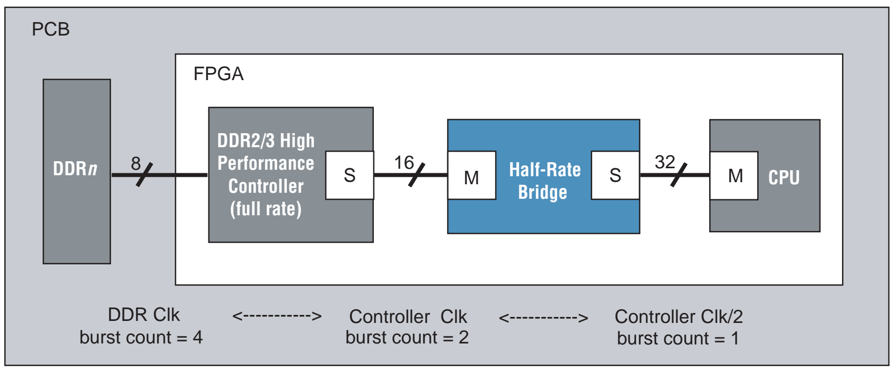
Avalon-MM DDR Memory Half-Rate Bridge

The Avalon Memory-Mapped (MM) Half-Rate Bridge core is a special-purpose clock-crossing bridge intended for CPUs that require low-latency access to high-speed memory. The core works under the assumption that the memory clock is twice the frequency of the CPU clock, with zero phase shift between the two. It allows high speed memory to run at full rate while providing low-latency interface for a CPU to access it by using lightweight logic that translates one single-word request into a two-word burst to a memory running at twice the clock frequency and half the width. For systems with a 8-bit DDR interface, using the Half-Rate DDR Bridge in conjunction with a DDR SDRAM high-performance memory controller creates a datapath that matches the throughput of the DDR memory to the CPU. This half-rate bridge provides the same functionality as the clock crossing bridge, but with significantly lower latency—2 cycles instead of 12.

The core's master interface is designed to be connected to a high-speed DDR SDRAM controller and thus only supports bursting. Because the slave interface is designed to receive single-word requests, it does not support bursting. Figure 11–14 shows a system including an 8-bit DDR memory, a high-performance memory controller, the Half-Rate DDR Bridge, and a CPU.

Figure 11–14. SOPC Builder Memory System Using a DDR Memory Half-Rate Bridge



The Avalon-MM DDR Memory Half-Rate Bridge core has the following features and requirements:

- SOPC Builder ready with TimeQuest Timing Analyzer constraints

© March 2009 Altera Corporation

- Requires master clock and slave clock to be synchronous
- Handles different bus sizes between CPU and memory
- Requires the frequency of the master clock to be double of the slave clock
- Has configurable address and data port widths in the master interface

Resource Usage and Performance

This section lists the resource usage and performance data for supported devices when operating the Half-Rate Bridge with a full-rate DDR SDRAM high-performance memory controller.

Using the Half-Rate Bridge with a full-rate DDR SDRAM high-performance memory controller results an average of 48% performance improvement over a system using a half-rate DDR SDRAM high-performance memory controller in a series of embedded applications. The performance improvement is 62.2% based on the Dhrystone benchmark, and 87.7% when accessing memory bypassing the cache. For memory systems that use the Half-Rate bridge in conjunction with DDR2/3 High Performance Controller, the data throughput is the same on the Half-Rate Bridge master and slave interfaces. The decrease in memory latency on the Half-Rate Bridge slave interface results in higher performance for the processor.

Table 11–2 shows the resource usage for Stratix® II and Stratix III devices.

Table 11–2. Resource Utilization Data for Stratix Devices

Device Family	Combinational ALUTs	ALMs	Logic Register	Memory M512/M4K/ M-RAM

Functional Description

The Avalon MM DDR Memory Half Rate Bridge works under two constraints:

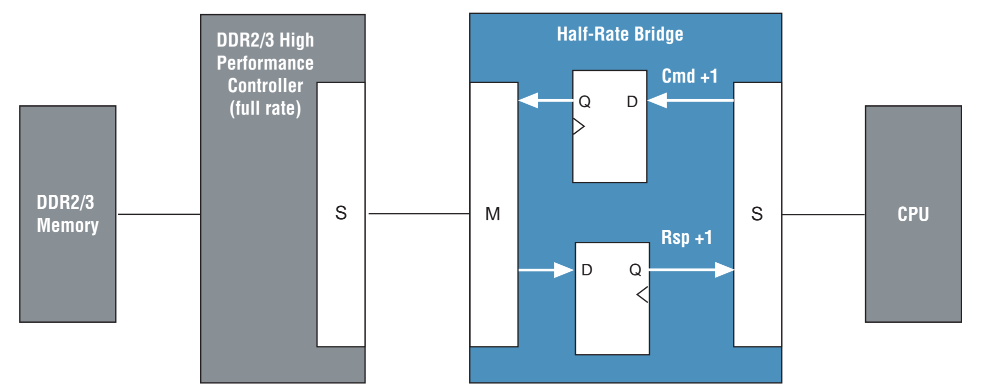
- Its memory-side master has a clock frequency that is synchronous (zero phase shift) to, and twice the frequency of, the CPU-side slave.
- Its memory-side master is half as wide as its CPU-side slave.

The bridge leverages these two constraints to provide lightweight, low-latency clock-crossing logic between the CPU and the memory. These constraints are in contrast with the Avalon-MM Clock-Crossing Bridge, which makes no assumptions about the frequency/phase relationship between the master- and slave-side clocks, and provides higher-latency logic that fully-synchronizes all signals that pass between the two domains.

The Avalon MM DDR Memory Half-Rate Bridge has an Avalon-MM slave interface that accepts single-word (non-bursting) transactions. When the slave interface receives a transaction from a connected CPU, it issues a two-word burst transaction on its master interface (which is half as wide and twice as fast). If the transaction is a read request, the bridge's master interface waits for the slave's two-word response, concatenates the two words, and presents them as a single readdata word on its slave interface to the CPU. Every time the data width is halved, the clock rate is doubled. As a result, the data throughput is matched between the CPU and the off-chip memory device.

Figure 11–15 shows the latency in the Avalon-MM Half-Rate Bridge core. The core adds two cycles of latency in the slave clock domain for read transactions. The first cycle is introduced during the command phase of the transaction and the second cycle, during the response phase of the transaction. The total latency is 2+<*x*>, where <*x*> refers to the latency of the DDR SDRAM high-performance memory controller. Using the clock crossing bridge for this same purpose would impose approximately 12 cycles of additional latency.

Figure 11–15. Avalon-MM DDR Memory Half-Rate Bridge Block Diagram



Instantiating the Core in SOPC Builder

Use the MegaWizard Plug-In Manager for the Avalon-MM Half-Rate Bridge core in SOPC Builder to specify the core's configuration. Table 11–4 describes the parameters that can be configured for the Avalon-MM Half-Rate Bridge core.

Table 11–4. Configurable Parameters for Avalon-MM DDR Memory Half-Rate Bridge Core

Parameters	Value	Description
Data Width	8, 16, 32, 64, 128, 256, 512	The width of the data signal in the master interface.
Address Width	1 - 32	The width of the address signal in the master interface.

Table 11–5 describes the parameters that are derived based on the **Data Width** and **Address Width** settings for the Avalon-MM Half-Rate Bridge core.

Table 11–5. Derived Parameters for Avalon-MM DDR Memory Half-Rate Bridge Core

Parameter	Description
Master interface's Byte Enable Width	The width of the byte-enable signal in the master interface.
Slave interface's Data Width	The width of the data signal in the slave interface.
Slave interface's Address Width	The width of the address signal in the slave interface.
Slave interface's Byte Enable Width	The width of the byte-enable signal in the slave interface.

Example System

The following example provides high-level steps showing how the Avalon-MM DDR Memory Half-Rate Bridge core is connected in a system. This example assumes that you are familiar with the SOPC Builder GUI.

For a quick introduction to this tool, read of the one-hour online course, *Using SOPC Builder*.

1. Add a **Nios II Processor** to the system.
2. Add a **DDR2 SDRAM High-Performance Controller** and configure it to **full-rate** mode.
3. Add **Avalon-MM DDR Memory Half-Rate Bridge** to the system.
4. Configure the parameters of the Avalon-MM DDR Memory Half-Rate Bridge based on the memory controller. For example, for a 32 MByte DDR memory controller in full rate mode with 8 DQ pins (see Figure 11–14), the parameters should be set as the following:
   - **Data Width** = 16

     For a memory controller that has 8 DQ pins, its local interface width is 16 bits. The local interface width and the data width must be the same, therefore data width is set to 16 bits.
   - **Address Width** = 25

     For a memory capacity of 32 MBytes, the byte address is 25 bits. Because the master address of the bridge is byte aligned, the address width is set to 25 bits.
5. Connect `altmemddr_auxhalf` to the slave clock interface (`clk_s1`) of the Half-Rate Bridge.
6. Connect `altmemddr_sysclk` to the master clock interface (`clk_m1`) of the Half-Rate Bridge.
7. Remove all connections between Nios II processor and the memory controller, if there are any.
8. Connect the master interface (`m1`) of the Avalon-MM DDR Memory Half-Rate Bridge to the memory controller slave interface.

9. Connect the slave interface (`s1`) of the Avalon-MM DDR Memory Half-Rate Bridge to the Nios II processor `data_master` interface.
10. Connect `altmemddr_auxhalf` to Nios II processor clock interface.

Device Support

Altera device support for the bridge components is listed in Table 11–6.

Table 11–6. Device Family Support

Device Family	Avalon-MM Pipeline Bridge Support	Avalon-MM Clock-Crossing Bridge Support
Arria® GX	Full	Full
Arria II GX	Full	Full
Stratix®	Full	Full
Stratix II	Full	Full
Stratix II GX	Full	Full
Stratix III	Full	Full
Stratix IV	Full	Full
Cyclone®	Full	Full
Cyclone II	Full	Full
Cyclone III	Full	Full
Hardcopy®	Full	Full
HardCopy II	Full	Full
HardCopy III	Full	Full
MAX®	Full	No support
MAX II	Full	No support

Hardware Simulation Considerations

The bridge components do not provide a simulation testbench for simulating a stand-alone instance of the component. However, you can use the standard SOPC Builder simulation flow to simulate the component design files inside an SOPC Builder system.

Software Programming Model

The bridge components do not have any user-visible control or status registers. Therefore, software cannot control or configure any aspect of the bridges during run-time. The bridges cannot generate interrupts.

Document Revision History

Table 11–7 shows the revision history for this chapter.

Table 11–7. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009, v9.0.0	■ Added information for synchronization when crossing clock domains.	New information to allow user control of metastability.
November 2008 v8.1	■ Clarified connection of clock signals. ■ Added section describing half-rate bridge. ■ Changed page size to 8.5 x 11 inches.	—
May 2008 v8.0	■ Chapter renumbered from 10 to 11. ■ Corrected Figure 11–4 to show correct connectivity between masters and bridges. Show JTAG debug modules for each CPU behind pipeline bridge. ■ Deleted references to Avalon Memory-Mapped and Streaming Interface Specifications and replaced with new Avalon Interface Specifications. ■ Moved clock crossing bridge section from Chapter 2 to this chapter. ■ Added note after Figure 10-4.	—

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

12. Avalon Streaming Interconnect Components

QII54021-9.0.0

Introduction to Interconnect Components

Avalon® Streaming (Avalon-ST) interconnect components facilitate the design of high-speed, low-latency datapaths for the system-on-a-programmable-chip (SOPC) environment. Interconnect components in SOPC Builder act as a part of the system interconnect fabric. They are not end points, but adapters that allow you to connect different, but compatible, streaming interfaces. You use Avalon-ST interconnect components to connect cores that send and receive high-bandwidth data, including multiplexed streams, packets, cells, time-division multiplexed (TDM) frames, and digital signal processor (DSP) data.

The interconnect components that you add to an SOPC Builder system insert logic between a source and sink interface, enabling that interface to operate correctly. This chapter describes four Avalon-ST interconnect components, also called adapters:

- "Timing Adapter" on page 12–3—adapts between sinks and sources that have different characteristics, such as ready latencies.
- "Data Format Adapter" on page 12–6—adapts source and sink interfaces that have different data widths.
- "Channel Adapter" on page 12–8—adapts source and sink interfaces that have different settings for the `channel` signal.
- "Error Adapter" on page 12–9—ensures that per-bit error information recorded at the source is correctly transferred to the sink

All of these interconnect components adapt initially incompatible Avalon-ST source and sink interfaces so that they function correctly, facilitating the development of high-speed, low-latency datapaths.

Interconnect Component Usage

Interconnect components can adapt the data or control signals of the Avalon-ST interface. Typical adaptations to control signals include:

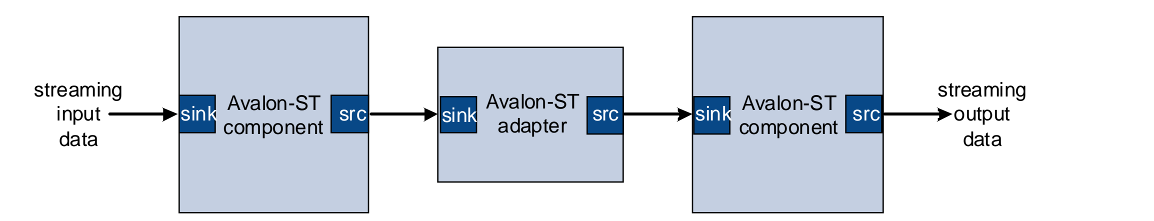
- Adding pipeline stages to adjust the timing of the `ready` signal
- Tying signals that are not used by either the source or sink to 0 or 1

Typical adaptations to data signals include:

- Changing the number of symbols (words) that are driven per cycle
- Changing the number of channels driven

When the interconnect component adapts the data interface, it has one Avalon-ST sink interface and one Avalon-ST source interface, as shown in Figure 12–1. You configure the adapter components manually, using SOPC Builder. In contrast to the Avalon-MM interface, which allows you to create various topologies with a number of different master and slave components, you always use the Avalon-ST interconnect components to adapt point-to-point connections between streaming cores.

Figure 12–1. Example of an Avalon-ST Interconnect Component in an SOPC Builder System

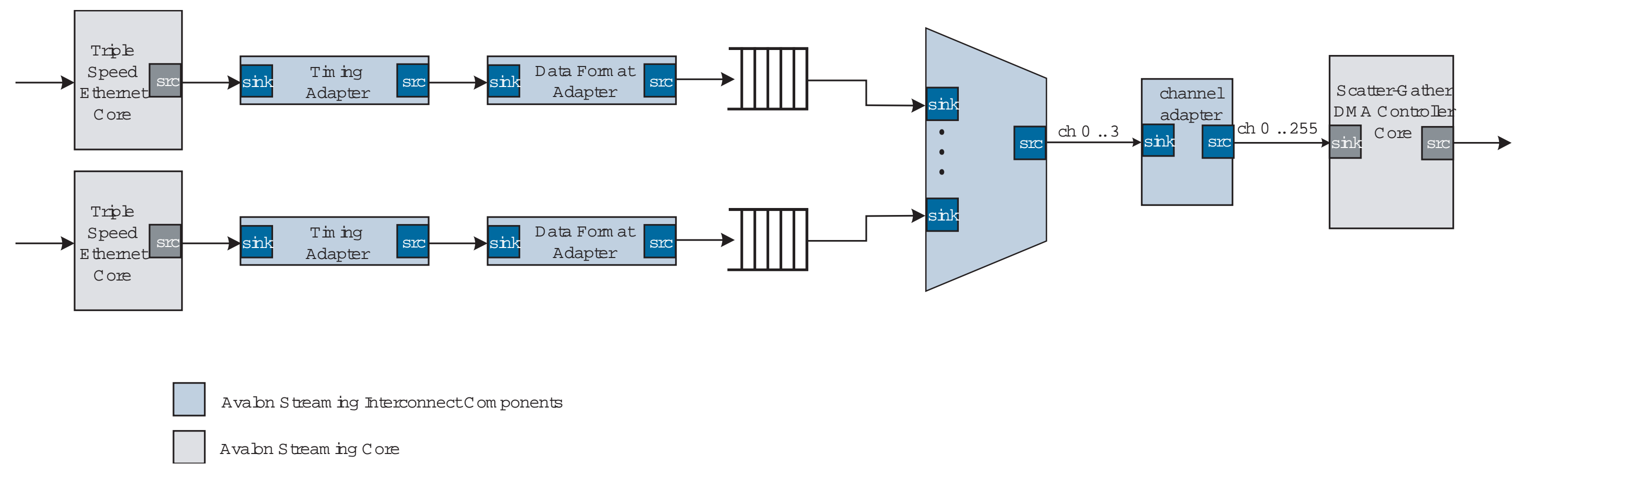


For details about the system interconnect fabric, refer to the *System Interconnect Fabric for Streaming Interfaces* chapter in volume 4 of the *Quartus II Handbook*. For details about the Avalon-ST interface protocol, refer to the *Avalon Interface Specifications*.

Figure 12–2 illustrates a datapath that connects a Triple Speed Ethernet MegaCore function to a Scatter-Gather DMA controller core using a timing adapter, data format adapter, and channel adapter so that the cores can interoperate.

Address Mapping

Figure 12–2. Avalon-ST Datapath Constructed Using Avalon Streaming Interconnect Components



The control and status signals for the components containing source or sink interfaces can be mapped to a slave interface which is then accessible in the global Avalon address space.

Timing Adapter

The timing adapter has two functions:

- It adapts source and sink interfaces that support the `ready` signal and those that do not.
- It adapts source and sink interfaces that support the `valid` signal and those that do not.
- It adapts source and sink interfaces that have different ready latencies.

The timing adapter treats all signals other than the `ready` and `valid` signals as payload, and simply drives them from the source to the sink. Table 12–1 outlines the adaptations that the timing adapter provides.

Table 12–1. Timing Adapter

Condition	Adaptation
The source has `ready`, but the sink does not.	In this case, the source can respond to backpressure, but the sink never needs to apply it. The `ready` input to the source interface is connected directly to logical 1.
The source does not have `ready`, but the sink does.	The sink may apply backpressure, but the source is unable to respond to it. There is no logic that the adapter can insert that prevents data loss when the source asserts `valid` but the sink is not ready. The adapter provides simulation time error messages and an error indication if data is ever lost. The user is presented with a warning, and the connection is allowed.
The source and sink both support backpressure, but the sink's ready latency is greater than the source's.	The source responds to `ready` assertion or deassertion faster than the sink requires it. A number of pipeline stages equal to the difference in ready latency are inserted in the `ready` path from the sink back to the source, causing the source and the sink to see the same cycles as `ready` cycles.
The source and sink both support backpressure, but the sink's ready latency is less than the source's.	The source cannot respond to `ready` assertion or deassertion in time to satisfy the sink. A buffer whose depth is equal to the difference in ready latency is inserted to compensate for the source's inability to respond in time.

Resource Usage and Performance

Resource utilization for the timing adapter depends upon the function that it performs. Table 12–2 provides estimated resource utilization for seven different configurations of the timing adapter

Table 12–2. Timing Adapter Estimated Resource Usage and Performance

Input Ready Latency	Output Ready Latency	Stratix® II and Stratix II GX (Approximate LEs)			Cyclone® II		Stratix (Approximate LEs)		
		f_{MAX} (MHz)	ALM Count	Mem Bits	f_{MAX} (MHz)	Logic Cells	f_{MAX} (MHz)	Logic Cells	Mem Bits
1	2	500	2	0	420	2	422	1	0
1	3	500	2	0	420	3	422	2	0
1	4	500	4	0	420	4	422	3	0
1	0	500	21	80	420	183	422	20	80
2	1	456	21	80	401	188	317	21	80
3	1	456	21	80	401	188	317	21	80
4	1	456	21	80	401	188	317	21	80

Instantiating the Timing Adapter in SOPC Builder

You can use the Avalon-ST configuration wizard in SOPC Builder to specify the hardware features. Table 12–3 describes the options available on the **Parameter Settings** page of the configuration wizard

Table 12–3. Avalon-ST Timing Adapter Parameters

Input Interface Parameters	
Parameter	**Description**
Support Backpressure with the ready signal	Turn on this option to add the backpressure functionality to the interface.
Ready Latency	When the `ready` signal is used, the value for `ready_latency` indicates the number of cycles between when the `ready` signal is asserted and when valid data is driven.
Include valid signal	Turn this option on if the interface includes the `valid` signal. Turning this option off means that data being received is always valid.
Output Interface Parameters	
Support Backpressure with the ready signal	Turn on this option to add the backpressure functionality to the interface.
Ready Latency	When the `ready` signal is used, the value for `ready_latency` indicates the number of cycles between when the `ready` signal is asserted and when valid data is driven.
Include valid signal	Turn this option on if the interface includes the `valid` signal. Turning this option off means that data driven is always valid.
Common to Input and Output Interfaces	
Channel Signal Width (bits)	Type the width of the `channel` signal. A channel width of 4 allows up to 16 channels. The maximum width of the `channel` signal is eight bits. Set to 0 if channels are not used.
Max Channel	Type the maximum number of channels that the interface supports. Valid values are 0–255.
Data Bits Per Symbol	Type the number of bits per symbol.
Data Symbols Per Beat	Type the number of symbols per active transfer.
Include Packet Support	Turn this option on if the interfaces supports a packet protocol, including the `startofpacket`, `endofpacket` and `empty` signals.
Include Empty Signal	You can use this signal to specify the number of empty symbols in the cycle that includes the `endofpacket` signal. This signal is not necessary if the number of symbols per beat is 1.
Error Signal Width (Bits)	Type the width of the error signal. Valid values are 0–31 bits. Type `0` if the error signal is not used.
Error Signal Description	Type the description for each of the error bits. Separate the description fields by semicolons. For a connection to be made, the description of the error bits in the source and sink must match. Refer to “Error Adapter” on page 12–9 for the adaptations that can be made when the bits do not match.

Data Format Adapter

The data format adapter handles interfaces that have different definitions for the data signal. One of the more common adaptations that this component performs is data width adaptation, such as converting a data interface that drives two, 8-bit symbols per beat to an interface that drives four, 8-bit symbols per beat. The available data format adaptations are listed in Table 12–4.

Table 12–4. Data Format Adapter

Condition	Description of Adapter Logic
The source and sink's bits per symbol are different.	The connection cannot be made.
The source and sink have a different number of symbols per beat.	The adapter converts from the source's width to the sink's width. If the adaptation is from a wider to a narrower interface, a beat of data at the input corresponds to multiple beats of data at the output. If the input `error` signal is asserted for a single beat, it is asserted on output for multiple beats. If the adaptation is from a narrow to a wider interface, multiple input beats are required to fill a single output beat, and the output `error` is the logical OR of the input `error` signal.

Resource Usage and Performance

Resource utilization for the data format adapter depends upon the function that it performs. Table 12–5 provides estimated resource utilization for numerous configurations of the data format adapter.

Table 12–5. Data Format Adapter Estimated Resource Usage and Performance, 8 Bits per Symbol (Part 1 of 2)

Input Symbols per Beat	Output Symbols per Beat	Number of Channels	Packet Support	Stratix II and Stratix II GX (Approximate LEs)			Cyclone II			Stratix (Approximate LEs)		
				f_{MAX} (MHz)	ALM Count	Memory Bits	f_{MAX} (MHz)	Logic Cells	Memory Bits	f_{MAX} (MHz)	Logic Cells	Memory Bits
1	2	1	y	500	96	0	391	93	0	375	105	0
4	1	1	y	459	106	0	311	97	0	306	76	0

4	16	36	n	227	255	105	391	93	0	146	491	105

Instantiating the Data Format Adapter in SOPC Builder

You can use the Avalon-ST configuration wizard in SOPC Builder to specify the hardware features. Table 12–6 describes the options available on the **Parameter Settings** page of the configuration wizard.

Table 12–6. Data Format Adapter Parameters

Input Interface Parameters	
Parameter	**Description**
Data Symbols Per Beat	Type the number of symbols transferred per active cycle.
Include the empty signal	Turn this option on if the cycle that includes the `endofpacket` signal can include empty symbols. This signal is not necessary if the number of symbols per beat is 1.
Output Interface Parameters	
Data Symbols Per Beat	Type the number of symbols transferred per active cycle.
Include the empty signal	Turn this option on if the cycle that includes the `endofpacket` signal can include empty symbols. This signal is not necessary if the number of symbols per beat is 1.
Common to Input & Output	
Channel Signal Width (bits)	Type the width of the `channel` signal. A channel width of 4 allows up to 16 channels. The maximum width of the channel signal is 8 bits. Type `0` if you do not need to send channel numbers.
Max Channel	Type the maximum number of channels that the interface supports. Valid values are 0–255.
Include Packet Support	Turn this option on if the interface supports a packet protocol, including the `startofpacket`, `endofpacket`, and `empty` signals.
Error Signal Width (Bits)	Type the width of the error signal. Valid values are 0–31 bits. Type `0` if the error signal is not used.
Error Signal Description	Type the description for each of the error bits. Separate the description fields by semicolons. For a connection to be made, the description of the error bits in the source and sink must match. Refer to "Error Adapter" on page 12–9 for the adaptations that can be made when the bits do not match.
Data Bits Per Symbol	Type the number of bits per symbol.

Channel Adapter

The channel adapter provides adaptations between interfaces that have different support for the `channel` signal or for the maximum number of channels supported. The adaptations are described in Table 12–7.

Table 12–7. Channel Adapter

Condition	Description of Adapter Logic
The source uses channels, but the sink does not.	You are given a warning at generation time. The adapter provides a simulation error and signals an error for data for any channel from the source other than 0.
The sink has channel, but the source does not.	You are given a warning, and the channel inputs to the sink are all tied to a logical 0.
The source and sink both support channels, and the source's maximum number of channels is less than the sink's.	The source's channel is connected to the sink's channel unchanged. If the sink's channel signal has more bits, the higher bits are tied to a logical 0.
The source and sink both support channels, but the source's maximum number of channels is greater than the sink's.	The source’s channel is connected to the sink’s channel unchanged. If the source’s channel signal has more bits, the higher bits are left unconnected. You are given a warning that channel information may be lost. An adapter provides a simulation error message and an error indication if the value of channel from the source is greater than the sink's maximum number of channels. In addition, the `valid` signal to the sink is deasserted so that the sink never sees data for channels that are out of range.

Resource Usage and Performance

The channel adapter typically uses fewer than 30 LEs. Its frequency is limited by the maximum frequency of the device you choose.

Instantiating the Channel Adapter in SOPC Builder

You can use the Avalon-ST configuration wizard in SOPC Builder to specify the hardware features. Table 12–8 describes the options available on the **Parameter Settings** page of the configuration wizard.

Table 12–8. Avalon-ST Channel Adapter Parameters (Part 1 of 2)

Parameter	Description
Input Interface Parameters	
Channel Signal Width (bits)	Type the width of the `channel` signal. A channel width of 4 allows up to 16 channels. The maximum width of the `channel` signal is eight bits. Set to 0 if channels are not used.
Max Channel	Type the maximum number of channels that the interface supports. Valid values are 0–255.
Output Interface Parameters	
Channel Signal Width (bits)	Type the width of the `channel` signal. A channel width of 4 allows up to 16 channels. The maximum width of the `channel` signal is eight bits. Set to 0 if channels are not used.
Max Channel	Type the maximum number of channels that the interface supports. Valid values are 0–255.

Table 12–8. Avalon-ST Channel Adapter Parameters (Part 2 of 2)

Parameter	Description
Common to Input and Output Interfaces	
Support Backpressure with the ready signal	Turn on this option to add the backpressure functionality to the interface.
Ready Latency	When the `ready` signal is used, the value for `ready_latency` indicates the number of cycles between when the `ready` signal is asserted and when valid data is driven.
Data Bits Per Symbol	Type the number of bits per symbol.
Data Symbols Per Beat	Type the number of symbols per active transfer.
Include Packet Support	Turn this option on if the interfaces supports a packet protocol, including the `startofpacket`, `endofpacket` and `empty` signals.
Include Empty Signal	You can use this signal to specify the number of empty symbols in the cycle that includes the `endofpacket` signal. This signal is not necessary if the number of symbols per beat is 1.
Error Signal Width (bits)	Type the width of the error signal. Valid values are 0–31 bits. Type 0 if you do not need to send error values.
Error Signal Description	Type the description for each of the error bits. Separate the description fields by semicolons. For a connection to be made, the description of the error bits in the source and sink must match. Refer to "Error Adapter" on page 12–9 for the adaptations that can be made when the bits do not match.

Error Adapter

The error adapter ensures that per-bit error information provided by source interfaces is correctly connected to the sink interface's input error signal. The adaptations are described in Table 12–9.

Instantiating the Error Adapter in SOPC Builder

You can use the Avalon-ST configuration wizard in SOPC Builder to specify the hardware features. Table 12–9 describes the options available on the **Parameter Settings** page of the configuration wizard.

Table 12–9. Avalon-ST Error Adapter Parameters (Part 1 of 2)

Parameter	Description
Input Interface Parameters	
Error Signal Width (bits)	Type the width of the error signal. Valid values are 0–31 bits. Type 0 if the error signal is not used.
Error Signal Description	Type the description for each of the error bits. Separate the description fields by semicolons. For a connection to be made, the description of the error bits in the source and sink must match. Refer to "Error Adapter" on page 12–9 for the adaptations that can be made when the bits do not match.
Output Interface Parameters	
Error Signal Width (bits)	Type the width of the error signal. Valid values are 0–31 bits. Type 0 if you do not need to send error values.

Table 12–9. Avalon-ST Error Adapter Parameters (Part 2 of 2)

Parameter	Description
Error Signal Description	Type the description for each of the error bits. Separate the description fields by semicolons. For a connection to be made, the description of the error bits in the source and sink must match. Refer to "Error Adapter" on page 12–9 for the adaptations that can be made when the bits do not match.
Common to Input and Output Interfaces	
Support Backpressure with the ready signal	Turn on this option to add the backpressure functionality to the interface.
Ready Latency	When the `ready` signal is used, the value for `ready_latency` indicates the number of cycles between when the ready signal is asserted and when valid data is driven.
Channel Signal Width (bits)	Type the width of the `channel` signal. A channel width of 4 allows up to 16 channels. The maximum width of the `channel` signal is eight bits. Set to 0 if channels are not used.
Max Channel	Type the maximum number of channels that the interface supports. Valid values are 0–255.
Data Bits Per Symbol	Type the number of bits per symbol.
Data Symbols Per Beat	Type the number of symbols per active transfer.
Include Packet Support	Turn this option on if the interfaces supports a packet protocol, including the `startofpacket`, `endofpacket` and `empty` signals.
Include Empty Signal	Turn this option on if the cycle that includes the `endofpacket` signal can include empty symbols. This signal is not necessary if the number of symbols per beat is 1.

Installation and Licensing

The Avalon-ST interconnect components are included in the Altera MegaCore® IP Library, which is part of the Quartus II software installation. After you install the MegaCore IP Library, SOPC Builder recognizes these components and can instantiate them into a system.

You can use the Avalon-ST components without a license in any design that targets an Altera device.

Hardware Simulation Considerations

The Avalon-ST interconnect components do not provide a simulation testbench for simulating a stand-alone instance of the component. However, you can use the standard SOPC Builder simulation flow to simulate the component design files inside an SOPC Builder system.

Software Programming Model

The Avalon-ST interconnect components do not have any control or status registers that you can see. Therefore, software cannot control or configure any aspect of the interconnect components at run-time. These components cannot generate interrupts.

Additional Information

About this Handbook

This handbook provides comprehensive information about the Altera® Quartus® II design software, version 9.0.

How to Contact Altera

For the most up-to-date information about Altera products, see the following table.

Contact *(Note 1)*	Contact Method	Address
Technical support	Website	www.altera.com/support
Technical training	Website	www.altera.com/training
	Email	custrain@altera.com
Altera literature services	Email	literature@altera.com
Non-technical support (General)	Email	nacomp@altera.com
(Software Licensing)	Email	authorization@altera.com

Note:

(1) You can also contact your local Altera sales office or sales representative.

Third-Party Software Product Information

Third-party software products described in this handbook are not Altera products, are licensed by Altera from third parties, and are subject to change without notice. Updates to these third-party software products may not be concurrent with Quartus II software releases. Altera has assumed responsibility for the selection of such third-party software products and its use in the Quartus II 9.0 software release. To the extent that the software products described in this handbook are derived from third-party software, no third party warrants the software, assumes any liability regarding use of the software, or undertakes to furnish you any support or information relating to the software. EXCEPT AS EXPRESSLY SET FORTH IN THE APPLICABLE ALTERA PROGRAM LICENSE SUBSCRIPTION AGREEMENT UNDER WHICH THIS SOFTWARE WAS PROVDED TO YOU, ALTERA AND THIRD-PARTY LICENSORS DISCLAIM ALL WARRANTIES WITH RESPECT TO THE USE OF SUCH THIRD-PARTY SOFTWARE CODE OR DOCUMENTATION IN THE SOFTWARE, INCLUDING, WITHOUT LIMITATION, ANY WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, TITLE, AND NONINFRINGEMENT. For more information, including the latest available version of specific third-party software products, refer to the documentation for the software in question.

Typographic Conventions

The following table shows the typographic conventions that this document uses.

Visual Cue	Meaning
Bold Type with Initial Capital Letters	Command names, dialog box titles, checkbox options, and dialog box options are shown in bold, initial capital letters. Example: **Save As** dialog box.
bold type	External timing parameters, directory names, project names, disk drive names, file names, file name extensions, and software utility names are shown in bold type. Examples: $\mathbf{f_{MAX}}$, **\qdesigns** directory, **d:** drive, **chiptrip.gdf** file.
Italic Type with Initial Capital Letters	Document titles are shown in italic type with initial capital letters. Example: *AN 75: High-Speed Board Design.*
Italic type	Internal timing parameters and variables are shown in italic type. Examples: t_{PIA}, $n + 1$. Variable names are enclosed in angle brackets (< >) and shown in italic type. Example: <*file name*>, <*project name*>**.pof** file.
Initial Capital Letters	Keyboard keys and menu names are shown with initial capital letters. Examples: Delete key, the Options menu.
"Subheading Title"	References to sections within a document and titles of on-line help topics are shown in quotation marks. Example: "Typographic Conventions."
`Courier type`	Signal and port names are shown in lowercase Courier type. Examples: `data1`, `tdi`, `input`. Active-low signals are denoted by suffix `n`, e.g., `resetn`. Anything that must be typed exactly as it appears is shown in Courier type. For example: `c:\qdesigns\tutorial\chiptrip.gdf`. Also, sections of an actual file, such as a Report File, references to parts of files (e.g., the AHDL keyword `SUBDESIGN`), as well as logic function names (e.g., `TRI`) are shown in Courier.
1., 2., 3., and a., b., c., etc.	Numbered steps are used in a list of items when the sequence of the items is important, such as the steps listed in a procedure.
■ ■	Bullets are used in a list of items when the sequence of the items is not important.
✓	The checkmark indicates a procedure that consists of one step only.
☞	The hand points to information that requires special attention.
CAUTION	A caution calls attention to a condition or possible situation that can damage or destroy the product or the user's work.
WARNING	A warning calls attention to a condition or possible situation that can cause injury to the user.
↵	The angled arrow indicates you should press the Enter key.
👣	The feet direct you to more information on a particular topic.

Chapter 3. Common Flash Interface Controller Core

Core Overview . . . 3-1
Functional Description . . . 3-2
Device and Tools Support . . . 3-2
Instantiating the Core in SOPC Builder . . . 3-2
Attributes Page . . . 3-3
Presets Settings . . . 3-3
Size Settings . . . 3-3
Timing Page . . . 3-3
Software Programming Model . . . 3-4
HAL System Library Support . . . 3-4
Limitations . . . 3-4
Software Files . . . 3-4
Referenced Documents . . . 3-5
Document Revision History . . . 3-5

Chapter 4. EPCS Device Controller Core

Core Overview . . . 4-1
Functional Description . . . 4-1
Avalon-MM Slave Interface and Registers . . . 4-3
Device and Tools Support . . . 4-4
Instantiating the Core in SOPC Builder . . . 4-4
Software Programming Model . . . 4-4
HAL System Library Support . . . 4-4
Software Files . . . 4-4
Referenced Documents . . . 4-5
Document Revision History . . . 4-5

Chapter 5. JTAG UART Core

Core Overview . . . 5-1
Functional Description . . . 5-2
Avalon Slave Interface and Registers . . . 5-2
Read and Write FIFOs . . . 5-2
JTAG Interface . . . 5-3
Host-Target Connection . . . 5-3
Device and Tools Support . . . 5-4
Instantiating the Core in SOPC Builder . . . 5-4
Configuration Page . . . 5-4
Write FIFO Settings . . . 5-4
Read FIFO Settings . . . 5-5
Simulation Settings . . . 5-5
Simulated Input Character Stream . . . 5-5
Prepare Interactive Windows . . . 5-5
Hardware Simulation Considerations . . . 5-6
Software Programming Model . . . 5-6
HAL System Library Support . . . 5-6
Driver Options: Fast vs. Small Implementations . . . 5-8
ioctl() Operations . . . 5-8
Software Files . . . 5-9
Accessing the JTAG UART Core via a Host PC . . . 5-9

Register Map 5-9
Data Register 5-10
Control Register 5-10
Interrupt Behavior 5-11
Referenced Documents 5-12
Document Revision History 5-12

Chapter 6. UART Core
Core Overview 6-1
Functional Description 6-1
Avalon-MM Slave Interface and Registers 6-2
RS-232 Interface 6-2
Transmitter Logic 6-2
Receiver Logic 6-3
Baud Rate Generation 6-3
Device Support 6-3
Instantiating the Core in SOPC Builder 6-3
Configuration Settings 6-4
Baud Rate Options 6-4
Data Bits, Stop Bits, Parity 6-5
Synchronizer Stages 6-5
Flow Control 6-5
Streaming Data (DMA) Control 6-6
Simulation Settings 6-6
Simulated RXD-Input Character Stream 6-7
Prepare Interactive Windows 6-7
Simulated Transmitter Baud Rate 6-7
Simulation Considerations 6-7
Software Programming Model 6-8
HAL System Library Support 6-8
Driver Options: Fast Versus Small Implementations 6-9
ioctl() Operations 6-10
Limitations 6-10
Software Files 6-10
Register Map 6-11
rxdata Register 6-11
txdata Register 6-12
status Register 6-12
control Register 6-14
divisor Register (Optional) 6-14
endofpacket Register (Optional) 6-15
Interrupt Behavior 6-15
Referenced Documents 6-15
Document Revision History 6-16

Chapter 7. SPI Core
Core Overview 7-1
Functional Description 7-1
Example Configurations 7-2
Transmitter Logic 7-3
Receiver Logic 7-3
Master and Slave Modes 7-3
Master Mode Operation 7-3

Slave Mode Operation 7-4
Multi-Slave Environments 7-5
Avalon-MM Interface 7-5
Instantiating the SPI Core in SOPC Builder 7-5
Master/Slave Settings 7-5
Number of Select (SS_n) Signals 7-5
SPI Clock (sclk) Rate 7-5
Specify Delay 7-6
Data Register Settings 7-6
Timing Settings 7-7
Device Support 7-8
Software Programming Model 7-8
Hardware Access Routines 7-8
alt_avalon_spi_command() 7-9
Software Files 7-9
Register Map 7-9
rxdata Register 7-10
txdata Register 7-10
status Register 7-11
control Register 7-12
slaveselect Register 7-12
Referenced Documents 7-12
Document Revision History 7-13

Chapter 8. Optrex 16207 LCD Controller Core

Core Overview 8-1
Functional Description 8-1
Device and Tools Support 8-2
Instantiating the Core in SOPC Builder 8-2
Software Programming Model 8-2
HAL System Library Support 8-2
Displaying Characters on the LCD 8-3
Software Files 8-3
Register Map 8-4
Interrupt Behavior 8-4
Referenced Documents 8-4
Document Revision History 8-4

Chapter 9. PIO Core

Core Overview 9-1
Functional Description 9-1
Data Input and Output 9-2
Edge Capture 9-2
IRQ Generation 9-3
Example Configurations 9-3
Avalon-MM Interface 9-3
Instantiating the PIO Core in SOPC Builder 9-4
Basic Settings 9-4
Width 9-4
Direction 9-4
Output Port Reset Value 9-4
Output Register 9-4
Input Options 9-4

Edge Capture Register 9-4
Interrupt 9-5
Simulation 9-5
Device Support 9-5
Software Programming Model 9-5
Software Files 9-5
Register Map 9-6
data Register 9-6
direction Register 9-6
interruptmask Register 9-7
edgecapture Register 9-7
outset and outclear Registers 9-7
Interrupt Behavior 9-7
Software Files 9-7
Document Revision History 9-8

Chapter 10. Avalon-ST JTAG Interface Core
Core Overview 10-1
Functional Description 10-1
Interfaces 10-2
Special characters 10-2
Operation 10-2
Instantiating the Core in SOPC Builder 10-3
Device Support 10-3
Referenced Documents 10-3
Document Revision History 10-3

Chapter 11. Avalon-ST Serial Peripheral Interface Core
Core Overview 11-1
Functional Description 11-1
Interfaces 11-2
Operation 11-2
Timing 11-3
Limitations 11-3
Instantiating the Core in SOPC Builder 11-3
Device Support 11-3
Referenced Documents 11-4
Document Revision History 11-4

Chapter 12. SPI Slave/JTAG to Avalon Master Bridge Cores
Core Overview 12-1
Functional Description 12-1
Instantiating the Core in SOPC Builder 12-3
Device Support 12-3
Referenced Documents 12-4
Document Revision History 12-4

Chapter 13. PCI Lite Core
Core Overview 13-1
Performance and Resource Utilization 13-1
Functional Description 13-2
PCI-Avalon Bridge Blocks 13-2
Avalon-MM Ports 13-3

Master and Target Performance . . . 13-5
Master Performance . . . 13-5
Target Performance . . . 13-5
PCI-to-Avalon Address Translation . . . 13-6
Avalon-to-PCI Address Translation . . . 13-6
Avalon-To-PCI Read and Write Operation . . . 13-8
Avalon-to-PCI Write Requests . . . 13-9
Avalon-to-PCI Read Requests . . . 13-9
Ordering of Requests . . . 13-10
PCI Interrupt . . . 13-10
Instantiating the Core in SOPC Builder . . . 13-11
PCI Timing Constraint Files . . . 13-12
Additional Tcl Option . . . 13-13
Device Support . . . 13-14
Simulation Considerations . . . 13-14
Features . . . 13-14
Master Transactor (mstr_tranx) . . . 13-14
TASKS Sections . . . 13-14
INITIALIZATION Section . . . 13-15
USER COMMANDS Section . . . 13-15
Simulation Flow . . . 13-15
Referenced Documents . . . 13-17
Document Revision History . . . 13-17

Section II. On-Chip Storage Peripherals

Chapter 14. Avalon-ST Single Clock and Dual Clock FIFO Cores

Core Overview . . . 14-1
Functional Description . . . 14-1
Interfaces . . . 14-2
Operations . . . 14-2
Instantiating the Core in SOPC Builder . . . 14-3
Device Support . . . 14-3
Software Programming Model . . . 14-4
HAL System Library Support . . . 14-4
Register Map . . . 14-4
Referenced Documents . . . 14-4
Document Revision History . . . 14-4

Chapter 15. On-Chip FIFO Memory Core

Core Overview . . . 15-1
Functional Description . . . 15-1
Avalon-MM Write Slave to Avalon-MM Read Slave . . . 15-2
Avalon-ST Sink to Avalon-ST Source . . . 15-2
Avalon-MM Write Slave to Avalon-ST Source . . . 15-3
Avalon-ST Sink to Avalon-MM Read Slave . . . 15-4
Status Interface . . . 15-5
Clocking Modes . . . 15-6
Device Support . . . 15-6
Instantiating the Core in SOPC Builder . . . 15-6
FIFO Settings . . . 15-6
Depth . . . 15-6
Clock Settings . . . 15-6

 © March 2009 Altera Corporation

Status Port 15-6

Chapter Revision Dates

The chapters in this book, *Quartus II Handbook Version 9.0 Volume 5: Embedded Peripherals*, were revised on the following dates. Where chapters or groups of chapters are available separately, part numbers are listed.

Chapter 1 SDRAM Controller Core
Revised: *March 2009*
Part Number: *NII51005-9.0.0*

Chapter 2 CompactFlash Core
Revised: *March 2009*
Part Number: *QII55005-9.0.0*

Chapter 3 Common Flash Interface Controller Core
Revised: *March 2009*
Part Number: *NII51013-9.0.0*

Chapter 4 EPCS Device Controller Core
Revised: *March 2009*
Part Number: *NII51012-9.0.0*

Chapter 5 JTAG UART Core
Revised: *March 2009*
Part Number: *NII51009-9.0.0*

Chapter 6 UART Core
Revised: *March 2009*
Part Number: *NII51010-9.0.0*

Chapter 7 SPI Core
Revised: *March 2009*
Part Number: *NII51011-9.0.0*

Chapter 8 Optrex 16207 LCD Controller Core

Section I. Off-Chip Interface Peripherals

This section describes the interfaces to off-chip devices provided for SOPC Builder systems.

This section includes the following chapters:

- Chapter 1, SDRAM Controller Core
- Chapter 2, CompactFlash Core
- Chapter 3, Common Flash Interface Controller Core
- Chapter 4, EPCS Device Controller Core
- Chapter 5, JTAG UART Core
- Chapter 6, UART Core
- Chapter 7, SPI Core
- Chapter 8, Optrex 16207 LCD Controller Core
- Chapter 9, PIO Core
- Chapter 10, Avalon-ST JTAG Interface Core
- Chapter 11, Avalon-ST Serial Peripheral Interface Core
- Chapter 12, SPI Slave/JTAG to Avalon Master Bridge Cores
- Chapter 13, PCI Lite Core

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

1. SDRAM Controller Core

NII51005-9.0.0

Core Overview

The SDRAM controller core with Avalon® interface provides an Avalon Memory-Mapped (Avalon-MM) interface to off-chip SDRAM. The SDRAM controller allows designers to create custom systems in an Altera® device that connect easily to SDRAM chips. The SDRAM controller supports standard SDRAM as described in the PC100 specification.

SDRAM is commonly used in cost-sensitive applications requiring large amounts of volatile memory. While SDRAM is relatively inexpensive, control logic is required to perform refresh operations, open-row management, and other delays and command sequences. The SDRAM controller connects to one or more SDRAM chips, and handles all SDRAM protocol requirements. Internal to the device, the core presents an Avalon-MM slave port that appears as linear memory (flat address space) to Avalon-MM master peripherals.

The core can access SDRAM subsystems with various data widths (8, 16, 32, or 64 bits), various memory sizes, and multiple chip selects. The Avalon-MM interface is latency-aware, allowing read transfers to be pipelined. The core can optionally share its address and data buses with other off-chip Avalon-MM tri-state devices. This feature is valuable in systems that have limited I/O pins, yet must connect to multiple memory chips in addition to SDRAM.

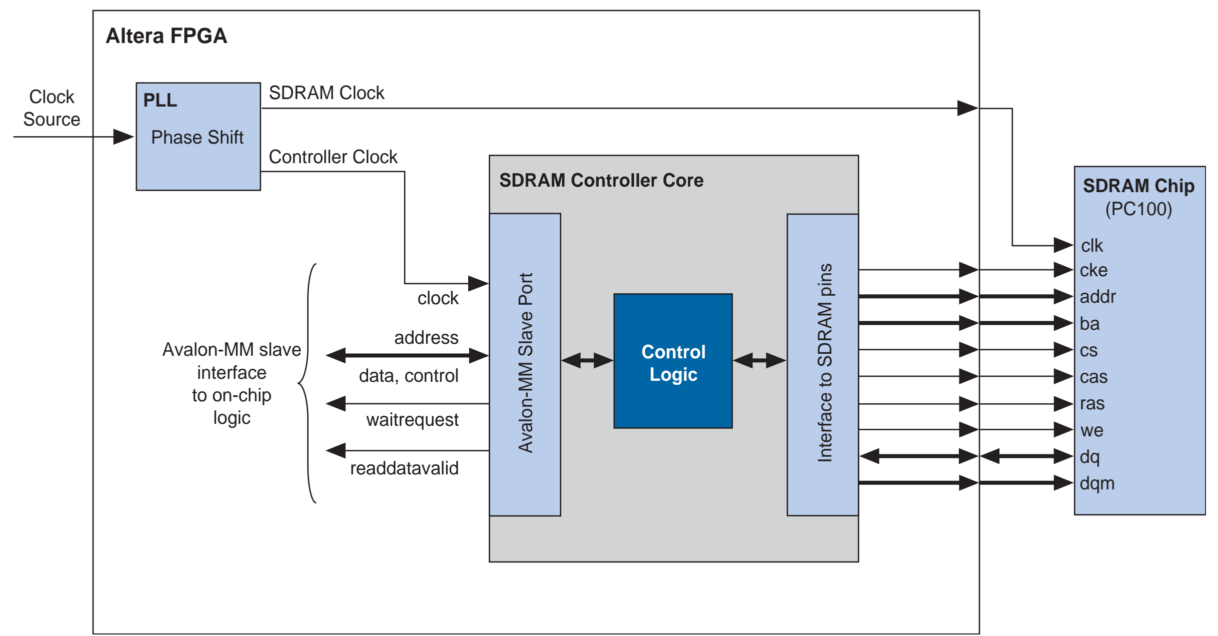
The SDRAM controller core with Avalon interface is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- "Functional Description" on page 1–2
- "Device Support" on page 1–5
- "Instantiating the Core in SOPC Builder" on page 1–5
- "Hardware Simulation Considerations" on page 1–7
- "Software Programming Model" on page 1–10
- "Clock, PLL and Timing Considerations" on page 1–10

Functional Description

Figure 1–1 shows a block diagram of the SDRAM controller core connected to an external SDRAM chip.

Figure 1–1. SDRAM Controller with Avalon Interface Block Diagram



The following sections describe the components of the SDRAM controller core in detail. All options are specified at system generation time, and cannot be changed at runtime.

Avalon-MM Interface

The Avalon-MM slave port is the user-visible part of the SDRAM controller core. The slave port presents a flat, contiguous memory space as large as the SDRAM chip(s). When accessing the slave port, the details of the PC100 SDRAM protocol are entirely transparent. The Avalon-MM interface behaves as a simple memory interface. There are no memory-mapped configuration registers.

The Avalon-MM slave port supports peripheral-controlled wait states for read and write transfers. The slave port stalls the transfer until it can present valid data. The slave port also supports read transfers with variable latency, enabling high-bandwidth, pipelined read transfers. When a master peripheral reads sequential addresses from the slave port, the first data returns after an initial period of latency. Subsequent reads can produce new data every clock cycle. However, data is not guaranteed to return every clock cycle, because the SDRAM controller must pause periodically to refresh the SDRAM.

For details about Avalon-MM transfer types, refer to the *Avalon Interface Specifications*.

Off-Chip SDRAM Interface

The interface to the external SDRAM chip presents the signals defined by the PC100 standard. These signals must be connected externally to the SDRAM chip(s) through I/O pins on the Altera device.

Signal Timing and Electrical Characteristics

The timing and sequencing of signals depends on the configuration of the core. The hardware designer configures the core to match the SDRAM chip chosen for the system. See "Instantiating the Core in SOPC Builder" on page 1–5 for details. The electrical characteristics of the device pins depend on both the target device family and the assignments made in the Quartus® II software. Some device families support a wider range of electrical standards, and therefore are capable of interfacing with a greater variety of SDRAM chips. For details, refer to the device handbook for the target device family.

Synchronizing Clock and Data Signals

The clock for the SDRAM chip (SDRAM clock) must be driven at the same frequency as the clock for the Avalon-MM interface on the SDRAM controller (controller clock). As in all synchronous designs, you must ensure that address, data, and control signals at the SDRAM pins are stable when a clock edge arrives. As shown in Figure 1–1, you can use an on-chip phase-locked loop (PLL) to alleviate clock skew between the SDRAM controller core and the SDRAM chip. At lower clock speeds, the PLL might not be necessary. At higher clock rates, a PLL is necessary to ensure that the SDRAM clock toggles only when signals are stable on the pins. The PLL block is not part of the SDRAM controller core. If a PLL is necessary, you must instantiate it manually. You can instantiate the PLL core interface, which is an SOPC Builder component, or instantiate an ALTPLL megafunction outside the SOPC Builder system module.

If you use a PLL, you must tune the PLL to introduce a clock phase shift so that SDRAM clock edges arrive after synchronous signals have stabilized. See "Clock, PLL and Timing Considerations" on page 1–10 for details.

For more information about instantiating a PLL in your SOPC Builder system, refer to *PLL Core* chapter in volume 5 of the *Quartus II Handbook*. The Nios® II development tools provide example hardware designs that use the SDRAM controller core in conjunction with a PLL, which you can use as a reference for your custom designs. The Nios II development tools are available free for download from www.altera.com.

Clock Enable (CKE) Not Supported

The SDRAM controller does not support clock-disable modes. The SDRAM controller permanently asserts the CKE signal on the SDRAM.

Sharing Pins with Other Avalon-MM Tri-State Devices

If an Avalon-MM tri-state bridge is present in the SOPC Builder system, the SDRAM controller core can share pins with the existing tri-state bridge. In this case, the core's `addr`, `dq` (data) and `dqm` (byte-enable) pins are shared with other devices connected to the Avalon-MM tri-state bridge. This feature conserves I/O pins, which is valuable in systems that have multiple external memory chips (for example, flash, SRAM, and SDRAM), but too few pins to dedicate to the SDRAM chip. See "Performance Considerations" for details about how pin sharing affects performance.

The SDRAM addresses must connect all address bits regardless of the size of the word so that the low-order address bits on the tri-state bridge align with the low-order address bits on the memory device. The Avalon-MM tristate address signal always presents a byte address. It is not possible to drop A0 of the tri-state bridge for memories when the smallest access size is 16 bits or A0-A1 of the tri-state bridge when the smallest access size is 32 bits.

Board Layout and Pinout Considerations

When making decisions about the board layout and device pinout, try to minimize the skew between the SDRAM signals. For example, when assigning the device pinout, group the SDRAM signals, including the SDRAM clock output, physically close together. Also, you can use the **Fast Input Register** and **Fast Output Register** logic options in the Quartus II software. These logic options place registers for the SDRAM signals in the I/O cells. Signals driven from registers in I/O cells have similar timing characteristics, such as t_{CO}, t_{SU}, and t_{H}.

Performance Considerations

Under optimal conditions, the SDRAM controller core’s bandwidth approaches one word per clock cycle. However, because of the overhead associated with refreshing the SDRAM, it is impossible to reach one word per clock cycle. Other factors affect the core’s performance, as described in the following sections.

Open Row Management

SDRAM chips are arranged as multiple banks of memory, in which each bank is capable of independent open-row address management. The SDRAM controller core takes advantage of open-row management for a single bank. Continuous reads or writes within the same row and bank operate at rates approaching one word per clock. Applications that frequently access different destination banks require extra management cycles to open and close rows.

Sharing Data and Address Pins

When the controller shares pins with other tri-state devices, average access time usually increases and bandwidth decreases. When access to the tri-state bridge is granted to other devices, the SDRAM incurs overhead to open and close rows. Furthermore, the SDRAM controller has to wait several clock cycles before it is granted access again.

To maximize bandwidth, the SDRAM controller automatically maintains control of the tri-state bridge as long as back-to-back read or write transactions continue within the same row and bank.

This behavior may degrade the average access time for other devices sharing the Avalon-MM tri-state bridge.

The SDRAM controller closes an open row whenever there is a break in back-to-back transactions, or whenever a refresh transaction is required. As a result:

- The controller cannot permanently block access to other devices sharing the tri-state bridge.

- The controller is guaranteed not to violate the SDRAM's row open time limit.

Hardware Design and Target Device

The target device affects the maximum achievable clock frequency of a hardware design. Certain device families achieve higher f_{MAX} performance than other families. Furthermore, within a device family, faster speed grades achieve higher performance. The SDRAM controller core can achieve 100 MHz in Altera's high-performance device families, such as Stratix® series. However, the core might not achieve 100 MHz performance in all Altera device families.

The f_{MAX} performance also depends on the SOPC Builder system design. The SDRAM controller clock can also drive other logic in the system module, which might affect the maximum achievable frequency. For the SDRAM controller core to achieve f_{MAX} performance of 100 MHz, all components driven by the same clock must be designed for a 100 MHz clock rate, and timing analysis in the Quartus II software must verify that the overall hardware design is capable of 100 MHz operation.

Device Support

The SDRAM Controller with Avalon interface core supports all Altera device families. Different device families support different I/O standards, which may affect the ability of the core to interface to certain SDRAM chips. For details about supported I/O types, refer to the device handbook for the target device family.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ interface for the SDRAM controller in SOPC Builder to specify hardware and simulation features. The SDRAM controller MegaWizard has two pages: **Memory Profile** and **Timing**. This section describes the options available on each page.

The **Presets** list offers several pre-defined SDRAM configurations as a convenience. If the SDRAM subsystem on the target board matches one of the preset configurations, you can configure the SDRAM controller core easily by selecting the appropriate preset value. The following preset configurations are defined:

- Micron MT8LSDT1664HG module
- Four SDR100 8 MByte × 16 chips
- Single Micron MT48LC2M32B2-7 chip
- Single Micron MT48LC4M32B2-7 chip
- Single NEC D4564163-A80 chip (64 MByte × 16)
- Single Alliance AS4LC1M16S1-10 chip
- Single Alliance AS4LC2M8S0-10 chip

Selecting a preset configuration automatically changes values on the **Memory Profile** and **Timing** tabs to match the specific configuration. Altering a configuration setting on any page changes the **Preset** value to **custom**.

Memory Profile Page

The **Memory Profile** page allows you to specify the structure of the SDRAM subsystem such as address and data bus widths, the number of chip select signals, and the number of banks. Table 1–1 lists the settings available on the **Memory Profile** page.

Table 1–1. Memory Profile Page Settings

Settings		Allowed Values	Default Values	Description
Data Width		8, 16, 32, 64	32	SDRAM data bus width. This value determines the width of the `dq` bus (data) and the `dqm` bus (byte-enable).
Architecture Settings	Chip Selects	1, 2, 4, 8	1	Number of independent chip selects in the SDRAM subsystem. By using multiple chip selects, the SDRAM controller can combine multiple SDRAM chips into one memory subsystem.
	Banks	2, 4	4	Number of SDRAM banks. This value determines the width of the `ba` bus (bank address) that connects to the SDRAM. The correct value is provided in the data sheet for the target SDRAM.
Address Width Settings	Row	11, 12, 13, 14	12	Number of row address bits. This value determines the width of the `addr` bus. The Row and Column values depend on the geometry of the chosen SDRAM. For example, an SDRAM organized as 4096 (2^{12}) rows by 512 columns has a Row value of 12.
	Column	>= 8, and less than Row value	8	Number of column address bits. For example, the SDRAM organized as 4096 rows by 512 (2^9) columns has a Column value of 9.
Share pins via tri-state bridge dq/dqm/addr I/O pins		On, Off	Off	When set to No, all pins are dedicated to the SDRAM chip. When set to Yes, the `addr`, `dq`, and `dqm` pins can be shared with a tristate bridge in the system. In this case, select the appropriate tristate bridge from the pull-down menu.
Include a functional memory model in the system testbench		On, Off	On	When on, SOPC Builder creates a functional simulation model for the SDRAM chip. This default memory model accelerates the process of creating and verifying systems that use the SDRAM controller. See “Hardware Simulation Considerations” on page 1–7.

Based on the settings entered on the **Memory Profile** page, the wizard displays the expected memory capacity of the SDRAM subsystem in units of megabytes, megabits, and number of addressable words. Compare these expected values to the actual size of the chosen SDRAM to verify that the settings are correct.

Timing Page

The **Timing** page allows designers to enter the timing specifications of the SDRAM chip(s) used. The correct values are available in the manufacturer's data sheet for the target SDRAM. Table 1–2 lists the settings available on the **Timing** page.

Table 1–2. Timing Page Settings

Settings	Allowed Values	Default Value	Description
CAS latency	1, 2, 3	3	Latency (in clock cycles) from a read command to data out.
Initialization refresh cycles	1–8	2	This value specifies how many refresh cycles the SDRAM controller performs as part of the initialization sequence after reset.
Issue one refresh command every	—	15.625 µs	This value specifies how often the SDRAM controller refreshes the SDRAM. A typical SDRAM requires 4,096 refresh commands every 64 ms, which can be achieved by issuing one refresh command every 64 ms / 4,096 = 15.625 µs.
Delay after power up, before initialization	—	100 µs	The delay from stable clock and power to SDRAM initialization.
Duration of refresh command (t_rfc)	—	70 ns	Auto Refresh period.
Duration of precharge command (t_rp)	—	20 ns	Precharge command period.
ACTIVE to READ or WRITE delay (t_rcd)	—	20 ns	ACTIVE to READ or WRITE delay.
Access time (t_ac)	—	17 ns	Access time from clock edge. This value may depend on CAS latency.
Write recovery time (t_wr, No auto precharge)	—	14 ns	Write recovery if explicit precharge commands are issued. This SDRAM controller always issues explicit precharge commands.

Regardless of the exact timing values you specify, the actual timing achieved for each parameter is an integer multiple of the Avalon clock period. For the **Issue one refresh command every** parameter, the actual timing is the greatest number of clock cycles that does not exceed the target value. For all other parameters, the actual timing is the smallest number of clock ticks that provides a value greater than or equal to the target value.

Hardware Simulation Considerations

This section discusses considerations for simulating systems with SDRAM. Three major components are required for simulation:

- A simulation model for the SDRAM controller.
- A simulation model for the SDRAM chip(s), also called the memory model.
- A simulation testbench that wires the memory model to the SDRAM controller pins.

Some or all of these components are generated by SOPC Builder at system generation time.

SDRAM Controller Simulation Model

The SDRAM controller design files generated by SOPC Builder are suitable for both synthesis and simulation. Some simulation features are implemented in the HDL using "translate on/off" synthesis directives that make certain sections of HDL code invisible to the synthesis tool.

The simulation features are implemented primarily for easy simulation of Nios and Nios II processor systems using the ModelSim® simulator. The SDRAM controller simulation model is not ModelSim specific. However, minor changes may be required to make the model work with other simulators.

If you change the simulation directives to create a custom simulation flow, be aware that SOPC Builder overwrites existing files during system generation. Take precautions to ensure your changes are not overwritten.

Refer to *AN 351: Simulating Nios II Processor Designs* for a demonstration of simulation of the SDRAM controller in the context of Nios II embedded processor systems.

SDRAM Memory Model

This section describes the two options for simulating a memory model of the SDRAM chip(s).

Using the Generic Memory Model

If the **Include a functional memory model the system testbench** option is enabled at system generation, SOPC Builder generates an HDL simulation model for the SDRAM memory. In the auto-generated system testbench, SOPC Builder automatically wires this memory model to the SDRAM controller pins.

Using the automatic memory model and testbench accelerates the process of creating and verifying systems that use the SDRAM controller. However, the memory model is a generic functional model that does not reflect the true timing or functionality of real SDRAM chips. The generic model is always structured as a single, monolithic block of memory. For example, even for a system that combines two SDRAM chips, the generic memory model is implemented as a single entity.

Using the SDRAM Manufacturer's Memory Model

If the **Include a functional memory model the system testbench** option is not enabled, you are responsible for obtaining a memory model from the SDRAM manufacturer, and manually wiring the model to the SDRAM controller pins in the system testbench.

Example Configurations

The following examples show how to connect the SDRAM controller outputs to an SDRAM chip or chips. The bus labeled `ctl` is an aggregate of the remaining signals, such as `cas_n`, `ras_n`, `cke` and `we_n`.

Figure 1–2 shows a single 128-Mbit SDRAM chip with 32-bit data. The address, data, and control signals are wired directly from the controller to the chip. The result is a 128-Mbit (16-Mbyte) memory space.

Figure 1–2. Single 128-Mbit SDRAM Chip with 32-Bit Data

Figure 1–3 shows two 64-Mbit SDRAM chips, each with 16-bit data. The address and control signals connect in parallel to both chips. The chips share the chipselect (`cs_n`) signal. Each chip provides half of the 32-bit data bus. The result is a logical 128-Mbit (16-Mbyte) 32-bit data memory.

Figure 1–3. Two 64-MBit SDRAM Chips Each with 16-Bit Data

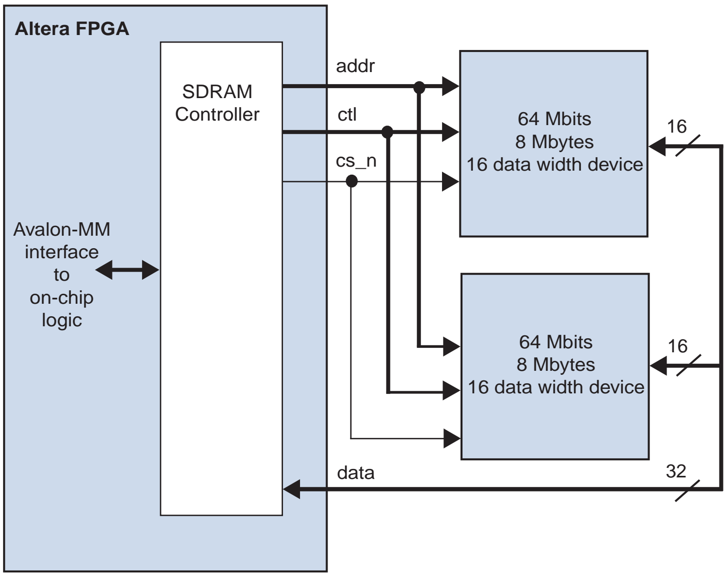


Figure 1–4 shows two 128-Mbit SDRAM chips, each with 32-bit data. The address, data, and control signals connect in parallel to the two chips. The chipselect bus (`cs_n[1:0]`) determines which chip is selected. The result is a logical 256-Mbit 32-bit wide memory.

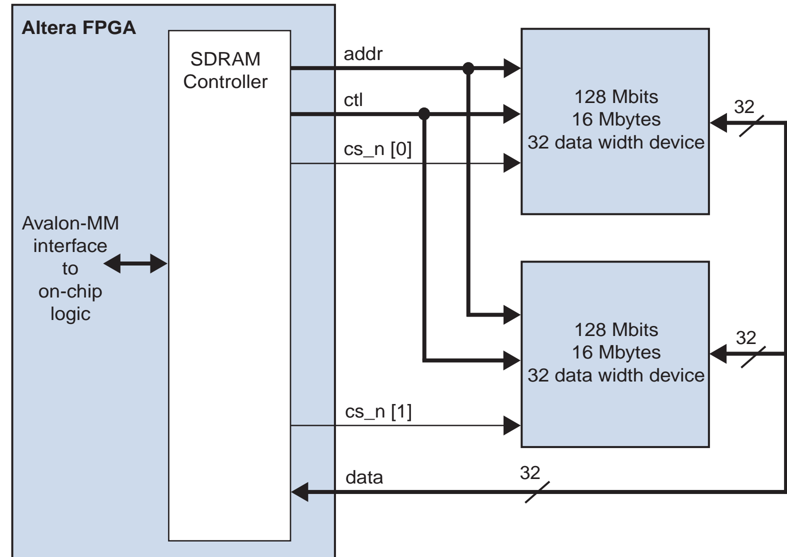
Figure 1–4. Two 128-Mbit SDRAM Chips Each with 32-Bit Data



Software Programming Model

The SDRAM controller behaves like simple memory when accessed via the Avalon-MM interface. There are no software-configurable settings and no memory-mapped registers. No software driver routines are required for a processor to access the SDRAM controller.

Clock, PLL and Timing Considerations

This section describes issues related to synchronizing signals from the SDRAM controller core with the clock that drives the SDRAM chip. During SDRAM transactions, the address, data, and control signals are valid at the SDRAM pins for a window of time, during which the SDRAM clock must toggle to capture the correct values. At slower clock frequencies, the clock naturally falls within the valid window. At higher frequencies, you must compensate the SDRAM clock to align with the valid window.

Determine when the valid window occurs either by calculation or by analyzing the SDRAM pins with an oscilloscope. Then use a PLL to adjust the phase of the SDRAM clock so that edges occur in the middle of the valid window. Tuning the PLL might require trial-and-error effort to align the phase shift to the properties of your target board.

For details about the PLL circuitry in your target device, refer to the appropriate device family handbook. For details about configuring the PLLs in Altera devices, refer to the *ALTPLL Megafunction User Guide*.

Factors Affecting SDRAM Timing

The location and duration of the window depends on several factors:

- Timing parameters of the device and SDRAM I/O pins — I/O timing parameters vary based on device family and speed grade.
- Pin location on the device — I/O pins connected to row routing have different timing than pins connected to column routing.
- Logic options used during the Quartus II compilation — Logic options such as the **Fast Input Register** and **Fast Output Register** logic affect the design fit. The location of logic and registers inside the device affects the propagation delays of signals to the I/O pins.
- SDRAM CAS latency

As a result, the valid window timing is different for different combinations of FPGA and SDRAM devices. The window depends on the Quartus II software fitting results and pin assignments.

Symptoms of an Untuned PLL

Detecting when the PLL is not tuned correctly might be difficult. Data transfers to or from the SDRAM might not fail universally. For example, individual transfers to the SDRAM controller might succeed, whereas burst transfers fail. For processor-based systems, if software can perform read or write data to SDRAM, but cannot run when the code is located in SDRAM, the PLL is probably tuned incorrectly.

Estimating the Valid Signal Window

This section describes how to estimate the location and duration of the valid signal window using timing parameters provided in the SDRAM datasheet and the Quartus II software compilation report. After finding the window, tune the PLL so that SDRAM clock edges occur exactly in the middle of the window.

Calculating the window is a two-step process. First, determine by how much time the SDRAM clock can lag the controller clock, and then by how much time it can lead. After finding the maximum lag and lead values, calculate the midpoint between them.

These calculations provide an estimation only. The following delays can also affect proper PLL tuning, but are not accounted for by these calculations.

- Signal skew due to delays on the printed circuit board — These calculations assume zero skew.
- Delay from the PLL clock output nodes to destinations — These calculations assume that the delay from the PLL SDRAM-clock output-node to the pin is the same as the delay from the PLL controller-clock output-node to the clock inputs in the SDRAM controller. If these clock delays are significantly different, you must account for this phase shift in your window calculations.

Figure 1–5 shows how to calculate the maximum length of time that the SDRAM clock can lag the controller clock, and Figure 1–6 shows how to calculate the maximum lead. Lag is a negative time shift, relative to the controller clock, and lead is a positive time shift. The SDRAM clock can lag the controller clock by the lesser of the maximum lag for a read cycle or that for a write cycle. In other words, *Maximum Lag* = minimum(*Read Lag*, *Write Lag*). Similarly, the SDRAM clock can lead by the lesser of the maximum lead for a read cycle or for a write cycle. In other words, *Maximum Lead* = minimum(*Read Lead*, *Write Lead*).

Figure 1–5. Calculating the Maximum SDRAM Clock Lag

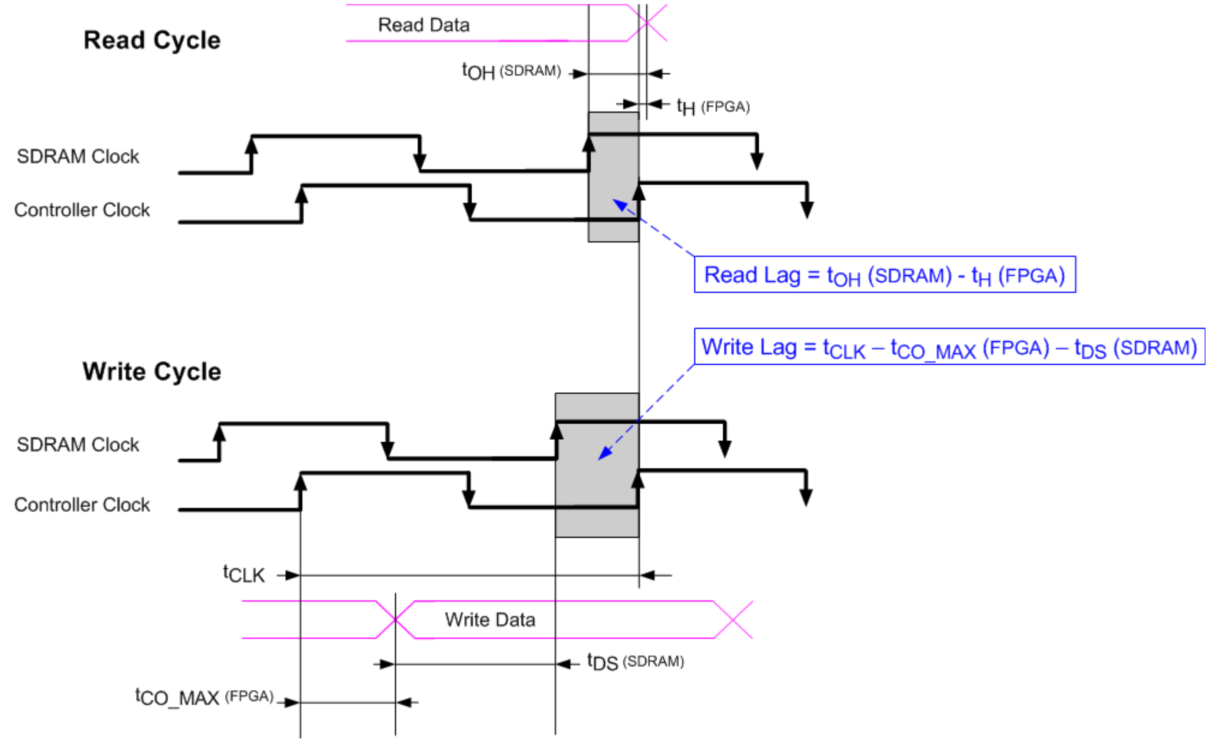


Figure 1–6. Calculating the Maximum SDRAM Clock Lead

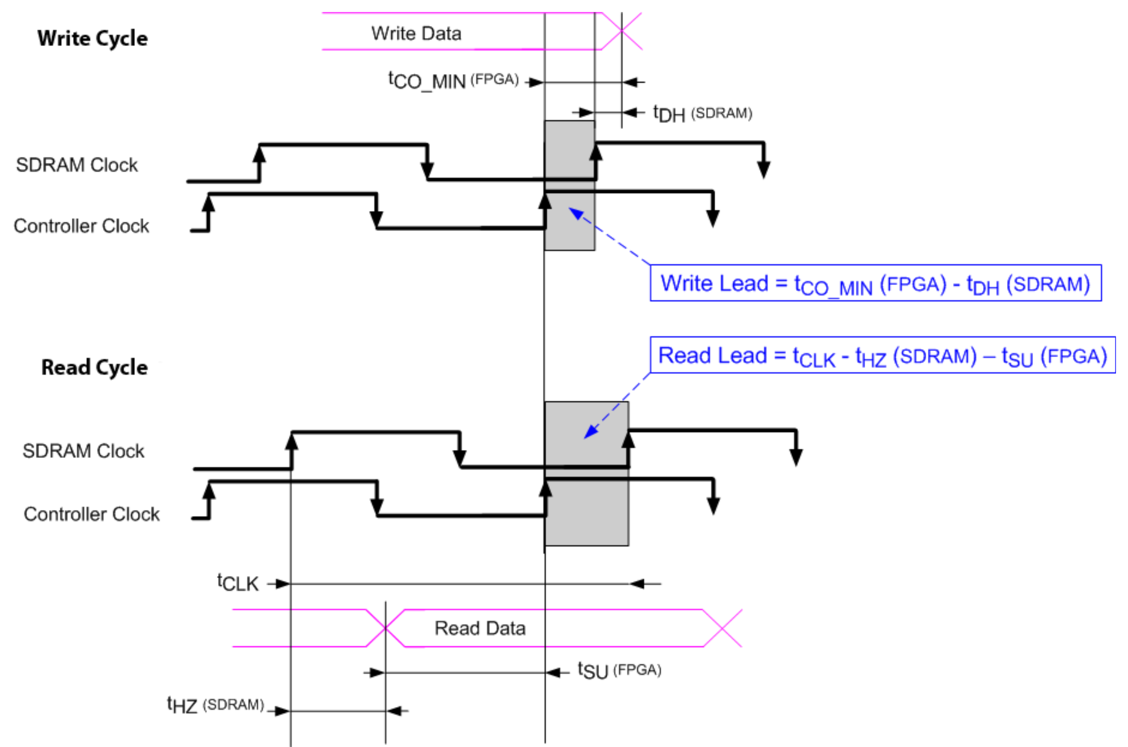

Example Calculation

This section demonstrates a calculation of the signal window for a Micron MT48LC4M32B2-7 SDRAM chip and design targeting the Stratix II EP2S60F672C5 device. This example uses a CAS latency (CL) of 3 cycles, and a clock frequency of 50 MHz. All SDRAM signals on the device are registered in I/O cells, enabled with the **Fast Input Register** and **Fast Output Register** logic options in the Quartus II software.

Table 1–3 shows the relevant timing parameters excerpted from the MT48LC4M32B2 device datasheet.

Table 1–3. Timing Parameters for Micron MT48LC4M32B2 SDRAM Device (Part 1 of 2)

Parameter		Symbol	Value (ns) in -7 Speed Grade	
			Min.	**Max.**
Access time from CLK (pos. edge)	CL = 3	$t_{AC(3)}$	—	5.5
	CL = 2	$t_{AC(2)}$	—	8
	CL = 1	$t_{AC(1)}$	—	17
Address hold time		t_{AH}	1	—
Address setup time		t_{AS}	2	—
CLK high-level width		t_{CH}	2.75	—
CLK low-level width		t_{CL}	2.75	—

Table 1–3. Timing Parameters for Micron MT48LC4M32B2 SDRAM Device (Part 2 of 2)

Parameter		Symbol	Value (ns) in -7 Speed Grade	
			Min.	**Max.**
Clock cycle time	CL = 3	$t_{CK(3)}$	7	—
	CL = 2	$t_{CK(2)}$	10	—
	CL = 1	$t_{CK(1)}$	20	—
CKE hold time		t_{CKH}	1	—
CKE setup time		t_{CKS}	2	—
CS#, RAS#, CAS#, WE#, DQM hold time		t_{CMH}	1	—
CS#, RAS#, CAS#, WE#, DQM setup time		t_{CMS}	2	—
Data-in hold time		t_{DH}	1	
Data-in setup time		t_{DS}	2	
Data-out high-impedance time	CL = 3	$t_{HZ(3)}$		5.5
	CL = 2	$t_{HZ(2)}$	—	8
	CL = 1	$t_{HZ(1)}$	—	17
Data-out low-impedance time		t_{LZ}	1	—
Data-out hold time		t_{OH}	2.5	

Table 1–4 shows the relevant timing information, obtained from the Timing Analyzer section of the Quartus II Compilation Report. The values in the table are the maximum or minimum values among all device pins related to the SDRAM. The variance in timing between the SDRAM pins on the device is small (less than 100 ps) because the registers for these signals are placed in the I/O cell.

Table 1–4. FPGA I/O Timing Parameters

Parameter	Symbol	Value (ns)
Clock period	t_{CLK}	20
Minimum clock-to-output time	t_{CO_MIN}	2.399
Maximum clock-to-output time	t_{CO_MAX}	2.477
Maximum hold time after clock	t_{H_MAX}	–5.607
Maximum setup time before clock	t_{SU_MAX}	5.936

You must compile the design in the Quartus II software to obtain the I/O timing information for the design. Although Altera device family datasheets contain generic I/O timing information for each device, the Quartus II Compilation Report provides the most precise timing information for your specific design.

The timing values found in the compilation report can change, depending on fitting, pin location, and other Quartus II logic settings. When you recompile the design in the Quartus II software, verify that the I/O timing has not changed significantly.

© March 2009 Altera Corporation

The following examples illustrate the calculations from Figure 1–5 and Figure 1–6 using the values from Table 1–3 and Table 1–4.

The SDRAM clock can lag the controller clock by the lesser of *Read Lag* or *Write Lag*:

Read Lag = t_{OH}(SDRAM) – t_{H_MAX}(FPGA)

= 2.5 ns – (–5.607 ns) = 8.107 ns

or

Write Lag= t_{CLK} – t_{CO_MAX}(FPGA) – t_{DS}(SDRAM)

= 20 ns – 2.477 ns – 2 ns = 15.523 ns

The SDRAM clock can lead the controller clock by the lesser of *Read Lead* or *Write Lead*:

Read Lead= t_{CO_MIN}(FPGA) – t_{DH}(SDRAM)

= 2.399 ns – 1.0 ns = 1.399 ns

or

Write Lead= t_{CLK} – $t_{HZ(3)}$(SDRAM) – t_{SU_MAX}(FPGA)

= 20 ns – 5.5 ns – 5.936 ns = 8.564 ns

Therefore, for this example you can shift the phase of the SDRAM clock from –8.107 ns to 1.399 ns relative to the controller clock. Choosing a phase shift in the middle of this window results in the value (–8.107 + 1.399)/2 = –3.35 ns.

2. CompactFlash Core

QII55005-9.0.0

Core Overview

The CompactFlash core allows you to connect SOPC Builder systems to CompactFlash storage cards in true IDE mode by providing an Avalon® Memory-Mapped (Avalon-MM) interface to the registers on the storage cards. The core supports PIO mode 0.

The CompactFlash core also provides an Avalon-MM slave interface which can be used by Avalon-MM master peripherals such as a Nios® II processor to communicate with the CompactFlash core and manage its operations.

The CompactFlash core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated systems.

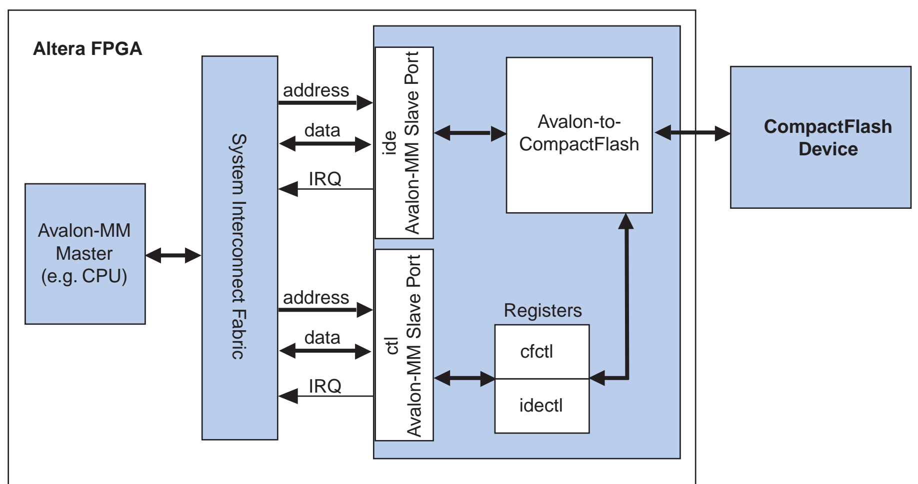
This chapter contains the following sections:

- "Functional Description"
- "Instantiating the Core in SOPC Builder" on page 2–2
- "Device Support" on page 2–3
- "Software Programming Model" on page 2–3

Functional Description

Figure 2–1 shows a block diagram of the CompactFlash core in a typical system configuration.

Figure 2–1. SOPC Builder System With a CompactFlash Core



As shown in Figure 2–1, the CompactFlash core provides two Avalon-MM slave interfaces: the `ide` slave port for accessing the registers on the CompactFlash device and the `ctl` slave port for accessing the core's internal registers. These registers can be used by Avalon-MM master peripherals such as a Nios II processor to control the operations of the CompactFlash core and to transfer data to and from the CompactFlash device.

You can set the CompactFlash core to generate two active-high interrupt requests (IRQs): one signals the insertion and removal of a CompactFlash device and the other passes interrupt signals from the CompactFlash device.

The CompactFlash core maps the Avalon-MM bus signals to the CompactFlash device with proper timing, thus allowing Avalon-MM master peripherals to directly access the registers on the CompactFlash device.

For more information, refer to the CF+ and CompactFlash specifications available at www.compactflash.org.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ interface for the CompactFlash core in SOPC Builder to add the core to a system. There are no user-configurable settings for this core.

Required Connections

Table 2–1 lists the required connections between the CompactFlash core and the CompactFlash device.

Table 2–1. Required Connections (Part 1 of 2)

Device Support

The CompactFlash interface core supports all Altera® device families.

Software Programming Model

This section describes the software programming model for the CompactFlash core.

HAL System Library Support

The Altera-provided HAL API functions include a device driver that you can use to initialize the CompactFlash core. To perform other operations, use the low-level macros provided. For more information on the macros, refer to the files listed in the section "Software Files" on page 2–4.

Software Files

The CompactFlash core provides the following software files. These files define the low-level access to the hardware. Application developers should not modify these files.

- **altera_avalon_cf_regs.h**—The header file that defines the core's register maps.
- **altera_avalon_cf.h, altera_avalon_cf.c**—The header and source code for the functions and variables required to integrate the driver into the HAL system library.

Register Maps

This section describes the register maps for the Avalon-MM slave interfaces.

Ide Registers

The `ide` port in the CompactFlash core allows you to access the IDE registers on a CompactFlash device. Table 2–2 shows the register map for the `ide` port.

Table 2–2. Ide Register Map

Offset	Register Names	
	Read Operation	Write Operation
0	`RD Data`	`WR Data`
1	`Error`	`Features`
2	`Sector Count`	`Sector Count`
3	`Sector No`	`Sector No`
4	`Cylinder Low`	`Cylinder Low`
5	`Cylinder High`	`Cylinder High`
6	`Select Card/Head`	`Select Card/Head`
7	`Status`	`Command`
14	`Alt Status`	`Device Control`

Ctl Registers

The `ctl` port in the CompactFlash core provides access to the registers which control the core's operation and interface. Table 2–3 shows the register map for the `ctl` port.

Table 2–3. Ctl Register Map

Offset	Register	Fields				
		31:4	3	2	1	0
0	`cfctl`	Reserved	`IDET`	`RST`	`PWR`	`DET`
1	`idectl`	Reserved				`IIDE`
2	Reserved	Reserved				
3	Reserved	Reserved				

Cfctl Register

The `cfctl` register controls the operations of the CompactFlash core. Reading the `cfctl` register clears the interrupt. Table 2–4 describes the `cfctl` register bits.

Table 2–4. cfctl Register Bits

Bit Number	Bit Name	Read/Write	Description
0	`DET`	RO	Detect. This bit is set to 1 when the core detects a CompactFlash device.
1	`PWR`	RW	Power. When this bit is set to 1, power is being supplied to the CompactFlash device.
2	`RST`	RW	Reset. When this bit is set to 1, the CompactFlash device is held in a reset state. Setting this bit to 0 returns the device to its active state.
3	`IDET`	RW	Detect Interrupt Enable. When this bit is set to 1, the CompactFlash core generates an interrupt each time the value of the `det` bit changes.

Idectl Register

The `idectl` register controls the interface to the CompactFlash device. Table 2–5 describes the `idectl` register bit.

Table 2–5. idectl Register

Bit Number	Bit Name	Read/Write	Description
0	`IIDE`	RW	IDE Interrupt Enable. When this bit is set to 1, the CompactFlash core generates an interrupt following an interrupt generated by the CompactFlash device. Setting this bit to 0 disables the IDE interrupt.

Document Revision History

Table 2–6 shows the revision history for this chapter.

Table 2–6. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	No change from previous release.	—
November 2008 v8.1.0	Changed to 8-1/2 x 11 page size. No change to content.	—
May 2008 v8.0.0	Added the mode supported by the CompactFlash core.	—

3. Common Flash Interface Controller Core

NII51013-9.0.0

Core Overview

The common flash interface controller core with Avalon® interface (CFI controller) allows you to easily connect SOPC Builder systems to external flash memory that complies with the Common Flash Interface (CFI) specification. The CFI controller is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system.

For the Nios® II processor, Altera provides hardware abstraction layer (HAL) driver routines for the CFI controller. The drivers provide universal access routines for CFI-compliant flash memories. Therefore, you do not need to write any additional code to program CFI-compliant flash devices. The HAL driver routines take advantage of the HAL generic device model for flash memory, which allows you to access the flash memory using the familiar HAL application programming interface (API), the ANSI C standard library functions for file I/O, or both.

The Nios II Embedded Design Suite (EDS) provides a flash programmer utility based on the Nios II processor and the CFI controller. The flash programmer utility can be used to program any CFI-compliant flash memory connected to an Altera® device.

For more information about how to read and write flash using the HAL API, refer to the *Nios II Software Developer's Handbook*. For more information on the flash programmer utility, refer to the *Nios II Flash Programmer User Guide*.

Further information about the Common Flash Interface specification is available at www.intel.com. As an example of a flash device supported by the CFI controller, see the data sheet for the AMD Am29LV065D-120R, available at www.amd.com.

The common flash interface controller core supersedes previous Altera flash cores distributed with SOPC Builder or Nios development kits. All flash chips associated with these previous cores comply with the CFI specification, and therefore are supported by the CFI controller.

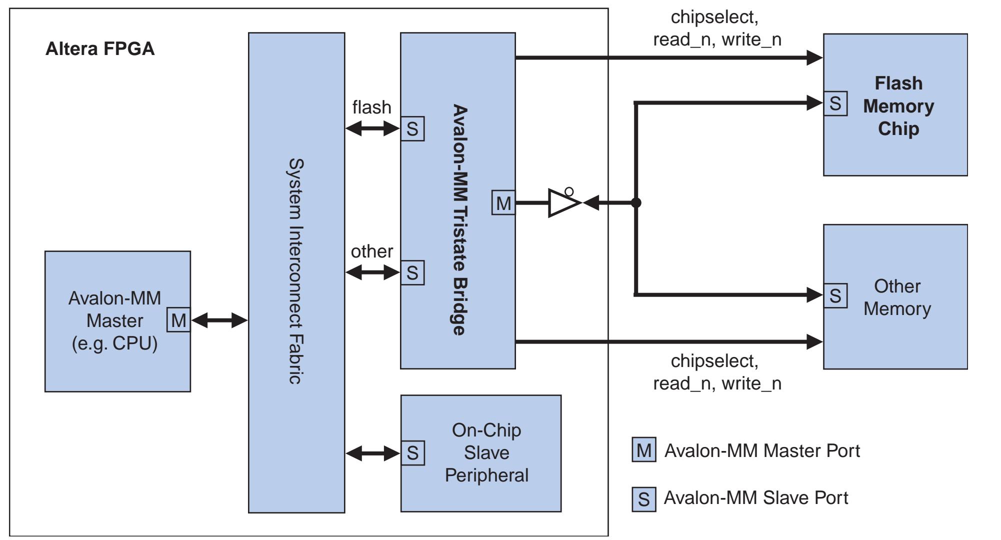
This chapter contains the following sections:

- "Functional Description" on page 3–2
- "Device and Tools Support" on page 3–2
- "Instantiating the Core in SOPC Builder" on page 3–2
- "Software Programming Model" on page 3–4

Functional Description

Figure 3–1 shows a block diagram of the CFI controller in a typical system configuration. As shown in Figure 3–1, the Avalon Memory-Mapped (Avalon-MM) interface for flash devices is connected through an Avalon-MM tristate bridge. The tristate bridge creates an off-chip memory bus that allows the flash chip to share address and data pins with other memory chips. It provides separate chipselect, read, and write pins to each chip connected to the memory bus. The CFI controller hardware is minimal; it is simply an Avalon-MM tristate slave port configured with waitstates, setup, and hold time appropriate for the target flash chip. This slave port is capable of Avalon-MM tristate slave read and write transfers.

Figure 3–1. An SOPC Builder System Integrating a CFI Controller



Avalon-MM master ports can perform read transfers directly from the CFI controller's Avalon-MM port. See "Software Programming Model" on page 3–4 for more detail on writing/erasing flash memory.

Device and Tools Support

The CFI controller supports all Altera device families. The CFI controller provides drivers for the Nios II HAL system library.

Instantiating the Core in SOPC Builder

Hardware designers use the MegaWizard™ interface for the CFI controller in SOPC Builder to specify the core features. The following sections describe the available options.

Attributes Page

The options on this page control the basic hardware configuration of the CFI controller.

Presets Settings

The **Presets** setting is a drop-down menu of flash chips that have already been characterized for use with the CFI controller. After you select one of the chips in the **Presets** menu, the wizard updates all settings on both tabs (except for the Board Info setting) to work with the specified flash chip.

The options provided are not intended to cover the wide range of flash devices available in the market. If the flash chip on your target board does not appear in the **Presets** list, you must configure the other settings manually.

Size Settings

The size setting specifies the size of the flash device. There are two settings:

- **Address Width**—The width of the flash chip's address bus.
- **Data Width—**The width of the flash chip's data bus

The size settings cause SOPC Builder to allocate the correct amount of address space for this device. SOPC Builder will automatically generate dynamic bus sizing logic that appropriately connects the flash chip to Avalon-MM master ports of different data widths.

For details about dynamic bus sizing, refer to the *Avalon Interface Specifications*.

Timing Page

The options on this page specify the timing requirements for read and write transfers with the flash device.

Refer to the specifications provided with the common flash device you are using to obtain the timing values you need to calculate the values of the parameters on the **Timing** page.

The settings available on the **Timing** page are:

- **Setup**—After asserting `chipselect`, the time required before asserting the `read` or `write` signals. You can determine the value of this parameter by using the following formula:

  Setup = t_{CE} (chip enable to output delay) - t_{OE} (output enable to output delay)

- **Wait**—The time required for the `read` or `write` signals to be asserted for each transfer. Use the following guideline to determine an appropriate value for this parameter:

  The sum of **Setup**, **Wait**, and board delay must be less than t_{ACC}, where:

  - Board delay is determined by the T_{CO} on the device address pins, T_{SU} on the device data pins and propagation delay on the board traces in both directions.
  - t_{ACC} is the address to output delay.

- **Hold**—After deasserting the `write` signal, the time required before deasserting the `chipselect` signal.
- **Units**—The timing units used for the **Setup**, **Wait**, and **Hold** values. Possible values include ns, µs, ms, and clock cycles.

For more information about signal timing for the Avalon-MM interface, refer to the *Avalon Interface Specifications*.

Software Programming Model

This section describes the software programming model for the CFI controller. In general, any Avalon-MM master in the system can read the flash chip directly as a memory device. For Nios II processor users, Altera provides HAL system library drivers that enable you to erase and write the flash memory using the HAL API functions.

HAL System Library Support

The Altera-provided driver implements a HAL flash device driver that integrates into the HAL system library for Nios II systems. Programs call the familiar HAL API functions to program CFI-compliant flash memory. You do not need to know anything about the details of the underlying drivers.

The HAL API for programming flash, including C code examples, is described in detail in the *Nios II Software Developer's Handbook*. The Nios II EDS also provides a reference design called Flash Tests that demonstrates erasing, writing, and reading flash memory.

Limitations

Currently, the Altera-provided drivers for the CFI controller support only Intel, AMD and Spansion flash chips.

Software Files

The CFI controller provides the following software files. These files define the low-level access to the hardware, and provide the routines for the HAL flash device driver. Application developers should not modify these files.

- **altera_avalon_cfi_flash.h, altera_avalon_cfi_flash.c**—The header and source code for the functions and variables required to integrate the driver into the HAL system library.
- **altera_avalon_cfi_flash_funcs.h**, **altera_avalon_cfi_flash_table.c**—The header and source code for functions concerned with accessing the CFI table.
- **altera_avalon_cfi_flash_amd_funcs.h**, **altera_avalon_cfi_flash_amd.c**—The header and source code for programming AMD CFI-compliant flash chips.
- **altera_avalon_cfi_flash_intel_funcs.h**, **altera_avalon_cfi_flash_intel.c**—The header and source code for programming Intel CFI-compliant flash chips.

Document Revision History

Table 3–1 shows the revision history for this chapter.

Table 3–1. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	No change from previous release.	—
November 2008 v8.1.0	Changed to 8-1/2 x 11 page size. Added description to parameters on **Timing** page.	—
May 2008 v8.0.0	Updated the CFI controllers supported by Altera-provided drivers.	Updates made to comply with the Quartus II software version 8.0 release.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

4. EPCS Device Controller Core

NII51012-9.0.0

Core Overview

The EPCS device controller core with Avalon® interface allows Nios® II systems to access an Altera® EPCS serial configuration device. Altera provides drivers that integrate into the Nios II hardware abstraction layer (HAL) system library, allowing you to read and write the EPCS device using the familiar HAL application program interface (API) for flash devices.

Using the EPCS device controller core, Nios II systems can:

- Store program code in the EPCS device. The EPCS device controller core provides a boot-loader feature that allows Nios II systems to store the main program code in an EPCS device.
- Store non-volatile program data, such as a serial number, a NIC number, and other persistent data.
- Manage the device configuration data. For example, a network-enabled embedded system can receive new FPGA configuration data over a network, and use the core to program the new data into an EPCS serial configuration device.

The EPCS device controller core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. The flash programmer utility in the Nios II IDE allows you to manage and program data contents into the EPCS device.

For information about the EPCS serial configuration device family, refer to the *Serial Configuration Devices (EPCS1, EPCS4, EPCS16, EPCS64 and EPCS128) Data Sheet*. For details about using the Nios II HAL API to read and write flash memory, refer to the *Nios II Software Developer's Handbook*. For details about managing and programming the EPCS memory contents, refer to the *Nios II Flash Programmer User Guide*.

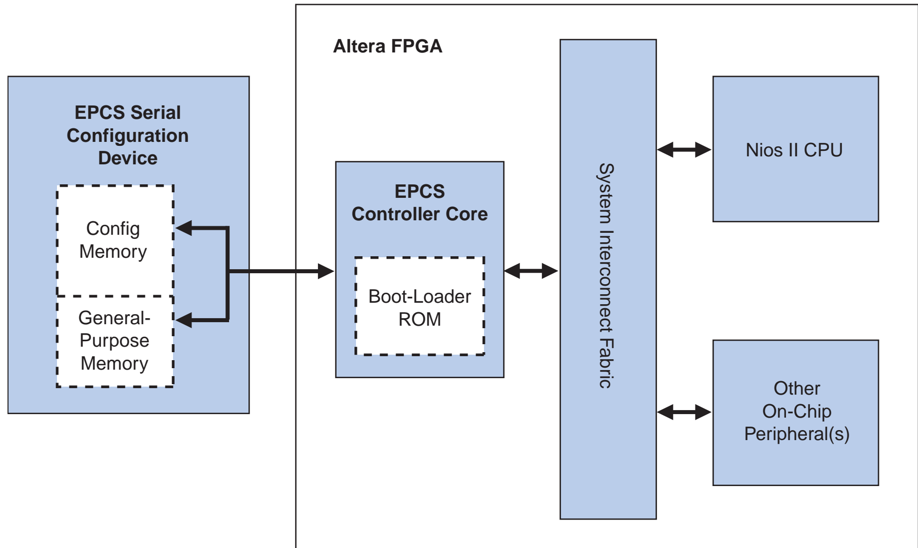
For Nios II processor users, the EPCS device controller core supersedes the Active Serial Memory Interface (ASMI) device. New designs should use the EPCS device controller core instead of the ASMI core.

Functional Description

Figure 4–1 shows a block diagram of the EPCS device controller core in a typical system configuration. As shown in Figure 4–1, the EPCS device's memory can be thought of as two separate regions:

- **FPGA configuration memory**—FPGA configuration data is stored in this region.
- **General-purpose memory**—If the FPGA configuration data does not fill up the entire EPCS device, any left-over space can be used for general-purpose data and system startup code.

Figure 4–1. Nios II System Integrating an EPCS Device Controller Core



By virtue of the HAL generic device model for flash devices, accessing the EPCS device using the HAL API is the same as accessing any flash memory. The EPCS device has a special-purpose hardware interface, so Nios II programs must read and write the EPCS memory using the provided HAL flash drivers.

The EPCS device controller core contains an on-chip memory for storing a boot-loader program. When used in conjunction with Cyclone®, Cyclone II, and Cyclone III devices, the core requires 512 bytes of boot-loader ROM. For Stratix® II and Stratix III devices, the core requires 1 KByte of boot-loader ROM. The Nios II processor can be configured to boot from the EPCS device controller core. To do so, set the Nios II reset address to the base address of the EPCS device controller core. In this case, after reset the CPU first executes code from the boot-loader ROM, which copies data from the EPCS general-purpose memory region into a RAM. Then, program control transfers to the RAM. The Nios II IDE provides facilities to compile a program for storage in the EPCS device, and create a programming file to program into the EPCS device.

For more information, refer to the *Nios II Flash Programmer User Guide*.

The Altera EPCS configuration device connects to the FPGA through dedicated pins on the FPGA, not through general-purpose I/O pins. In all Altera device families except Cyclone III, the EPCS device controller core does not create any I/O ports on the top-level SOPC Builder system module. If the EPCS device and the FPGA are wired together on a board for configuration using the EPCS device (in other words, active serial configuration mode), no further connection is necessary between the EPCS device controller core and the EPCS device. When you compile the SOPC Builder system in the Quartus II software, the EPCS device controller core signals are routed automatically to the device pins for the EPCS device.

If you program the EPCS device using the Quartus® II Programmer, all previous content is erased. To program the EPCS device with a combination of FPGA configuration data and Nios II program data, use the Nios II IDE flash programmer utility.

You have the flexibility to connect the output pins of Cyclone III devices, which are exported to the top-level design, to any EPCS devices. Perform the following tasks in the Quartus® II software to make the necessary pin assignments:

- On the **Dual-purpose pins** page (**Assignments** > **Devices** > **Device and Pin Options**), ensure that the following pins are assigned to the respective values:
  - `Data[0]` = **Use as regular I/O**
  - `Data[1]` = **Use as regularr I/O**
  - `DCLK` = **Use as regular I/O**
  - `FLASH_nCE/nCS0` = **Use as regular I/O**
- Using the Pin Planner (**Assignments > Pins**), ensure that the following pins are assigned to the respective configuration functions on the device:
  - `data0_to_the_epcs_controller` = `DATA0`
  - `sdo_from the_epcs_controller` = `DATA1,ASDO`
  - `dclk_from_epcs_controller` = `DCLK`
  - `sce_from_the_epcs_controller` = `FLASH_nCE`

For more information about the configuration pins in Cyclone III devices, refer to the Pin-Out Files for Altera Device page.

Avalon-MM Slave Interface and Registers

The EPCS device controller core has a single Avalon-MM slave interface that provides access to both boot-loader code and registers that control the core. As shown in Table 4–1, the first segment is dedicated to the boot-loader code, and the next seven words are control and data registers. A Nios II CPU can read the instruction words, starting from the core's base address as flat memory space, which enables the CPU to reset the core's address space.

The EPCS device controller core includes an interrupt signal that can be used to interrupt the CPU when a transfer has completed.

Table 4–1. EPCS Device Controller Core Register Map

Offset—Cyclone and Cyclone II (32-bit Word Address)	Offset—Other Device Families (32-bit Word Address)	Register Name	R/W	Bit Description 31:0
`0x000 .. 0x0FF`	`0x000 .. 0x1FF`	`Boot ROM Memory`	R	Boot Loader Code
`0x100`	`0x080`	`Read Data`	R	*(1)*
`0x101`	`0x081`	`Write Data`	W	
`0x102`	`0x082`	`Status`	R/W	
`0x103`	`0x083`	`Control`	R/W	
`0x104`	`0x084`	`Reserved`	—	
`0x105`	`0x085`	`Slave Enable`	R/W	
`0x106`	`0x086`	`End of Packet`	R/W	

Note to Table 4–1:

(1) Altera does not publish the usage of the control and data registers. To access the EPCS device, you must use the HAL drivers provided by Altera.

Device and Tools Support

The EPCS device controller core supports all Altera device families except the Hardcopy® series. The core must be connected to a Nios II processor. The core provides drivers for HAL-based Nios II systems, and the precompiled boot loader code compatible with the Nios II processor.

Instantiating the Core in SOPC Builder

You can add the EPCS device controller core from the **System Contents** tab in SOPC Builder. There are no user-configurable settings for this component.

Only one EPCS device controller core can be instantiated in each FPGA design.

Software Programming Model

This section describes the software programming model for the EPCS device controller core. Altera provides HAL system library drivers that enable you to erase and write the EPCS memory using the HAL API functions. Altera does not publish the usage of the cores registers. Therefore, you must use the HAL drivers provided by Altera to access the EPCS device.

HAL System Library Support

The Altera-provided driver implements a HAL flash device driver that integrates into the HAL system library for Nios II systems. Programs call the familiar HAL API functions to program the EPCS memory. You do not need to know the details of the underlying drivers to use them.

The HAL API for programming flash, including C-code examples, is described in detail in the *Nios II Software Developer's Handbook*. For details about managing and programming the EPCS device contents, refer to the *Nios II Flash Programmer User Guide*.

Software Files

The EPCS device controller core provides the following software files. These files provide low-level access to the hardware and drivers that integrate into the Nios II HAL system library. Application developers should not modify these files.

- **altera_avalon_epcs_flash_controller.h**, **altera_avalon_epcs_flash_controller.c**—Header and source files that define the drivers required for integration into the HAL system library.
- **epcs_commands.h**, **epcs_commands.c**—Header and source files that directly control the EPCS device hardware to read and write the device. These files also rely on the Altera SPI core drivers.

5. JTAG UART Core

NII51009-9.0.0

Core Overview

The JTAG UART core with Avalon® interface implements a method to communicate serial character streams between a host PC and an SOPC Builder system on an Altera® FPGA. In many designs, the JTAG UART core eliminates the need for a separate RS-232 serial connection to a host PC for character I/O. The core provides an Avalon interface that hides the complexities of the JTAG interface from embedded software programmers. Master peripherals (such as a Nios® II processor) communicate with the core by reading and writing control and data registers.

The JTAG UART core uses the JTAG circuitry built in to Altera FPGAs, and provides host access via the JTAG pins on the FPGA. The host PC can connect to the FPGA via any Altera JTAG download cable, such as the USB-Blaster™ cable. Software support for the JTAG UART core is provided by Altera. For the Nios II processor, device drivers are provided in the HAL system library, allowing software to access the core using the ANSI C Standard Library **stdio.h** routines. For the host PC, Altera provides JTAG terminal software that manages the connection to the target, decodes the JTAG data stream, and displays characters on screen.

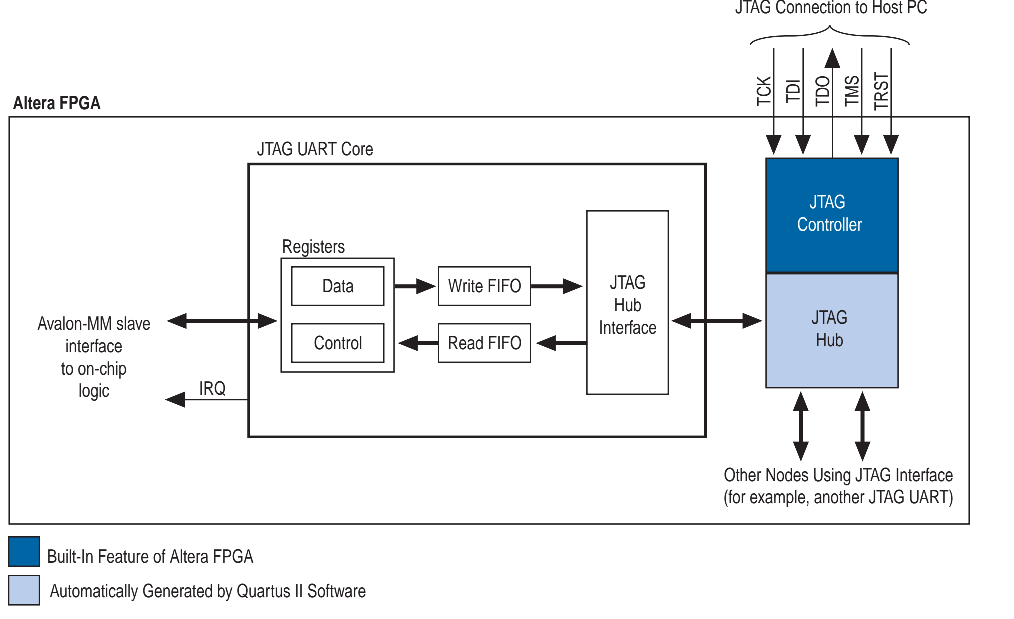
The JTAG UART core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- "Functional Description" on page 5–2
- "Device and Tools Support" on page 5–4
- "Instantiating the Core in SOPC Builder" on page 5–4
- "Hardware Simulation Considerations" on page 5–6
- "Software Programming Model" on page 5–6

Functional Description

Figure 5–1 shows a block diagram of the JTAG UART core and its connection to the JTAG circuitry inside an Altera FPGA. The following sections describe the components of the core.

Figure 5–1. JTAG UART Core Block Diagram



Avalon Slave Interface and Registers

The JTAG UART core provides an Avalon slave interface to the JTAG circuitry on an Altera FPGA. The user-visible interface to the JTAG UART core consists of two 32-bit registers, `data` and `control`, that are accessed through an Avalon slave port. An Avalon master, such as a Nios II processor, accesses the registers to control the core and transfer data over the JTAG connection. The core operates on 8-bit units of data at a time; eight bits of the `data` register serve as a one-character payload.

The JTAG UART core provides an active-high interrupt output that can request an interrupt when read data is available, or when the write FIFO is ready for data. For further details see "Interrupt Behavior" on page 5–11.

Read and Write FIFOs

The JTAG UART core provides bidirectional FIFOs to improve bandwidth over the JTAG connection. The FIFO depth is parameterizable to accommodate the available on-chip memory. The FIFOs can be constructed out of memory blocks or registers, allowing you to trade off logic resources for memory resources, if necessary.

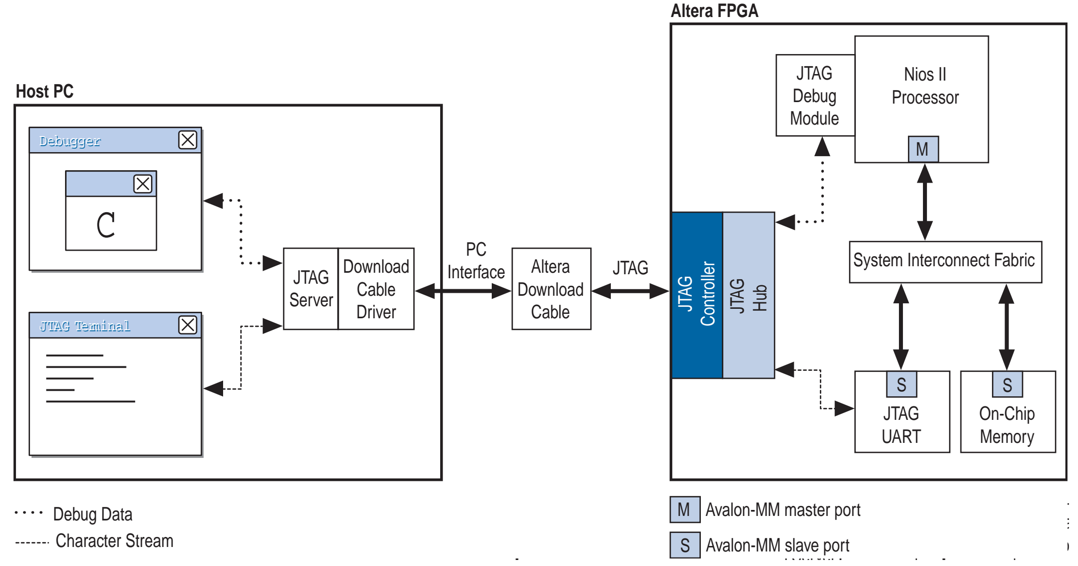
JTAG Interface

Altera FPGAs contain built-in JTAG control circuitry between the device's JTAG pins and the logic inside the device. The JTAG controller can connect to user-defined circuits called *nodes* implemented in the FPGA. Because several nodes may need to communicate via the JTAG interface, a JTAG hub, which is a multiplexer, is necessary. During logic synthesis and fitting, the Quartus® II software automatically generates the JTAG hub logic. No manual design effort is required to connect the JTAG circuitry inside the device; the process is presented here only for clarity.

Host-Target Connection

Figure 5–2 shows the connection between a host PC and an SOPC Builder-generated system containing a JTAG UART core.

Figure 5–2. Example System Using the JTAG UART Core



The JTAG controller on the FPGA and the download cable driver on the host PC implement a simple data-link layer between host and target. All JTAG nodes inside the FPGA are multiplexed through the single JTAG connection. JTAG server software on the host PC controls and decodes the JTAG data stream, and maintains distinct connections with nodes inside the FPGA.

The example system in Figure 5–2 contains one JTAG UART core and a Nios II processor. Both agents communicate with the host PC over a single Altera download cable. Thanks to the JTAG server software, each host application has an independent connection to the target. Altera provides the JTAG server drivers and host software required to communicate with the JTAG UART core.

Systems with multiple JTAG UART cores are possible, and all cores communicate via the same JTAG interface. To maintain coherent data streams, only one processor should communicate with each JTAG UART core.

Device and Tools Support

The JTAG UART core supports all Altera® device families. The JTAG UART core is supported by the Nios II hardware abstraction layer (HAL) system library.

To view the character stream on the host PC, the JTAG UART core must be used in conjunction with the JTAG terminal software provided by Altera. Nios II processor users access the JTAG UART via the Nios II IDE or the **nios2-terminal** command-line utility.

For further details, refer to the *Nios II Software Developer's Handbook* or the Nios II IDE online help.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ interface for the JTAG UART core in SOPC Builder to specify the core features. The following sections describe the available options.

Configuration Page

The options on this page control the hardware configuration of the JTAG UART core. The default settings are pre-configured to behave optimally with the Altera-provided device drivers and JTAG terminal software. Most designers should not change the default values, except for the **Construct using registers instead of memory blocks** option.

Write FIFO Settings

The write FIFO buffers data flowing from the Avalon interface to the host. The following settings are available:

- **Depth**—The write FIFO depth can be set from 8 to 32,768 bytes. Only powers of two are allowed. Larger values consume more on-chip memory resources. A depth of 64 is generally optimal for performance, and larger values are rarely necessary.
- **IRQ Threshold—**The write IRQ threshold governs how the core asserts its IRQ in response to the FIFO emptying. As the JTAG circuitry empties data from the write FIFO, the core asserts its IRQ when the number of characters remaining in the FIFO reaches this threshold value. For maximum bandwidth, a processor should service the interrupt by writing more data and preventing the write FIFO from emptying completely. A value of 8 is typically optimal. See "Interrupt Behavior" on page 5–11 for further details.
- **Construct using registers instead of memory blocks**—Turning on this option causes the FIFO to be constructed out of on-chip logic resources. This option is useful when memory resources are limited. Each byte consumes roughly 11 logic elements (LEs), so a FIFO depth of 8 (bytes) consumes roughly 88 LEs.

Read FIFO Settings

The read FIFO buffers data flowing from the host to the Avalon interface. Settings are available to control the depth of the FIFO and the generation of interrupts.

- **Depth**—The read FIFO depth can be set from 8 to 32,768 bytes. Only powers of two are allowed. Larger values consume more on-chip memory resources. A depth of 64 is generally optimal for performance, and larger values are rarely necessary.
- **IRQ Threshold—**The IRQ threshold governs how the core asserts its IRQ in response to the FIFO filling up. As the JTAG circuitry fills up the read FIFO, the core asserts its IRQ when the amount of space remaining in the FIFO reaches this threshold value. For maximum bandwidth, a processor should service the interrupt by reading data and preventing the read FIFO from filling up completely. A value of 8 is typically optimal. See "Interrupt Behavior" on page 5–11 for further details.
- **Construct using registers instead of memory blocks**—Turning on this option causes the FIFO to be constructed out of logic resources. This option is useful when memory resources are limited. Each byte consumes roughly 11 LEs, so a FIFO depth of 8 (bytes) consumes roughly 88 LEs.

Simulation Settings

At system generation time, when SOPC Builder generates the logic for the JTAG UART core, a simulation model is also constructed. The simulation model offers features to simplify simulation of systems using the JTAG UART core. Changes to the simulation settings do not affect the behavior of the core in hardware; the settings affect only functional simulation.

Simulated Input Character Stream

You can enter a character stream that will be simulated entering the read FIFO upon simulated system reset. The MegaWizard Interface accepts an arbitrary character string, which is later incorporated into the test bench. After reset, this character string is pre-initialized in the read FIFO, giving the appearance that an external JTAG terminal program is sending a character stream to the JTAG UART core.

Prepare Interactive Windows

At system generation time, the JTAG UART core generator can create ModelSim® macros to open interactive windows during simulation. These windows allow the user to send and receive ASCII characters via a console, giving the appearance of a terminal session with the system executing in hardware. The following options are available:

- **Do not generate ModelSim aliases for interactive windows**—This option does not create any ModelSim macros for character I/O.
- **Create ModelSim alias to open a window showing output as ASCII text**—This option creates a ModelSim macro to open a console window that displays output from the write FIFO. Values written to the write FIFO via the Avalon interface are displayed in the console as ASCII characters.

- **Create ModelSim alias to open an interactive stimulus/response window**—This option creates a ModelSim macro to open a console window that allows input and output interaction with the core. Values written to the write FIFO via the Avalon interface are displayed in the console as ASCII characters. Characters typed into the console are fed into the read FIFO, and can be read via the Avalon interface. When this option is enabled, the simulated character input stream option is ignored.

Hardware Simulation Considerations

The simulation features were created for easy simulation of Nios II processor systems when using the ModelSim simulator. The simulation model is implemented in the JTAG UART core's top-level HDL file. The synthesizable HDL and the simulation HDL are implemented in the same file. Some simulation features are implemented using `translate on/off` synthesis directives that make certain sections of HDL code visible only to the synthesis tool.

For complete details about simulating the JTAG UART core in Nios II systems, refer to *AN 351: Simulating Nios II Processor Designs*.

Other simulators can be used, but require user effort to create a custom simulation process. You can use the auto-generated ModelSim scripts as references to create similar functionality for other simulators.

Do not edit the simulation directives if you are using Altera's recommended simulation procedures. If you change the simulation directives to create a custom simulation flow, be aware that SOPC Builder overwrites existing files during system generation. Take precautions to ensure your changes are not overwritten.

Software Programming Model

The following sections describe the software programming model for the JTAG UART core, including the register map and software declarations to access the hardware. For Nios II processor users, Altera provides HAL system library drivers that enable you to access the JTAG UART using the ANSI C standard library functions, such as `printf()` and `getchar()`.

HAL System Library Support

The Altera-provided driver implements a HAL character-mode device driver that integrates into the HAL system library for Nios II systems. HAL users should access the JTAG UART via the familiar HAL API and the ANSI C standard library, rather than accessing the JTAG UART registers. `ioctl()` requests are defined that allow HAL users to control the hardware-dependent aspects of the JTAG UART.

If your program uses the Altera-provided HAL device driver to access the JTAG UART hardware, accessing the device registers directly will interfere with the correct behavior of the driver.

For Nios II processor users, the HAL system library API provides complete access to the JTAG UART core's features. Nios II programs treat the JTAG UART core as a character mode device, and send and receive data using the ANSI C standard library functions, such as `getchar()` and `printf()`.

Example 5–1 demonstrates the simplest possible usage, printing a message to `stdout` using `printf()`. In this example, the SOPC Builder system contains a JTAG UART core, and the HAL system library is configured to use this JTAG UART device for `stdout`.

Example 5–1. *Printing Characters to a JTAG UART Core as stdout*

```
#include <stdio.h>
int main ()
{
   printf("Hello world.\n");
   return 0;
}
```

Example 5–2 demonstrates reading characters from and sending messages to a JTAG UART core using the C standard library. In this example, the SOPC Builder system contains a JTAG UART core named `jtag_uart` that is not necessarily configured as the `stdout` device. In this case, the program treats the device like any other node in the HAL file system.

Example 5–2. Transmitting Characters to a JTAG UART Core

```
/* A simple program that recognizes the characters 't' and 'v' */
#include <stdio.h>
#include <string.h>
int main ()
{
   char* msg = "Detected the character 't'.\n";
   FILE* fp;
   char prompt = 0;

fp = fopen ("/dev/jtag_uart", "r+"); //Open file for reading and writing
if (fp)
{
   while (prompt != 'v')
   {  // Loop until we receive a 'v'.
      prompt = getc(fp);  // Get a character from the JTAG UART.
      if (prompt == 't')
      {  // Print a message if character is 't'.
         fwrite (msg, strlen (msg), 1, fp);
      }

      if (ferror(fp))// Check if an error occurred with the file
      pointer clearerr(fp);// If so, clear it.
   }

   fprintf(fp, "Closing the JTAG UART file handle.\n");
   fclose (fp);
   }

   return 0;
}
```

In this example, the `ferror(fp)` is used to check if an error occurred on the JTAG UART connection, such as a disconnected JTAG connection. In this case, the driver detects that the JTAG connection is disconnected, reports an error (`EIO`), and discards data for subsequent transactions. If this error ever occurs, the C library latches the value until you explicitly clear it with the `clearerr()` function.

For complete details of the HAL system library, refer to the *Nios II Software Developer's Handbook*.

The Nios II Embedded Design Suite (EDS) provides a number of software example designs that use the JTAG UART core.

Driver Options: Fast vs. Small Implementations

To accommodate the requirements of different types of systems, the JTAG UART driver has two variants, a fast version and a small version. The fast behavior is used by default. Both the fast and small drivers fully support the C standard library functions and the HAL API.

The fast driver is an interrupt-driven implementation, which allows the processor to perform other tasks when the device is not ready to send or receive data. Because the JTAG UART data rate is slow compared to the processor, the fast driver can provide a large performance benefit for systems that could be performing other tasks in the interim. In addition, the fast version of the Altera Avalon JTAG UART monitors the connection to the host. The driver discards characters if no host is connected, or if the host is not running an application that handles the I/O stream.

The small driver is a polled implementation that waits for the JTAG UART hardware before sending and receiving each character. The performance of the small driver is poor if you are sending large amounts of data. The small version assumes that the host is always connected, and will never discard characters. Therefore, the small driver will hang the system if the JTAG UART hardware is ever disconnected from the host while the program is sending or receiving data. There are two ways to enable the small footprint driver:

- Enable the small footprint setting for the HAL system library project. This option affects device drivers for all devices in the system.
- Specify the preprocessor option `-DALTERA_AVALON_JTAG_UART_SMALL`. Use this option if you want the small, polled implementation of the JTAG UART driver, but you do not want to affect the drivers for other devices.

ioctl() Operations

The fast version of the JTAG UART driver supports the `ioctl()` function to allow HAL-based programs to request device-specific operations. Specifically, you can use the `ioctl()` operations to control the timeout period, and to detect whether or not a host is connected. The fast driver defines the `ioctl()` operations shown in Table 5–1.

Table 5–1. JTAG UART ioctl() Operations for the Fast Driver Only

Request	Meaning
`TIOCSTIMEOUT`	Set the timeout (in seconds) after which the driver will decide that the host is not connected. A timeout of 0 makes the target assume that the host is always connected. The `ioctl` arg parameter passed in must be a pointer to an integer.
`TIOCGCONNECTED`	Sets the integer arg parameter to a value that indicates whether the host is connected and acting as a terminal (1), or not connected (0). The `ioctl` arg parameter passed in must be a pointer to an integer.

For details about the `ioctl()` function, refer to the *Nios II Software Developer's Handbook*.

Software Files

The JTAG UART core is accompanied by the following software files. These files define the low-level interface to the hardware, and provide the HAL drivers. Application developers should not modify these files.

- **altera_avalon_jtag_uart_regs.h**—This file defines the core's register map, providing symbolic constants to access the low-level hardware. The symbols in this file are used only by device driver functions.
- **altera_avalon_jtag_uart.h**, **altera_avalon_jtag_uart.c**—These files implement the HAL system library device driver.

Accessing the JTAG UART Core via a Host PC

Host software is necessary for a PC to access the JTAG UART core. The Nios II IDE supports the JTAG UART core, and displays character I/O in a console window. Altera also provides a command-line utility called **nios2-terminal** that opens a terminal session with the JTAG UART core.

For further details, refer to the *Nios II Software Developer's Handbook* and Nios II IDE online help.

Register Map

Programmers using the HAL API never access the JTAG UART core directly via its registers. In general, the register map is only useful to programmers writing a device driver for the core.

The Altera-provided HAL device driver accesses the device registers directly. If you are writing a device driver, and the HAL driver is active for the same device, your driver will conflict and fail to operate.

Table 5–2 shows the register map for the JTAG UART core. Device drivers control and communicate with the core through the two, 32-bit memory-mapped registers.

Table 5–2. JTAG UART Core Register Map

Offset	Register Name	R/W	Bit Description															
			31	...	16	15	14	...	11	10	9	8	7	...	2	1	0
0	`data`	RW	`RAVAIL`			`RVALID`	Reserved						`DATA`				
1	`control`	RW	`WSPACE`			Reserved				`AC`	`WI`	`RI`	Reserved			`WE`	`RE`

Note to Table 5–2:

(1) Reserved fields—Read values are undefined. Write zero.

Data Register

Embedded software accesses the read and write FIFOs via the `data` register. Table 5–3 describes the function of each bit.

Table 5–3. data Register Bits

Bit(s)	Name	Access	Description
[7:0]	`DATA`	R/W	The value to transfer to/from the JTAG core. When writing, the `DATA` field holds a character to be written to the write FIFO. When reading, the `DATA` field holds a character read from the read FIFO.
[15]	`RVALID`	R	Indicates whether the `DATA` field is valid. If `RVALID`=1, the `DATA` field is valid, otherwise `DATA` is undefined.
[32:16]	`RAVAIL`	R	The number of characters remaining in the read FIFO (after the current read).

A read from the `data` register returns the first character from the FIFO (if one is available) in the `DATA` field. Reading also returns information about the number of characters remaining in the FIFO in the `RAVAIL` field. A write to the `data` register stores the value of the `DATA` field in the write FIFO. If the write FIFO is full, the character is lost.

Control Register

Embedded software controls the JTAG UART core's interrupt generation and reads status information via the `control` register. Table 5–4 describes the function of each bit.

Table 5–4. Control Register Bits

Bit(s)	Name	Access	Description
0	`RE`	R/W	Interrupt-enable bit for read interrupts.
1	`WE`	R/W	Interrupt-enable bit for write interrupts.
8	`RI`	R	Indicates that the read interrupt is pending.
9	`WI`	R	Indicates that the write interrupt is pending.
10	`AC`	R/C	Indicates that there has been JTAG activity since the bit was cleared. Writing 1 to `AC` clears it to 0.
[32:16]	`WSPACE`	R	The number of spaces available in the write FIFO.

A read from the `control` register returns the status of the read and write FIFOs. Writes to the register can be used to enable/disable interrupts, or clear the `AC` bit.

© March 2009 Altera Corporation

The RE and WE bits enable interrupts for the read and write FIFOs, respectively. The WI and RI bits indicate the status of the interrupt sources, qualified by the values of the interrupt enable bits (WE and RE). Embedded software can examine RI and WI to determine the condition that generated the IRQ. See "Interrupt Behavior" on page 5–11 for further details.

The AC bit indicates that an application on the host PC has polled the JTAG UART core via the JTAG interface. Once set, the AC bit remains set until it is explicitly cleared via the Avalon interface. Writing 1 to AC clears it. Embedded software can examine the AC bit to determine if a connection exists to a host PC. If no connection exists, the software may choose to ignore the JTAG data stream. When the host PC has no data to transfer, it can choose to poll the JTAG UART core as infrequently as once per second. Delays caused by other host software using the JTAG download cable could cause delays of up to 10 seconds between polls.

Interrupt Behavior

The JTAG UART core generates an interrupt when either of the individual interrupt conditions is pending and enabled.

Interrupt behavior is of interest to device driver programmers concerned with the bandwidth performance to the host PC. Example designs and the JTAG terminal program provided with Nios II Embedded Design Suite (EDS) are pre-configured with optimal interrupt behavior.

The JTAG UART core has two kinds of interrupts: write interrupts and read interrupts. The WE and RE bits in the `control` register enable/disable the interrupts.

The core can assert a write interrupt whenever the write FIFO is nearly empty. The nearly empty threshold, `write_threshold`, is specified at system generation time and cannot be changed by embedded software. The write interrupt condition is set whenever there are `write_threshold` or fewer characters in the write FIFO. It is cleared by writing characters to fill the write FIFO beyond the `write_threshold`. Embedded software should only enable write interrupts after filling the write FIFO. If it has no characters remaining to send, embedded software should disable the write interrupt.

The core can assert a read interrupt whenever the read FIFO is nearly full. The nearly full threshold value, `read_threshold`, is specified at system generation time and cannot be changed by embedded software. The read interrupt condition is set whenever the read FIFO has `read_threshold` or fewer spaces remaining. The read interrupt condition is also set if there is at least one character in the read FIFO and no more characters are expected. The read interrupt is cleared by reading characters from the read FIFO.

For optimum performance, the interrupt thresholds should match the interrupt response time of the embedded software. For example, with a 10-MHz JTAG clock, a new character is provided (or consumed) by the host PC every 1 µs. With a threshold of 8, the interrupt response time must be less than 8 µs. If the interrupt response time is too long, performance suffers. If it is too short, interrupts occurs too often.

For Nios II processor systems, read and write thresholds of 8 are an appropriate default.

6. UART Core

NII51010-9.0.0

Core Overview

The UART core with Avalon® interface implements a method to communicate serial character streams between an embedded system on an Altera® FPGA and an external device. The core implements the RS-232 protocol timing, and provides adjustable baud rate, parity, stop, and data bits, and optional RTS/CTS flow control signals. The feature set is configurable, allowing designers to implement just the necessary functionality for a given system.

The core provides an Avalon Memory-Mapped (Avalon-MM) slave interface that allows Avalon-MM master peripherals (such as a Nios® II processor) to communicate with the core simply by reading and writing control and data registers.

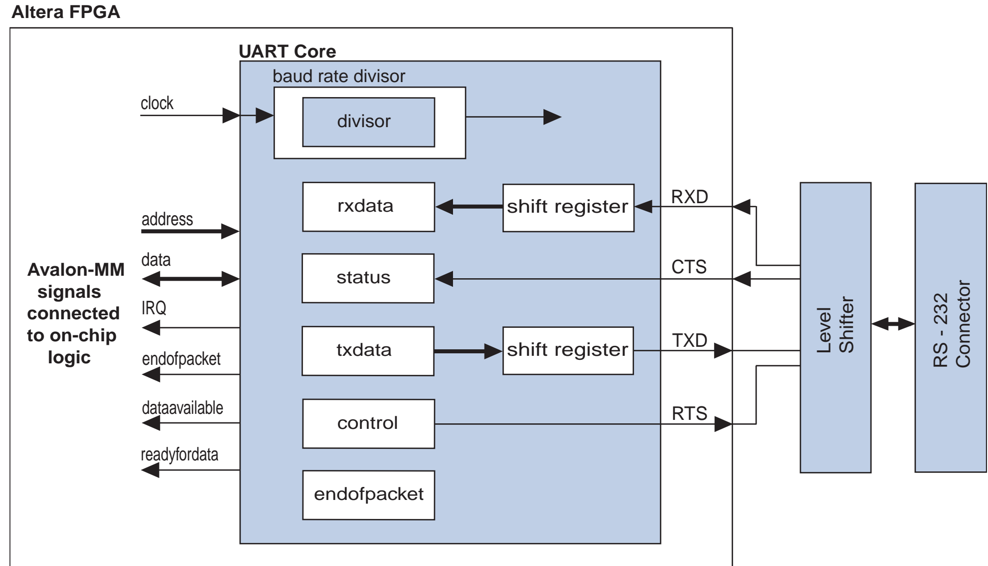
The UART core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- "Functional Description"
- "Device Support" on page 6–3
- "Instantiating the Core in SOPC Builder" on page 6–3
- "Simulation Considerations" on page 6–7
- "Software Programming Model" on page 6–8

Functional Description

Figure 6–1 shows a block diagram of the UART core.

Figure 6–1. Block Diagram of the UART Core in a Typical System



The core has two user-visible parts:

- The register file, which is accessed via the Avalon-MM slave port
- The RS-232 signals, `RXD`, `TXD`, `CTS`, and `RTS`

Avalon-MM Slave Interface and Registers

The UART core provides an Avalon-MM slave interface to the internal register file. The user interface to the UART core consists of six, 16-bit registers: `control`, `status`, `rxdata`, `txdata`, `divisor`, and `endofpacket`. A master peripheral, such as a Nios II processor, accesses the registers to control the core and transfer data over the serial connection.

The UART core provides an active-high interrupt request (IRQ) output that can request an interrupt when new data has been received, or when the core is ready to transmit another character. For further details, refer "Interrupt Behavior" on page 6–15.

The Avalon-MM slave port is capable of transfers with flow control. The UART core can be used in conjunction with a direct memory access (DMA) peripheral with Avalon-MM flow control to automate continuous data transfers between, for example, the UART core and memory.

For more information, refer to the *Timer Core* chapter in volume 5 of the *Quartus II Handbook*. For details about the Avalon-MM interface, refer to the *Avalon Interface Specifications*.

RS-232 Interface

The UART core implements RS-232 asynchronous transmit and receive logic. The UART core sends and receives serial data via the `TXD` and `RXD` ports. The I/O buffers on most Altera FPGA families do not comply with RS-232 voltage levels, and may be damaged if driven directly by signals from an RS-232 connector. To comply with RS-232 voltage signaling specifications, an external level-shifting buffer is required (for example, Maxim MAX3237) between the FPGA I/O pins and the external RS-232 connector.

The UART core uses a logic 0 for mark, and a logic 1 for space. An inverter inside the FPGA can be used to reverse the polarity of any of the RS-232 signals, if necessary.

Transmitter Logic

The UART transmitter consists of a 7-, 8-, or 9-bit `txdata` holding register and a corresponding 7-, 8-, or 9-bit transmit shift register. Avalon-MM master peripherals write the `txdata` holding register via the Avalon-MM slave port. The transmit shift register is loaded from the `txdata` register automatically when a serial transmit shift operation is not currently in progress. The transmit shift register directly feeds the `TXD` output. Data is shifted out to `TXD` LSB first.

These two registers provide double buffering. A master peripheral can write a new value into the `txdata` register while the previously written character is being shifted out. The master peripheral can monitor the transmitter's status by reading the `status` register's transmitter ready (`TRDY`), transmitter shift register empty (`tmt`), and transmitter overrun error (`TOE`) bits.

The transmitter logic automatically inserts the correct number of start, stop, and parity bits in the serial TXD data stream as required by the RS-232 specification.

Receiver Logic

The UART receiver consists of a 7-, 8-, or 9-bit receiver-shift register and a corresponding 7-, 8-, or 9-bit `rxdata` holding register. Avalon-MM master peripherals read the `rxdata` holding register via the Avalon-MM slave port. The `rxdata` holding register is loaded from the receiver shift register automatically every time a new character is fully received.

These two registers provide double buffering. The `rxdata` register can hold a previously received character while the subsequent character is being shifted into the receiver shift register.

A master peripheral can monitor the receiver's status by reading the `status` register's read-ready (`RRDY`), receiver-overrun error (`ROE`), break detect (`BRK`), parity error (`PE`), and framing error (`FE`) bits. The receiver logic automatically detects the correct number of start, stop, and parity bits in the serial RXD stream as required by the RS-232 specification. The receiver logic checks for four exceptional conditions, frame error, parity error, receive overrun error, and break, in the received data and sets corresponding `status` register bits.

Baud Rate Generation

The UART core's internal baud clock is derived from the Avalon-MM clock input. The internal baud clock is generated by a clock divider. The divisor value can come from one of the following sources:

- A constant value specified at system generation time
- The 16-bit value stored in the `divisor` register

The `divisor` register is an optional hardware feature. If it is disabled at system generation time, the divisor value is fixed and the baud rate cannot be altered.

Device Support

The UART core supports all Altera® device families.

Instantiating the Core in SOPC Builder

Instantiating the UART in hardware creates at least two I/O ports for each UART core: An `RXD` input, and a `TXD` output. Optionally, the hardware may include flow control signals, the `CTS` input and `RTS` output.

Use the MegaWizard™ interface for the UART core in SOPC Builder to configure the hardware feature set. The following sections describe the available options.

Configuration Settings

This section describes the configuration settings.

Baud Rate Options

The UART core can implement any of the standard baud rates for RS-232 connections. The baud rate can be configured in one of two ways:

- **Fixed rate**—The baud rate is fixed at system generation time and cannot be changed via the Avalon-MM slave port.
- **Variable rate**—The baud rate can vary, based on a clock divisor value held in the `divisor` register. A master peripheral changes the baud rate by writing new values to the `divisor` register.

The baud rate is calculated based on the clock frequency provided by the Avalon-MM interface. Changing the system clock frequency in hardware without regenerating the UART core hardware results in incorrect signaling.

Baud Rate (bps) Setting

The **Baud Rate** setting determines the default baud rate after reset. The **Baud Rate** option offers standard preset values.

The baud rate value is used to calculate an appropriate clock divisor value to implement the desired baud rate. Baud rate and divisor values are related as shown in Equation 6–1 and Equation 6–2:

Equation 6–1.

$$\text{divisor} = \text{int}\left(\frac{\text{clock frequency}}{\text{baud rate}} + 0.5\right)$$

Equation 6–2.

$$\text{baud rate} = \frac{\text{clock frequency}}{\text{divisor} + 1}$$

Baud Rate Can Be Changed By Software Setting

When this setting is on, the hardware includes a 16-bit `divisor` register at address offset 4. The `divisor` register is writable, so the baud rate can be changed by writing a new value to this register.

When this setting is off, the UART hardware does not include a `divisor` register. The UART hardware implements a constant baud divisor, and the value cannot be changed after system generation. In this case, writing to address offset 4 has no effect, and reading from address offset 4 produces an undefined result.

 © March 2009 Altera Corporation

Data Bits, Stop Bits, Parity

The UART core's parity, data bits and stop bits are configurable. These settings are fixed at system generation time; they cannot be altered via the register file. Table 6–1 explains the settings.

Table 6–1. Data Bits Settings

Setting	Legal Values	Description
Data Bits	7, 8, 9	This setting determines the widths of the `txdata`, `rxdata`, and `endofpacket` registers.
Stop Bits	1, 2	This setting determines whether the core transmits 1 or 2 stop bits with every character. The core always terminates a receive transaction at the first stop bit, and ignores all subsequent stop bits, regardless of this setting.
Parity	None, Even, Odd	This setting determines whether the UART core transmits characters with parity checking, and whether it expects received characters to have parity checking. When **Parity** is set to **None**, the transmit logic sends data without including a parity bit, and the receive logic presumes the incoming data does not include a parity bit. The `PE` bit in the `status` register is not implemented; it always reads 0. When **Parity** is set to **Odd** or **Even**, the transmit logic computes and inserts the required parity bit into the outgoing TXD bitstream, and the receive logic checks the parity bit in the incoming RXD bitstream. If the receiver finds data with incorrect parity, the `PE` bit in the `status` register is set to 1. When **Parity** is **Even**, the parity bit is 0 if the character has an even number of 1 bits; otherwise the parity bit is 1. Similarly, when parity is **Odd**, the parity bit is 0 if the character has an odd number of 1 bits.

Synchronizer Stages

The option **Synchronizer Stages** allows you to specify the length of synchronization register chains. These register chains are used when a metastable event is likely to occur and the length specified determines the meantime before failure. The register chain length, however, affects the latency of the core.

For more information on metastability in Altera devices, refer to *AN 42: Metastability in Altera Devices*. For more information on metastability analysis and synchronization register chains, refer to the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*.

Flow Control

When the option **Include CTS/RTS pins and control register bits** is turned on, the UART core includes the following features:

- `cts_n` (logic negative CTS) input port
- `rts_n` (logic negative RTS) output port
- `CTS` bit in the `status` register
- `DCTS` bit in the `status` register
- `RTS` bit in the `control` register
- `IDCTS` bit in the `control` register

Based on these hardware facilities, an Avalon-MM master peripheral can detect CTS and transmit RTS flow control signals. The CTS input and RTS output ports are tied directly to bits in the status and control registers, and have no direct effect on any other part of the core. When using flow control, be sure the terminal program on the host side is also configured for flow control.

When the **Include CTS/RTS pins and control register bits** setting is off, the core does not include the aforementioned hardware and continuous writes to the UART may loose data. The control/status bits CTS, DCTS, IDCTS, and RTS are not implemented; they always read as 0.

Streaming Data (DMA) Control

The UART core's Avalon-MM interface optionally implements Avalon-MM transfers with flow control. Flow control allows an Avalon-MM master peripheral to write data only when the UART core is ready to accept another character, and to read data only when the core has data available. The UART core can also optionally include the end-of-packet register.

Include End-of-Packet Register

When this setting is on, the UART core includes:

- A 7-, 8-, or 9-bit endofpacket register at address-offset 5. The data width is determined by the **Data Bits** setting.
- EOP bit in the status register.
- IEOP bit in the control register.
- endofpacket signal in the Avalon-MM interface to support data transfers with flow control to and from other master peripherals in the system.

End-of-packet (EOP) detection allows the UART core to terminate a data transaction with an Avalon-MM master with flow control. EOP detection can be used with a DMA controller, for example, to implement a UART that automatically writes received characters to memory until a specified character is encountered in the incoming RXD stream. The terminating (EOP) character's value is determined by the endofpacket register.

When the EOP register is disabled, the UART core does not include the EOP resources. Writing to the endofpacket register has no effect, and reading produces an undefined value.

Simulation Settings

When the UART core's logic is generated, a simulation model is also created. The simulation model offers features to simplify and accelerate simulation of systems that use the UART core. Changes to the simulation settings do not affect the behavior of the UART core in hardware; the settings affect only functional simulation.

For examples of how to use the following settings to simulate Nios II systems, refer to *AN 351: Simulating Nios II Embedded Processor Designs*.

Simulated RXD-Input Character Stream

You can enter a character stream that is simulated entering the `RXD` port upon simulated system reset. The UART core's MegaWizard™ interface accepts an arbitrary character string, which is later incorporated into the UART simulation model. After reset in reset, the string is input into the `RXD` port character-by-character as the core is able to accept new data.

Prepare Interactive Windows

At system generation time, the UART core generator can create ModelSim macros that facilitate interaction with the UART model during simulation. You can turn on the following options:

- **Create ModelSim alias to open streaming output window** to create a ModelSim macro that opens a window to display all output from the `TXD` port.
- **Create ModelSim alias to open interactive stimulus window** to create a ModelSim macro that opens a window to accept stimulus for the `RXD` port. The window sends any characters typed in the window to the `RXD` port.

Simulated Transmitter Baud Rate

RS-232 transmission rates are often slower than any other process in the system, and it is seldom useful to simulate the functional model at the true baud rate. For example, at 115,200 bps, it typically takes thousands of clock cycles to transfer a single character. The UART simulation model has the ability to run with a constant clock divisor of 2, allowing the simulated UART to transfer bits at half the system clock speed, or roughly one character per 20 clock cycles. You can choose one of the following options for the simulated transmitter baud rate:

- **Accelerated (use divisor = 2)**—`TXD` emits one bit per 2 clock cycles in simulation.
- **Actual (use true baud divisor)**—`TXD` transmits at the actual baud rate, as determined by the `divisor` register.

Simulation Considerations

The simulation features were created for easy simulation of Nios II processor systems when using the ModelSim simulator. The documentation for the processor documents the suggested usage of these features. Other usages may be possible, but will require additional user effort to create a custom simulation process.

The simulation model is implemented in the UART core's top-level HDL file; the synthesizable HDL and the simulation HDL are implemented in the same file. The simulation features are implemented using `translate on` and `translate off` synthesis directives that make certain sections of HDL code visible only to the synthesis tool.

Do not edit the simulation directives if you are using Altera's recommended simulation procedures. If you do change the simulation directives for your custom simulation flow, be aware that SOPC Builder overwrites existing files during system generation. Take precaution so that your changes are not overwritten.

For details about simulating the UART core in Nios II processor systems, refer to *AN 351: Simulating Nios II Processor Designs*.

Software Programming Model

The following sections describe the software programming model for the UART core, including the register map and software declarations to access the hardware. For Nios II processor users, Altera provides hardware abstraction layer (HAL) system library drivers that enable you to access the UART core using the ANSI C standard library functions, such as `printf()` and `getchar()`.

HAL System Library Support

The Altera-provided driver implements a HAL character-mode device driver that integrates into the HAL system library for Nios II systems. HAL users should access the UART via the familiar HAL API and the ANSI C standard library, rather than accessing the UART registers. `ioctl()` requests are defined that allow HAL users to control the hardware-dependent aspects of the UART.

If your program uses the HAL device driver to access the UART hardware, accessing the device registers directly interferes with the correct behavior of the driver.

For Nios II processor users, the HAL system library API provides complete access to the UART core's features. Nios II programs treat the UART core as a character mode device, and send and receive data using the ANSI C standard library functions.

The driver supports the CTS/RTS control signals when they are enabled in SOPC Builder. Refer to "Driver Options: Fast Versus Small Implementations" on page 6–9.

The following code demonstrates the simplest possible usage, printing a message to `stdout` using `printf()`. In this example, the SOPC Builder system contains a UART core, and the HAL system library has been configured to use this device for `stdout`.

Example 6–1. Example: Printing Characters to a UART Core as stdout

```
#include <stdio.h>
int main ()
{
   printf("Hello world.\n");
   return 0;
}
```

The following code demonstrates reading characters from and sending messages to a UART device using the C standard library. In this example, the SOPC Builder system contains a UART core named `uart1` that is not necessarily configured as the `stdout` device. In this case, the program treats the device like any other node in the HAL file system.

Example 6–2. Example: Sending and Receiving Characters

```
/* A simple program that recognizes the characters 't' and 'v' */
#include <stdio.h>
#include <string.h>
int main ()
{
    char* msg = "Detected the character 't'.\n";
    FILE* fp;
    char prompt = 0;

    fp = fopen ("/dev/uart1", "r+"); //Open file for reading and writing
    if (fp)
    {
        while (prompt != 'v')
        {  // Loop until we receive a 'v'.
            prompt = getc(fp);  // Get a character from the UART.
            if (prompt == 't')
            {  // Print a message if character is 't'.
                fwrite (msg, strlen (msg), 1, fp);
            }
        }

        fprintf(fp, "Closing the UART file.\n");
        fclose (fp);
    }

    return 0;
}
```

For more information about the HAL system library, refer to the *Nios II Software Developer's Handbook*.

Driver Options: Fast Versus Small Implementations

To accommodate the requirements of different types of systems, the UART driver provides two variants: a fast version and a small version. The fast version is the default. Both fast and small drivers fully support the C standard library functions and the HAL API.

The fast driver is an interrupt-driven implementation, which allows the processor to perform other tasks when the device is not ready to send or receive data. Because the UART data rate is slow compared to the processor, the fast driver can provide a large performance benefit for systems that could be performing other tasks in the interim.

The small driver is a polled implementation that waits for the UART hardware before sending and receiving each character. There are two ways to enable the small footprint driver:

- Enable the small footprint setting for the HAL system library project. This option affects device drivers for all devices in the system as well.
- Specify the preprocessor option `-DALTERA_AVALON_UART_SMALL`. You can use this option if you want the small, polled implementation of the UART driver, but do not want to affect the drivers for other devices.

Refer to the help system in the Nios II IDE for details about how to set HAL properties and preprocessor options.

If the CTS/RTS flow control signals are enabled in hardware, the fast driver automatically uses them. The small driver always ignores them.

ioctl() Operations

The UART driver supports the `ioctl()` function to allow HAL-based programs to request device-specific operations. Table 6–2 defines operation requests that the UART driver supports.

Table 6–2. UART ioctl() Operations

Request	Description
`TIOCEXCL`	Locks the device for exclusive access. Further calls to `open()` for this device will fail until either this file descriptor is closed, or the lock is released using the `TIOCNXCL` `ioctl` request. For this request to succeed there can be no other existing file descriptors for this device. The parameter `arg` is ignored.
`TIOCNXCL`	Releases a previous exclusive access lock. The parameter `arg` is ignored.

Additional operation requests are also optionally available for the fast driver only, as shown in Table 6–3. To enable these operations in your program, you must set the preprocessor option `-DALTERA_AVALON_UART_USE_IOCTL`.

Table 6–3. Optional UART ioctl() Operations for the Fast Driver Only

Request	Description
`TIOCMGET`	Returns the current configuration of the device by filling in the contents of the input termios structure. *(1)* A pointer to this structure is supplied as the value of the parameter `opt`.
`TIOCMSET`	Sets the configuration of the device according to the values contained in the input termios structure. *(1)* A pointer to this structure is supplied as the value of the parameter `arg`.

Note to Table 8–3:

(1) The termios structure is defined by the Newlib C standard library. You can find the definition in the file <*Nios II EDS install path*>**/components/altera_hal/HAL/inc/sys/termios.h**.

For details about the `ioctl()` function, refer to the *Nios II Software Developer's Handbook*.

Limitations

The HAL driver for the UART core does not support the endofpacket register. Refer to "Register Map" for details.

Software Files

The UART core is accompanied by the following software files. These files define the low-level interface to the hardware, and provide the HAL drivers. Application developers should not modify these files.

- **altera_avalon_uart_regs.h**—This file defines the core's register map, providing symbolic constants to access the low-level hardware. The symbols in this file are used only by device driver functions.
- **altera_avalon_uart.h**, **altera_avalon_uart.c**—These files implement the UART core device driver for the HAL system library.

© March 2009 Altera Corporation

Register Map

Programmers using the HAL API never access the UART core directly via its registers. In general, the register map is only useful to programmers writing a device driver for the core.

The Altera-provided HAL device driver accesses the device registers directly. If you are writing a device driver and the HAL driver is active for the same device, your driver will conflict and fail to operate.

Table 6–4 shows the register map for the UART core. Device drivers control and communicate with the core through the memory-mapped registers.

Table 6–4. UART Core Register Map

Offset	Register Name	R/W	Description/Register Bits													
			15:13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	`rxdata`	RO	Reserved					*(1)*	*(1)*	Receive Data						
1	`txdata`	WO	Reserved					*(1)*	*(1)*	Transmit Data						
2	`status` *(2)*	RW	Reserved	eop	cts	dcts	(1)	e	rrdy	trdy	tmt	toe	roe	brk	fe	pe
3	`control`	RW	Reserved	ieop	rts	idcts	trbk	ie	irrdy	itrdy	itmt	itoe	iroe	ibrk	ife	ipe
4	`divisor` *(3)*	RW	Baud Rate Divisor													
5	`endof-packet` *(3)*	RW	Reserved					*(1)*	*(1)*	End-of-Packet Value						

Notes to Table 6–4:

(1) These bits may or may not exist, depending on the **Data Width** hardware option. If they do not exist, they read zero, and writing has no effect.

(2) Writing zero to the `status` register clears the `dcts`, `e`, `toe`, `roe`, `brk`, `fe`, and `pe` bits.

(3) This register may or may not exist, depending on hardware configuration options. If it does not exist, reading returns an undefined value and writing has no effect.

Some registers and bits are optional. These registers and bits exists in hardware only if it was enabled at system generation time. Optional registers and bits are noted in the following sections.

rxdata Register

The `rxdata` register holds data received via the `RXD` input. When a new character is fully received via the `RXD` input, it is transferred into the `rxdata` register, and the `status` register's `rrdy` bit is set to 1. The `status` register's `rrdy` bit is set to 0 when the `rxdata` register is read. If a character is transferred into the `rxdata` register while the `rrdy` bit is already set (in other words, the previous character was not retrieved), a receiver-overrun error occurs and the `status` register's `roe` bit is set to 1. New characters are always transferred into the `rxdata` register, regardless of whether the previous character was read. Writing data to the `rxdata` register has no effect.

txdata Register

Avalon-MM master peripherals write characters to be transmitted into the txdata register. Characters should not be written to txdata until the transmitter is ready for a new character, as indicated by the TRDY bit in the status register. The TRDY bit is set to 0 when a character is written into the txdata register. The TRDY bit is set to 1 when the character is transferred from the txdata register into the transmitter shift register. If a character is written to the txdata register when TRDY is 0, the result is undefined. Reading the txdata register returns an undefined value.

For example, assume the transmitter logic is idle and an Avalon-MM master peripheral writes a first character into the txdata register. The TRDY bit is set to 0, then set to 1 when the character is transferred into the transmitter shift register. The master can then write a second character into the txdata register, and the TRDY bit is set to 0 again. However, this time the shift register is still busy shifting out the first character to the TXD output. The TRDY bit is not set to 1 until the first character is fully shifted out and the second character is automatically transferred into the transmitter shift register.

status Register

The status register consists of individual bits that indicate particular conditions inside the UART core. Each status bit is associated with a corresponding interrupt-enable bit in the control register. The status register can be read at any time. Reading does not change the value of any of the bits. Writing zero to the status register clears the DCTS, E, TOE, ROE, BRK, FE, and PE bits.

The status register bits are shown in Table 6–5.

Table 6–5. status Register Bits (Part 1 of 2)

Bit	Name	Access	Description
0 *(1)*	PE	RC	Parity error. A parity error occurs when the received parity bit has an unexpected (incorrect) logic level. The PE bit is set to 1 when the core receives a character with an incorrect parity bit. The PE bit stays set to 1 until it is explicitly cleared by a write to the status register. When the PE bit is set, reading from the rxdata register produces an undefined value. If the **Parity** hardware option is not enabled, no parity checking is performed and the PE bit always reads 0. Refer to “Data Bits, Stop Bits, Parity” on page 6–5.
1	FE	RC	Framing error. A framing error occurs when the receiver fails to detect a correct stop bit. The FE bit is set to 1 when the core receives a character with an incorrect stop bit. The FE bit stays set to 1 until it is explicitly cleared by a write to the status register. When the FE bit is set, reading from the rxdata register produces an undefined value.
2	BRK	RC	Break detect. The receiver logic detects a break when the RXD pin is held low (logic 0) continuously for longer than a full-character time (data bits, plus start, stop, and parity bits). When a break is detected, the BRK bit is set to 1. The BRK bit stays set to 1 until it is explicitly cleared by a write to the status register.
3	ROE	RC	Receive overrun error. A receive-overrun error occurs when a newly received character is transferred into the rxdata holding register before the previous character is read (in other words, while the RRDY bit is 1). In this case, the ROE bit is set to 1, and the the previous contents of rxdata are overwritten with the new character. The ROE bit stays set to 1 until it is explicitly cleared by a write to the status register.

 © March 2009 Altera Corporation

Table 6–5. status Register Bits (Part 2 of 2)

Bit	Name	Access	Description
4	TOE	RC	Transmit overrun error. A transmit-overrun error occurs when a new character is written to the txdata holding register before the previous character is transferred into the shift register (in other words, while the TRDY bit is 0). In this case the TOE bit is set to 1. The TOE bit stays set to 1 until it is explicitly cleared by a write to the status register.
5	TMT	R	Transmit empty. The TMT bit indicates the transmitter shift register's current state. When the shift register is in the process of shifting a character out the TXD pin, TMT is set to 0. When the shift register is idle (in other words, a character is not being transmitted) the TMT bit is 1. An Avalon-MM master peripheral can determine if a transmission is completed (and received at the other end of a serial link) by checking the TMT bit.
6	TRDY	R	Transmit ready. The TRDY bit indicates the txdata holding register's current state. When the txdata register is empty, it is ready for a new character, and TRDY is 1. When the txdata register is full, TRDY is 0. An Avalon-MM master peripheral must wait for TRDY to be 1 before writing new data to txdata.
7	RRDY	R	Receive character ready. The RRDY bit indicates the rxdata holding register's current state. When the rxdata register is empty, it is not ready to be read and RRDY is 0. When a newly received value is transferred into the rxdata register, RRDY is set to 1. Reading the rxdata register clears the RRDY bit to 0. An Avalon-MM master peripheral must wait for RRDY to equal 1 before reading the rxdata register.
8	E	RC	Exception. The E bit indicates that an exception condition occurred. The E bit is a logical-OR of the TOE, ROE, BRK, FE, and PE bits. The E bit and its corresponding interrupt-enable bit (IE) bit in the control register provide a convenient method to enable/disable IRQs for all error conditions. The E bit is set to 0 by a write operation to the status register.
10 *(1)*	DCTS	RC	Change in clear to send (CTS) signal. The DCTS bit is set to 1 whenever a logic-level transition is detected on the CTS_N input port (sampled synchronously to the Avalon-MM clock). This bit is set by both falling and rising transitions on CTS_N. The DCTS bit stays set to 1 until it is explicitly cleared by a write to the status register. If the **Flow Control** hardware option is not enabled, the DCTS bit always reads 0. Refer to "Flow Control" on page 6–5.
11 *(1)*	CTS	R	Clear-to-send (CTS) signal. The CTS bit reflects the CTS_N input's instantaneous state (sampled synchronously to the Avalon-MM clock). The CTS_N input has no effect on the transmit or receive processes. The only visible effect of the CTS_N input is the state of the CTS and DCTS bits, and an IRQ that can be generated when the control register's idcts bit is enabled. If the **Flow Control** hardware option is not enabled, the CTS bit always reads 0. Refer to "Flow Control" on page 6–5.
12 *(1)*	EOP	R	End of packet encountered. The EOP bit is set to 1 by one of the following events: ■ An EOP character is written to txdata ■ An EOP character is read from rxdata The EOP character is determined by the contents of the endofpacket register. The EOP bit stays set to 1 until it is explicitly cleared by a write to the status register. If the **Include End-of-Packet Register** hardware option is not enabled, the EOP bit always reads 0. Refer to "Streaming Data (DMA) Control" on page 6–6.

Note to Table 6–5:

(1) This bit is optional and may not exist in hardware.

control Register

The control register consists of individual bits, each controlling an aspect of the UART core's operation. The value in the control register can be read at any time.

Each bit in the control register enables an IRQ for a corresponding bit in the status register. When both a status bit and its corresponding interrupt-enable bit are 1, the core generates an IRQ.

The control register bits are shown in Table 6–6.

Table 6–6. control Register Bits

Bit	Name	Access	Description
0	IPE	RW	Enable interrupt for a parity error.
1	IFE	RW	Enable interrupt for a framing error.
2	IBRK	RW	Enable interrupt for a break detect.
3	IROE	RW	Enable interrupt for a receiver overrun error.
4	ITOE	RW	Enable interrupt for a transmitter overrun error.
5	ITMT	RW	Enable interrupt for a transmitter shift register empty.
6	ITRDY	RW	Enable interrupt for a transmission ready.
7	IRRDY	RW	Enable interrupt for a read ready.
8	IE	RW	Enable interrupt for an exception.
9	TRBK	RW	Transmit break. The TRBK bit allows an Avalon-MM master peripheral to transmit a break character over the TXD output. The TXD signal is forced to 0 when the TRBK bit is set to 1. The TRBK bit overrides any logic level that the transmitter logic would otherwise drive on the TXD output. The TRBK bit interferes with any transmission in process. The Avalon-MM master peripheral must set the TRBK bit back to 0 after an appropriate break period elapses.
10	IDCTS	RW	Enable interrupt for a change in CTS signal.
11 *(1)*	RTS	RW	Request to send (RTS) signal. The RTS bit directly feeds the RTS_N output. An Avalon-MM master peripheral can write the RTS bit at any time. The value of the RTS bit only affects the RTS_N output; it has no effect on the transmitter or receiver logic. Because the RTS_N output is logic negative, when the RTS bit is 1, a low logic-level (0) is driven on the RTS_N output. If the **Flow Control** hardware option is not enabled, the RTS bit always reads 0, and writing has no effect. Refer to "Flow Control" on page 6–5.
12	IEOP	RW	Enable interrupt for end-of-packet condition.

Note to Table 6–6:

(1) This bit is optional and may not exist in hardware.

divisor Register (Optional)

The value in the divisor register is used to generate the baud rate clock. The effective baud rate is determined by the formula:

Baud Rate = (Clock frequency) / (divisor + 1)

The divisor register is an optional hardware feature. If the **Baud Rate Can Be Changed By Software** hardware option is not enabled, the divisor register does not exist. In this case, writing divisor has no effect, and reading divisor returns an undefined value. For more information, refer to "Baud Rate Options" on page 6–4.

endofpacket Register (Optional)

The value in the `endofpacket` register determines the end-of-packet character for variable-length DMA transactions. After reset, the default value is zero, which is the ASCII null character (\0). For more information, refer to Table 6–5 on page 6–12 for the description for the `EOP` bit.

The `endofpacket` register is an optional hardware feature. If the **Include end-of-packet register** hardware option is not enabled, the `endofpacket` register does not exist. In this case, writing `endofpacket` has no effect, and reading returns an undefined value.

Interrupt Behavior

The UART core outputs a single IRQ signal to the Avalon-MM interface, which can connect to any master peripheral in the system, such as a Nios II processor. The master peripheral must read the `status` register to determine the cause of the interrupt.

Every interrupt condition has an associated bit in the `status` register and an interrupt-enable bit in the `control` register. When any of the interrupt conditions occur, the associated `status` bit is set to 1 and remains set until it is explicitly acknowledged. The IRQ output is asserted when any of the status bits are set while the corresponding interrupt-enable bit is 1. A master peripheral can acknowledge the IRQ by clearing the `status` register.

At reset, all interrupt-enable bits are set to 0; therefore, the core cannot assert an IRQ until a master peripheral sets one or more of the interrupt-enable bits to 1.

All possible interrupt conditions are listed with their associated status and control (interrupt-enable) bits in Table 6–5 on page 6–16 and Table 6–6 on page 6–18. Details of each interrupt condition are provided in the `status` bit descriptions.

7. SPI Core

NII51011-9.0.0

Core Overview

SPI is an industry-standard serial protocol commonly used in embedded systems to connect microprocessors to a variety of off-chip sensor, conversion, memory, and control devices. The SPI core with Avalon® interface implements the SPI protocol and provides an Avalon Memory-Mapped (Avalon-MM) interface on the back end.

The SPI core can implement either the master or slave protocol. When configured as a master, the SPI core can control up to 32 independent SPI slaves. The width of the receive and transmit registers are configurable between 1 and 32 bits. Longer transfer lengths can be supported with software routines. The SPI core provides an interrupt output that can flag an interrupt whenever a transfer completes.

The SPI core is SOPC Builder ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- "Functional Description"
- "Instantiating the SPI Core in SOPC Builder" on page 7–5
- "Device Support" on page 7–8
- "Software Programming Model" on page 7–8

Functional Description

The SPI core communicates using two data lines, a control line, and a synchronization clock:

- Master Out Slave In (`mosi`)—Output data from the master to the inputs of the slaves
- Master In Slave Out (`miso`)—Output data from a slave to the input of the master
- Serial Clock (`sclk`)—Clock driven by the master to slaves, used to synchronize the data bits
- Slave Select (`ss_n`)— Select signal (active low) driven by the master to individual slaves, used to select the target slave

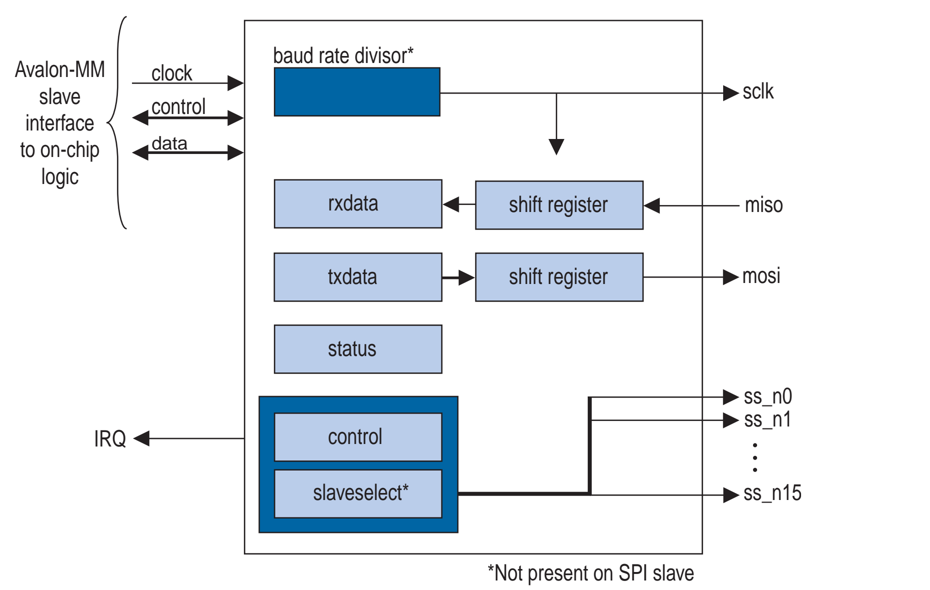
The SPI core has the following user-visible features:

- A memory-mapped register space comprised of five registers: `rxdata`, `txdata`, `status`, `control`, and `slaveselect`
- Four SPI interface ports: `sclk`, `ss_n`, `mosi`, and `miso`

The registers provide an interface to the SPI core and are visible via the Avalon-MM slave port. The `sclk`, `ss_n`, `mosi`, and `miso` ports provide the hardware interface to other SPI devices. The behavior of `sclk`, `ss_n`, `mosi`, and `miso` depends on whether the SPI core is configured as a master or slave.

Figure 7–1 shows a block diagram of the SPI core in master mode.

Figure 7–1. SPI Core Block Diagram



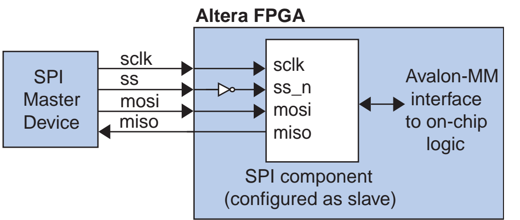
The SPI core logic is synchronous to the clock input provided by the Avalon-MM interface. When configured as a master, the core divides the Avalon-MM clock to generate the SCLK output. When configured as a slave, the core's receive logic is synchronized to SCLK input. The core's Avalon-MM interface is capable of Avalon-MM transfers with flow control. The SPI core can be used in conjunction with a DMA controller with flow control to automate continuous data transfers between, for example, the SPI core and memory.

For more details, refer to the *Interval Timer Core* chapter in volume 5 of the *Quartus II Handbook*.

Example Configurations

Figure 7–1 and Figure 7–2 show two possible configurations. In Figure 7–2, the SPI core provides a slave interface to an off-chip SPI master.

Figure 7–2. SPI Core Configured as a Slave



In Figure 7–1, the SPI core provides a master interface driving multiple off-chip slave devices. Each slave device in Figure 7–1 must tristate its `miso` output whenever its select signal is not asserted.

The ss_n signal is active-low. However, any signal can be inverted inside the FPGA, allowing the slave-select signals to be either active high or active low.

Transmitter Logic

The SPI core transmitter logic consists of a transmit holding register (txdata) and transmit shift register, each *n* bits wide. The register width *n* is specified at system generation time, and can be any integer value from 1 to 32. After a master peripheral writes a value to the txdata register, the value is copied to the shift register and then transmitted when the next operation starts.

The shift register and the txdata register provide double buffering during data transmission. A new value can be written into the txdata register while the previous data is being shifted out of the shift register. The transmitter logic automatically transfers the txdata register to the shift register whenever a serial shift operation is not currently in process.

In master mode, the transmit shift register directly feeds the mosi output. In slave mode, the transmit shift register directly feeds the miso output. Data shifts out LSB first or MSB first, depending on the configuration of the SPI core.

Receiver Logic

The SPI core receive logic consists of a receive holding register (rxdata) and receive shift register, each *n* bits wide. The register width *n* is specified at system generation time, and can be any integer value from 1 to 16. A master peripheral reads received data from the rxdata register after the shift register has captured a full *n*-bit value of data.

The shift register and the rxdata register provide double buffering while receiving data. The rxdata register can hold a previously received data value while subsequent new data is shifting into the shift register. The receiver logic automatically transfers the shift register content to the rxdata register when a serial shift operation completes.

In master mode, the shift register is fed directly by the miso input. In slave mode, the shift register is fed directly by the mosi input. The receiver logic expects input data to arrive LSB first or MSB first, depending on the configuration of the SPI core.

Master and Slave Modes

At system generation time, the designer configures the SPI core in either master mode or slave mode. The mode cannot be switched at runtime.

Master Mode Operation

In master mode, the SPI ports behave as shown in Table 7–1.

Table 7–1. Master Mode Port Configurations (Part 1 of 2)

Name	Direction	Description
mosi	output	Data output to slave(s)
miso	input	Data input from slave(s)

Table 7–1. Master Mode Port Configurations (Part 2 of 2)

Name	Direction	Description
sclk	output	Synchronization clock to all slaves
ss_n*M*	output	Slave select signal to slave *M*, where M is a number between 0 and 15.

In master mode, an intelligent host (for example, a microprocessor) configures the SPI core using the control and slaveselect registers, and then writes data to the txdata buffer to initiate a transaction. A master peripheral can monitor the status of the transaction by reading the status register. A master peripheral can enable interrupts to notify the host whenever new data is received (for example, a transfer has completed), or whenever the transmit buffer is ready for new data.

The SPI protocol is full duplex, so every transaction both sends and receives data at the same time. The master transmits a new data bit on the mosi output and the slave drives a new data bit on the miso input for each active edge of sclk. The SPI core divides the Avalon-MM system clock using a clock divider to generate the sclk signal.

When the SPI core is configured to interface with multiple slaves, the core has one ss_n signal for each slave, up to a maximum of sixteen slaves. During a transfer, the master asserts ss_n to each slave specified in the slaveselect register. Note that there can be no more than one slave transmitting data during any particular transfer, or else there will be a contention on the miso input. The number of slave devices is specified at system generation time.

Slave Mode Operation

In slave mode, the SPI ports behave as shown in Table 7–2.

Table 7–2. Slave Mode Port Configurations

Name	Direction	Description
mosi	input	Data input from the master
miso	output	Data output to the master
sclk	input	Synchronization clock
ss_n	input	Select signal

In slave mode, the SPI core simply waits for the master to initiate transactions. Before a transaction begins, the slave logic continuously polls the ss_n input. When the master asserts ss_n, the slave logic immediately begins sending the transmit shift register contents to the miso output. The slave logic also captures data on the mosi input, and fills the receive shift register simultaneously.

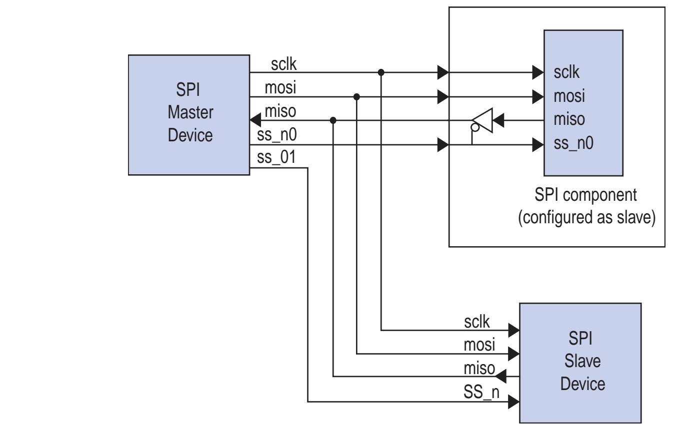
An intelligent host such as a microprocessor writes data to the txdata registers, so that it is transmitted the next time the master initiates an operation. A master peripheral reads received data from the rxdata register. A master peripheral can enable interrupts to notify the host whenever new data is received, or whenever the transmit buffer is ready for new data.

© March 2009 Altera Corporation

Multi-Slave Environments

When ss_n is not asserted, typical SPI cores set their miso output pins to high impedance. The Altera®-provided SPI slave core drives an undefined high or low value on its miso output when not selected. Special consideration is necessary to avoid signal contention on the miso output, if the SPI core in slave mode is connected to an off-chip SPI master device with multiple slaves. In this case, the ss_n input should be used to control a tristate buffer on the miso signal. Figure 7–3 shows an example of the SPI core in slave mode in an environment with two slaves.

Figure 7–3. SPI Core in a Multi-Slave Environment



Avalon-MM Interface

The SPI core's Avalon-MM interface consists of a single Avalon-MM slave port. In addition to fundamental slave read and write transfers, the SPI core supports Avalon-MM read and write transfers with flow control.

Instantiating the SPI Core in SOPC Builder

You can use the MegaWizard™ interface for the SPI core in SOPC Builder to configure the hardware feature set. The following sections describe the available options.

Master/Slave Settings

The designer can select either master mode or slave mode to determine the role of the SPI core. When master mode is selected, the following options are available: **Number of select (SS_n) signals, SPI clock rate**, and **Specify delay**.

Number of Select (SS_n) Signals

This setting specifies how many slaves the SPI master connects to. The range is 1 to 32. The SPI master core presents a unique ss_n signal for each slave.

SPI Clock (sclk) Rate

This setting determines the rate of the sclk signal that synchronizes data between master and slaves. The target clock rate can be specified in units of Hz, kHz or MHz. The SPI master core uses the Avalon-MM system clock and a clock divisor to generate sclk.

The actual frequency of `sclk` may not exactly match the desired target clock rate. The achievable clock values are:

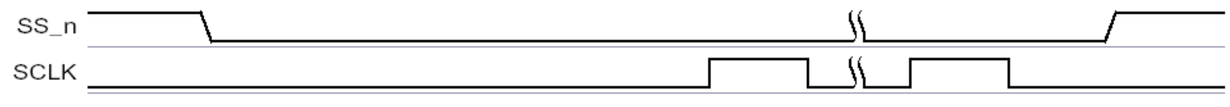
<Avalon-MM system clock frequency> / [2, 4, 6, 8, ...]

The actual frequency achieved will not be greater than the specified target value. For example, if the system clock frequency is 50 MHz and the target value is 25 MHz, the clock divisor is 2 and the actual `sclk` frequency achieves exactly 25 MHz.

Specify Delay

Turning on this option causes the SPI master to add a time delay between asserting the `ss_n` signal and shifting the first bit of data. This delay is required by certain SPI slave devices. If the delay option is on, you must also specify the delay time in units of ns, µs or ms. An example is shown in Figure 7–4.

Figure 7–4. Time Delay Between Asserting ss_n and Toggling sclk



The delay generation logic uses a granularity of half the period of `sclk`. The actual delay achieved is the desired target delay rounded up to the nearest multiple of half the `sclk` period, as shown in Equation 7–1 and Equation 7–2:

Equation 7–1.

$$p = \frac{1}{2} \times (\text{period of sclk})$$

Equation 7–2.

$$\text{actual delay} = \text{ceiling} \times \left(\frac{\text{desired delay}}{p}\right) \times p$$

Data Register Settings

The data register settings affect the size and behavior of the data registers in the SPI core. There are two data register settings:

- **Width**—This setting specifies the width of `rxdata`, `txdata`, and the receive and transmit shift registers. The range is from 1 to 32.
- **Shift direction**—This setting determines the direction that data shifts (MSB first or LSB first) into and out of the shift registers.

Timing Settings

The timing settings affect the timing relationship between the `ss_n`, `sclk`, `mosi` and `miso` signals. In this discussion the `mosi` and `miso` signals are referred to generically as *data*. There are two timing settings:

- **Clock polarity**—This setting can be 0 or 1. When clock polarity is set to 0, the idle state for `sclk` is low. When clock polarity is set to 1, the idle state for `sclk` is high.
- **Clock phase**—This setting can be 0 or 1. When clock phase is 0, data is latched on the leading edge of `sclk`, and data changes on trailing edge. When clock phase is 1, data is latched on the trailing edge of `sclk`, and data changes on the leading edge.

Figure 7–5 through Figure 7–8 demonstrate the behavior of signals in all possible cases of clock polarity and clock phase.

Figure 7–5. Clock Polarity = 0, Clock Phase = 0

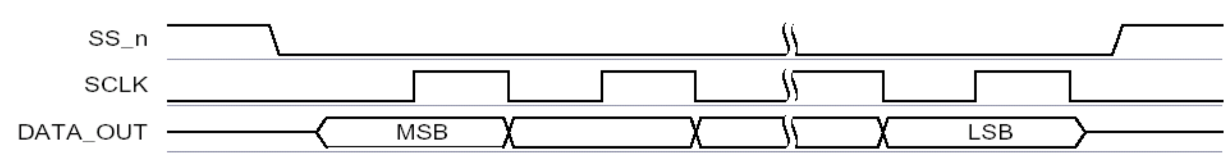


Figure 7–6. Clock Polarity = 0, Clock Phase = 1

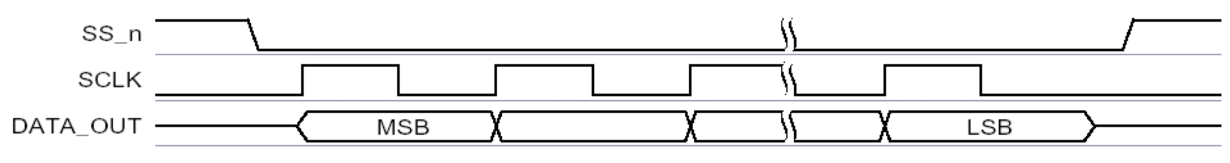

Figure 7–7. Clock Polarity = 1, Clock Phase = 0

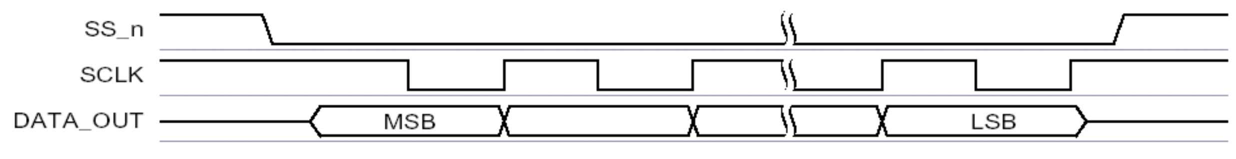

Figure 7–8. Clock Polarity = 1, Clock Phase = 1

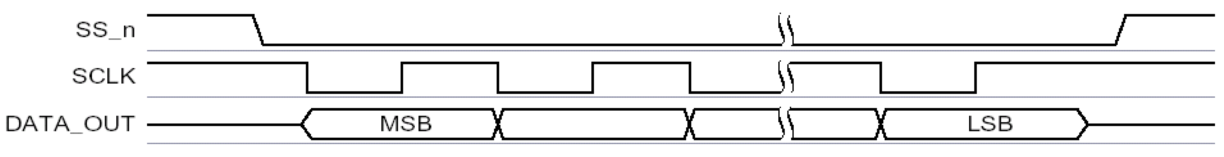

Device Support

The SPI core supports all Altera® device families.

Software Programming Model

The following sections describe the software programming model for the SPI core, including the register map and software constructs used to access the hardware. For Nios® II processor users, Altera provides the HAL system library header file that defines the SPI core registers. The SPI core does not match the generic device model categories supported by the HAL, so it cannot be accessed via the HAL API or the ANSI C standard library. Altera provides a routine to access the SPI hardware that is specific to the SPI core.

Hardware Access Routines

Altera provides one access routine, `alt_avalon_spi_command()`, that provides general-purpose access to an SPI core configured as a master.

alt_avalon_spi_command()

Prototype:

```
int alt_avalon_spi_command(alt_u32 base, alt_u32 slave,
                           alt_u32 write_length,
                           const alt_u8* wdata,
                           alt_u32 read_length,
                           alt_u8* read_data,
                           alt_u32 flags)
```

Thread-safe: No.

Available from ISR: No.

Include: <altera_avalon_spi.h>

Description: `alt_avalon_spi_command()` is used to perform a control sequence on the SPI bus. This routine is designed for SPI masters of 8-bit data width or less. Currently, it does not support SPI hardware with data-width greater than 8 bits. A single call to this function writes a data buffer of arbitrary length out the MOSI port, and then reads back an arbitrary amount of data from the MISO port. The function performs the following actions:

(1) Asserts the slave select output for the specified slave. The first slave select output is numbered 0, the next is 1, etc.

(2) Transmits `write_length` bytes of data from `wdata` through the SPI interface, discarding the incoming data on MISO.

(3) Reads `read_length` bytes of data, storing the data into the buffer pointed to by `read_data`. MOSI is set to zero during the read transaction.

(4) De-asserts the slave select output, unless the flags field contains the value `ALT_AVALON_SPI_COMMAND_MERGE`. If you want to transmit from scattered buffers then you can call the function multiple times, specifying the merge flag on all the accesses except the last.

This function is not thread safe. If you want to access the SPI bus from more than one thread, you should use a semaphore or mutex to ensure that only one thread is executing within this function at any time.

Returns: The number of bytes stored in the `read_data` buffer.

Software Files

The SPI core is accompanied by the following software files. These files provide a low-level interface to the hardware.

- **altera_avalon_spi.h**—This file defines the core's register map, providing symbolic constants to access the low-level hardware.
- **altera_avalon_spi.c**—This file implements low-level routines to access the hardware.

Register Map

An Avalon-MM master peripheral controls and communicates with the SPI core via the six 32-bit registers, shown in Table 7–3. The table assumes an *n*-bit data width for `rxdata` and `txdata`.

Table 7–3. Register Map for SPI Master Device

Internal Address	Register Name	32..11	10	9	8	7	6	5	4	3	2	1	0
0	`rxdata` *(1)*	`RXDATA` (n-1..0)											
1	`txdata` *(1)*	`TXDATA` (n-1..0)											
2	`status` *(2)*				`E`	`RRDY`	`TRDY`	`TMT`	`TOE`	`ROE`			
3	`control`		`SSO` *(3)*		`IE`	`IRRDY`	`ITRDY`		`ITOE`	`IROE`			
4	Reserved												
5	`slaveselect` *(3)*	Slave Select Mask											

Notes to Table 7–3:

(1) Bits 15 to *n* are undefined when *n* is less than 16.

(2) A write operation to the `status` register clears the `ROE`, `TOE`, and `E` bits.

(3) Present only in master mode.

Reading undefined bits returns an undefined value. Writing to undefined bits has no effect.

rxdata Register

A master peripheral reads received data from the `rxdata` register. When the receive shift register receives a full *n* bits of data, the `status` register's `RRDY` bit is set to 1 and the data is transferred into the `rxdata` register. Reading the `rxdata` register clears the `RRDY` bit. Writing to the `rxdata` register has no effect.

New data is always transferred into the `rxdata` register, whether or not the previous data was retrieved. If `RRDY` is 1 when data is transferred into the `rxdata` register (that is, the previous data was not retrieved), a receive-overrun error occurs and the `status` register's `ROE` bit is set to 1. In this case, the contents of `rxdata` are undefined.

txdata Register

A master peripheral writes data to be transmitted into the `txdata` register. When the `status` register's `TRDY` bit is 1, it indicates that the `txdata` register is ready for new data. The `TRDY` bit is set to 0 whenever the `txdata` register is written. The `TRDY` bit is set to 1 after data is transferred from the `txdata` register into the transmitter shift register, which readies the `txdata` holding register to receive new data.

A master peripheral should not write to the `txdata` register until the transmitter is ready for new data. If `TRDY` is 0 and a master peripheral writes new data to the `txdata` register, a transmit-overrun error occurs and the `status` register's `TOE` bit is set to 1. In this case, the new data is ignored, and the content of `txdata` remains unchanged.

© March 2009 Altera Corporation

As an example, assume that the SPI core is idle (that is, the txdata register and transmit shift register are empty), when a CPU writes a data value into the txdata holding register. The TRDY bit is set to 0 momentarily, but after the data in txdata is transferred into the transmitter shift register, TRDY returns to 1. The CPU writes a second data value into the txdata register, and again the TRDY bit is set to 0. This time the shift register is still busy transferring the original data value, so the TRDY bit remains at 0 until the shift operation completes. When the operation completes, the second data value is transferred into the transmitter shift register and the TRDY bit is again set to 1.

status Register

The status register consists of bits that indicate status conditions in the SPI core. Each bit is associated with a corresponding interrupt-enable bit in the control register, as discussed in "control Register" on page 7–12. A master peripheral can read status at any time without changing the value of any bits. Writing status does clear the ROE, TOE and E bits. Table 7–4 describes the individual bits of the status register.

Table 7–4. status Register Bits

#	Name	Description
3	ROE	**Receive-overrun error** The ROE bit is set to 1 if new data is received while the rxdata register is full (that is, while the RRDY bit is 1). In this case, the new data overwrites the old. Writing to the status register clears the ROE bit to 0.
4	TOE	**Transmitter-overrun error** The TOE bit is set to 1 if new data is written to the txdata register while it is still full (that is, while the TRDY bit is 0). In this case, the new data is ignored. Writing to the status register clears the TOE bit to 0.
5	TMT	**Transmitter shift-register empty** In master mode, the TMT bit is set to 0 when a transaction is in progress and set to 1 when the shift register is empty. In slave mode, the TMT bit is set to 0 when the slave is selected (SS_n is low) or when the SPI Slave register interface is not ready to receive data.
6	TRDY	**Transmitter ready** The TRDY bit is set to 1 when the txdata register is empty.
7	RRDY	**Receiver ready** The RRDY bit is set to 1 when the rxdata register is full.
8	E	**Error** The E bit is the logical OR of the TOE and ROE bits. This is a convenience for the programmer to detect error conditions. Writing to the status register clears the E bit to 0.

control Register

The control register consists of data bits to control the SPI core's operation. A master peripheral can read control at any time without changing the value of any bits.

Most bits (IROE, ITOE, ITRDY, IRRDY, and IE) in the control register control interrupts for status conditions represented in the status register. For example, bit 1 of status is ROE (receiver-overrun error), and bit 1 of control is IROE, which enables interrupts for the ROE condition. The SPI core asserts an interrupt request when the corresponding bits in status and control are both 1.

The control register bits are shown in Table 7–5.

Table 7–5. control Register Bits

#	Name	Description
3	IROE	Setting IROE to 1 enables interrupts for receive-overrun errors.
4	ITOE	Setting ITOE to 1 enables interrupts for transmitter-overrun errors.
6	ITRDY	Setting ITRDY to 1 enables interrupts for the transmitter ready condition.
7	IRRDY	Setting IRRDY to 1 enables interrupts for the receiver ready condition.
8	IE	Setting IE to 1 enables interrupts for any error condition.
10	SSO	Setting SSO to 1 forces the SPI core to drive its ss_n outputs, regardless of whether a serial shift operation is in progress or not. The slaveselect register controls which ss_n outputs are asserted. SSO can be used to transmit or receive data of arbitrary size, for example, greater than 32 bits.

After reset, all bits of the control register are set to 0. All interrupts are disabled and no ss_n signals are asserted.

slaveselect Register

The slaveselect register is a bit mask for the ss_n signals driven by an SPI master. During a serial shift operation, the SPI master selects only the slave device(s) specified in the slaveselect register.

The slaveselect register is only present when the SPI core is configured in master mode. There is one bit in slaveselect for each ss_n output, as specified by the designer at system generation time.

A master peripheral can set multiple bits of slaveselect simultaneously, causing the SPI master to simultaneously select multiple slave devices as it performs a transaction. For example, to enable communication with slave devices 1, 5, and 6, set bits 1, 5, and 6 of slaveselect. However, consideration is necessary to avoid signal contention between multiple slaves on their miso outputs.

Upon reset, bit 0 is set to 1, and all other bits are cleared to 0. Thus, after a device reset, slave device 0 is automatically selected.

8. Optrex 16207 LCD Controller Core

NII51019-9.0.0

Core Overview

The Optrex 16207 LCD controller core with Avalon® Interface (LCD controller core) provides the hardware interface and software driver required for a Nios® II processor to display characters on an Optrex 16207 (or equivalent) 16×2-character LCD panel. Device drivers are provided in the HAL system library for the Nios II processor. Nios II programs access the LCD controller as a character mode device using ANSI C standard library routines, such as `printf()`. The LCD controller is SOPC Builder-ready, and integrates easily into any SOPC Builder-generated system.

The Nios II Embedded Design Suite (EDS) includes an Optrex LCD module and provide several ready-made example designs that display text on the Optrex 16207 via the LCD controller. For details about the Optrex 16207 LCD module, see the manufacturer's *Dot Matrix Character LCD Module User's Manual* available at www.optrex.com.

This chapter contains the following sections:

- "Functional Description"
- "Device and Tools Support" on page 8–2
- "Instantiating the Core in SOPC Builder" on page 8–2
- "Software Programming Model" on page 8–2

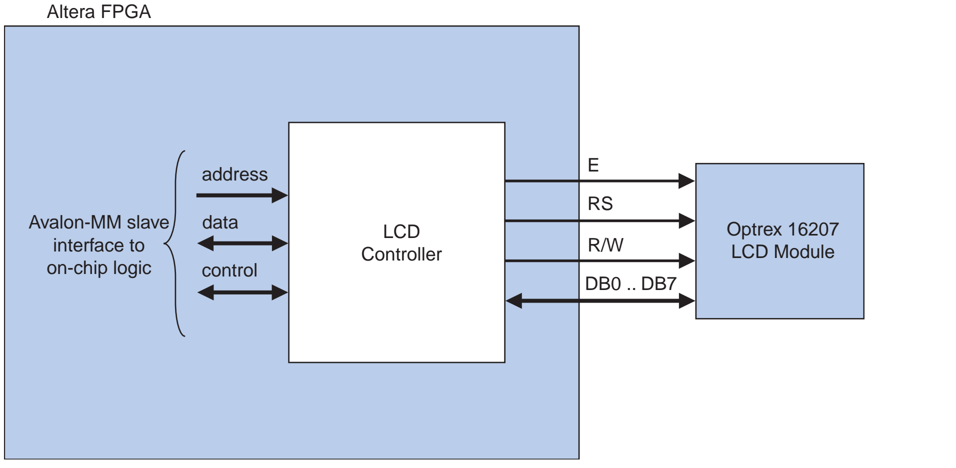
Functional Description

The LCD controller core consists of two user-visible components:

- Eleven signals that connect to pins on the Optrex 16207 LCD panel—These signals are defined in the Optrex 16207 data sheet.
  - `E`—Enable (output)
  - `RS`—Register Select (output)
  - `R/W`—Read or Write (output)
  - `DB0` through `DB7`—Data Bus (bidirectional)
- An Avalon Memory-Mapped (Avalon-MM) slave interface that provides access to 4 registers.

Figure 8–1 shows a block diagram of the LCD controller core.

Figure 8–1. LCD Controller Block Diagram



Device and Tools Support

The LCD controller core supports all Altera device families. The LCD controller drivers support the Nios II processor.

Instantiating the Core in SOPC Builder

You can add the LCD controller core from the **System Contents** tab in SOPC Builder. In SOPC Builder, the LCD controller core has the name Character LCD (16×2, Optrex 16207). There are no user-configurable settings for this component.

Software Programming Model

This section describes the software programming model for the LCD controller.

HAL System Library Support

Altera provides HAL system library drivers for the Nios II processor that enable you to access the LCD controller using the ANSI C standard library functions. The Altera-provided drivers integrate into the HAL system library for Nios II systems. The LCD driver is a standard character-mode device, as described in the *Nios II Software Developer's Handbook*. Therefore, using `printf()` is the easiest way to write characters to the display.

The LCD driver requires that the HAL system library include the system clock driver.

Displaying Characters on the LCD

The driver implements VT100 terminal-like behavior on a miniature scale for the 16×2 screen. Characters written to the LCD controller are stored to an 80-column × 2-row buffer maintained by the driver. As characters are written, the cursor position is updated. Visible characters move the cursor position to the right. Any visible characters written to the right of the buffer are discarded. The line feed character (`\n`) moves the cursor down one line and to the left-most column.

The buffer is scrolled up as soon as a printable character is written onto the line below the bottom of the buffer. Rows do not scroll as soon as the cursor moves down to allow the maximum useful information in the buffer to be displayed.

If the visible characters in the buffer fit on the display, all characters are displayed. If the buffer is wider than the display, the display scrolls horizontally to display all the characters. Different lines scroll at different speeds, depending on the number of characters in each line of the buffer.

The LCD driver supports a small subset of ANSI and VT100 escape sequences that can be used to control the cursor position, and clear the display as shown in Table 8–1.

Table 8–1. Escape Sequence Supported by the LCD Controller

Sequence	Meaning
`BS (\b)`	Moves the cursor to the left by one character.
`CR (\r)`	Moves the cursor to the start of the current line.
`LF (\n)`	Moves the cursor to the start of the line and move it down one line.
`ESC( (\x1B)`	Starts a VT100 control sequence.
`ESC [ <y> ; <x> H`	Moves the cursor to the y, x position specified – positions are counted from the top left which is 1;1.
`ESC [ K`	Clears from current cursor position to end of line.
`ESC [ 2 J`	Clears the whole screen.

The LCD controller is an output-only device. Therefore, attempts to read from it returns immediately indicating that no characters have been received.

The LCD controller drivers are not included in the system library when the **Reduced device drivers** option is enabled for the system library. If you want to use the LCD controller while using small drivers for other devices, add the preprocessor option—`DALT_USE_LCD_16207` to the preprocessor options.

Software Files

The LCD controller is accompanied by the following software files. These files define the low-level interface to the hardware and provide the HAL drivers. Application developers should not modify these files.

- **altera_avalon_lcd_16207_regs.h** — This file defines the core's register map, providing symbolic constants to access the low-level hardware.
- **altera_avalon_lcd_16207.h**, **altera_avalon_lcd_16207.c** — These files implement the LCD controller device drivers for the HAL system library.

Register Map

The HAL device drivers make it unnecessary for you to access the registers directly. Therefore, Altera does not publish details about the register map. For more information, the **altera_avalon_lcd_16207_regs.h** file describes the register map, and the *Dot Matrix Character LCD Module User's Manual* from Optrex describes the register usage.

Interrupt Behavior

The LCD controller does not generate interrupts. However, the LCD driver's text scrolling feature relies on the HAL system clock driver, which uses interrupts for timing purposes.

9. PIO Core

NII51007-9.0.0

Core Overview

The parallel input/output (PIO) core with Avalon® interface provides a memory-mapped interface between an Avalon® Memory-Mapped (Avalon-MM) slave port and general-purpose I/O ports. The I/O ports connect either to on-chip user logic, or to I/O pins that connect to devices external to the FPGA.

The PIO core provides easy I/O access to user logic or external devices in situations where a "bit banging" approach is sufficient. Some example uses are:

- Controlling LEDs
- Acquiring data from switches
- Controlling display devices
- Configuring and communicating with off-chip devices, such as application-specific standard products (ASSP)

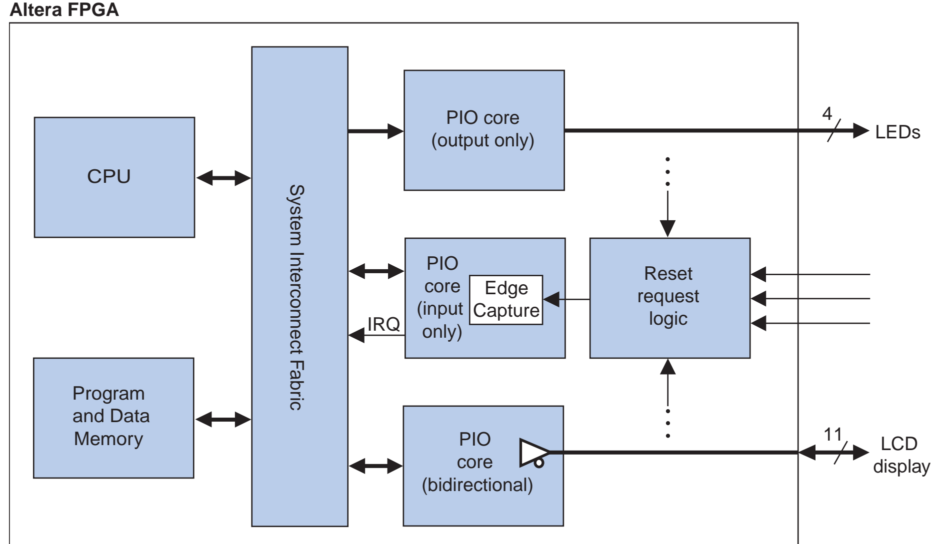
The PIO core interrupt request (IRQ) output can assert an interrupt based on input signals. The PIO core is SOPC Builder ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- "Functional Description"
- "Example Configurations" on page 9–3
- "Instantiating the PIO Core in SOPC Builder" on page 9–4
- "Device Support" on page 9–5
- "Software Programming Model" on page 9–5

Functional Description

Each PIO core can provide up to 32 I/O ports. An intelligent host such as a microprocessor controls the PIO ports by reading and writing the register-mapped Avalon-MM interface. Under control of the host, the PIO core captures data on its inputs and drives data to its outputs. When the PIO ports are connected directly to I/O pins, the host can tristate the pins by writing control registers in the PIO core. Figure 9–1 shows an example of a processor-based system that uses multiple PIO cores to drive LEDs, capture edges from on-chip reset-request control logic, and control an off-chip LCD display.

Figure 9–1. An Example System Using Multiple PIO Cores



When integrated into an SOPC Builder-generated system, the PIO core has two user-visible features:

- A memory-mapped register space with four registers: `data`, `direction`, `interruptmask`, and `edgecapture`
- 1 to 32 I/O ports

The I/O ports can be connected to logic inside the FPGA, or to device pins that connect to off-chip devices. The registers provide an interface to the I/O ports via the Avalon-MM interface. See Table 9–2 on page 9–6 for a description of the registers.

Data Input and Output

The PIO core I/O ports can connect to either on-chip or off-chip logic. The core can be configured with inputs only, outputs only, or both inputs and outputs. If the core is used to control bidirectional I/O pins on the device, the core provides a bidirectional mode with tristate control.

The hardware logic is separate for reading and writing the data register. Reading the data register returns the value present on the input ports (if present). Writing data affects the value driven to the output ports (if present). These ports are independent; reading the data register does not return previously-written data.

Edge Capture

The PIO core can be configured to capture edges on its input ports. It can capture low-to-high transitions, high-to-low transitions, or both. Whenever an input detects an edge, the condition is indicated in the `edgecapture` register. The types of edges detected is specified at system generation time, and cannot be changed via the registers.

© March 2009 Altera Corporation

IRQ Generation

The PIO core can be configured to generate an IRQ on certain input conditions. The IRQ conditions can be either:

- *Level-sensitive*—The PIO core hardware can detect a high level. A NOT gate can be inserted external to the core to provide negative sensitivity.
- *Edge-sensitive*—The core's edge capture configuration determines which type of edge causes an IRQ

Interrupts are individually maskable for each input port. The interrupt mask determines which input port can generate interrupts.

Example Configurations

Figure 9–2 shows a block diagram of the PIO core configured with input and output ports, as well as support for IRQs.

Figure 9–2. PIO Core with Input Ports, Output Ports, and IRQ Support

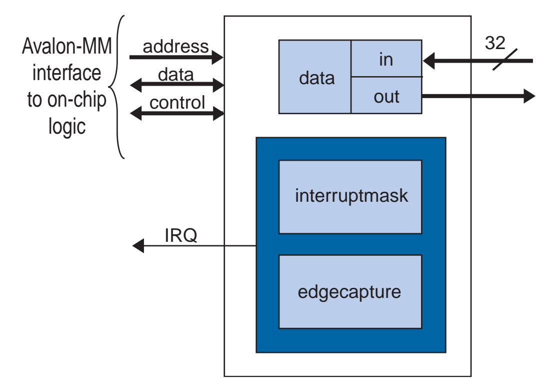


Figure 9–3 shows a block diagram of the PIO core configured in bidirectional mode, without support for IRQs.

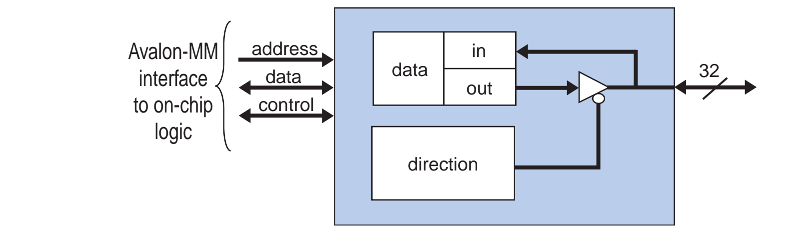
Figure 9–3. PIO Core with Bidirectional Ports



Avalon-MM Interface

The PIO core's Avalon-MM interface consists of a single Avalon-MM slave port. The slave port is capable of fundamental Avalon-MM read and write transfers. The Avalon-MM slave port provides an IRQ output so that the core can assert interrupts.

Instantiating the PIO Core in SOPC Builder

Use the MegaWizard™ interface for the PIO core in SOPC Builder to configure the core. The following sections describe the available options.

Basic Settings

The **Basic Settings** page allows you to specify the width, direction and reset value of the I/O ports.

Width

The width of the I/O ports can be set to any integer value between 1 and 32.

Direction

You can set the port direction to one of the options shown in Table 9–1.

Table 9–1. Direction Settings

Setting	Description
Bidirectional (tristate) ports	In this mode, each PIO bit shares one device pin for driving and capturing data. The direction of each pin is individually selectable. To tristate an FPGA I/O pin, set the direction to input.
Input ports only	In this mode the PIO ports can capture input only.
Output ports only	In this mode the PIO ports can drive output only.
Both input and output ports	In this mode, the input and output ports buses are separate, unidirectional buses of *n* bits wide.

Output Port Reset Value

You can specify the reset value of the output ports. The range of legal values depends on the port width.

Output Register

The option **Enable individual bit set/clear output register** allows you to set or clear individual bits of the output port. When this option is turned on, two additional registers—`outset` and `outclear`—are implemented. You can use these registers to specify the output bit to set and clear.

Input Options

The **Input Options** page allows you to specify edge-capture and IRQ generation settings. The **Input Options** page is not available when **Output ports only** is selected on the **Basic Settings** page.

Edge Capture Register

Turn on **Synchronously capture** to include the edge capture register, `edgecapture`, in the core. The edge capture register allows the core to detect and generate an optional interrupt when an edge of the specified type occurs on an input port. The user must further specify the following features:

- Select the type of edge to detect:
  - **Rising Edge**
  - **Falling Edge**
  - **Either Edge**
- Turn on **Enable bit-clearing for edge capture register** to clear individual bit in the edge capture register. To clear a given bit, write 1 to the bit in the edge capture register.

Interrupt

Turn on **Generate IRQ** to assert an IRQ output when a specified event occurs on input ports. The user must further specify the cause of an IRQ event:

- **Level—**The core generates an IRQ whenever a specific input is high and interrupts are enabled for that input in the `interruptmask` register.
- **Edge**—The core generates an IRQ whenever a specific bit in the edge capture register is high and interrupts are enabled for that bit in the `interruptmask` register.

When **Generate IRQ** is off, the `interruptmask` register does not exist.

Simulation

The **Simulation** page allows you to specify the value of the input ports during simulation. Turn on **Hardwire PIO inputs in test bench** to set the PIO input ports to a certain value in the testbench, and specify the value in **Drive inputs to** field.

Device Support

The PIO core supports all Altera® device families.

Software Programming Model

This section describes the software programming model for the PIO core, including the register map and software constructs used to access the hardware. For Nios® II processor users, Altera provides the HAL system library header file that defines the PIO core registers. The PIO core does not match the generic device model categories supported by the HAL, so it cannot be accessed via the HAL API or the ANSI C standard library.

The Nios II Embedded Design Suite (EDS) provides several example designs that demonstrate usage of the PIO core. In particular, the **count_binary.c** example uses the PIO core to drive LEDs, and detect button presses using PIO edge-detect interrupts.

Software Files

The PIO core is accompanied by one software file, **altera_avalon_pio_regs.h**. This file defines the core's register map, providing symbolic constants to access the low-level hardware.

Register Map

An Avalon-MM master peripheral, such as a CPU, controls and communicates with the PIO core via the four 32-bit registers, shown in Table 9–2. The table assumes that the PIO core's I/O ports are configured to a width of *n* bits.

Table 9–2. Register Map for the PIO Core

Offset	Register Name		R/W	(n-1)	...	2	1	0
0	`data`	read access	R	Data value currently on PIO inputs				
		write access	W	New value to drive on PIO outputs				
1	`direction` *(1)*		R/W	Individual direction control for each I/O port. A value of 0 sets the direction to input; 1 sets the direction to output.				
2	`interruptmask` *(1)*		R/W	IRQ enable/disable for each input port. Setting a bit to 1 enables interrupts for the corresponding port.				
3	`edgecapture` *(1)*, *(2)*		R/W	Edge detection for each input port.				
4	`outset`		W	Specifies which bit of the output port to set.				
5	`outclear`		W	Specifies which output bit to clear.				

Notes to Table 9–2:

(1) This register may not exist, depending on the hardware configuration. If a register is not present, reading the register returns an undefined value, and writing the register has no effect.

(2) Writing any value to `edgecapture` clears all bits to 0.

data Register

Reading from `data` returns the value present at the input ports. If the PIO core hardware is configured in output-only mode, reading from `data` returns an undefined value.

Writing to `data` stores the value to a register that drives the output ports. If the PIO core hardware is configured in input-only mode, writing to `data` has no effect. If the PIO core hardware is in bidirectional mode, the registered value appears on an output port only when the corresponding bit in the `direction` register is set to 1 (output).

direction Register

The `direction` register controls the data direction for each PIO port, assuming the port is bidirectional. When bit *n* in `direction` is set to 1, port *n* drives out the value in the corresponding bit of the `data` register.

The `direction` register only exists when the PIO core hardware is configured in bidirectional mode. The mode (input, output, or bidirectional) is specified at system generation time, and cannot be changed at runtime. In input-only or output-only mode, the `direction` register does not exist. In this case, reading `direction` returns an undefined value, writing `direction` has no effect.

After reset, all bits of direction are 0, so that all bidirectional I/O ports are configured as inputs. If those PIO ports are connected to device pins, the pins are held in a high-impedance state. In bi-directional mode, to change the direction of the PIO port, reprogram the `direction` register.

interruptmask Register

Setting a bit in the `interruptmask` register to 1 enables interrupts for the corresponding PIO input port. Interrupt behavior depends on the hardware configuration of the PIO core. See "Interrupt Behavior" on page 9–7.

The `interruptmask` register only exists when the hardware is configured to generate IRQs. If the core cannot generate IRQs, reading `interruptmask` returns an undefined value, and writing to `interruptmask` has no effect.

After reset, all bits of `interruptmask` are zero, so that interrupts are disabled for all PIO ports.

edgecapture Register

Bit *n* in the `edgecapture` register is set to 1 whenever an edge is detected on input port *n*. An Avalon-MM master peripheral can read the `edgecapture` register to determine if an edge has occurred on any of the PIO input ports. If the option **Enable bit-clearing for edge capture register** is turned off, writing any value to the `edgecapture` register clears all bits in the register. Otherwise, writing a 1 to a particular bit in the register clears only that bit.

The type of edge(s) to detect is fixed in hardware at system generation time. The `edgecapture` register only exists when the hardware is configured to capture edges. If the core is not configured to capture edges, reading from `edgecapture` returns an undefined value, and writing to `edgecapture` has no effect.

outset and outclear Registers

You can use the `outset` and `outclear` registers to set and clear individual bits of the output port. For example, to set bit 6 of the output port, write `0x40` to the `outset` register. Writing `0x08` to the `outclear` register clears bit 3 of the output port.

These registers are only present when the option **Enable individual bit set/clear output register** is turned on.

Interrupt Behavior

The PIO core outputs a single IRQ signal that can connect to any master peripheral in the system. The master can read either the `data` register or the `edgecapture` register to determine which input port caused the interrupt.

When the hardware is configured for level-sensitive interrupts, the IRQ is asserted whenever corresponding bits in the `data` and `interruptmask` registers are 1. When the hardware is configured for edge-sensitive interrupts, the IRQ is asserted whenever corresponding bits in the `edgecapture` and `interruptmask` registers are 1. The IRQ remains asserted until explicitly acknowledged by disabling the appropriate bit(s) in `interruptmask`, or by writing to `edgecapture`.

Software Files

The PIO core is accompanied by the following software file. This file provide low-level access to the hardware. Application developers should not modify the file.

- **altera_avalon_pio_regs.h**—This file defines the core's register map, providing symbolic constants to access the low-level hardware. The symbols in this file are used by device driver functions.

Document Revision History

Table 9–3 shows the revision history for this chapter.

Table 9–3. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	Added a section on new registers, `outset` and `outclear`.	—
November 2008 v8.1.0	Changed to 8-1/2 x 11 page size. Added the description for **Output Port Reset Value** and **Simulation** parameters.	—
May 2008 v8.0.0	No change from previous release.	—

10. Avalon-ST JTAG Interface Core

QII55008-9.0.0

Core Overview

The Avalon® Streaming (Avalon-ST) JTAG Interface core enables communication between SOPC Builder systems and JTAG hosts via Avalon-ST interface. Data is serially transferred on the JTAG interface, and presented on the Avalon-ST interface as bytes.

The SPI Slave/JTAG to Avalon Master Bridge is an example of how this core is used. For more information about the bridge, refer to the *SPI Slave/JTAG to Avalon Master Bridge Cores* chapter in volume 5 of the *Quartus II Handbook*.

The Avalon-ST JTAG Interface core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated systems.

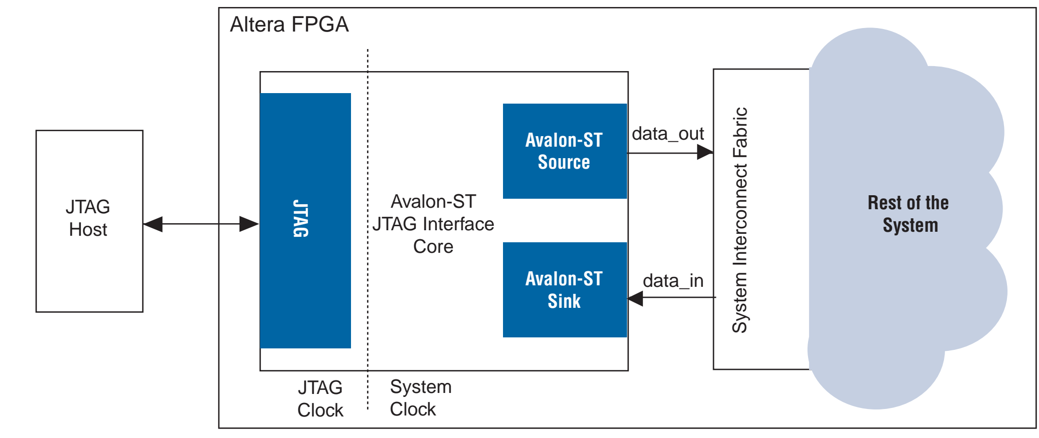
This chapter contains the following sections:

- "Functional Description"
- "Instantiating the Core in SOPC Builder" on page 10–3
- "Device Support" on page 10–3

Functional Description

Figure 10–1 shows a block diagram of the Avalon-ST JTAG Interface core in a typical system configuration.

Figure 10–1. SOPC Builder System with an Avalon-ST JTAG Interface Core



Interfaces

Table 10–1 shows the properties of the Avalon-ST interfaces.

Table 10–1. Properties of Avalon-ST Interfaces

Feature	Property
Backpressure	Only supported on the sink interface.
Data Width	Data width = 8 bits; Bits per symbol = 8.
Channel	Not supported.
Error	Not used.
Packet	Not supported.

For more information about Avalon-ST interfaces, refer to the *Avalon Interface Specifications*.

Special characters

Table 10–2 lists the special characters recognized by the core.

Table 10–2. Special Characters

Character	Description
`0x4a`	Idle. Idle characters are inserted into data streams when there is no data to send.
`0x4d`	Idle escape. An idle escape character is inserted into data stream when the data to send is a special character, followed by the data which is XORed with `0x20`.

Operation

The Avalon-ST JTAG Interface core accepts incoming data in bits on its JTAG interface and packs the bits into bytes. After each byte is formed, the core checks for the following special characters:

- `0x4a`—Idle character. The core drops the idle character.
- `0x4d`—Escape character. The core drops the escape character, and `XOR`s the following byte with `0x20`.

Each valid byte is then transferred to the core's Avalon-ST source interface. As there are no means to backpressure this interface, you must ensure that sufficient storage is in place to avoid data loss.

In the opposite direction, the core serializes each byte received on its Avalon-ST sink interface and sends the bits to the JTAG interface. If there is no data on the sink interface, the core sends out idle characters. If the data is a special character, the core inserts an escape character and `XOR`s the data with `0x20`.

The core supports four operation modes. From the system console, you can set the instruction register (IR) to enable the following supported modes:

- Normal mode—The core works as a bridge between a JTAG host and an SOPC Builder system. Set the IR to 0 to enable this mode.
- Loopback—Data received by the core is sent back to the host. Set the IR to 1 to enable this mode.

- Troubleshoot—The core retrieves the value of the system reset and clock signals, and return them to the JTAG host. Set the IR to 2 to enable this mode.

A TimeQuest SDC file (**.sdc**) is provided to cut any paths internal to the core.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ interface for the Avalon-ST JTAG Interface core in SOPC Builder to add the core to a system. There are no user-configurable parameters for this core.

Device Support

The Avalon-ST JTAG Interface core supports all Altera® device families.

11. Avalon-ST Serial Peripheral Interface Core

QII55009-9.0.0

Core Overview

The Avalon® Streaming (Avalon-ST) Serial Peripheral Interface (SPI) core is an SPI slave that allows data transfers between SOPC Builder systems and off-chip SPI devices via Avalon-ST interfaces. Data is serially transferred on the SPI, and sent to and received from the Avalon-ST interface in bytes.

The SPI Slave to Avalon Master Bridge is an example of how this core is used. For more information on the bridge, refer to the *SPI Slave/JTAG to Avalon Master Bridge Cores* chapter in volume 5 of the *Quartus II Handbook*.

The Avalon-ST Serial Peripheral Interface core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system.

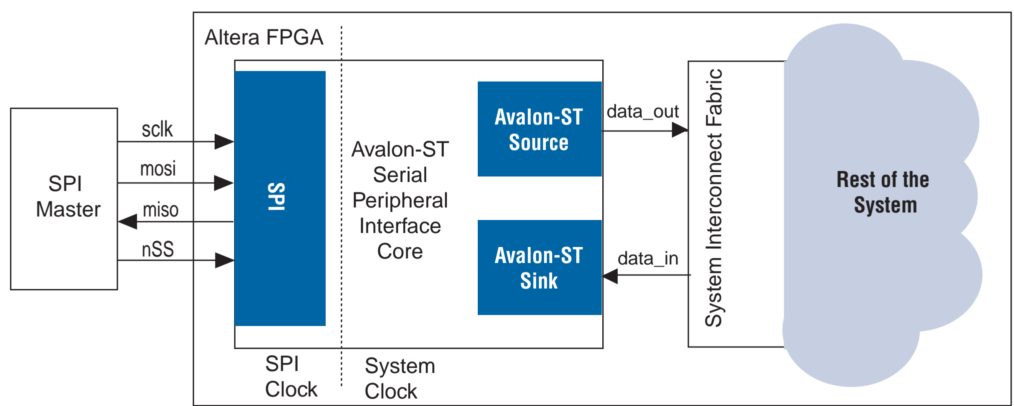
This chapter contains the following sections:

- "Functional Description"
- "Instantiating the Core in SOPC Builder" on page 11–3
- "Device Support" on page 11–3

Functional Description

Figure 11–1 shows a block diagram of the Avalon-ST Serial Peripheral Interface core in a typical system configuration.

Figure 11–1. SOPC Builder System with an Avalon-ST SPI Core



Interfaces

The serial peripheral interface is full-duplex and does not support backpressure. It supports SPI clock phase bit, CPHA = 1, and SPI clock polarity bit, CPOL = 0.

Table 11–1 shows the properties of the Avalon-ST interfaces.

Table 11–1. Properties of Avalon-ST Interfaces

Feature	Property
Backpressure	Not supported.
Data Width	Data width = 8 bits; Bits per symbol = 8.
Channel	Not supported.
Error	Not used.
Packet	Not supported.

For more information about Avalon-ST interfaces, refer to the *Avalon Interface Specifications*.

Operation

The Avalon-ST SPI core waits for the `nSS` signal to be asserted low, signifying that the SPI master is initiating a transaction. The core then starts shifting in bits from the input signal `mosi`. The core packs the bits received on the SPI to bytes and checks for the following special characters:

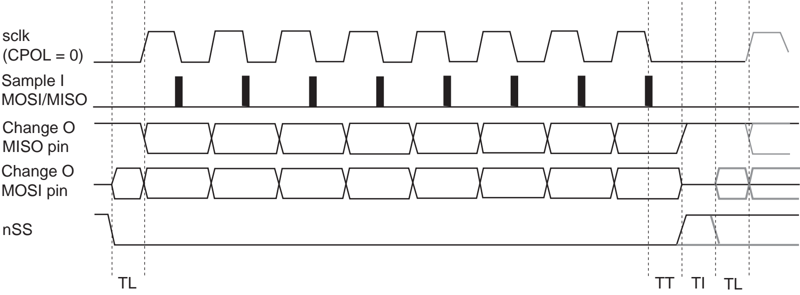
- `0x4a`—Idle character. The core drops the idle character.
- `0x4d`—Escape character. The core drops the escape character, and `XOR`s the following byte with `0x20`.

For each valid byte of data received, the core asserts the `valid` signal on its Avalon-ST source interface and presents the byte on the interface for a clock cycle.

At the same time, the core shifts data out from the Avalon-ST sink to the output signal `miso` beginning with from the most significant bit. If there is no data to shift out, the core shifts out idle characters (`0x4a`). If the data is a special character, the core inserts an escape character (`0x4d`) and XORs the data with `0x20`.

Figure 11–2 shows the SPI transfer protocol.

Figure 11–2. SPI Transfer Protocol



Notes to Figure 11–2:

(1) TL = The worst recovery time of `sclk` with respect with `nSS`.
(2) TT = The worst hold time for `MOSI` and `MISO` data.
(3) TI = The minimum width of a reset pulse required by Altera FPGA families.

Timing

The core requires a lead time (TL) between asserting the `nSS` signal and the SPI clock, and a lag time (TT) between the last edge of the SPI clock and deasserting the `nSS` signal. The `nSS` signal must be deasserted for a minimum idling time (TI) of one SPI clock between byte transfers. A TimeQuest SDC file (**.sdc**) is provided to remove false timing paths. The frequency of the SPI master's clock must be equal to or lower than the frequency of the core's clock.

Limitations

Daisy-chain configuration, where the output line `miso` of an instance of the core is connected to the input line `mosi` of another instance, is not supported.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ interface for the Avalon-ST SPI core in SOPC Builder to add the core to a system. The parameter **Number of synchronizer stages: Depth** allows you to specify the length of synchronization register chains. These register chains are used when a metastable event is likely to occur and the length specified determines the meantime before failure. The register chain length, however, affects the latency of the core.

For more information on metastability in Altera devices, refer to *AN 42: Metastability in Altera Devices*. For more information on metastability analysis and synchronization register chains, refer to the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*.

Device Support

The Avalon-ST SPI core supports all Altera® device families.

12. SPI Slave/JTAG to Avalon Master Bridge Cores

QII55011-9.0.0

Core Overview

The SPI Slave to Avalon® Master Bridge and the JTAG to Avalon Master Bridge cores provide a connection between host systems and SOPC Builder systems via the respective physical interfaces. Host systems can initiate Avalon Memory-Mapped (Avalon-MM) transactions by sending encoded streams of bytes via the cores' physical interfaces. The cores support reads and writes, but not burst transactions.

The SPI Slave to Avalon Master Bridge and the JTAG to Avalon Master Bridge are SOPC Builder-ready and integrates easily into any SOPC Builder-generated systems.

This chapter contains the following sections:

- "Functional Description"
- "Instantiating the Core in SOPC Builder" on page 12–3
- "Device Support" on page 12–3

Functional Description

Figure 12–1 shows a block diagram of the SPI Slave to Avalon Master Bridge core and its location in a typical system configuration.

Figure 12–1. SOPC Builder System with a SPI Slave to Avalon Master Bridge Core

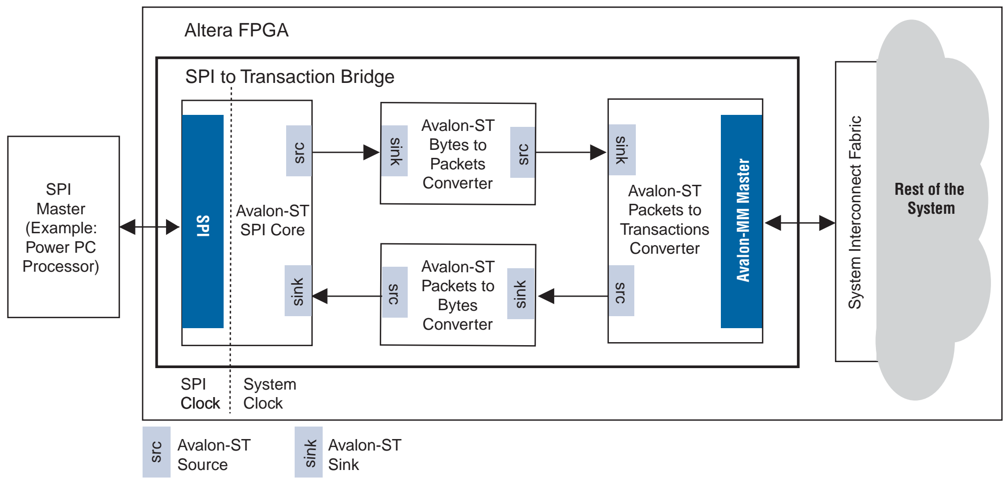

Figure 12–2 shows a block diagram of the JTAG to Avalon Master Bridge core and its location in a typical system configuration.

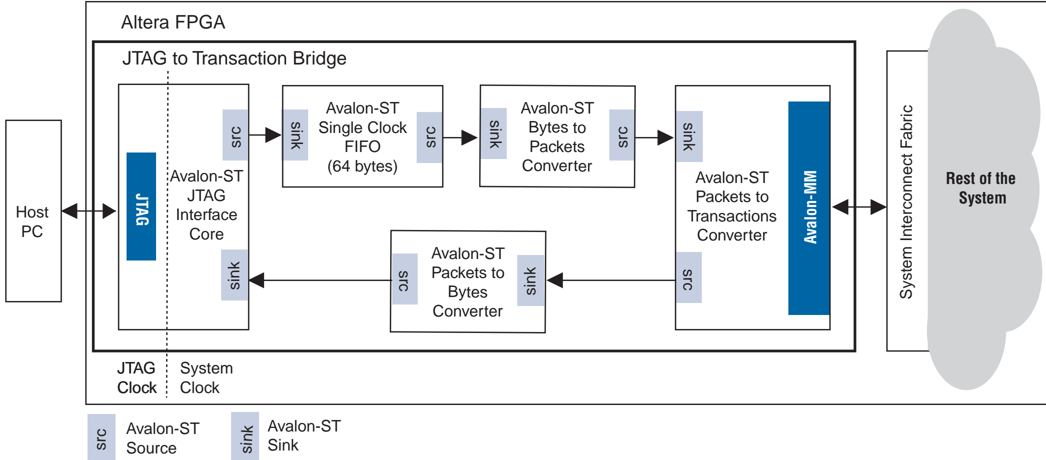
Figure 12–2. SOPC Builder System with a JTAG to Avalon Master Bridge Core



The SPI Slave to Avalon Master Bridge and the JTAG to Avalon Master Bridge cores accept encoded streams of bytes with transaction data on their respective physical interfaces and initiate Avalon-MM transactions on their Avalon-MM interfaces. Each bridge consists of the following cores, which are available as stand-alone components in SOPC Builder:

- **Avalon-ST Serial Peripheral Interface and Avalon-ST JTAG Interface**—Accepts incoming data in bits and packs them into bytes.
- **Avalon-ST Bytes to Packets Converter**—Transforms packets into encoded stream of bytes, and a likewise encoded stream of bytes into packets.
- **Avalon-ST Packets to Transactions Converter**—Transforms packets with data encoded according to a specific protocol into Avalon-MM transactions, and encodes the responses into packets using the same protocol.
- **Avalon-ST Single Clock FIFO**—Buffers data from the Avalon-ST JTAG Interface core. The FIFO is only used in the JTAG to Avalon Master Bridge.

For the bridges to successfully transform the incoming streams of bytes to Avalon-MM transactions, the streams of bytes must be constructed according to the protocols used by the cores.

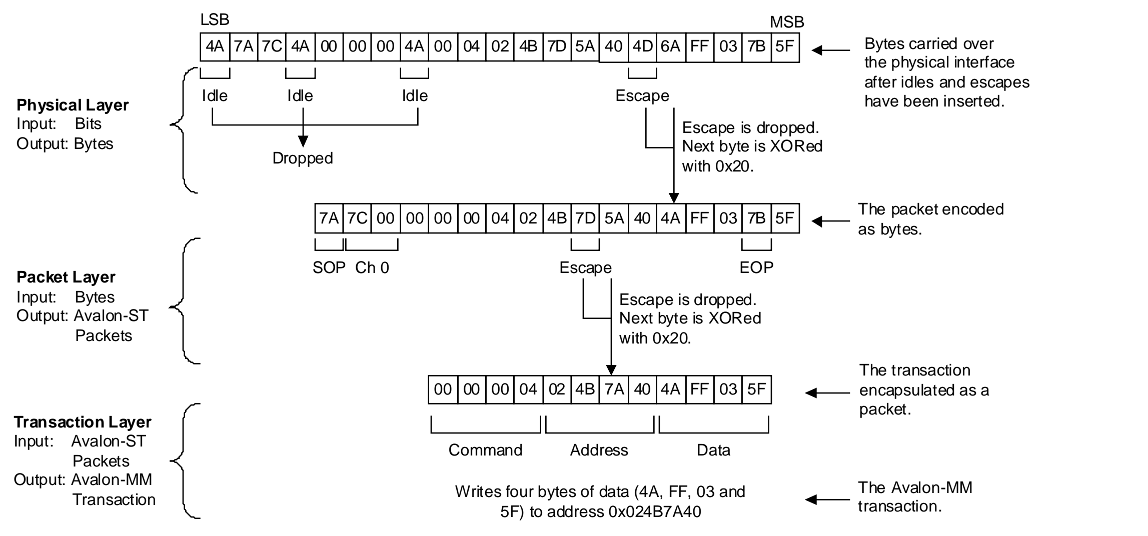
For more information about the protocol at each layer of the bridges and the single clock FIFO, refer to the following chapters:

- *Avalon-ST Serial Peripheral Interface Core* chapter in volume 5 of the *Quartus II Handbook*
- *Avalon-ST JTAG Interface Core* chapter in volume 5 of the *Quartus II Handbook*
- *Avalon-ST Bytes to Packets and Packets to Bytes Converter Cores* chapter in volume 5 of the *Quartus II Handbook*

- *Avalon Packets to Transactions Converter Core* chapter in volume 5 of the *Quartus II Handbook*
- *Avalon-ST Single Clock and Dual Clock FIFO Cores* chapter in volume 5 of the *Quartus II Handbook*

The following example shows how a bytestream changes as it is transferred through the different layers in the bridges.

Figure 12–3. Bits to Avalon-MM Transaction



When the transaction is complete, the bridges send a response to the host system using the same protocol.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ interface for the SPI Slave to Avalon Master Bridge and the JTAG to Avalon Master Bridge in SOPC Builder to add the cores to a system. There are no user-configurable settings for the JTAG to Avalon Master Bridge core.

For the SPI Slave to Avalon Master Bridge core, the parameter **Number of synchronizer stages: Depth** allows you to specify the length of synchronization register chains. These register chains are used when a metastable event is likely to occur and the length specified determines the meantime before failure. The register chain length, however, affects the latency of the core.

For more information on metastability in Altera devices, refer to *AN 42: Metastability in Altera Devices*. For more information on metastability analysis and synchronization register chains, refer to the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*.

Device Support

The SPI Slave to Avalon Master bridge supports all Altera® device families.

13. PCI Lite Core

QII55010-9.0.0

Core Overview

The PCI Lite core is a protocol interface that translates PCI transactions to Avalon® Memory-Mapped (Avalon-MM) transactions with low latency and high throughput. The PCI Lite core uses the PCI-Avalon bridge to connect the PCI bus to the interconnect fabric, allowing you to easily create simple PCI systems that include one or more SOPC Builder components. This core has the following features:

- SOPC Builder ready
- PCI complexities, such as retry and disconnect are handled by the PCI/Avalon Bridge logic and transparent to the user
- Run-time configurable (dynamic) Avalon-to-PCI address translation
- Separate Avalon Memory-Mapped (Avalon-MM) slave ports for PCI bus access (PBA) and control register access (CRA)
- Support for Avalon-MM burst mode
- Common PCI and Avalon clock domains
- Option to increase PCI read performance by increasing the number of pending reads and maximum read burst size.

This chapter contains the following sections:

- "Performance and Resource Utilization"
- "Functional Description" on page 13–2
- "Instantiating the Core in SOPC Builder" on page 13–11
- "Device Support" on page 13–14
- "Simulation Considerations" on page 13–14

Performance and Resource Utilization

This section lists the resource utilization and performance data for supported devices when operating in the PCI Target-Only, and PCI Master/Target device modes for each of the application-specific performance settings.

The estimates are obtained by compiling the core using the Quartus® II software. Performance results vary depending on the parameters that you specify for the system module.

Table 13–1 shows the resource utilization and performance data for a Stratix® III device (EP3SE50F780C2). The performance of the MegaCore function in the Stratix IV family is similar to the Stratix III family.

Table 13–1. Memory Utilization and Performance Data for the Stratix III Family

PCI Device Mode	PCI Target	PCI Master	ALUTs *(2)*	Logic Register	M9K Memory Blocks	I/O Pins
Min *(1)*	Enabled	N/A	715	517	2	48
Max *(1)*	Enabled	Enabled	1,347	876	5	50

Notes to Table 13–1:

(1) **Min** = One BAR with minimum settings for each parameter.
Max = Three BARs with maximum settings for each parameter.

(2) The logic element (LE) count for the Stratix III family is based on the number of adaptive look-up tables (ALUTs) used for the design as reported by the Quartus II software.

Table 13–2 lists the resource utilization and performance data for a Cyclone III device (EP3C40F780C6).

Table 13–2. Memory Utilization and Performance Data for the Cyclone III Family

PCI Device Mode	PCI Target	PCI Master	Logic Elements	Logic Register	M4K Memory Blocks	I/O Pins
Min *(1)*	Enabled	N/A	1,057	511	2	48
Max *(1)*	Enabled	Enabled	2,027	878	5	50

Note to Table 13–2:

(1) **Min** = One BAR with minimum settings for each parameter.
Max = Three BARs with maximum settings for each parameter.

Functional Description

The following sections provide a functional description of the PCI Lite Core.

PCI-Avalon Bridge Blocks

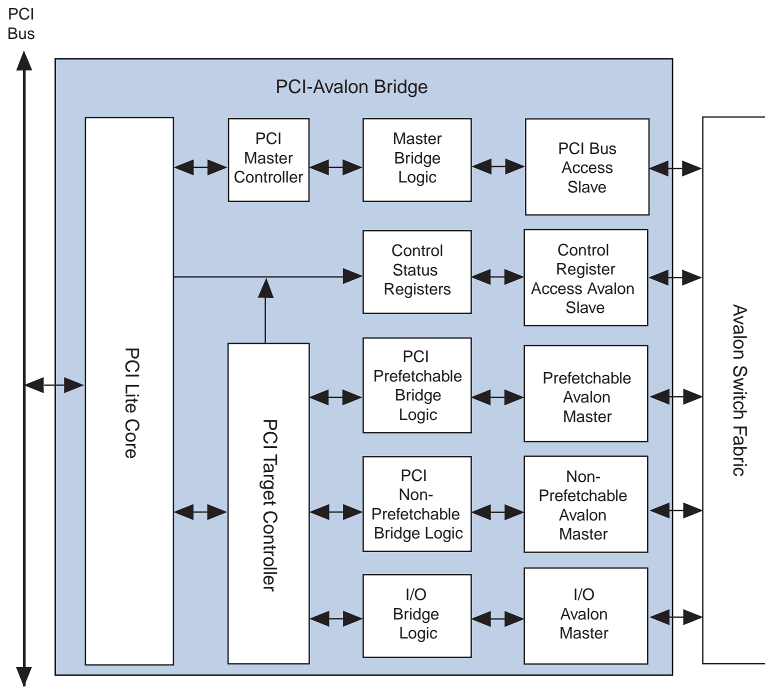
The PCI-Avalon bridge's blocks manage the connectivity for the following PCI operational modes:

- PCI Target-Only Peripheral
- PCI Master/Target Peripheral
- PCI Host-Bridge Device

Depending on the operational mode, the PCI-Avalon bridge uses some or all of the predefined Avalon-MM ports. Figure 13–1 shows a generic PCI-Avalon bridge block diagram, which includes the following blocks:

- Five predefined Avalon-MM ports
- Control registers
- PCI master controller (when applicable)
- PCI target controller

Figure 13–1. Generic PCI-Avalon Bridge Block Diagram



Avalon-MM Ports

The Avalon bridge comprises up to five predefined ports to communicate with the interconnect (depending on device operating mode).

This section discusses the five Avalon-MM ports:

- Prefetchable Avalon-MM master
- Non-Prefetchable Avalon-MM master
- I/O Avalon-MM master
- PCI bus access slave
- Control register access (CRA) Avalon-MM slave

Prefetchable Avalon-MM Master

The prefetchable Avalon-MM master port provides a high bandwidth PCI memory request access to Avalon-MM slave peripherals. This master port is capable of generating Avalon-MM burst transactions for PCI requests that hit a prefetchable base address register (BAR). You should only connect prefetchable Avalon-MM slaves to this port, typically RAM or ROM memory devices.

This port is optimized for high bandwidth transfers as a PCI target and it does not support single cycle transactions.

Non-Prefetchable Avalon-MM Master

The Non-Prefetchable Avalon-MM master port provides a low latency PCI memory request access to Avalon-MM slave peripherals. Burst operations are not supported on this master port. Only the exact amount of data needed to service the initial data phase is read from the interconnect. Therefore, the PCI byte enables (for the first data phase of the PCI read transaction) are passed directly to the interconnect.

This Avalon-MM master port is optimized for low latency access from PCI-to-Avalon-MM slaves. This is optimal for providing PCI target access to simple Avalon-MM peripherals.

I/O Avalon-MM Master

The I/O Avalon-MM master port provides a low latency PCI I/O request access to Avalon-MM slave peripherals. Burst operations are not supported on this master port. As only the exact amount of data needed to service the initial data phase is read from the interconnect, the PCI byte enables (for the first data phase of the PCI read transaction) are passed directly to the interconnect.

This Avalon-MM master port is also optimized for I/O access from PCI-to-Avalon-MM slaves for providing PCI target access to simple Avalon-MM peripherals.

PCI Bus Access Slave

This Avalon-MM slave port propagates the following transactions from the interconnect to the PCI bus:

- Single cycle memory read and write requests
- Burst memory read and write requests
- I/O read and write requests
- Configuration read and write requests

Burst requests from the interconnect are the only way to create burst transactions on the PCI bus.

This slave port is not implemented in the PCI Target-Only Peripheral mode.

Control Register Access (CRA) Avalon-MM Slave

This Avalon-MM slave port is used to access control registers in the PCI-Avalon bridge. To provide external PCI master access to these registers, one of the bridge's master ports must be connected to this port. There is no internal access inside the bridge from the PCI bus to these registers. You can only write to these registers from the interconnect. The `Control Register Access Avalon Slave` port is only enabled on Master/Target selection. The range of values supported by PCI CRA is 0x1000 to 0x1FFF. Depending on the system design, these values can be accessed by PCI processors, Avalon processors or both.

Table 13–3 on page 13–5 shows the instructions on how to use these values. The address translation table is writable via the `Control Register Access Avalon Slave` port. If the **Number of Address Pages** field is set to the maximum of **512**, `0x1FF8` contains `A2P_ADDR_MAP_LO511` and `0x1FFC` contains `A2P_ADDR_MAP_HI511`.

Each entry in the PCI address translation table is always 8 bytes wide. The lower order address bits that are treated as a pass through between Avalon-MM and PCI, and the number of pass-through bits, are defined by the size of page in the address translation table and are always forced to 0 in the hardware table. For example, if the page size is 4 KBytes, the number of pass-through bits is $\log_2$ (page size) = $\log_2$ (4 KBytes) = 12.

Refer to "Avalon-to-PCI Address Translation" on page 13–6 for more details.

Table 13–3. Avalon-to-PCI Address Translation Table – Address Range: 0x1000-0x1FFF

Address	Bit	Name	Access Mode	Description
0x1000	1:0	A2P_ADDR_SPACE0	W	Address space indication for entry 0. See Table 13–4 on page 13–7 for the definition of these bits.
	31:2	A2P_ADDR_MAP_LO0	W	Lower bits of Avalon-to-PCI address map entry 0. The pass through bits are not writable and are forced to 0.
0x1004	31:0	A2P_ADDR_MAP_HI0	W	Reserved.
0x1008	1:0	A2P_ADDR_SPACE1	W	Address Space indication for entry 1. See Table 13–4 on page 13–7 for the definition of these bits.
	31:2	A2P_ADDR_MAP_LO1	W	Lower bits of Avalon-to-PCI address map entry 1. Pass through bits are not writable and are forced to 0. This entry is only implemented if the number of pages in the address translation table is greater than 1.
0x100C	31:0	A2P_ADDR_MAP_HI1	W	Reserved.

Master and Target Performance

The performance of the PCI Lite core is designed to provide low-latency single-cycle and burst transactions.

Master Performance

The master provides high throughput for transactions initiated by Avalon-MM master devices to PCI target devices via the PCI bus master interface. Avalon-MM read transactions are implemented as latent read transfers. The PCI master device issues only one read transaction at a time.

The PCI bus access (PBA) handles the Avalon master transaction system interconnect hold state for 6 clock cycles. This is the maximum number of cycles supported by the PCI specification.

Target Performance

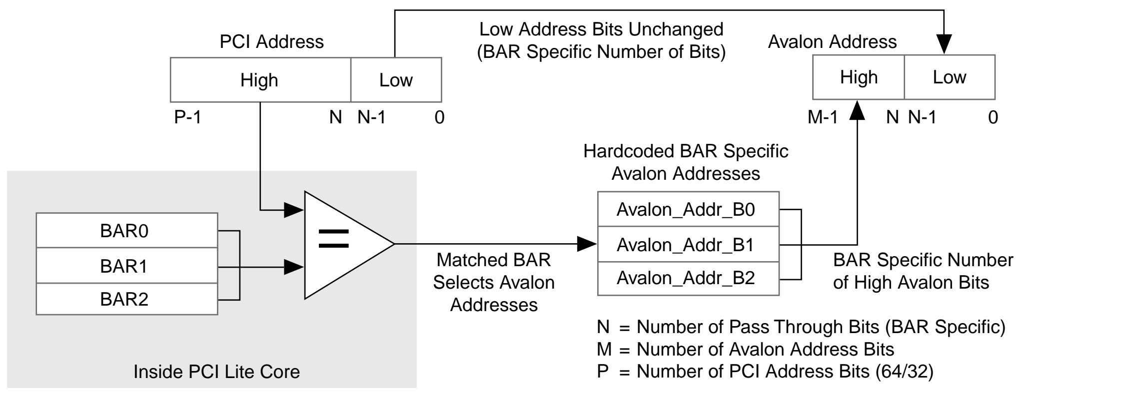
The target allows high throughput read/write operations to Avalon-MM slave peripherals. Read/write accesses to prefetchable base address registers (BARs) use dual-port buffers to enable burst transactions on both the PCI and Avalon-MM sides. This profile also allows access to the PCI BARs (Prefetchable, Non-Prefetchable, and I/O) to use their respective Avalon-MM master ports to initiate transfers to Avalon-MM slave peripherals. Prefetchable handles burst transaction and Non-Prefetchable and I/O handles only single-cycle transaction.

All PCI read transactions are completed as delayed reads. However, only one delayed read is accepted and processed at a time.

PCI-to-Avalon Address Translation

Figure 13–2 shows the PCI-to-Avalon address translation. The bits in the PCI address that are used in the BAR matching process are replaced by an Avalon-MM base address that is specific to that BAR.

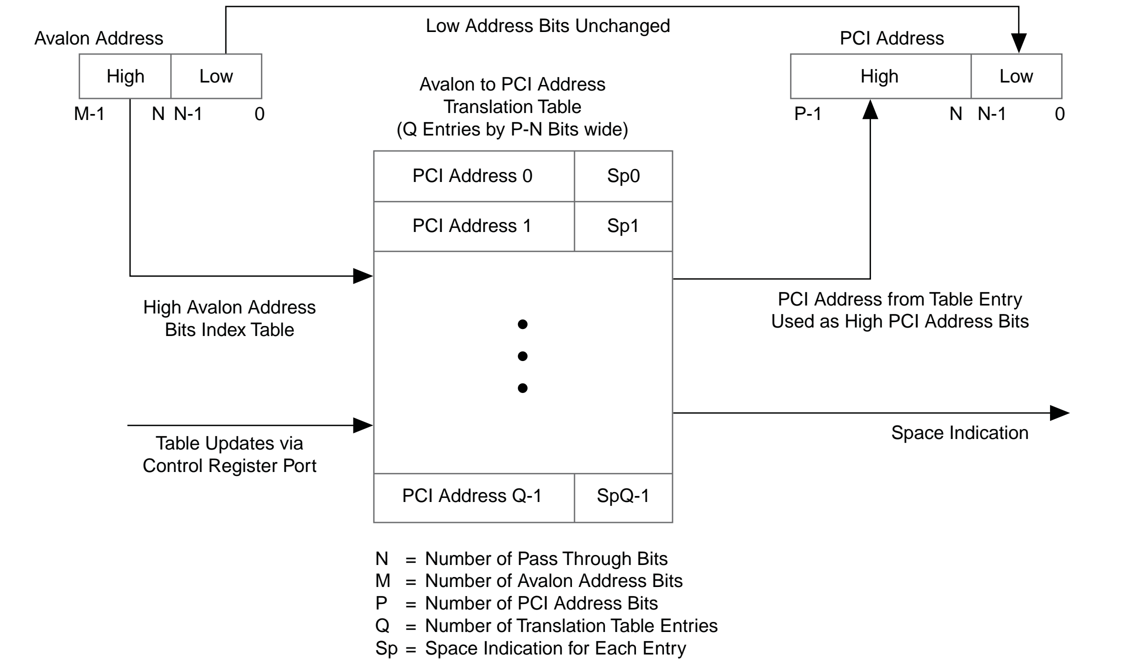
Figure 13–2. PCI-to-Avalon Address Translation



Avalon-to-PCI Address Translation

Avalon-to-PCI address translation is done through a translation table. Low order Avalon-MM address bits are passed to PCI unchanged; higher order Avalon-MM address bits are used to index into the address translation table. The value found in the table entry is used as the higher order PCI address bits. Figure 13–3 depicts this process.

Figure 13–3. Avalon-to-PCI Address Translation



The address size selections in the translation table determine both the number of entries in the Avalon-to-PCI address translation table, and the number of bits that are passed through the transaction table unchanged.

Each entry in the address translation table also has two address space indication bits, which specify the type of address space being mapped. If the type of address space being mapped is memory, the bits also indicate the resulting PCI address is a 32-bit address.

Table 13–4 shows the address space field's format of the address translation table entries.

Table 13–4. Address Space Bit Encodings

Address Space Indicator (Bits 1:0)	Description
`00`	Memory space, 32-bit PCI address. Address bits 63:32 of the translation table entries are ignored.
`01`	Reserved.
`10`	I/O space. The address from the translation table process is modified as described in Table 13–5.
`11`	Configuration space. The address from the translation table process is treated as a type 1 configuration address and is modified as described in Table 13–5.

If the space indication bits specify configuration or I/O space, subsequent modifications to the PCI address are performed. See Table 13–5.

Table 13–5. Configuration and I/O Space Address Modifications

Address Space	Modifications Performed
I/O	■ Address bits 2:0 are set to point to the first enabled byte according to the Avalon byte enables. (Bit 2 only needs to be modified when a 64-bit data path is in use.) ■ Address bits 31:3 are handled normally.
Configuration address bits 23:16 == 0 (bus number == 0)	■ Address bits 1:0 are set to `00` to indicate a type 0 configuration request. ■ Address bits 10:2 are passed through as normal. ■ Address bits 31:11 are set to be a one-hot encoding of the device number field (15:11) of the address from the translation table. For example, if the device number is `0x00`, address bit 11 is set to 1 and bits 31:12 are set to 0. If the device number is `0x01`, address bit 12 is set to 1 and bits 31:13, 11 are set to 0. ■ Address bits 31:24 of the original PCI address are ignored.
Configuration address bits 23:16 > 0 (bus number > 0)	■ Address bits 1:0 are set to `01` to indicate a type 1 configuration request. ■ Address bits 31:2 are passed through unchanged.

Avalon-To-PCI Read and Write Operation

The PCI Bus Access Slave port is a burst-capable slave that attempts to create PCI bursts that match the bursts requested from the interconnect.

The PCI-Avalon bridge is capable of handling bursts up to 512 bytes with a 32-bit PCI bus. In other words, the maximum supported Avalon-MM burst count is 128.

Bursts from Avalon-MM can be received on any boundary. However, when internal PCI-Avalon bridge bursts cross the Avalon-to-PCI address page boundary, they are broken into two pieces. Two bursts are used because the address translation can change at that boundary, requiring a different PCI address for the second portion of the burst with a burst count greater than 1.

Avalon-MM burst read requests are treated as if they are going to prefetchable PCI space. Therefore, if the PCI target space is non-prefetchable, you should not use read bursts.

Several factors control how Avalon-MM transactions (bursts or single cycle) are translated to PCI transactions. These cases are discussed in Table 13–6.

Table 13–6. Translation of Avalon Requests to PCI Requests

Data Path Width	Avalon Burst Count	Type of Operation	Avalon Byte Enables	Resulting PCI Operation and Byte Enables
32	1	Read or Write	Any value	Single data phase read or write, PCI byte enables identical to Avalon byte enables
32	>1	Read	Any value	Attempt to burst on PCI. All data phases have all PCI bytes enabled.
32	>1	Write	Any value	Attempt to burst on PCI. All data phases have PCI byte enables identical to the Avalon byte enables.

© March 2009 Altera Corporation

Avalon-to-PCI Write Requests

For write requests from the interconnect, the write request is pushed onto the PCI bus as a configuration write, I/O write, or memory write. When the Avalon-to-PCI command/write data buffer either has enough data to complete the full burst or 8 data phases (32 bytes on a 32-bit PCI bus) are exceeded, the PCI master controller issues the PCI write transaction.

The PCI write is issued to configuration, I/O, or memory space based on the address translation table. See "Avalon-to-PCI Address Translation" on page 13–6.

A PCI write burst can be terminated for various reasons. Table 13–7 describes the resulting action for the PCI master write request termination condition.

Table 13–7. PCI Master Write Request Termination Conditions

Termination condition	Resulting Action
Burst count satisfied	Normal master-initiated termination on PCI bus, command completes, and the master controller proceeds to the next command.
Latency timer expiring during configuration, I/O, or memory write command	Normal master-initiated termination on PCI bus, the continuation of the PCI write is requested from the master controller arbiter.
Avalon-to-PCI command/write data buffer running out of data	Normal master-initiated termination on the PCI bus. Master controller waits for the buffer to reach 8 DWORDs on a 32-bit PCI or 16 DWORDs on a 64-bit PCI, or there is enough data to complete the remaining burst count. Once enough data is available, the master controller arbiter continues wth the PCI write.
PCI target disconnect	The master controller arbiter attempts to initiate the PCI write until the transaction is successful.
PCI target retry	
PCI target-abort	The rest of the write data is read from the buffer and discarded.
PCI master-abort	

Avalon-to-PCI Read Requests

For read requests from the interconnect, the request is pushed on the PCI bus by a configuration read, I/O read, memory read, memory read line, or memory read multiple command. The PCI read is issued to configuration, I/O, or memory space based on the address translation table entry. See "Avalon-to-PCI Address Translation" on page 13–6.

If a memory space read request can be completed in a single data phase, it is issued as a memory read command. If the memory space read request spans more than one data phase but does not cross a cacheline boundary (as defined by the cacheline size register), it is issued as a memory read line command. If the memory space read request crosses a cache line boundary, it is issued as multiple memory read commands.

Read requests on PCI may initially be retried. Retries depend on the response time from the target. The master continues to retry until it gets the required data.

Table 13–8 shows PCI master read request termination conditions.

Table 13–8. PCI Master Read Request Termination Conditions

Termination Condition	Resulting Action
Burst count satisfied	Normal master initiated termination on the PCI bus. Master controller proceeds to the next command.
Latency timer expired	Normal master initiated termination on PCI bus. The continuation of the PCI read is made pending as a request from the master controller arbiter.
PCI target disconnect	The continuation of the PCI read is requested from the master controller arbiter.
PCI target retry	
PCI target-abort	Dummy data is returned to complete the Avalon-MM read request. The next operation is then attempted in a normal fashion.
PCI master-abort	

Ordering of Requests

The PCI-Avalon bridge handles the following types of requests:

- PMW—Posted memory write.
- DRR—Delayed read request.
- DWR—Delayed write request. DWRs are I/O or configuration write operation requests. The PCI-Avalon bridge does not handle DWRs as delayed writes.
  - As a PCI master, I/O or configuration writes are generated from posted Avalon-MM writes. If required to verify completion, you must issue a subsequent read request to the same target.
  - As a PCI target, configuration writes are the only requests accepted, which are never delayed. These requests are handled directly by the PCI core.
- DRC—Delayed read completion.
- DWC—Delayed write completion. These are never passed through to the core in either direction. Incoming configuration writes are never delayed. Delayed write completion status is not passed back at all.

Every single transaction that is initiated, locks the core until it is completed. Only then can a new transaction be accepted.

PCI Interrupt

When Avalon-MM asserts the `IRQ` signal, an interrupt on the PCI bus occurs. The Avalon-MM `IRQ` input causes a bit to be set in the PCI interrupt status register.

Instantiating the Core in SOPC Builder

Table 13–9 describes the parameters that can be configured in SOPC Builder for the PCI Lite core.

Table 13–9. Parameters for PCI Lite Core (Part 1 of 2)

Parameters	Legal Values	Description
Enable Master/Target Mode	On or Off	Turning this option **On** enables Master/Target mode. This option enables allows Avalon-MM master devices to access PCI target devices via the PCI bus master interface, and PCI bus master devices to access Avalon-MM slave devices via the PCI bus target interface. Turning this option **Off** means you have selected Target Only mode, which allows PCI bus mastering devices to access Avalon-MM slave devices via the PCI bus target interface.
Enable Host Bridge Mode	On or Off	Turning this option **On** enables this mode. In addition to the same features provided by the PCI Master/Target mode, Host Bridge Mode provides host bridge functionality including hardwiring the master enable bit to 1 in the PCI command register and allowing self-configuration. This value can only be set if the **Enable Master/Target Mode** option is turned **On**.
Number of Address Pages	2, 4, 8, or 16	The number of translation/pages supported by the device for Avalon to PCI address translation.
Size of Address Pages	12–27	The supported address size (in bits) that can be assigned to each map number entries.
Prefetchable BAR	On or Off	Turning this option **On** invokes a Prefetchable Master (PM) Bar in the PCI system. This option allows PCI-Avalon Bridge Lite to accept and process PM transactions.
Prefetchable BAR Size	10–31	The allowed reserved address range supported by the PM BAR. The reserved memory space is 1 KByte (10 bits) to 4 GBytes (31 bits).
Prefetchable BAR Avalon Address Translation Offset	*<BAR translation value>*	The direct translation of the value that hits the BAR and modified to a fixed address in the Avalon space. Refer to "PCI-to-Avalon Address Translation" on page 13–6.
Non-Prefetchable BAR	On or Off	Turning this option **On** invokes a Non-Prefetchable Master (NPM) Bar in the PCI system. This option allows the PCI-Avalon Bridge Lite to accept and process NPM transactions.
Non-Prefetchable BAR Size	10–31	Specifies the allowed reserved address range supported by the NPM BAR. The reserved memory space is 1 KByte (10 bits) to 4 GBytes (31 bits).
Non-Prefetchable BAR Avalon Address Translation Offset	*<BAR translation value>*	The direct translation of the value that hits the BAR and modified to a fixed address in the Avalon space. Refer to "PCI-to-Avalon Address Translation" on page 13–6.
I/O BAR	On or Off	Turning this option **On** enables an I/O BAR in the system. This option allows PCI-Avalon Bridge Lite to accept and process I/O type transactions.
I/O BAR Size	2–8	The allowed reserved address range supported by the I/O BAR. The reserved memory space is 4 bytes (2 bits) to 256 bytes (8 bits).
I/O BAR Avalon Address Translation Offset	*<BAR translation value>*	The direct translation of the value that hits the BAR and modified to a fixed address in the Avalon address space. Refer to "PCI-to-Avalon Address Translation" on page 13–6.

Table 13–9. Parameters for PCI Lite Core (Part 2 of 2)

Parameters	Legal Values	Description
Maximum Target Read Burst Size	1, 2, 4, 8, 16, 32, 64, or 128	Specifies the maximum FIFO depth that is used for reading. Larger values allow more reads to be read in a single transaction but also require more time to clear the FIFO content.
Device ID	<*register value*>	Device ID register. This parameter is a 16-bit hexadecimal value that sets the device ID register in the configuration space.
Vendor ID	<*register value*>	Vendor ID register.This parameter is a 16-bit read-only register that identifies the manufacturer of the device. The value of this register is assigned by the PCI Special Interest Group (SIG).
Class Code	<*register value*>	Class code register. This parameter is a 24-bit hexadecimal value that sets the class code register in the configuration space. The value entered for this parameter must be valid PCI SIG-assigned class code register value.
Revision ID	<*register value*>	Revision ID register. This parameter is an 8-bit read-only register that identifies the revision number of the device. The value of this register is assigned by the manufacturer.
Subsystem ID	<*register value*>	Subsystem ID register. This parameter is a 16-bit hexadecimal value that sets the subsystem ID register in the PCI configuration space. Any value can be entered for this parameter.
Subsystem Vendor ID	<*register value*>	Subsystem vendor ID register. This parameter is a 16-bit hexadecimal value that sets the subsystem vendor ID register in the PCI configuration space. The value for this parameter must be a valid PCI SIG-assigned vendor ID number.
Maximum Latency	<*register value*>	Maximum latency register. This parameter is an 8-bit hexadecimal value that sets the maximum latency register in the configuration space. This parameter must be set according to the guidelines in the PCI specifications. Only meaningful when the **Enable Master/Target Mode** option is turned **On**.
Minimum Grant	<*register value*>	Minimum grant register. This parameter is an 8-bit hexadecimal value that sets the minimum grant register in the PCI configuration space. This parameter must be set according to the guidelines in the PCI specifications. Only meaningful when the **Enable Master/Target Mode** option is turned **On**.

PCI Timing Constraint Files

The PCI Lite core supplies a Tcl timing constraint file for your target device family.

When run, the constraint file automatically sets the PCI Lite core assignments for your design such as PCI Lite core hierarchy, device family, density and package type used in your Quartus II project.

To run a PCI constraint file, perform the following steps:

1. Copy **pci_constraints.tcl** from **<quartus_root>/ip/sopc_builder_ip/altera_avalon_pci_lite**.

2. Update the pin list in the Tcl constraint file. Edit the `get_user_pin_name` procedure in the Tcl constraint file to match the default pin names. To edit the PCI constraint file, follow these steps:

   a. Locate the `get_user_pin_name` procedure. This procedure maps the default PCI pin names to user PCI pin names. The following lines are the first few lines of the procedure:

```
proc get_user_pin_name { internal_pin_name } {

    #---------------- Do NOT change ------------------------------- ---- Change -----
    array set map_user_pin_name_to_internal_pin_name {ad                          ad       }
```

   b. Edit the pin names under the `Change` header in the file to match the PCI pin names used in your Quartus II project. In the following example, the name `ad` is changed to `pci_ad`:

```
    #---------------- Do NOT change -------------------------------     ---- Change -----
    array set map_user_pin_name_to_internal_pin_name { ad                pci_ad         }
```

The Tcl constraint file uses the default PCI pin names to make assignments. When overwriting existing assignments, the Tcl constraint file checks the new assignment pin names against the default PCI pin names. You must update the assignment pin names if there is a mismatch between the assignment pin names and the default PCI pin names.

3. Source the constraint file by typing the following in the Quartus II Tcl Console window:

   `source pci_constraints.tcl ↵`

4. Add the PCI constraints to your project by typing the following command in the Quartus II Tcl Console window:

   `add_pci_constraints ↵`

   See "Additional Tcl Option" on page 13–13 for the option supported by the **add_pci_constraints** command.

   When you add the timing constraints file as described in Step 4 above, the Quartus II software generates a Synopsys Design Constraints (**.sdc**) file with the file name format, <*variation name*>**.sdc**. The Quartus II TimeQuest timing analyzer uses the constraints specified in this file.

For more information about **.sdc** files or TimeQuest timing analyzer, refer to Quartus II Help.

Additional Tcl Option

If you do not want to compile your project and prefer to skip analysis and synthesis, you can use the `-no_compile` option:

```
add_pci_contraints [-no_compile]
```

By default, the `add_pci_constraints` command performs analysis and synthesis in the Quartus II software to determine the hierarchy of your PCI Lite core design. You should only use this option if you have already performed analysis and synthesis or fully compiled your project prior to using this script.

Device Support

The PCI Lite core supports the Arria® GX, Arria II, Cyclone® III, Hardcopy® II, Stratix® III, and Stratix IV device families.

Simulation Considerations

The PCI Lite core includes a testbench that facilitates the design and verification of systems that implement the Altera PCI-Avalon bridge. The testbench only works for master systems and is provided in Verilog HDL only.

To use the PCI testbench, you must have a basic understanding of PCI bus architecture and operations.This section describes the features and applications of the PCI testbench to help you successfully design and verify your design.

Features

The PCI testbench includes the following features:

- Easy to use simulation environment for any standard Verilog HDL simulator
- Open source Verilog HDL files
- Flexible PCI bus functional model to verify your application that uses any PCI Lite core
- Simulates all basic PCI transactions including memory read/write operations, I/O read/write transactions, and configuration read/write transactions
- Simulates all abnormal PCI transaction terminations including target retry, target disconnect, target abort, and master abort
- Simulates PCI bus parking

Master Transactor (mstr_tranx)

The master transactor simulates the master behavior on the PCI bus. It serves as an initiator of PCI transactions for PCI testbench. The master transactor has three main sections:

- TASKS (Verilog HDL)
- INITIALIZATION
- USER COMMANDS

TASKS Sections

The TASKS (Verilog HDL) sections define the events that are executed for the user commands supported by the master transactor. The events written in the TASKS sections follow the phases of a standard PCI transaction as defined by the *PCI Local Bus Specification, Revision 3.0*, including:

- Address phase
- Turn-around phase (read transactions)
- Data phases
- Turn-around phase

The master transactor terminates the PCI transactions in the following cases:

- The PCI transaction has successfully transferred all the intended data.
- The PCI target terminates the transaction prematurely with a target retry, disconnect, or abort as defined in the *PCI Local Bus Specification, Revision 3.0*.
- A target does not claim the transaction resulting in a master abort.

The bus monitor informs the master transactor of a successful data transaction or a target termination. Refer to the source code, which shows you how the master transactor uses these termination signals from the bus monitor.

The PCI testbench master transactor TASKS sections implement basic PCI transaction functionality. If your application requires different functionality, modify the events to change the behavior of the master transactor. Additionally, you can create new procedures or tasks in the master transactor by using the existing events as an example.

INITIALIZATION Section

This user-defined section defines the parameters and reset length of your PCI bus on power-up. Specifically, the system should reset the bus and write the configuration space of the PCI agents. You can modify the master transactor INITIALIZATION section to match your system requirements by changing the time that the system reset is asserted and by modifying the data written in the configuration space of the PCI agents.

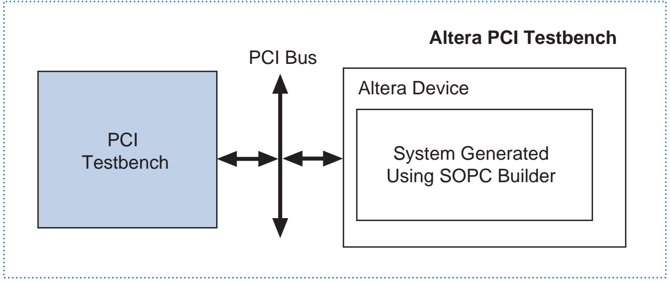
USER COMMANDS Section

The master transactor USER COMMANDS section contains the commands that initiate the PCI transactions you want to run for your tests. The list of events that are executed by these commands is defined in the TASKS sections. Customize the USER COMMANDS section to execute the sequence of commands needed to test your design.

Simulation Flow

This section describes the simulation flow using Altera PCI testbench. Figure 13–4 shows the block diagram of a typical verification environment using the PCI testbench.

Figure 13–4. Typical Verification Environment Using the PCI Testbench



The simulation flow using Altera PCI testbench comprises the following steps.

1. Use SOPC Builder to create your system. SOPC creates the <*variation name*_**system>_sim** folder in your project directory.
2. Source **pci_constraints.tcl**.
3. Copy **<quartus_root>/ip/sopc_builder_ip/altera_avalon_pci_lite/pci_sim/verilog/pci_lite/trgt_tranx_mem_init.dat** to **<project_directory>/<variation name_system>_sim** folder.
4. Edit the top level HDL verilog files in the testbench. Insert the following lines just before `module test_bench`.

```
'include
"<quartus_root>/ip/sopc_builder_ip/altera_avalon_pci_lite/pci_sim/
verilog/pci_lite/pci_tb.v"
'include
"<quartus_root>/ip/sopc_builder_ip/altera_avalon_pci_lite/pci_sim/
verilog/pci_lite/clk_gen.v"
'include
"<quartus_root>/ip/sopc_builder_ip/altera_avalon_pci_lite/pci_sim/
verilog/pci_lite/arbiter.v"
'include
"<quartus_root>/ip/sopc_builder_ip/altera_avalon_pci_lite/pci_sim/
verilog/pci_lite/pull_up.v"
'include
"<quartus_root>/ip/sopc_builder_ip/altera_avalon_pci_lite/pci_sim/
verilog/pci_lite/monitor.v"
'include
"<quartus_root>/ip/sopc_builder_ip/altera_avalon_pci_lite/pci_sim/
verilog/pci_lite/trgt_tranx.v"
'include "mstr_tranx.v"
```

Modify **mstr_tranx.v** in your project directory to add the PCI transactions to your system. If you regenerate your system, SOPC Builder overwrites the testbench files in the **<sopc_system>_sim** directory. If you want the default testbench files, regenerate the system. Then resource **pci_constraints.tcl** or simply copy the **mstr_tranx.v** from **<quartus_ip>/ip/sopc_builder_ip/altera_avalon_pci_lite/pci_sim/verilog/pci_lite** into your project folder and repeat steps 3 and 4.

5. Set the initialization parameters, which are defined in the master transactor model source code. These parameters control the address space reserved by the target transactor model and other PCI agents on the PCI bus.
6. The master transactor defines the tasks (Verilog HDL) needed to initiate PCI transactions in your testbench. Add the commands that correspond to the transactions you want to implement in your tests to the master transactor model source code. At a minimum, you must add configuration commands to set the BAR for the target transactor model and write the configuration space of the PCI Lite core. Additionally, you can add commands to initiate memory or I/O transactions to the PCI Lite core.

7. Compile the files in your simulator, including the testbench modules and the files created by SOPC Builder.
8. Simulate the testbench for the desired time period.

Document Revision History

Table 13–10 shows the revision history for this chapter.

Table 13–10. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	No change from previous release.	—
November 2008 v8.1.0	Changed to 8-1/2 x 11 page size. Edited the command errors in the **Simulation Flow** section.	—
May 2008 v8.0.0	Initial release.	—

Section II. On-Chip Storage Peripherals

This section describes on-chip storage peripherals provided for SOPC Builder systems.

This section includes the following chapters:

- Chapter 14, Avalon-ST Single Clock and Dual Clock FIFO Cores
- Chapter 15, On-Chip FIFO Memory Core
- Chapter 16, Avalon-ST Multi-Channel Shared Memory FIFO Core

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

14. Avalon-ST Single Clock and Dual Clock FIFO Cores

QII55014-9.0.0

Core Overview

The Avalon® Streaming (Avalon-ST) Single Clock and Avalon-ST Dual Clock FIFO cores are FIFO buffers which operate with a single clock and separate clocks for input and output ports, respectively. You can configure the cores to include Avalon Memory-Mapped (Avalon-MM) status interfaces to report the FIFO fill level.

The Avalon-ST Single Clock and Avalon-ST Dual Clock FIFO cores are SOPC Builder-ready and integrates easily into any SOPC Builder-generated systems.

This chapter contains the following sections:

- "Functional Description"
- "Instantiating the Core in SOPC Builder" on page 14–3
- "Device Support" on page 14–3
- "Software Programming Model" on page 14–4

Functional Description

Figure 14–1 and Figure 14–2 show block diagrams of the Avalon-ST Single Clock and Avalon-ST Dual Clock FIFO cores.

Figure 14–1. Avalon-ST Single Clock FIFO Core

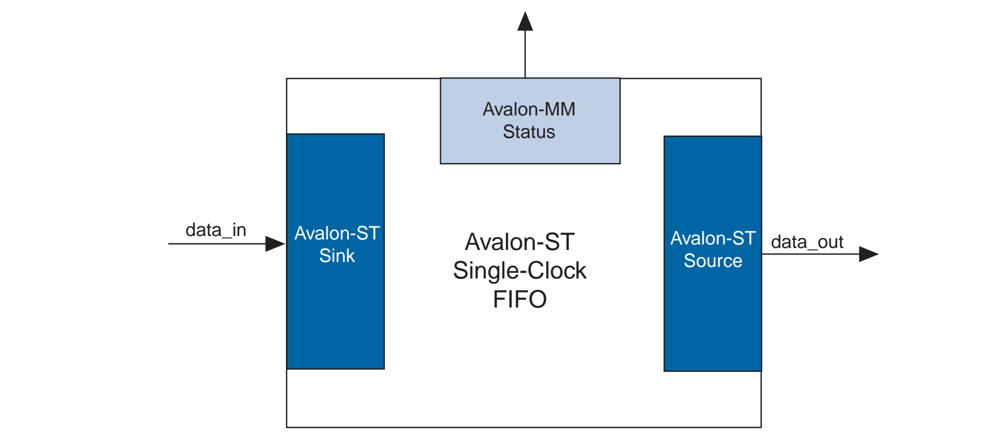

Figure 14–2. Avalon-ST Dual Clock FIFO Core

Interfaces

Table 14–1 shows the properties of the Avalon-ST interfaces.

Table 14–1. Properties of Avalon-ST Interfaces

Feature	Property
Backpressure	Ready latency = 0.
Data Width	Configurable.
Channel	Supported, up to 255 channels.
Error	Configurable.
Packet	Configurable.

For more information about Avalon-ST interfaces, refer to the *Avalon Interface Specifications*.

Operations

The Avalon-ST Single Clock and Avalon-ST Dual Clock FIFO cores are simple FIFO buffers with Avalon-ST input and output interfaces.

You can include an optional Avalon-MM status interface by setting the `Use_Fill_Level` parameter to 1. This interface reports the FIFO fill level. In the Dual Clock FIFO, you can implement separate status interfaces for the input and output clock domains.

Due to the latency of the clock crossing logic, the fill levels reported in the input and output clock domains may be different at any given instance. In both cases, the fill level is pessimistic for the clock domain; the fill level is reported high in the input clock domain and low in the output clock domain.

In the Avalon-ST Dual Clock FIFO, the FIFO has an output pipeline stage to improve f_{MAX}. This output stage is accounted for when calculating the output fill level, but not when calculating the input fill level. Hence, the best measure of the amount of data in the FIFO is given by the fill level in the output clock domain, while the fill level in the input clock domain represents the amount of space available in the FIFO (Available space = **FIFO depth** – input fill level).

Instantiating the Core in SOPC Builder

Use the MegaWizard™ interface for the Avalon-ST Single Clock and Avalon-ST Dual Clock FIFO cores in SOPC Builder to add the cores to a system.

Table 14–2 lists and describes the parameters you can configure.

Table 14–2. Configurable Parameters

Parameter	Legal Values	Description
Bits per symbol	1–32	The symbol width in bits.
Symbols per beat	1–32	The number of symbols transferred in a beat.
Error width	0–32	The width of the `error` signal.
FIFO depth	1–32	The FIFO depth. An output pipeline stage is added to the FIFO to increase performance, which increases the FIFO depth by one.
Use packets	0 or 1	Setting this parameter to 1 enables packet support on the Avalon-ST data interfaces.
Avalon-ST Single Clock FIFO Only		
Use fill level	0 or 1	Setting this parameter to 1 enables the Avalon-MM status interface.
Avalon-ST Dual Clock FIFO Only		
Use sink fill level	0 or 1	Setting this parameter to 1 enables the input clock domain Avalon-MM status interface.
Use source fill level	0 or 1	Setting this parameter to 1 enables the output clock domain Avalon-MM status interface.
Write pointer synchronizer length	2–8	The length of the write pointer synchronizer chain. Setting this parameter to a higher value leads to better metastability while increasing the latency of the core.
Read pointer synchronizer length	2–8	The length of the read pointer synchronizer chain. Setting this parameter to a higher value leads to better metastability.

For more information on metastability in Altera devices, refer to *AN 42: Metastability in Altera Devices*. For more information on metastability analysis and synchronization register chains, refer to the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*.

Device Support

The Avalon-ST Single Clock and Avalon-ST Dual Clock FIFO cores support all Altera device families.

Software Programming Model

The following sections describe the software programming model for the Avalon-ST Single Clock and Avalon-ST Dual Clock FIFO cores.

HAL System Library Support

The Altera-provided driver implements a HAL device driver that integrates into the HAL system library for Nios II systems. HAL users should access the Avalon-ST Single Clock and Avalon-ST Dual Clock FIFO cores via the familiar HAL API and the ANSI C standard library.

Register Map

The Avalon-MM status interface reports the FIFO fill level. Table 14–3 shows the register map for the status interface of the cores.

Table 14–3. Register Map—Status Interface

Offset	Name	Access	Description
Base + 0	`Fill Level`	R	24-bit FIFO fill level. Bits 24 to 31 are unused.

May 2008 v8.0.0	Initial release.	—

15. On-Chip FIFO Memory Core

QII55002-9.0.0

Core Overview

The on-chip FIFO memory core is a configurable component used to buffer data and provide flow control in an SOPC Builder system. The FIFO can operate with a single clock or with separate clocks for the input and output ports.

The input interface to the FIFO may be an Avalon® Memory Mapped (Avalon-MM) write slave or an Avalon Streaming (Avalon-ST) sink. The output interface can be an Avalon-ST source or an Avalon-MM read slave. The data is delivered to the output interface in the same order that it was received at the input interface, regardless of the value of channel, packet, frame, or any other signals.

In single clock mode, the on-chip FIFO memory includes an optional status interface that provides information about the fill-level of the FIFO. In dual clock mode, separate, optional status interfaces can be included for the input and output interfaces. The status interface also includes registers to set and control interrupts.

The on-chip FIFO memory core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. Device drivers are provided in the HAL system library allowing software to access the core using ANSI C.

This chapter contains the following sections:

- "Functional Description"
- "Device Support" on page 15–6
- "Instantiating the Core in SOPC Builder" on page 15–6
- "Software Programming Model" on page 15–8
- "Programming with the On-Chip FIFO Memory" on page 15–8
- "On-Chip FIFO Memory API" on page 15–13

Functional Description

The on-chip FIFO memory has four configurations:

- Avalon-MM write slave to Avalon-MM read slave
- Avalon-ST sink to Avalon-ST source
- Avalon-MM write slave to Avalon-ST source
- Avalon-ST sink to Avalon-MM read slave

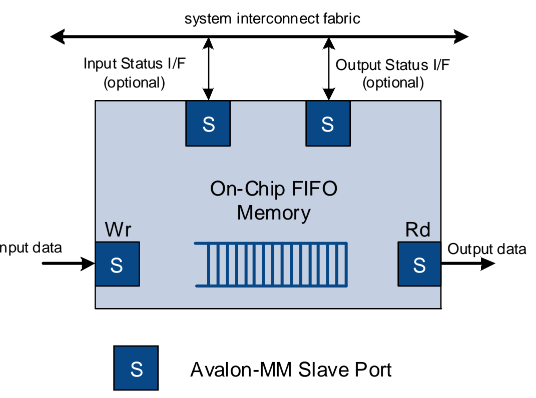
In all configurations, the input and output interfaces can use the optional backpressure signals to prevent underflow and overflow conditions. For the Avalon-MM interface, backpressure is implemented using the `waitrequest` signal. For Avalon-ST interfaces, backpressure is implemented using the `ready` and `valid` signals. For the on-chip FIFO memory, the delay between the sink asserts `ready` and the source drives valid data is one cycle.

Avalon-MM Write Slave to Avalon-MM Read Slave

In this mode, the FIFO's input is a zero-address-width Avalon-MM write slave. An Avalon-MM write master pushes data into the FIFO by writing to the input interface, and a read master (possibly the same master) pops data by reading from its output interface. The FIFO's input and output data must be the same width.

If **Allow backpressure** is turned on, the `waitrequest` signal is asserted whenever the `data_in` master tries to write to a full FIFO. `waitrequest` is only deasserted when there is enough space in the FIFO for a new transaction to complete. `waitrequest` is asserted for read operations when there is no data to be read from the FIFO, and is deasserted when the FIFO has data.

Figure 15–1. FIFO with Avalon-MM Input and Output Interfaces



Avalon-ST Sink to Avalon-ST Source

This FIFO has streaming input and output interfaces as illustrated in Figure 15–2. You can parameterize most aspects of the Avalon-ST interfaces including the **bits per symbol**, **symbols per beat**, and the width of `error` and `channel` signals. The input and output interfaces must be the same width. If **Allow backpressure** is on in the SOPC Builder MegaWizard, both interfaces use the `ready` and `valid` signals to indicate when space is available in the FIFO and when valid data is available.

For more information about the Avalon-ST interface protocol, refer to the *Avalon Interface Specifications*.

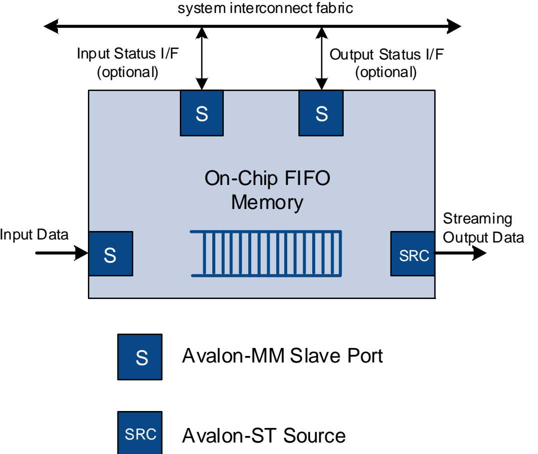
SNK Avalon-ST Sink
SRC Avalon-ST Source
S Avalon-MM Slave Port

Avalon-MM Write Slave to Avalon-ST Source

In this mode, the FIFO's input is an Avalon-MM write slave with a width of 32 bits as shown in Figure 15–3. The Avalon-ST output (source) data width must also be 32 bits. You can configure output interface parameters, including: **bits per symbol**, **symbols per beat**, and the width of the `channel` and `error` signals. The FIFO performs the endian conversion to conform to the output interface protocol.

The signals that comprise this interface are mapped into bits in the Avalon's address space. If **Allow backpressure** is on, the input interface asserts `waitrequest` to indicate that the FIFO does not have enough space for the transaction to complete.

Figure 15–3. FIFO with Avalon-MM Input Interface and Avalon-ST Output Interface



The example memory map in Table 15–1 illustrates the layout of memory for a FIFO with a 32-bit Avalon-MM input interface and an Avalon-ST output interface. The output interface has 8-bit symbols, a 5-bit channel signal, and a 3-bit error signal, with packet support.

Table 15–1. Avalon-MM to Avalon-ST Memory Map

Offset	31 24	23 19	18 16	15 13	12 8	7 4	3 2	1	0
base + 0	Symbol 3	Symbol 2		Symbol 1		Symbol 0			
base + 1	reserved	reserved	`error`	reserved	`channel`	reserved	empty	`EOP`	`SOP`

If **Enable packet data** is off, the Avalon-MM write master writes all data at address offset 0 repeatedly to push data into the FIFO.

If **Enable packet data** is on, the Avalon-MM write master starts by writing the `SOP`, `error` (optional), `channel` (optional), `EOP`, and empty packet status information at address offset 1. Writing to address offset 1 does not push data into the FIFO. The Avalon-MM master then writes packet data to the FIFO repeatedly at address offset 0, pushing 8-bit symbols into the FIFO. Whenever a valid write occurs at address offset 0, the data and its respective packet information is pushed into the FIFO. Subsequent data is written at address offset 0 without the need to clear the `SOP`. Rewriting to address offset 1 is not required each time if the subsequent data to be pushed into the FIFO is not the end-of-packet data, as long as `error` and `channel` do not change.

At the end of each packet, the Avalon-MM master writes to the address at offset 1 to set the `EOP` bit to 1, before writing the last symbol of the packet at offset 0. The write master uses the empty field to indicate the number of unused symbols at the end of the transfer. If the last packet data is not aligned with the **symbols per beat**, the empty field indicates the number of empty symbols in the last packet data. For example, if the Avalon-ST interface has **symbols per beat** of 4, and the last packet only has 3 symbols, the empty field will be 1, indicating that one symbol (the least significant symbol in the memory map) is empty.

Avalon-ST Sink to Avalon-MM Read Slave

In this mode, the FIFO's input is an Avalon-ST sink and the output is an Avalon-MM read slave with a width of 32 bits (Figure 15–4). The Avalon-ST input (sink) data width must also be 32 bits. You can configure input interface parameters, including: **bits per symbol**, **symbols per beat**, and the width of the `channel` and `error` signals. The FIFO performs the endian conversion to conform to the output interface protocol.

An Avalon-MM master reads the data from the FIFO. The signals are mapped into bits in the Avalon's address space. If **Allow backpressure** is on in the SOPC Builder MegaWizard, the input (sink) interface uses the `ready` and `valid` signals to indicate when space is available in the FIFO and when valid data is available. For the output interface, `waitrequest` is asserted for read operations when there is no data to be read from the FIFO. It is deasserted when the FIFO has data to send.

Figure 15–4. FIFO with Avalon-ST Input and Avalon-MM Output

As shown in Table 15–2, the memory map for the Avalon-ST to Avalon-MM slave FIFO is exactly the same as for Avalon-MM to Avalon-ST FIFO.

Table 15–2. Avalon-ST to Avalon-MM Memory Map

Offset	31 24	23 19	18 16	15 13	12 8	7 4	3 2	1	0
base + 0	Symbol 3	Symbol 2		Symbol 1		Symbol 0			
base + 1	reserved	reserved	`error`	reserved	`channel`	reserved	empty	`EOP`	`SOP`

If **Enable packet data** is off, read data repeatedly at address offset 0 to pop the data from the FIFO.

If **Enable packet data** is on, the Avalon-MM read master starts reading from address offset 0. If the read is valid, that is, the FIFO is not empty, both data and packet status information are popped from the FIFO. The packet status information is obtained by reading at address offset 1. Reading from address offset 1 does not pop data from the FIFO. The `error`, `channel`, `SOP`, `EOP` and empty fields are available at address offset 1 to determine the status of the packet data read from address offset 0.

The empty field indicates the number of empty symbols in the data field. For example, if the Avalon-ST interface has symbols-per-beat of 4, and the last packet data only has 1 symbol, then the empty field will be 3 to indicate that 3 symbols (the 3 least significant symbols in the memory map) are empty.

Status Interface

The FIFO provides two optional status interfaces, one for the master writing to the input interface and a second for the read master reading from the output interface. For FIFOs that operate in a single domain, a single status interface is sufficient to monitor the status of the FIFO. For FIFOs using a dual clocking scheme, a second status interface using the output clock is necessary to accurately monitor the status of the FIFO in both clock domains.

Clocking Modes

When single clock mode is used, the FIFO being used is SCFIFO. When dual-clock mode is chosen, the FIFO being used is DCFIFO. In dual-clock mode, input data and write-side status interfaces use the write side clock domain; the output data and read-side status interfaces use the read-side clock domain.

Device Support

The on-chip FIFO memory supports all Altera® device families except the Hardcopy® series.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ interface for the on-chip FIFO memory in SOPC Builder to specify the core configuration. The following sections describe the available options.

FIFO Settings

The following sections outline the settings that pertain to the FIFO as a whole.

Depth

Depth indicates the depth of the FIFO, in Avalon-ST beats or Avalon-MM words. The default depth is 16. When dual clock mode is used, the actual FIFO depth is equal to depth-3. This is due to clock crossing and to avoid FIFO overflow.

Clock Settings

The two options are **Single clock mode** and **Dual clock mode**. In **Single clock mode**, all interface ports use the same clock. In **Dual clock mode**, input data and input side status are on the input clock domain. Output data and output side status are on the output clock domain.

Status Port

The optional status ports are Avalon-MM slaves. To include the optional input side status interface, turn on **Create status interface for input** on the SOPC Builder MegaWizard. For FIFOs whose input and output ports operate in separate clock domains, you can include a second status interface by turning on **Create status interface for output**. Turning on **Enable IRQ for status ports** adds an interrupt signal to the status ports.

FIFO Implementation

This option determines if the FIFO is built from registers or embedded memory blocks. The default is to construct the FIFO from embedded memory blocks.

Interface Parameters

The following sections outline the options for the input and output interfaces.

Input

Available input interfaces are **Avalon-MM** write slave and **Avalon-ST** sink.

Output

Available output interfaces are **Avalon-MM** read slave and **Avalon-ST** source.

Allow Backpressure

When **Allow backpressure** is on, an Avalon-MM interface includes the `waitrequest` signal which is asserted to prevent a master from writing to a full FIFO or reading from an empty FIFO. An Avalon-ST interface includes the `ready` and `valid` signals to prevent underflow and overflow conditions.

Avalon-MM Port Settings

Valid **Data widths** are 8, 16, and 32 bits.

If Avalon-MM is selected for one interface and Avalon-ST for the other, the data width is fixed at 32 bits.

The Avalon-MM interface accesses data 4 bytes at a time. For data widths other than 32 bits, be careful of potential overflow and underflow conditions.

Avalon-ST Port Settings

The following parameters allow you to specify the size and error handling of the Avalon-ST port or ports:

- **Bits per symbol**
- **Symbols per beat**
- **Channel width**
- **Error width**

If the symbol size is not a power of two, it is rounded up to the next power of two. For example, if the **bits per symbol** is 10, the symbol will be mapped to a 16-bit memory location. With 10-bit symbols, the maximum number of **symbols per beat** is two.

Enable packet data provides an option for packet transmission.

Software Programming Model

The following sections describe the software programming model for the on-chip FIFO memory core, including the register map and software declarations to access the hardware. For Nios II processor users, Altera provides HAL system library drivers that enable you to access the on-chip FIFO memory core using its HAL API.

HAL System Library Support

The Altera-provided driver implements a HAL device driver that integrates into the HAL system library for Nios II systems. HAL users should access the on-chip FIFO memory via the familiar HAL API, rather than accessing the registers directly.

Software Files

Altera provides the following software files for the on-chip FIFO memory core:

- **altera_avalon_fifo_regs.h**—This file defines the core's register map, providing symbolic constants to access the low-level hardware.
- **altera_avalon_fifo_util.h**—This file defines functions to access the on-chip FIFO memory core hardware. It provides utilities to initialize the FIFO, read and write status, enable flags and read events.
- **altera_avalon_fifo.h**—This file provides the public interface to the on-chip FIFO memory
- **altera_avalon_fifo_util.c**—This file implements the utilities listed in **altera_avalon_fifo_util.h**.

Programming with the On-Chip FIFO Memory

This section describes the low-level software constructs for manipulating the on-chip FIFO memory core hardware. Table 15–3 lists all of the available functions.

Table 15–3. On-Chip FIFO Memory Functions (Part 1 of 2)

Function Name	Description
`altera_avalon_fifo_init()`	Initializes the FIFO.
`altera_avalon_fifo_read_status()`	Returns the integer value of the specified bit of the status register. To read all of the bits at once, use the `ALTERA_AVALON_FIFO_STATUS_ALL` mask.
`altera_avalon_fifo_read_ienable()`	Returns the value of the specified bit of the interrupt enable register. To read all of the bits at once, use the `ALTERA_AVALON_FIFO_EVENT_ALL` mask.
`altera_avalon_fifo_read_almostfull()`	Returns the value of the `almostfull` register.
`altera_avalon_fifo_read_almostempty()`	Returns the value of the `almostempty` register.
`altera_avalon_fifo_read_event()`	Returns the value of the specified bit of the event register. All of the event bits can be read at once by using the `ALTERA_AVALON_FIFO_STATUS_ALL` mask.
`altera_avalon_fifo_read_level()`	Returns the fill level of the FIFO.
`altera_avalon_fifo_clear_event()`	Clears the specified bits and the event register and performs error checking.

Table 15–3. On-Chip FIFO Memory Functions (Part 2 of 2)

Function Name	Description
altera_avalon_fifo_write_ienable()	Writes the specified bits of the interruptenable register and performs error checking.
altera_avalon_fifo_write_almostfull()	Writes the specified value to the almostfull register and performs error checking.
altera_avalon_fifo_write_almostempty()	Writes the specified value to the almostempty register and performs error checking.
altera_avalon_fifo_write_fifo()	Writes the specified data to the write_address.
altera_avalon_fifo_write_other_info()	Writes the packet status information to the write_address. Only valid when the **Enable packet data** option is turned on.
altera_avalon_fifo_read_fifo()	Reads data from the specified read_address.
altera_avalon_fifo_read__other_info()	Reads the packet status information from the specified read_address. Only valid when the **Enable packet data** option is turned on.

Software Control

Table 15–4 provides the register map for the status register. The layout of status register for the input and output interfaces is identical.

Table 15–4. FIFO Status Register Memory Map

offset	31 24	23 16	15 8	7	6	5	4	3	2	1	0
base	fill_level										
base + 1						i_status					
base + 2						event					
base + 3						interrupt enable					
base + 4	almostfull										
base + 5	almostempty										

Table 15–5 outlines the use of the various fields of the status register.

Table 15–5. FIFO Status Field Descriptions (Part 1 of 2)

Field	Type	Description
fill_level	RO	The instantaneous fill level of the FIFO, provided in units of symbols for a FIFO with an Avalon-ST FIFO and words for an Avalon-MM FIFO.
i_status	RO	A 6-bit register that shows the FIFO's instantaneous status. See Table 15–6 for the meaning of each bit field.
event	RW1C	A 6-bit register with exactly the same fields as i_status. When a bit in the i_status register is set, the same bit in the event register is set. The bit in the event register is only cleared when software writes a 1 to that bit.
interruptenable	RW	A 6-bit interrupt enable register with exactly the same fields as the event and i_status registers. When a bit in the event register transitions from a 0 to a 1, and the corresponding bit in interruptenable is set, the master Is interrupted.

Table 15–5. FIFO Status Field Descriptions (Part 2 of 2)

Field	Type	Description
almostfull	RW	A threshold level used for interrupts and status. Can be written by the Avalon-MM status master at any time. The default threshold value for DCFIFO is Depth-4. The default threshold value for SCFIFO is Depth-1. The valid range of the threshold value is from 1 to the default. 1 is used when attempting to write a value smaller than 1. The default is used when attempting to write a value larger than the default.
almostempty	RW	A threshold level used for interrupts and status. Can be written by the Avalon-MM status master at any time. The default threshold value for DCFIFO is 1. The default threshold value for SCFIFO is 1. The valid range of the threshold value is from 1 to the maximum allowable almostfull threshold. 1 is used when attempting to write a value smaller than 1. The maximum allowable is used when attempting to write a value larger than the maximum allowable.

Table 15–6 describes the instantaneous status bits.

Table 15–6. Status Bit Field Descriptions

Bit(s)	Name	Description
0	FULL	Has a value of 1 if the FIFO is currently full.
1	EMPTY	Has a value of 1 if the FIFO is currently empty.
2	ALMOSTFULL	Has a value of 1 if the fill level of the FIFO is greater than the almostfull value.
3	ALMOSTEMPTY	Has a value of 1 if the fill level of the FIFO is less than the almostempty value.
4	OVERFLOW	Is set to 1 for 1 cycle every time the FIFO overflows. The FIFO overflows when an Avalon write master writes to a full FIFO. OVERFLOW is only valid when **Allow backpressure** is off.
5	UNDERFLOW	Is set to 1 for 1 cycle every time the FIFO underflows. The FIFO underflows when an Avalon read master reads from an empty FIFO. UNDERFLOW is only valid when **Allow backpressure** is off.

Table 15–7 lists the bit fields of the event register. These fields are identical to those in the status register and are set at the same time; however, these fields are only cleared when software writes a one to clear (W1C). The event fields can be used to determine if a particular event has occurred.

Table 15–7. Event Bit Field Descriptions

Bit(s)	Name	Description
1	E_FULL	Has a value of 1 if the FIFO has been full and the bit has not been cleared by software.
0	E_EMPTY	Has a value of 1 if the FIFO has been empty and the bit has not been cleared by software.
3	E_ALMOSTFULL	Has a value of 1 if the fill level of the FIFO has been greater than the almostfull threshold value and the bit has not been cleared by software.
2	E_ALMOSTEMPTY	Has a value of 1 if the fill level of the FIFO has been less than the almostempty value and the bit has not been cleared by software.
4	E_OVERFLOW	Has a value of 1 if the FIFO has overflowed and the bit has not been cleared by software.
5	E_UNDERFLOW	Has a value of 1 if the FIFO has underflowed and the bit has not been cleared by software.

Table 15–8 provides a mask for the six STATUS fields. When a bit in the event register transitions from a zero to a one, and the corresponding bit in the interruptenable register is set, the master is interrupted.

Table 15–8. InterruptEnable Bit Field Descriptions

Bit(s)	Name	Description
1	`IE_FULL`	Enables an interrupt if the FIFO is currently full.
0	`IE_EMPTY`	Enables an interrupt if the FIFO is currently empty.
3	`IE_ALMOSTFULL`	Enables an interrupt if the fill level of the FIFO is greater than the value of the `almostfull` register.
2	`IE_ALMOSTEMPTY`	Enables an interrupt if the fill level of the FIFO is less than the value of the `almostempty` register.
4	`IE_OVERFLOW`	Enables an interrupt if the FIFO overflows. The FIFO overflows when an Avalon write master writes to a full FIFO.
5	`IE_UNDERFLOW`	Enables an interrupt if the FIFO underflows. The FIFO underflows when an Avalon read master reads from an empty FIFO.
6	`ALL`	Enables all 6 status conditions to interrupt.

Macros to access all of the registers are defined in **altera_avalon_fifo_regs.h.** For example, this file includes the following macros to access the `status` register.

```
#define ALTERA_AVALON_FIFO_LEVEL_REG          0
#define ALTERA_AVALON_FIFO_STATUS_REG         1
#define ALTERA_AVALON_FIFO_EVENT_REG          2
#define ALTERA_AVALON_FIFO_IENABLE_REG        3
#define ALTERA_AVALON_FIFO_ALMOSTFULL_REG     4
#define ALTERA_AVALON_FIFO_ALMOSTEMPTY_REG    5
```

For a complete list of predefined macros and utilities to access the on-chip FIFO hardware, see:
<install_dir>\quartus\sopc_builder\components\altera_avalon_fifo\HAL\inc\alatera_avalon_fifo.h and
<install_dir>\quartus\sopc_builder\components\altera_avalon_fifo\HAL\inc\alatera_avalon_fifo_util.h.

Software Example

Example 15–1 shows sample codes for the core.

Example 15–1. Sample Code for the On-Chip FIFO Memory (Part 1 of 2)

```
/***********************************************************************/
//Includes
#include "altera_avalon_fifo_regs.h"
#include "altera_avalon_fifo_util.h"
#include "system.h"
#include "sys/alt_irq.h"
#include <stdio.h>
#include <stdlib.h>

#define ALMOST_EMPTY 2
#define ALMOST_FULL OUTPUT_FIFO_OUT_FIFO_DEPTH-5

volatile int input_fifo_wrclk_irq_event;

void print_status(alt_u32 control_base_address)
{
   printf("--------------------------------------\n");
   printf("LEVEL = %u\n", altera_avalon_fifo_read_level(control_base_address) );
   printf("STATUS = %u\n", altera_avalon_fifo_read_status(control_base_address,
ALTERA_AVALON_FIFO_STATUS_ALL) );
   printf("EVENT = %u\n", altera_avalon_fifo_read_event(control_base_address,
ALTERA_AVALON_FIFO_EVENT_ALL) );
   printf("IENABLE = %u\n", altera_avalon_fifo_read_ienable(control_base_address,
ALTERA_AVALON_FIFO_IENABLE_ALL) );
   printf("ALMOSTEMPTY = %u\n",
altera_avalon_fifo_read_almostempty(control_base_address) );

{
   int return_code = ALTERA_AVALON_FIFO_OK;

   /* Recast the IRQ History pointer to match the alt_irq_register() function
   * prototype. */
   void* input_fifo_wrclk_irq_event_ptr = (void*) &input_fifo_wrclk_irq_event;
   /* Enable all interrupts. */
```

Example 15–1. Sample Code for the On-Chip FIFO Memory (Part 2 of 2)

```
    /* Clear event register, set enable all irq, set almostempty and
    almostfull threshold */
    return_code = altera_avalon_fifo_init(INPUT_FIFO_IN_CSR_BASE,
                                           0, // Disabled interrupts
                                           ALMOST_EMPTY,
                                           ALMOST_FULL);
    /* Register the interrupt handler. */
    alt_irq_register( INPUT_FIFO_IN_CSR_IRQ,
input_fifo_wrclk_irq_event_ptr, handle_input_fifo_wrclk_interrupts );
    return return_code;
}
```

On-Chip FIFO Memory API

This section describes the application programming interface (API) for the on-chip FIFO memory core.

altera_avalon_fifo_init()

Prototype:	`int altera_avalon_fifo_init(alt_u32 address, alt_u32 ienable, alt_u32 emptymark, alt_u32 fullmark)`
Thread-safe:	No.
Available from ISR:	No.
Include:	<**altera_avalon_fifo_regs.h**>, <**altera_avalon_fifo_utils.h**>
Parameters:	`address`—the base address of the FIFO control slave `ienable`—the value to write to the `interruptenable` register `emptymark`—the value for the almost empty threshold level `fullmark`—the value for the almost full threshold level
Returns:	Returns 0 (`ALTERA_AVALON_FIFO_OK`) if successful, `ALTERA_AVALON_FIFO_EVENT_CLEAR_ERROR` for clear errors, `ALTERA_AVALON_FIFO_IENABLE_WRITE_ERROR` for interrupt enable write errors, `ALTERA_AVALON_FIFO_THRESHOLD_WRITE_ERROR` for errors writing the `almostfull` and `almostempty` registers.
Description:	Clears the `event` register, writes the `interruptenable` register, and sets the `almostfull` register and `almostempty` registers.

altera_avalon_fifo_read_status()

Prototype:	`int altera_avalon_fifo_read_status(alt_u32 address, alt_u32 mask)`
Thread-safe:	No.
Available from ISR:	No.
Include:	<**altera_avalon_fifo_regs.h**>, <**altera_avalon_fifo_utils.h**>
Parameters:	`address`—the base address of the FIFO control slave `mask`—masks the read value from the `status` register
Returns:	Returns the masked bits of the addressed register.
Description:	Gets the addressed register bits—the `AND` of the value of the addressed register and the mask.

altera_avalon_fifo_read_ienable()

Prototype: `int altera_avalon_fifo_read_ienable(alt_u32 address, alt_u32 mask)`

Thread-safe: No.

Available from ISR: No.

Include: <**altera_avalon_fifo_regs.h**>, <**altera_avalon_fifo_utils.h**>

Parameters: `address`—the base address of the FIFO control slave

`mask`—masks the read value from the `interruptenable` register

Returns: Returns the logical AND of the `interruptenable` register and the mask.

Description: Gets the logical AND of the `interruptenable` register and the mask.

altera_avalon_fifo_read_almostfull()

Prototype: `int altera_avalon_fifo_read_almostfull(alt_u32 address)`

Thread-safe: No.

Available from ISR: No.

Include: <**altera_avalon_fifo_regs.h**>, <**altera_avalon_fifo_utils.h**>

Parameters: `address`—the base address of the FIFO control slave

Returns: Returns the value of the `almostfull` register.

Description: Gets the value of the `almostfull` register.

altera_avalon_fifo_read_almostempty()

Prototype: `int altera_avalon_fifo_read_almostempty(alt_u32 address)`

Thread-safe: No.

Available from ISR: No.

Include: <**altera_avalon_fifo_regs.h**>, <**altera_avalon_fifo_utils.h**>

Parameters: `address`—the base address of the FIFO control slave

Returns: Returns the value of the `almostempty` register.

Description: Gets the value of the `almostempty` register.

altera_avalon_fifo_read_event()

Prototype: `int altera_avalon_fifo_read_event(alt_u32 address, alt_u32 mask)`

Thread-safe: No.

Available from ISR: No.

Include: <**altera_avalon_fifo_regs.h**>, <**altera_avalon_fifo_utils.h**>

Parameters: `address`—the base address of the FIFO control slave

`mask`—masks the read value from the `event` register

Returns: Returns the logical AND of the `event` register and the mask.

Description: Gets the logical AND of the `event` register and the mask. To read single bits of the event register use the single bit masks, for example: `ALTERA_AVALON_FIFO_FIFO_EVENT_F_MSK`.
To read the entire `event` register use the full mask: `ALTERA_AVALON_FIFO_EVENT_ALL`.

altera_avalon_fifo_read_level()

Prototype:	`int altera_avalon_fifo_read_level(alt_u32 address)`
Thread-safe:	No.
Available from ISR:	No.
Include:	<**altera_avalon_fifo_regs.h**>, <**altera_avalon_fifo_utils.h**>
Parameters:	`address`—the base address of the FIFO control slave
Returns:	Returns the fill level of the FIFO.
Description:	Gets the fill level of the FIFO.

altera_avalon_fifo_clear_event()

Prototype:	`int altera_avalon_fifo_clear_event(alt_u32 address, alt_u32 mask)`
Thread-safe:	No.
Available from ISR:	No.
Include:	<**altera_avalon_fifo_regs.h**>, <**altera_avalon_fifo_utils.h**>
Parameters:	`address`—the base address of the FIFO control slave `mask`—the mask to use for bit-clearing (1 means clear this bit, 0 means do not clear)
Returns:	Returns 0 (`ALTERA_AVALON_FIFO_OK`) if successful, `ALTERA_AVALON_FIFO_EVENT_CLEAR_ERROR` if unsuccessful.
Description:	Clears the specified bits of the `event` register.

altera_avalon_fifo_write_ienable()

Prototype:	`int altera_avalon_fifo_write_ienable(alt_u32 address, alt_u32 mask)`
Thread-safe:	No.
Available from ISR:	No.
Include:	<**altera_avalon_fifo_regs.h**>, <**altera_avalon_fifo_utils.h**>
Parameters:	`address`—the base address of the FIFO control slave `mask`—the value to write to the `interruptenable` register. See **altera_avalon_fifo_regs.h** for individual interrupt bit masks.
Returns:	Returns 0 (`ALTERA_AVALON_FIFO_OK`) if successful, `ALTERA_AVALON_FIFO_IENABLE_WRITE_ERROR` if unsuccessful.
Description:	Writes the specified bits of the `interruptenable` register.

altera_avalon_fifo_write_almostfull()

Prototype: `int altera_avalon_fifo_write_almostfull(alt_u32 address, alt_u32 data)`

Thread-safe: No.

Available from ISR: No.

Include: <**altera_avalon_fifo_regs.h**>, <**altera_avalon_fifo_utils.h**>

Parameters: `address`—the base address of the FIFO control slave

`data`—the value for the almost full threshold level

Returns: Returns 0 (`ALTERA_AVALON_FIFO_OK`) if successful, `ALTERA_AVALON_FIFO_THRESHOLD_WRITE_ERROR` if unsuccessful.

Description: Writes `data` to the `almostfull` register.

altera_avalon_fifo_write_almostempty()

Prototype: `int altera_avalon_fifo_write_almostempty(alt_u32 address, alt_u23 data)`

Thread-safe: No.

Available from ISR: No.

Include: <**altera_avalon_fifo_regs.h**>, <**altera_avalon_fifo_utils.h**>

Parameters: `address`—the base address of the FIFO control slave

`data`—the value for the almost empty threshold level

Returns: Returns 0 (`ALTERA_AVALON_FIFO_OK`) if successful, `ALTERA_AVALON_FIFO_THRESHOLD_WRITE_ERROR` if unsuccessful.

Description: Writes `data` to the `almostempty` register.

altera_avalon_write_fifo()

Prototype: `int altera_avalon_write_fifo(alt_u32 write_address, alt_u32 ctrl_address, alt_u32 data)`

Thread-safe: No.

Available from ISR: No.

Include: <**altera_avalon_fifo_regs.h**>, <**altera_avalon_fifo_utils.h**>

Parameters: `write_address`—the base address of the FIFO write slave

`ctrl_address`—the base address of the FIFO control slave

`data`—the value to write to address offset 0 for Avalon-MM to Avalon-ST transfers, the value to write to the single address available for Avalon-MM to Avalon-MM transfers. See the *Avalon Interface Specifications* for the data ordering.

Returns: Returns 0 (`ALTERA_AVALON_FIFO_OK`) if successful, `ALTERA_AVALON_FIFO_FULL` if unsuccessful.

Description: Writes `data` to the specified address if the FIFO is not full.

altera_avalon_write_other_info()

Prototype:	`int altera_avalon_write_other_info(alt_u32 write_address, alt_u32 ctrl_address, alt_u32 data)`
Thread-safe:	No.
Available from ISR:	No.
Include:	<**altera_avalon_fifo_regs.h**>, <**altera_avalon_fifo_utils.h**>
Parameters:	`write_address`—the base address of the FIFO write slave `ctrl_address`—the base address of the FIFO control slave `data`—the packet status information to write to address offset 1 of the Avalon interface. See the *Avalon Interface Specifications* for the ordering of the packet status information.
Returns:	Returns 0 (`ALTERA_AVALON_FIFO_OK`) if successful, `ALTERA_AVALON_FIFO_FULL` if unsuccessful.
Description:	Writes the packet status information to the `write_address`. Only valid when **Enable packet data** is on.

altera_avalon_fifo_read_fifo()

Prototype:	`int altera_avalon_fifo_read_fifo(alt_u32 read_address, alt_u32 ctrl_address)`
Thread-safe:	No.
Available from ISR:	No.
Include:	<**altera_avalon_fifo_regs.h**>, <**altera_avalon_fifo_utils.h**>
Parameters:	`read_address`—the base address of the FIFO read slave `ctrl_address`—the base address of the FIFO control slave
Returns:	Returns the data from address offset 0, or 0 if the FIFO is empty.
Description:	Gets the data addressed by `read_address`.

altera_avalon_fifo_read_other_info()

Prototype:	`int altera_avalon_fifo_read_other_info(alt_u32 read_address)`
Thread-safe:	No.
Available from ISR:	No.
Include:	<**altera_avalon_fifo_regs.h**>, <**altera_avalon_fifo_utils.h**>
Parameters:	`read_address`—the base address of the FIFO read slave
Returns:	Returns the packet status information from address offset 1 of the Avalon interface. See the *Avalon Interface Specifications* for the ordering of the packet status information.
Description:	Reads the packet status information from the specified `read_address`. Only valid when **Enable packet data** is on.

16. Avalon-ST Multi-Channel Shared Memory FIFO Core

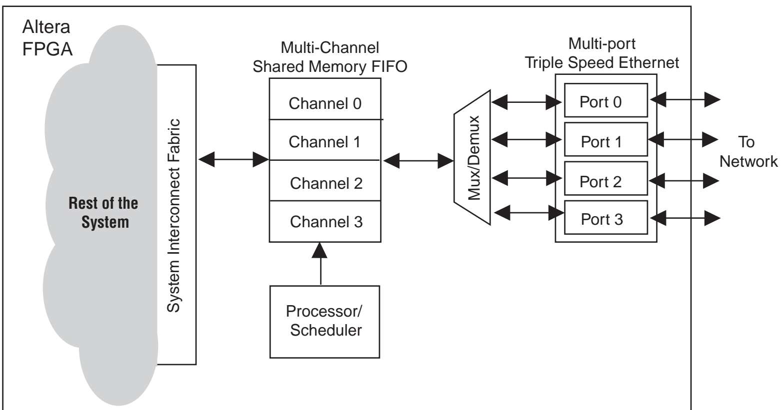
QII55015-9.0.0

Core Overview

The Avalon® Streaming (Avalon-ST) Multi-Channel Shared Memory FIFO core is a FIFO buffer with Avalon-ST data interfaces. The core, which supports up to 16 channels, is a contiguous memory space with dedicated segments of memory allocated for each channel. Data is delivered to the output interface in the same order it was received on the input interface for a given channel.

Figure 16–1 shows an example of how the core is used in a system. In this example, the core is used to buffer data going into and coming from a four-port Triple Speed Ethernet MegaCore function. A processor, if used, can request data for a particular channel to be delivered to the Triple Speed Ethernet MegaCore function.

Figure 16–1. Multi-Channel Shared Memory FIFO in a System—An Example



The Avalon-ST Multi-Channel Shared FIFO core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated systems.

This chapter contains the following sections:

- "Performance and Resource Utilization" on page 16–2
- "Functional Description" on page 16–3
- "Instantiating the Core in SOPC Builder" on page 16–5
- "Device Support" on page 16–5
- "Software Programming Model" on page 16–5

Performance and Resource Utilization

This section lists the resource utilization and performance data for various Altera device families. The estimates are obtained by compiling the core using the Quartus® II software.

Table 16–1 shows the resource utilization and performance data for a Stratix II GX device (EP2SGX130GF1508I4).

Table 16–1. Memory Utilization and Performance Data for Stratix II GX Devices

Channels	ALUTs	Logic Registers	Memory Blocks			f_{MAX} (MHz)
			M512	M4K	M-RAM	
4	559	382	0	0	1	> 125
12	1617	1028	0	0	6	> 125

Table 16–2 shows the resource utilization and performance data for a Stratix III device (EP3SL340F1760C3). The performance of the MegaCore function in Stratix IV devices is similar to Stratix III devices.

Table 16–2. Memory Utilization and Performance Data for Stratix III Devices

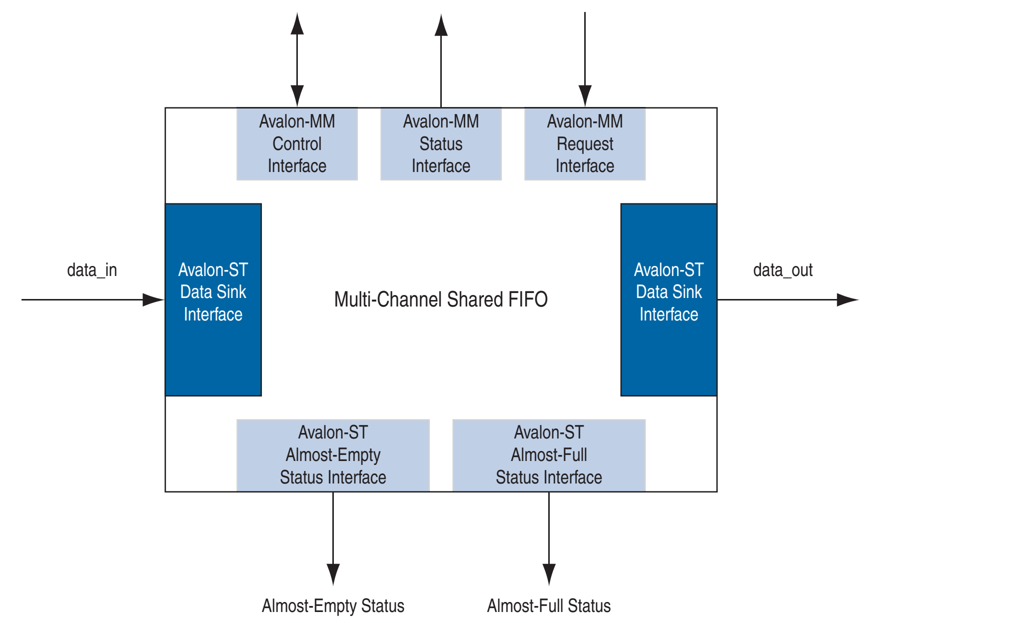
Functional Description

Figure 16–2 shows a block diagram of the Avalon-ST Multi-Channel Shared FIFO core.

Figure 16–2. Avalon-ST Multi-Channel Shared Memory FIFO Core



Interfaces

This section describes the core's interfaces.

Avalon-ST Interfaces

The core includes Avalon-ST interfaces for transferring data and almost-full status.

Table 16–4 shows the properties of the Avalon-ST data interfaces.

Table 16–4. Properties of Avalon-ST Interfaces

Feature	Property	
	Data Interfaces	Status Interfaces
Backpressure	Ready latency = 0.	Not supported.
Data Width	Configurable.	Data width = 2 bits. Symbols per beat = 1.
Channel	Supported, up to 16 channels.	Supported, up to 16 channels.
Error	Configurable.	Not used.
Packet	Supported.	Not supported.

Avalon-MM Interfaces

The core can have up to three Avalon-MM interfaces:

- **Avalon-MM control interface**—Allows master peripherals to set and access almost-full and almost-empty thresholds. The same set of thresholds is used by all channels.
- **Avalon-MM status interface—**Provides the FIFO fill level for a given channel. The FIFO fill level represents the amount of data in the FIFO at any given time. The fill level is available on the `readdata` bus one clock cycle after the read request is received.
- **Avalon-MM request interface—**Allows master peripherals to request data for a given channel. This interface is implemented only when the parameter **Use Request** is set to 1. The `request_address` signal contains the channel number. Only one FIFO entry is returned for each request.

For more information about Avalon interfaces, refer to the *Avalon Interface Specifications*.

Operation

The Avalon-ST Multi-Channel Shared FIFO core allocates dedicated memory segments within the FIFO for each channel, and is implemented such that the memory segments occupy a single memory block. The depth of each memory segment is determined by the parameter **FIFO depth**. If the core is configured to support more than one channel, the Avalon-MM request interface must be implemented to allow master peripherals to request data for a specific channel. Otherwise, only channel 0 is accessible.

When a request is received on the core's Avalon-MM request interface, the requested data is available on the Avalon-ST data source interface after three clock cycles. Only one word of data can be requested at a time. The core delivers the data to the Avalon-ST data source interface after a full packet is received.

The core does not implement any mechanism to accept incoming requests while processing. Once the core starts processing a request, incoming requests are dropped until the current one completes and data is transferred to the requesting component. Packets received on the Avalon-ST sink interface are dropped if the error signal is asserted.

You can configure almost-full thresholds to manage FIFO overflow. The current threshold status for each channel is available from the core's Avalon-ST status interfaces in a round-robin fashion. For example, if the threshold status for channel 0 is available on the interface in clock cycle *n*, the threshold status for channel 1 is available in clock cycle *n+1* and so forth.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ interface for the Avalon-ST Multi-Channel Shared FIFO core in SOPC Builder to add the core to a system.

Table 16–5 lists and describes the parameters you can configure.

Table 16–5. Configurable Parameters

Parameter	Legal Values	Description
Number of channels	1, 2, 4, 8, and 16	The total number of channels supported on the Avalon-ST data interfaces.
Symbols per beat	1–32	The number of symbols transferred in a beat on the Avalon-ST data interfaces
Bits per symbol	1–32	The symbol width in bits on the Avalon-ST data interfaces.
Error width	0–32	The width of the `error` signal on the Avalon-ST data interfaces.
FIFO depth	$2–2^{32}$	The depth of each memory segment allocated for a channel. The value must be a multiple of 2.
Use request	0 or 1	Setting this parameter to 1 implements the Avalon-MM request interface. If the request interface is disabled, only channel 0 can be used.
Address width	1–32	The width of the FIFO address. This parameter is determined by the parameter **FIFO depth**; **FIFO depth** = $2^{\text{Address Width}}$.

Device Support

The Avalon-ST Multi-Channel Shared FIFO core supports all Altera device families.

Software Programming Model

The following sections describe the software programming model for the Avalon-ST Multi-Channel Shared FIFO core.

HAL System Library Support

The Altera-provided driver implements a HAL device driver that integrates into the HAL system library for Nios II systems. HAL users should access the Avalon-ST Multi-Channel Shared FIFO core via the familiar HAL API and the ANSI C standard library.

Register Map

You can update and access the FIFO thresholds via the Avalon-MM control interface. Table 16–6 shows the register map for the control interface.

Table 16–6. Control Interface Register Map

Offset	Name	Access	Description
Base + 0	`Almost_Full_Threshold`	RW	The value of the primary almost-full threshold. The bit `Almost_full_data[0]` on the Avalon-ST almost-full status interface is set to 1 when the FIFO level is greater than or equal to this threshold.
Base + 8	`Almost_Full2_Threshold`	RW	The value of the secondary almost-full threshold. The bit `Almost_full_data[1]` on the Avalon-ST almost-full status interface is set to 1 when the FIFO level is greater than or equal to this threshold.

Referenced Documents

This chapter references *Avalon Interface Specifications*.

Document Revision History

Section III. Transport and Communication

This section describes communication and transport peripherals provided for SOPC Builder systems.

This section includes the following chapters:

- Chapter 17, Avalon Streaming Channel Multiplexer and Demultiplexer Cores
- Chapter 18, Avalon-ST Bytes to Packets and Packets to Bytes Converter Cores
- Chapter 19, Avalon Packets to Transactions Converter Core
- Chapter 20, Avalon-ST Round Robin Scheduler Core

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

17. Avalon Streaming Channel Multiplexer and Demultiplexer Cores

QII55004-9.0.0

Core Overview

The Avalon® streaming (Avalon-ST) channel multiplexer core receives data from a number of input interfaces and multiplexes the data into a single output interface, using the optional `channel` signal to indicate which input the output data is from. The Avalon-ST channel demultiplexer core receives data from a channelized input interface and drives that data to multiple output interfaces, where the output interface is selected by the input `channel` signal.

The multiplexer and demultiplexer can transfer data between interfaces on cores that support the unidirectional flow of data. The multiplexer and demultiplexer allow you to create multiplexed or de-multiplexer datapaths without having to write custom HDL code to perform these functions. The multiplexer includes a round-robin scheduler. Both cores are SOPC Builder-ready and integrate easily into any SOPC Builder-generated system. This chapter contains the following sections:

- "Multiplexer" on page 17–2
- "Demultiplexer" on page 17–4
- "Device Support" on page 17–6
- "Hardware Simulation Considerations" on page 17–6
- "Software Programming Model" on page 17–6

Resource Usage and Performance

Resource utilization for the cores depends upon the number of input and output interfaces, the width of the datapath and whether the streaming data uses the optional packet protocol. For the multiplexer, the parameterization of the scheduler also effects resource utilization. Table 17–1 provides estimated resource utilization for eleven different configurations of the multiplexer.

Table 17–1. Multiplexer Estimated Resource Usage and Performance (Part 1 of 2)

No. of Inputs	Data Width	Scheduling Size (Cycles)	Stratix® II and Stratix II GX (Approximate LEs)		Cyclone® II		Stratix	
			f_{MAX} (MHz)	ALM Count	f_{MAX} (MHz)	Logic Cells	f_{MAX} (MHz)	Logic Cells
2	Y	1	500	31	420	63	422	80
2	Y	2	500	36	417	60	422	58
2	Y	32	451	43	364	68	360	49
8	Y	2	401	150	257	233	228	298

16	2	328	280	218	451	222	443

Multiplexer

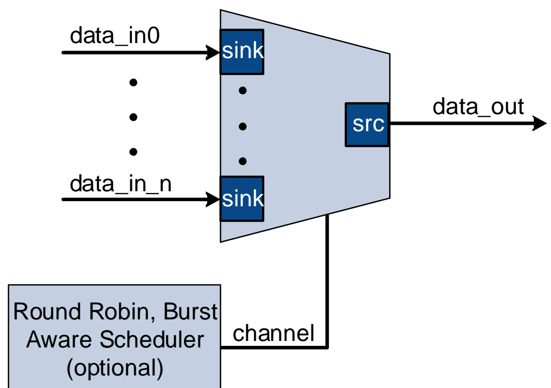
This section describes the hardware structure and functionality of the multiplexer component.

Functional Description

The Avalon-ST multiplexer takes data from a number of input data interfaces, and multiplexes the data onto a single output interface. The multiplexer includes a simple, round-robin scheduler that selects from the next input interface that has data. Each input interface has the same width as the output interface, so that all other input interfaces are backpressured when the multiplexer is carrying data from a different input interface.

The multiplexer includes an optional `channel` signal that enables each input interface to carry channelized data. When the `channel` signal is present on input interfaces, the multiplexer adds $\log_2$(num_input_interfaces) bits to make the output channel signal, such that the output channel signal has all of the bits of the input channel plus the bits required to indicate which input interface each cycle of data is from. These bits are appended to either the most or least significant bits of the output `channel` signal as specified in the SOPC Builder MegaWizard™ Interface.

Figure 17–1. Multiplexer



The internal scheduler considers one input interface at a time, selecting it for transfer. Once an input interface has been selected, data from that input interface is sent until one of the following scenarios occurs:

- The specified number of cycles have elapsed.
- The input interface has no more data to send and `valid` is deasserted on a ready cycle.
- When packets are supported, `endofpacket` is asserted.

Input Interfaces

Each input interface is an Avalon-ST data interface that optionally supports packets. The input interfaces are identical; they have the same symbol and data widths, error widths, and channel widths.

Output Interface

The output interface carries the multiplexed data stream with data from all of the inputs. The symbol, data, and error widths are the same as the input interfaces. The width of the `channel` signal is the same as the input interfaces, with the addition of the bits needed to indicate the input each datum was from.

Instantiating the Multiplexer in SOPC Builder

Use the MegaWizard Interface for the multiplexer core in SOPC Builder to specify the core configuration. The following sections list the available options in the MegaWizard Interface.

Functional Parameters

You can configure the following options for the multiplexer:

- **Number of Input Ports**—The number of input interfaces that the multiplexer supports. Valid values are 2–16.
- **Scheduling Size (Cycles)**—The number of cycles that are sent from a single channel before changing to the next channel.

- **Use Packet Scheduling**—When this option is on, the multiplexer only switches the selected input interface on packet boundaries. Hence, packets on the output interface are not interleaved.
- **Use high bits to indicate source port**—When this option is on, the high bits of the output channel signal are used to indicate the input interface that the data came from. For example, if the input interfaces have 4-bit channel signals, and the multiplexer has 4 input interfaces, the output interface has a 6-bit channel signal. If this parameter is true, bits [5:4] of the output channel signal indicate the input interface the data is from, and bits [3:0] are the channel bits that were presented at the input interface.

Output Interface

You can configure the following options for the output interface:

- **Data Bits Per Symbol**—The number of bits per symbol for the input and output interfaces. Valid values are 1–32 bits.
- **Data Symbols Per Beat**—The number of symbols (words) that are transferred per beat (transfer). Valid values are 1–32.
- **Include Packet Support**—Indicates whether or not packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.
- **Channel Signal Width (bits)**—The number of bits used for the `channel` signal for input interfaces. A value of 0 indicates that input interfaces do not have channels. A value of 4 indicates that up to 16 channels share the same input interface. The input channel can have a width between 0–31 bits. A value of 0 means that the optional `channel` signal is not used.
- **Error Signal Width (bits)**—The width of the `error` signal for input and output interfaces. A value of 0 means the `error` signal is not used.

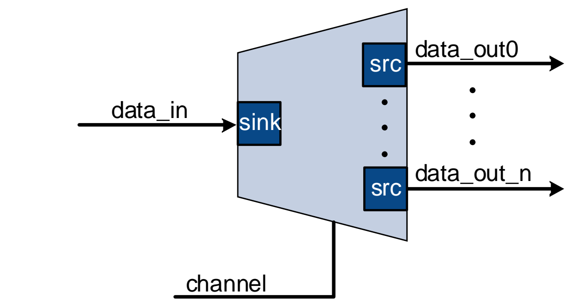
Demultiplexer

This section describes the hardware structure and functionality of the demultiplexer component.

Functional Description

That Avalon-ST demultiplexer takes data from a channelized input data interface and provides that data to multiple output interfaces, where the output interface selected for a particular transfer is specified by the input `channel` signal. The data is delivered to the output interfaces in the same order it was received at the input interface, regardless of the value of `channel`, `packet`, `frame`, or any other signal. Each of the output interfaces has the same width as the input interface, so each output interface is idle when the demultiplexer is driving data to a different output interface. The demultiplexer uses $\log_2$(num_output_interfaces) bits of the `channel` signal to select the output to which to forward the data; the remainder of the channel bits are forwarded to the appropriate output interface unchanged.

Figure 17–2. Demultiplexer



Input Interface

Each input interface is an Avalon-ST data interface that optionally supports packets.

Output Interfaces

Each output interface carries data from a subset of channels from the input interface. Each output interface is identical; all have the same symbol and data widths, error widths, and channel widths. The symbol, data, and error widths are the same as the input interface. The width of the `channel` signal is the same as the input interface, without the bits that were used to select the output interface.

Instantiating the Demultiplexer in SOPC Builder

Use the MegaWizard Interface for the demultiplexer core in SOPC Builder to specify the core configuration. The following sections list the available options in the MegaWizard Interface.

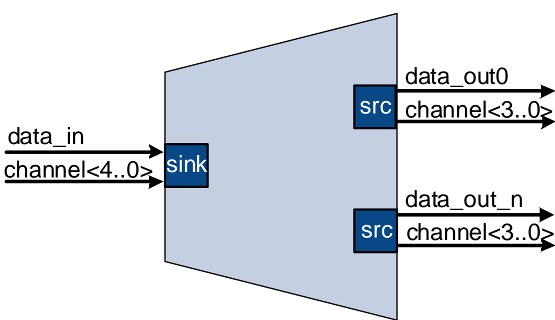
Functional Parameters

You can configure the following options for the demultiplexer as a whole:

- **Number of Output Ports**—The number of output interfaces that the multiplexer supports Valid values are 2–16.
- **High channel bits select output**—When this option is on, the high bits of the input channel signal are used by the de-multiplexing function and the low order bits are passed to the output. When this option is off, the low order bits are used and the high order bits are passed through.

  The following example illustrates the significance of the location of these signals. In Figure 17–3 there is one input interface and two output interfaces. If the low-order bits of the channel signal select the output interfaces, the even channels goes to channel 0 and the odd channels goes to channel 1. If the high-order bits of the channel signal select the output interface, channels 0–7 goes to channel 0 and channels 8–15 goes to channel 1.

Figure 17–3. Select Bits for Demultiplexer



Input Interface

You can configure the following options for the input interface:

- **Data Bits Per Symbol**—The number of bits per symbol for the input and output interfaces. Valid values are 1 to 32 bits.
- **Data Symbols Per Beat**—The number of symbols (words) that are transferred per beat (transfer). Valid values are 1 to 32.
- **Include Packet Support**—Indicates whether or not packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.
- **Channel Signal Width (bits)**—The number of bits used for the `channel` signal for output interfaces. A value of 0 means that output interfaces do not use the optional `channel` signal.
- **Error Signal Width (bits)**—The width of the `error` signal for input and output interfaces. A value of 0 means the `error` signal is not unused.

Device Support

The Avalon Streaming Channel Multiplexer and Demultiplexer cores support all Altera device families.

Hardware Simulation Considerations

The multiplexer and demultiplexer components do not provide a simulation testbench for simulating a stand-alone instance of the component. However, you can use the standard SOPC Builder simulation flow to simulate the component design files inside an SOPC Builder system.

Software Programming Model

The multiplexer and demultiplexer components do not have any user-visible control or status registers. Therefore, software cannot control or configure any aspect of the multiplexer or de-multiplexer at run-time. The components cannot generate interrupts.

18. Avalon-ST Bytes to Packets and Packets to Bytes Converter Cores

QII55012-9.0.0

Core Overview

The Avalon® Streaming (Avalon-ST) Bytes to Packets and Packets to Bytes Converter cores allow an arbitrary stream of packets to be carried over a byte interface, by encoding packet-related control signals such as `startofpacket` and `endofpacket` into byte sequences.The Avalon-ST Packets to Bytes Converter core encodes packet control and payload as a stream of bytes. The Avalon-ST Bytes to Packets Converter core accepts an encoded stream of bytes, and converts it into a stream of packets.

The SPI Slave to Avalon Master Bridge and JTAG to Avalon Master Bridge are examples of how the cores are used. For more information about the bridge, refer to the *SPI Slave/JTAG to Avalon Master Bridge Cores chapter* in volume 5 of the *Quartus II Handbook*.

Both of these cores are SOPC Builder-ready and integrate easily into any SOPC Builder-generated system.

This chapter contains the following sections:

- "Functional Description"
- "Instantiating the Core in SOPC Builder" on page 18–3
- "Device Support" on page 18–4

Functional Description

Figure 18–1 and Figure 18–2 show block diagrams of the Avalon-ST Bytes to Packets and Packets to Bytes Converter cores.

Figure 18–1. Avalon-ST Bytes to Packets Converter Core

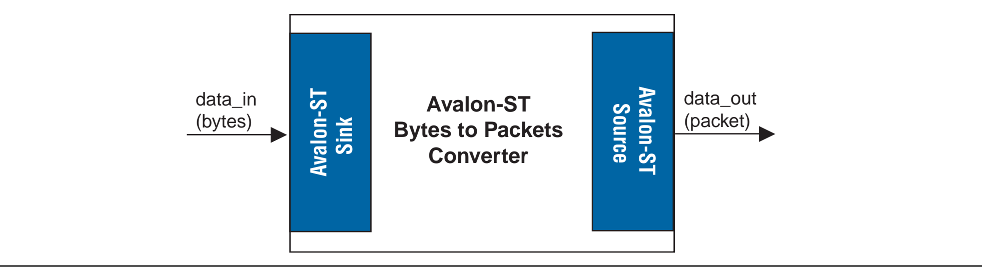

Figure 18–2. Avalon-ST Packets to Bytes Converter Core

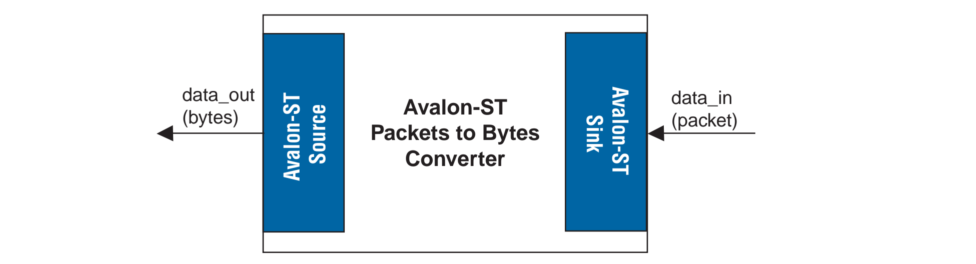


Interfaces

Table 18–1 shows the properties of the Avalon-ST interfaces.

Table 18–1. Properties of Avalon-ST Interfaces

Feature	Property
Backpressure	Ready latency = 0.
Data Width	Data width = 8 bits; Bits per symbol = 8.
Channel	Supported, up to 255 channels.
Error	Not used.
Packet	Supported only on the Avalon-ST Bytes to Packet Converter core's source interface and the Avalon-ST Packet to Bytes Converter core's sink interface.

For more information about Avalon-ST interfaces, refer to the *Avalon Interface Specifications*.

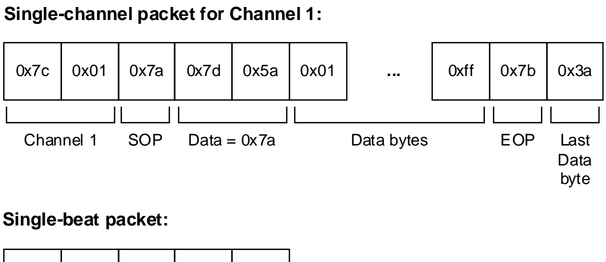
Operation—Avalon-ST Bytes to Packets Converter Core

The Avalon-ST Bytes to Packets Converter core receives streams of bytes and transforms them into packets. When parsing incoming bytestreams, the core decodes special characters in the following manner, with higher priority operations listed first:

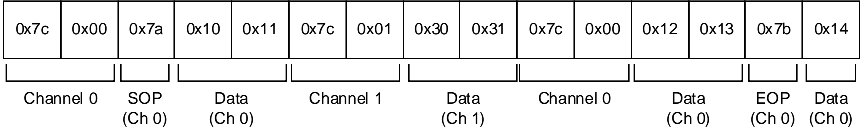
- Escape (`0x7d`)—The core drops the byte. The next byte is XORed with `0x20`.
- Start of packet (`0x7a`)—The core drops the byte and marks the next payload byte as the start of a packet by asserting the `startofpacket` signal on the Avalon-ST source interface.
- End of packet (`0x7b`)—The core drops the byte and marks the following byte as the end of a packet by asserting the `endofpacket` signal on the Avalon-ST source interface. For single beat packets, both the `startofpacket` and `endofpacket` signals are asserted in the same clock cycle.
- Channel number indicator (`0x7c`)—The core drops the byte and takes the next non-special character as the channel number.

Figure 18–3 shows examples of bytestreams.

Figure 18–3. Examples of Bytestreams



Interleaved channels in a packet:



Operation—Avalon-ST Packets to Bytes Converter Core

The Avalon-ST Packets to Bytes Converter core receives packetized data and transforms the packets to bytestreams. The core constructs outgoing bytestreams by inserting appropriate special characters in the following manner and sequence:

- If the `startofpacket` signal on the core's source interface is asserted, the core inserts the following special characters:
  - Channel number indicator (`0x7c`).
  - Channel number, escaping it if required.
  - Start of packet (`0x7a`).
- If the `endofpacket` signal on the core's source interface is asserted, the core inserts an end of packet (`0x7b`) before the last byte of data.
- If the `channel` signal on the core's source interface changes to a new value within a packet, the core inserts a channel number indicator (`0x7c`) followed by the new channel number.
- If a data byte is a special character, the core inserts an escape (`0x7d`) followed by the data XORed with `0x20`.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ Interface for the Avalon-ST Bytes to Packets and Packets to Bytes Converter cores in SOPC Builder to add the core to a system. There are no user-configurable parameters for this core.

Device Support

The Avalon-ST Bytes to Packets and Packets to Bytes Converter cores support all Altera device families.

19. Avalon Packets to Transactions Converter Core

QII55013-9.0.0

Core Overview

The Avalon® Packets to Transactions Converter core receives streaming data from upstream components and initiates Avalon Memory-Mapped (Avalon-MM) transactions. The core then returns Avalon-MM transaction responses to the requesting components.

The SPI Slave to Avalon Master Bridge and JTAG to Avalon Master Bridge are examples of how this core is used. For more information on the bridge, refer to the *SPI Slave/JTAG to Avalon Master Bridge Cores* chapter in volume 5 of the *Quartus II Handbook*.

The Avalon Packets to Transactions Converter core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated systems.

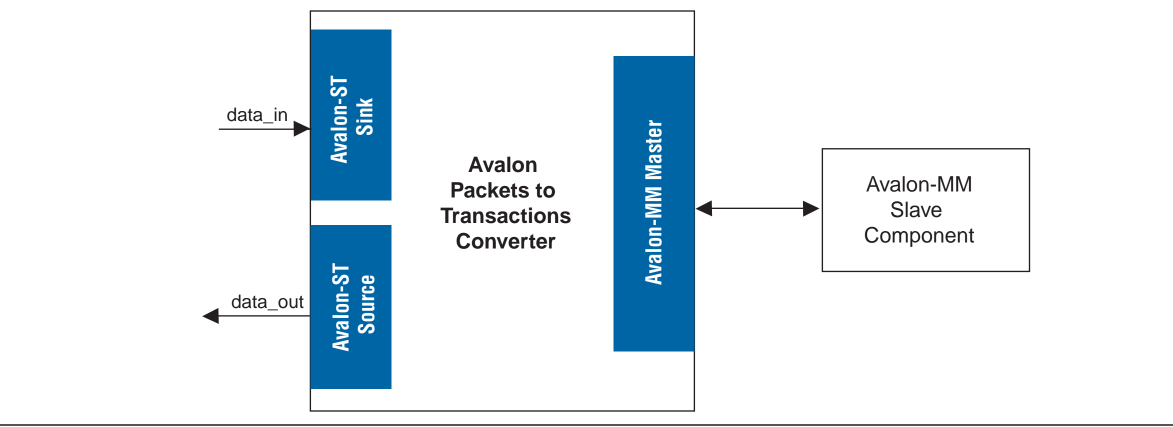
This chapter contains the following sections:

- "Functional Description"
- "Instantiating the Core in SOPC Builder" on page 19–4
- "Device Support" on page 19–4

Functional Description

Figure 19–1 shows a block diagram of the Avalon Packets to Transactions Converter core.

Figure 19–1. Avalon Packets to Transactions Converter Core



Interfaces

Table 19–1 shows the properties of the Avalon-ST interfaces.

Table 19–1. Properties of Avalon-ST Interfaces

Feature	Property
Backpressure	Ready latency = 0.
Data Width	Data width = 8 bits; Bits per symbol = 8.
Channel	Not supported.
Error	Not used.
Packet	Supported.

The Avalon-MM master interface supports read and write transactions. The data width is set to 32 bits and burst transactions are not supported.

For more information about Avalon-ST interfaces, refer to *Avalon Interface Specifications*.

Operation

The Avalon Packets to Transactions Converter core receives streams of packets on its Avalon-ST sink interface and initiates Avalon-MM transactions. Upon receiving transaction responses from Avalon-MM slaves, the core transforms the responses to packets and returns them to the requesting components via its Avalon-ST source interface. The core does not report Avalon-ST errors.

Packet Formats

The core expects incoming data streams to be in the format shown in Table 19–2. A response packet is returned for every write transaction. The core also returns a response packet if a no transaction (0x7f) is received. An invalid transaction code is regarded as a no transaction. For read transactions, the core simply returns the data read.

Table 19–2. Packet Formats

Byte	Field	Description
Transaction Packet Format		
0	`Transaction code`	Type of transaction. See Table 19–1.
1	Reserved	Reserved for future use.
[3:2]	`Size`	Transaction size in bytes. For write transactions, the size indicates the size of the `data` field. For read transactions, the size indicates the total number of bytes to read.
[7:4]	`Address`	32-bit address for the transaction.
[n:8]	`Data`	Transaction data; data to be written for write transactions.
Response Packet Format		
0	`Transaction code`	The transaction code with the most significant bit inversed.
1	Reserved	Reserved for future use.
[4:2]	`Size`	Total number of bytes read/written successfully.

Supported Transactions

Table 19–3 lists the Avalon-MM transactions supported by the core.

Table 19–3. Transaction Supported

Transaction Code	Avalon-MM Transaction	Description
`0x00`	Write, non-incrementing address.	Writes data to the given address until the total number of bytes written to the same word address equals to the value specified in the `size` field.
`0x04`	Write, incrementing address.	Writes transaction data starting at the given address.
`0x10`	Read, non-incrementing address.	Reads 32 bits of data from the given address until the total number of bytes read from the same address equals to the value specified in the `size` field.
`0x14`	Read, incrementing address.	Reads the number of bytes specified in the `size` field starting from the given address.
`0x7f`	No transaction.	No transaction is initiated. You can use this transaction type for testing purposes. Although no transaction is initiated on the Avalon-MM interface, the core still returns a response packet for this transaction code.

The core can handle only a single transaction at a time. The `ready` signal on the core's Avalon-ST sink interface is asserted only when the current transaction is completely processed.

No internal buffer is implemented on the data paths. Data received on the Avalon-ST interface is forwarded directly to the Avalon-MM interface and vice-versa. Asserting the `waitrequest` signal on the Avalon-MM interface backpressures the Avalon-ST sink interface. In the opposite direction, if the Avalon-ST source interface is backpressured, the `read` signal on the Avalon-MM interface is not asserted until the backpressure is alleviated. Backpressuring the Avalon-ST source in the middle of a read could result in data loss. In such cases, the core returns the data that is successfully received.

A transaction is considered complete when the core receives an EOP. For write transactions, the actual data size is expected to be the same as the value of the `size` field. Whether or not both values agree, the core always uses the EOP to determine the end of data.

Malformed Packets

The following are examples of malformed packets:

- Consecutive start of packet (SOP)—An SOP marks the beginning of a transaction. If an SOP is received in the middle of a transaction, the core drops the current transaction without returning a response packet for the transaction, and initiates a new transaction. This effectively handles packets without an end of packet(EOP).
- Unsupported transaction codes—The core treats unsupported transactions as a no transaction.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ Interface for the Avalon Packets to Transactions Converter core in SOPC Builder to add the core to a system. There are no user-configurable settings for this core.

Device Support

The Avalon Packets to Transactions Converter core supports all Altera device families.

20. Avalon-ST Round Robin Scheduler Core

QII55016-9.0.0

Core Overview

Avalon® Streaming (Avalon-ST) components in SOPC Builder provide a channel interface to stream data from multiple channels into a single component. In a multi-channel Avalon-ST component that stores data, the component can store data either in the sequence that it comes in (FIFO) or in segments according to the channel. When data is stored in segments according to channels, a scheduler is needed to schedule the read operations from that particular component. The most basic of the schedulers is the Avalon-ST Round Robin Scheduler core.

The Avalon-ST Round Robin Scheduler core is SOPC Builder-ready and can integrate easily into any SOPC Builder-generated systems.

This chapter contains the following sections:

- "Performance and Resource Utilization"
- "Functional Description" on page 20–2
- "Instantiating the Core in SOPC Builder" on page 20–4
- "Device Support" on page 20–4

Performance and Resource Utilization

This section lists the resource utilization and performance data for various Altera® device families. The estimates are obtained by compiling the core using the Quartus® II software.

Table 20–1 shows the resource utilization and performance data for a Stratix® II GX device (EP2SGX130GF1508I4).

Table 20–1. Resource Utilization and Performance Data for Stratix II GX Devices

Number of Channels	ALUTs	Logic Registers	Memory M512/M4K/ M-RAM	f_{MAX} (MHz)
4	7	7	0/0/0	> 125
12	25	17	0/0/0	> 125
24	62	30	0/0/0	> 125

Table 20–2 shows the resource utilization and performance data for a Stratix III device (EP3SL340F1760C3). The performance of the MegaCore® function in Stratix IV devices is similar to Stratix III devices.

Table 20–2. Resource Utilization and Performance Data for Stratix III Devices

Number of Channels	ALUTs	Logic Registers	Memory M9K/M144K/ MLAB	f_{MAX} (MHz)
4	7	7	0/0/0	> 125
12	25	17	0/0/0	> 125
24	67	30	0/0/0	> 125

Table 20–3 shows the resource utilization and performance data for a Cyclone® III device (EP3C120F780I7).

Table 20–3. Resource Utilization and Performance Data for Cyclone III Devices

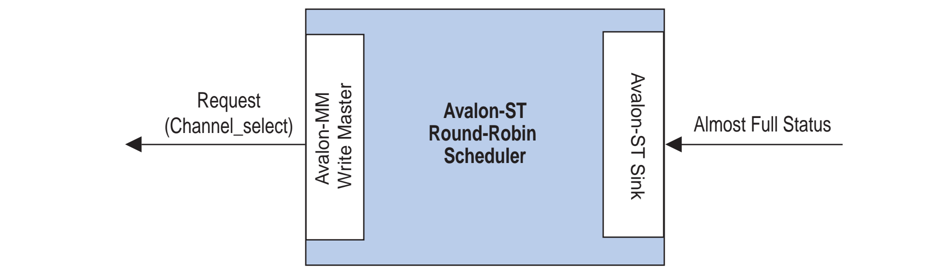
Number of Channels	Total Logic Elements	Total Registers	Memory M9K	f_{MAX} (MHz)
4	12	7	0	> 125
12	32	17	0	> 125
24	71	30	0	> 125

Functional Description

The Avalon-ST Round Robin Scheduler core controls the read operations from a multi-channel Avalon-ST component that buffers data by channels. It reads the almost-full threshold values from the multiple channels in the multi-channel component and issues the read request to the Avalon-ST source according to a round-robin scheduling algorithm.

Figure 20–1 shows the block diagram of the Avalon-ST Round Robin Scheduler.

Figure 20–1. Avalon-ST Round Robin Scheduler Block Diagram



Interfaces

The following interfaces are available in the Avalon-ST Round Robin Scheduler core:

- Almost-Full Status Interface
- Request Interface

Almost-Full Status Interface

The Almost-Full Status interface is an Avalon-ST sink interface. Table 20–4 describes the almost-full interface.

Table 20–4. Avalon-ST Interface Feature Support

Feature	Property
Backpressure	Not supported
Data Width	Data width = 1; Bits per symbol = 1
Channel	Maximum channel = 32; Channel width = 5
Error	Not supported
Packet	Not supported

The interface collects the almost-full status from the sink components for all the channels in the sequence provided.

Request Interface

The Request Interface is an Avalon Memory-Mapped (MM) Write Master interface. This interface requests data from a specific channel. The Avalon-ST Round Robin Scheduler core cycles through all of the channels it supports and schedules data to be read.

Operations

If a particular channel is almost full, the Avalon-ST Round Robin Scheduler will not schedule data to be read from that channel in the source component.

The Avalon-ST Round Robin Scheduler only requests 1 beat of data from a channel at each transaction. To request 1 beat of data from channel *n*, the scheduler writes the value `1` to address ($4 \times n$). For example, if the scheduler is requesting data from channel 3, the scheduler writes `1` to address `0xC`.

At every clock cycle, the Avalon-ST Round Robin Scheduler requests data from the next channel. Therefore, if the Avalon-ST Round Robin Scheduler starts requesting from channel 1, at the next clock cycle, it requests from channel 2. The Avalon-ST Round Robin Scheduler does not request data from a particular channel if the almost-full status for the channel is asserted. In this case, one clock cycle is used without a request transaction.

The Avalon-ST Round Robin Scheduler cannot determine if the requested component is able to service the request transaction. The component asserts `waitrequest` when it cannot accept new requests.

Table 20–5 shows the list of ports for the Avalon-ST Round Robin Scheduler core:

Table 20–5. Ports for the Avalon-ST Round Robin Scheduler (Part 1 of 2)

Signal	Direction	Description
Clock and Reset		
`clk`	In	Clock reference.
`reset_n`	In	Asynchronous active low reset.
Avalon-MM Request Interface		
`request_address` ($\log_2$ `Max_Channels-1:0`)	Out	The write address used to signal the channel the request is for.
`request_write`	Out	Write enable signal.

Table 20–5. Ports for the Avalon-ST Round Robin Scheduler (Part 2 of 2)

Signal	Direction	Description
request_writedata	Out	The amount of data requested from the particular channel. This value is always fixed at 1.
request_waitrequest	In	Wait request signal, used to pause the scheduler when the slave cannot accept a new request.
Avalon-ST Almost-Full Status Interface		
almost_full_valid	In	Indicates that almost_full_channel and almost_full_data are valid.
almost_full_channel (Channel_Width-1:0)	In	Indicates the channel for the current status indication.
almost_full_data ($\log_2$ Max_Channels-1:0)	In	A 1-bit signal that is asserted high to indicate that the channel indicated by almost_full_channel is almost full.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ Interface for the Avalon-ST Round Robin Scheduler core in SOPC Builder to specify the core's configuration. Table 20–6 describes the parameters that can be configured for the Avalon-ST Round Robin Scheduler component.

Table 20–6. Parameters for Avalon-ST Round Robin Scheduler Component

Parameters	Values	Description
Number of channels	2–32	Specifies the number of channels the Avalon-ST Round Robin Scheduler supports.
Use almost-full status	0–1	Specifies whether the almost-full interface is used. If the interface is not used, the core always requests data from the next channel at the next clock cycle.

Device Support

The Avalon-ST Round Robin Scheduler core supports supports all Altera device families.

Section IV. Peripherals

This section describes multiprocessor coordination peripherals provided by Altera® for SOPC Builder systems. These components provide reliable mechanisms for multiple Nios® II processors to communicate with each other, and coordinate operations.

This section includes the following chapters:

- Chapter 21, Scatter-Gather DMA Controller Core
- Chapter 22, DMA Controller Core
- Chapter 23, Video Sync Generator and Pixel Converter Cores
- Chapter 24, Interval Timer Core
- Chapter 25, System ID Core
- Chapter 26, Mutex Core
- Chapter 27, Mailbox Core

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

21. Scatter-Gather DMA Controller Core

QII55003-9.0.0

Core Overview

The Scatter-Gather Direct Memory Access (SG-DMA) controller core implements high-speed data transfer between two components. You can use the SG-DMA controller core to transfer data from:

- Memory to memory
- Data stream to memory
- Memory to data stream

The SG-DMA controller core transfers and merges non-contiguous memory to a continuous address space, and vice versa. The core reads a series of descriptors that specify the data to be transferred.

For applications requiring more than one DMA channel, multiple instantiations of the core can provide the required throughput. Each SG-DMA controller has its own series of descriptors specifying the data transfers. A single software module controls all of the DMA channels.

The SG-DMA controller core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. For the Nios® II processor, device drivers are provided in the HAL system library, allowing software to access the core using the provided driver.

Example Systems

Figure 21–1 shows a SG-DMA controller core in a block diagram for the DMA subsystem of a printed circuit board. The SG-DMA core in the FPGA reads streaming data from an internal streaming component and writes data to an external memory. A Nios II processor provides overall system control.

Figure 21–1. SG-DMA Controller Core with Streaming Peripheral and External Memory

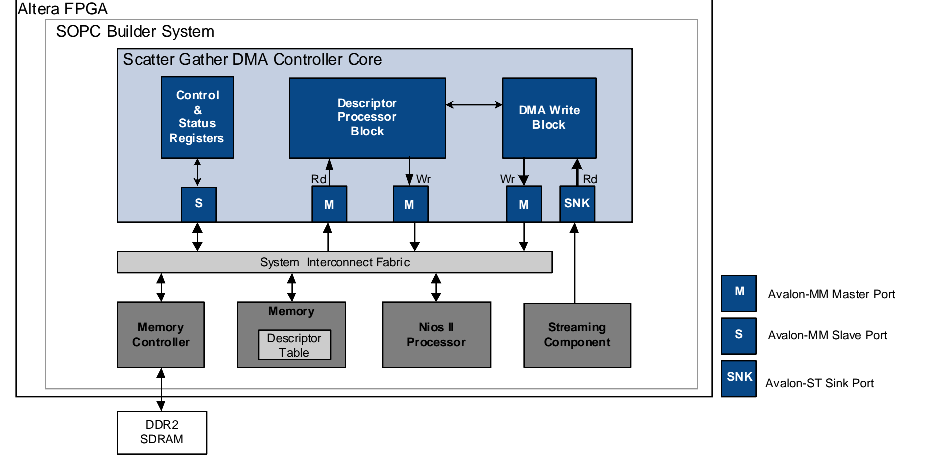

Figure 21–2 shows a different use of the SG-DMA controller core, where the core transfers data between an internal and external memory. The host processor and memory are connected to a system bus, typically either a PCI Express or Serial RapidIO™.

Figure 21–2. SG-DMA Controller Core with Internal and External Memory

Comparison of SG-DMA Controller Core and DMA Controller Core

The SG-DMA controller core provides a significant performance enhancement over the previously available DMA controller core, which could only queue one transfer at a time. Using the DMA Controller core, a CPU had to wait for the transfer to complete before writing a new descriptor to the DMA slave port. Transfers to non-contiguous memory could not be linked; consequently, the CPU overhead was substantial for small transfers, degrading overall system performance. In contrast, the SG-DMA controller core reads a series of descriptors from memory that describe the required transactions and performs all of the transfers without additional intervention from the CPU.

In This Chapter

This chapter contains the following sections:

- "Functional Description" on page 21–3
- "Device Support" on page 21–9
- "Instantiating the Core in SOPC Builder" on page 21–9
- "Simulation Considerations" on page 21–10
- "Software Programming Model" on page 21–10
- "Programming with SG-DMA Controller" on page 21–15

Resource Usage and Performance

Resource utilization for the core is 600–1400 logic elements, depending upon the width of the datapath, the parameterization of the core, the device family, and the type of data transfer. Table 21–1 provides the estimated resource usage for a SG-DMA controller core used for memory to memory transfer. The core is configurable and the resource utilization varies with the configuration specified.

Table 21–1. SG-DMA Estimated Resource Usage

Datapath	Cyclone® II	Stratix® (LEs)	Stratix II (ALUTs)
8-bit datapath	850	650	600
32-bit datapath	1100	850	700
64-bit datapath	1250	1250	800

The core operating frequency varies with the device and the size of the datapath. Table 21–2 provides an example of expected performance for SG-DMA cores instantiated in several different device families.

Table 21–2. SG-DMA Peak Performance

Device	Datapath	f_{MAX}	Throughput
Cyclone II	64 bits	150 MHz	9.6 Gbps
Cyclone III	64 bits	160 MHz	10.2 Gbps
Stratix II/Stratix II GX	64 bits	250 MHz	16.0 Gbps
Stratix III	64 bits	300 MHz	19.2 Gbps

Functional Description

The SG-DMA controller core comprises three major blocks: descriptor processor, DMA read, and DMA write. These blocks are combined to create three different configurations:

- Memory to memory
- Memory to stream
- Stream to memory

The type of devices you are transferring data to and from determines the configuration to implement. Examples of memory-mapped devices are PCI, PCIe and most memory devices. The Triple Speed Ethernet MAC, DSP MegaCore functions and many video IPs are examples of streaming devices. A recompilation is necessary each time you change the configuration of the SG-DMA controller core.

Functional Blocks and Configurations

The following sections describe each functional block and configuration.

Descriptor Processor

The descriptor processor reads descriptors from the descriptor list via its Avalon-MM read master port and pushes commands into the command FIFOs of the DMA read and write blocks. Each command includes the following fields to specify a transfer:

- Source address
- Destination address
- Number of bytes to transfer
- Increment read address after each transfer
- Increment write address after each transfer
- Generate start of packet (SOP) and end of packet (EOP)

After each command is processed by the DMA read or write block, a *status token* containing information about the transfer such as the number of bytes actually written is returned to the descriptor processor, where it is written to the respective fields in the descriptor.

DMA Read Block

The DMA read block is used in memory-to-memory and memory-to-stream configurations. The block performs the following operations:

- Reads commands from the input command FIFO.
- Reads a block of memory via the Avalon-MM read master port for each command.
- Pushes data into the data FIFO.

If burst transfer is enabled, an internal read FIFO with a depth of twice the maximum read burst size is instantiated. The DMA read block initiates burst reads only when the read FIFO has sufficient space to buffer the complete burst.

DMA Write Block

The DMA write block is used in memory-to-memory and stream-to-memory configurations. The block reads commands from its input command FIFO. For each command, the DMA write block reads data from its Avalon-ST sink port and writes it to the Avalon-MM master port.

If burst transfer is enabled, an internal write FIFO with a depth of twice the maximum write burst size is instantiated. Each burst write transfers a fixed amount of data equals to the write burst size, except for the last burst. In the last burst, the remaining data is transferred even if the amount of data is less than the write burst size.

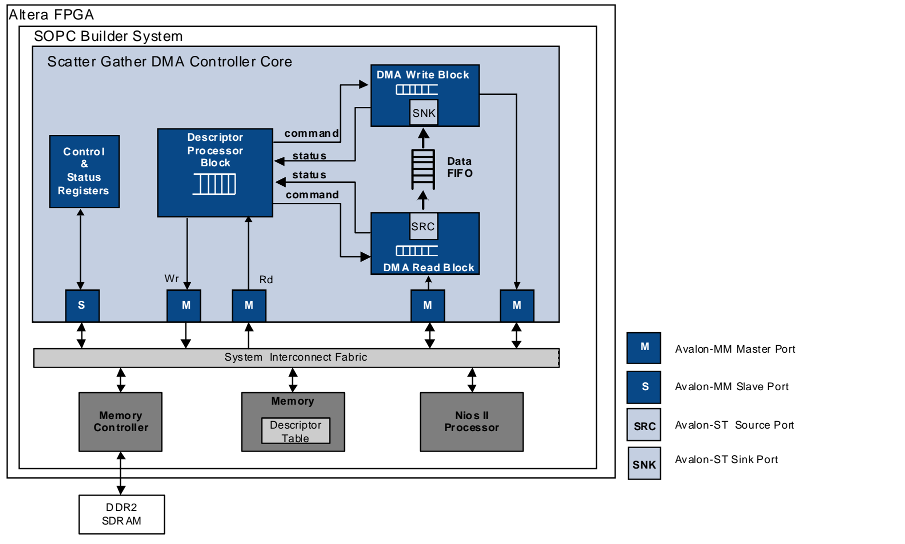
 © March 2009 Altera Corporation

Memory-to-Memory Configuration

Memory-to-memory configurations include all three blocks: descriptor processor, DMA read, and DMA write. An internal FIFO is also included to provide buffering and flow control for data transferred between the DMA read and write blocks.

Figure 21–3 illustrates one possible memory-to-memory configuration with an internal Nios II processor and descriptor list.

Figure 21–3. Example of Memory-to-Memory Configuration

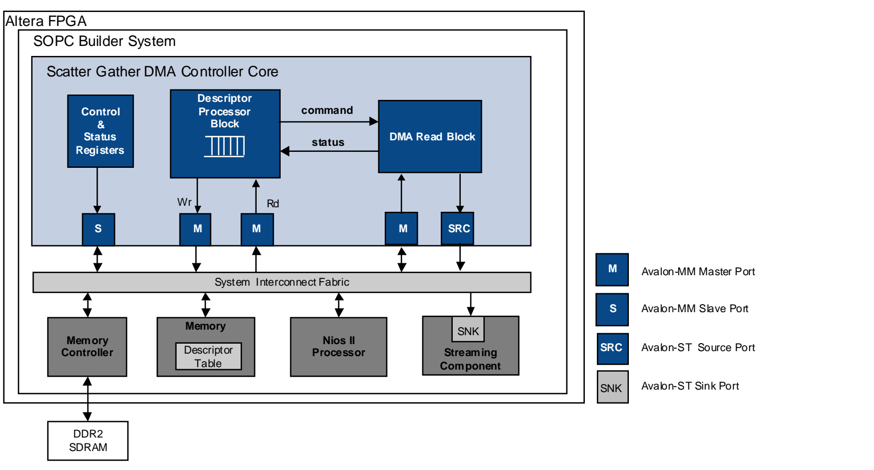


Memory-to-Stream Configuration

Memory-to-stream configurations include the descriptor processor and DMA read blocks. Figure 21–4 illustrates a memory-to-stream configuration.

In this example, the Nios II processor and descriptor table are in the FPGA. Data from an external DDR2 SDRAM is read by the SG-DMA controller and written to an on-chip streaming peripheral.

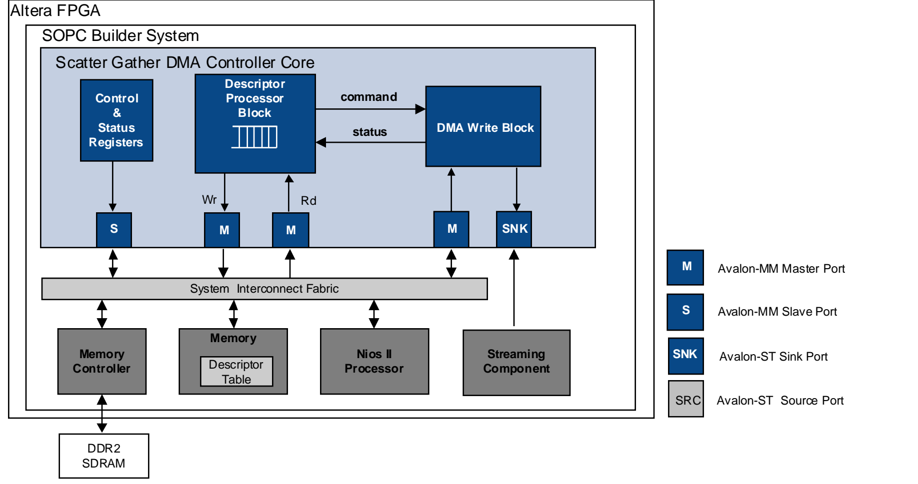
Figure 21–4. Example of Memory-to-Stream Configuration



Stream-to-Memory Configuration

Stream-to-memory configurations include the descriptor processor and DMA write blocks. This configuration is similar to the memory-to-stream configuration as Figure 21–5 illustrates.

Figure 21–5. Example of Memory-to-Stream Configuration



DMA Descriptors

DMA descriptors specify data transfers to be performed. The SG-DMA core uses a dedicated interface to read and write the descriptors. These descriptors, which are stored as a linked list, can be stored on an on-chip or off-chip memory and can be arbitrarily long.

Storing the descriptor list in an external memory frees up resources in the FPGA; however, an external descriptor list increases the overhead involved when the descriptor processor reads and updates the list. The SG-DMA core has an internal FIFO to store descriptors read from memory, which allows the core to perform descriptor read, execute, and write back operations in parallel, hiding the descriptor access and processing overhead.

The descriptors must be initialized and aligned on a 32-bit boundary. The last descriptor in the list must have its `OWNED_BY_HW` bit set to 0 because the core relies on a cleared `OWNED_BY_HW` bit to stop processing.

See "DMA Descriptors" on page 21–13 for the structure of the DMA descriptor.

Descriptor Processing

The following steps describe how the DMA descriptors are processed:

1. Software builds the descriptor linked list. See "Building and Updating Descriptor List" on page 21–8 for more information on how to build and update the descriptor linked list.
2. Software writes the address of the first descriptor to the `next_descriptor_pointer` register and initiates the transfer by setting the `RUN` bit in the `control` register to 1. See "Software Programming Model" on page 21–10 for more information on the registers.

   On the next clock cycle following the assertion of the `RUN` bit, the core sets the `BUSY` bit in the `status` register to 1 to indicate that descriptor processing is executing.
3. The descriptor processor block reads the address of the first descriptor from the `next_descriptor_pointer` register and pushes the retrieved descriptor into the command FIFO, which feeds commands to both the DMA read and write blocks. As soon as the first descriptor is read, the block reads the next descriptor and pushes it into the command FIFO. One descriptor is always read in advance thus maximizing throughput.
4. The core performs the data transfer.
   - In memory-to-memory configurations, the DMA read block receives the source address from its command FIFO and starts reading data to fill the FIFO on its stream port until the specified number of bytes are transferred. The DMA read block pauses when the FIFO is full until the FIFO has enough space to accept more data.

     The DMA write block gets the destination address from its command FIFO and starts writing until the specified number of bytes are transferred. If the data FIFO ever empties, the write block pauses until the FIFO has more data to write.
   - In memory-to-stream configurations, the DMA read block reads from the source address and transfers the data to the core's streaming port until the specified number of bytes are transferred or the end of packet is reached. The block uses the end-of-packet indicator for transfers with an unknown transfer size.
   - In stream-to-memory configurations, the DMA write block reads from the core's streaming port and writes to the destination address. The block continues reading until the specified number of bytes are transferred.
5. The descriptor processor block receives a status from the DMA read or write block and updates the `DESC_CONTROL`, `DESC_STATUS`, and `ACTUAL_BYTES_TRANSFERRED` fields in the descriptor. The `OWNED_BY_HW` bit in the `DESC_CONTROL` field is cleared unless the `PARK` bit is set to 1.

Once the core starts processing the descriptors, software must not update descriptors with `OWNED_BY_HW` bit set to 1. It is only safe for software to update a descriptor when its `OWNED_BY_HW` bit is cleared.

The SG-DMA core continues processing the descriptors until an error condition occurs and the STOP_DMA_ER bit is set to 1, or a descriptor with a cleared OWNED_BY_HW bit is encountered.

Building and Updating Descriptor List

Altera recommends the following method of building and updating the descriptor list:

1. Build the descriptor list and terminate the list with a non-hardware owned descriptor (OWNED_BY_HW = 0). The list can be arbitrarily long.
2. Set the interrupt IE_CHAIN_COMPLETED.
3. Write the address of the first descriptor in the first list to the next_descriptor_pointer register and set the RUN bit to 1 to initiate transfers.
4. While the core is processing the first list, build a second list of descriptors.
5. When the SD-DMA controller core finishes processing the first list, an interrupt is generated. Update the next_descriptor_pointer register with the address of the first descriptor in the second list. Clear the RUN bit and the status register. Set the RUN bit back to 1 to resume transfers.
6. If there are new descriptors to add, always add them to the list which the core is not processing. For example, if the core is processing the first list, add new descriptors to the second list and so forth.

This method ensures that the descriptors are not updated when the core is processing them. Because the method requires a response to the interrupt, a high-latency interrupt may cause a problem in systems where stalling data movement is not possible.

Error Conditions

The SG-DMA core has a configurable error width. Error signals are connected directly to the Avalon-ST source or sink to which the SG-DMA core is connected. Table 21–3 lists the error signals when the core is operating in the memory-to-stream configuration and connected to the transmit FIFO interface of the Altera Triple-Speed Ethernet MegaCore® function.

Table 21–3. Avalon-ST Transmit Error Types

Signal Type	Description
TSE_transmit_error[0]	Transmit Frame Error. Asserted to indicate that the transmitted frame should be viewed as invalid by the Ethernet MAC. The frame is then transferred onto the GMII interface with an error code during the frame transfer.

Table 21–4 lists the error signals when the core is operating in the stream-to-memory configuration and connected to the transmit FIFO interface of the Triple-Speed Ethernet MegaCore function.

Table 21–4. Avalon-ST Receive Error Types

Signal Type	Description
TSE_receive_error[0]	Receive Frame Error. This signal indicates that an error has occurred. It is the logical OR of receive errors 1 through 5.
TSE_receive_error[1]	Invalid Length Error. Asserted when the received frame has an invalid length as defined by the IEEE 802.3 standard.
TSE_receive_error[2]	CRC Error. Asserted when the frame has been received with a CRC-32 error.
TSE_receive_error[3]	Receive Frame Truncated. Asserted when the received frame has been truncated due to receive FIFO overflow.
TSE_receive_error[4]	Received Frame corrupted due to PHY error. (The PHY has asserted an error on the receive GMII interface.)
TSE_receive_error[5]	Collision Error. Asserted when the frame was received with a collision.

Each streaming core has a different set of error codes. Refer to the respective user guides for the codes.

Device Support

The SG-DMA Controller core supports all Altera device families.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ Interface for the SG-DMA Controller core in SOPC Builder to add the core to a system.

The SG-DMA controller core should be given a higher priority (lower IRQ value) than most of the components in a system to ensure high througput.

Table 21–5 lists and describes the parameters you can configure.

Table 21–5. Configurable Parameters (Part 1 of 2)

Parameter	Legal Values	Description
Transfer mode	Memory To Memory Memory To Stream Stream To Memory	Configuration to use. For more information about these configurations, see "Memory-to-Memory Configuration" on page 21–5
Enable bursting on descriptor read master	On/Off	If this option is on, the descriptor processor block uses Avalon-MM bursting when fetching descriptors and writing them back in memory. With 32-bit read and write ports, the descriptor processor block can fetch the 256-bit descriptor by performing 8-word burst as opposed to eight individual single-word transactions.
Allow unaligned transfers	On/Off	If this option is on, the core allows accesses to non-word-aligned addresses. This option doesn't apply for burst transfers. Unaligned transfers require extra logic that may negatively impact system performance.
Enable burst transfers	On/Off	Turning on this option enables burst reads and writes.

Table 21–5. Configurable Parameters (Part 2 of 2)

Parameter	Legal Values	Description
Read burstcount signal width	1–16	The width of the read `burstcount` signal. This value determines the maximum burst read size.
Write burstcount signal width	1–16	The width of the write `burstcount` signal. This value determines the maximum burst write size.
Data width	8, 16, 32, 64	The data width in bits for the Avalon-MM read and write ports.
Source error width	0–7	The width of the `error` signal for the Avalon-ST source port.
Sink error width	0 – 7	The width of the `error` signal for the Avalon-ST sink port.
Data transfer FIFO depth	2, 4, 8, 16, 32, 64	The depth of the internal data FIFO in memory-to-memory configurations with burst transfers disabled.

Simulation Considerations

Signals for hardware simulation are automatically generated as part of the Nios II simulation process available in the Nios II IDE.

Software Programming Model

The following sections describe the software programming model for the SG-DMA controller core.

HAL System Library Support

The Altera-provided driver implements a HAL device driver that integrates into the HAL system library for Nios II systems. HAL users should access the SG-DMA controller core via the familiar HAL API and the ANSI C standard library.

Software Files

The SG-DMA controller core provides the following software files. These files provide low-level access to the hardware and drivers that integrate into the Nios II HAL system library. Application developers should not modify these files.

- **altera_avalon_sgdma_regs.h**—defines the core's register map, providing symbolic constants to access the low-level hardware
- **altera_avalon_sgdma.h**—provides definitions for the Altera Avalon SG-DMA buffer control and status flags.
- **altera_avalon_sgdma.c**—provides function definitions for the code that implements the SG-DMA controller core.
- **altera_avalon_sgdma_descriptor.h**—defines the core's descriptor, providing symbolic constants to access the low-level hardware.

Register Maps

The SG-DMA controller core has three registers accessible from its Avalon-MM interface; `status`, `control` and `next_descriptor_pointer`. Software can configure the core and determines its current status by accessing the registers.

The control/status register has a 32-bit interface without byte-enable logic, and therefore cannot be properly accessed by a master with narrower data width than itself. To ensure correct operation of the core, always access the register with a master that is at least 32 bits wide.

Table 21–6 lists and describes the registers.

Table 21–6. Register Map

32-bit Word Offset	Register Name	Reset Value	Description
base + 0	status	0	This register indicates the core's current status such as what caused the last interrupt and if the core is still processing descriptors. See Table 21–4 on page 21–9 for the status register map.
base + 4	control	0	This register specifies the core's behavior such as what triggers an interrupt and when the core is started and stopped. The host processor can configure the core by setting the register bits accordingly. See Table 21–4 on page 21–9 for the control register map.
base + 8	next_descriptor_pointer	0	This register contains the address of the next descriptor to process. Set this register to the address of the first descriptor as part of the system initialization sequence. Altera recommends that user applications clear the RUN bit in the control register and wait until the BUSY bit of the status register is set to 0 before reading this register.

Table 21–7 provides a bit map for the control register.

Table 21–7. Control Register Bit Map (Part 1 of 2)

Bit	Bit Name	Access	Description
0	IE_ERROR	R/W	When this bit is set to 1, the core generates an interrupt if an Avalon-ST error occurs during descriptor processing. *(1)*
1	IE_EOP_ENCOUNTERED	R/W	When this bit is set to 1, the core generates an interrupt if an EOP is encountered during descriptor processing. *(1)*
2	IE_DESCRIPTOR_COMPLETED	R/W	When this bit is set to 1, the core generates an interrupt after each descriptor is processed. *(1)*
3	IE_CHAIN_COMPLETED	R/W	When this bit is set to 1, the core generates an interrupt after the last descriptor in the list is processed, that is when the core encounters a descriptor with a cleared OWNED_BY_HW bit. *(1)*
4	IE_GLOBAL	R/W	Global signal to enable all interrupts.
5	RUN	R/W	Set this bit to 1 to start the descriptor processor block which subsequently initiates DMA transactions. Prior to setting this bit to 1, ensure that the register next_descriptor_pointer is updated with the address of the first descriptor to process. The core continues to process descriptors in its queue as long as this bit is 1. Clear this bit to stop the core from processing the next descriptor in its queue. If this bit is cleared in the middle of processing a descriptor, the core completes the processing before stopping. The host processor can then modify the remaining descriptors and restart the core.

Table 21–7. Control Register Bit Map (Part 2 of 2)

Bit	Bit Name	Access	Description
6	STOP_DMA_ER	R/W	Set this bit to 1 to stop the core when an Avalon-ST error is encountered during a DMA transaction. This bit applies only to stream-to-memory configurations.
7	IE_MAX_DESC_PROCESSED	R/W	Set this bit to 1 to generate an interrupt after the number of descriptors specified by MAX_DESC_PROCESSED are processed.
8 .. 15	MAX_DESC_PROCESSED	R/W	Specifies the number of descriptors to process before the core generates an interrupt.
16	SW_RESET	R/W	Software can reset the core by writing to this bit twice. Upon the second write, the core is reset. The logic which sequences the software reset process then resets itself automatically. Executing a software reset when a DMA transfer is active may result in permanent bus lockup until the next system reset. Hence, Altera recommends that you use the software reset as your last resort.
17	PARK	R/W	Seting this bit to 0 causes the SG-DMA controller core to clear the OWNED_BY_HW bit in the descriptor after each descriptor is processed. If the PARK bit is set to 1, the core does not clear the OWNED_BY_HW bit, thus allowing the same descriptor to be processed repeatedly without software intervention. You also need to set the last descriptor in the list to point to the first one.
18..30	Reserved		
31	CLEAR_INTERRUPT	R/W	Set this bit to 1 to clear pending interrupts.

Note to Table 21–11:

(1) All interrupts are generated only after the descriptor is updated.

Table 21–8 provides a bit map for the status register. Altera recommends that you read the status register only after the RUN bit in the control register is cleared.

Table 21–8. Status Register Bit Map (Part 1 of 2)

Bit	Bit Name	Access	Description
0	ERROR	R/C *(1) (2)*	A value of 1 indicates that an Avalon-ST error was encountered during a transfer.
1	EOP_ENCOUNTERED	R/C	A value of 1 indicates that the transfer was terminated by an end-of-packet (EOP) signal generated on the Avalon-ST source interface. This condition is only possible in stream-to-memory configurations.
2	DESCRIPTOR_COMPLETED	R/C *(1) (2)*	A value of 1 indicates that a descriptor was processed to completion.
3	CHAIN_COMPLETED	R/C *(1) (2)*	A value of 1 indicates that the core has completed processing the descriptor chain.

Table 21–8. Status Register Bit Map (Part 2 of 2)

Bit	Bit Name	Access	Description
4	BUSY	R *(1) (3)*	A value of 1 indicates that descriptors are being processed. This bit is set to 1 on the next clock cycle after the RUN bit is asserted and does not get cleared until one of the following event occurs: ■ Descriptor processing completes and the RUN bit is cleared. ■ An error condition occurs, the STOP_DMA_ER bit is set to 1 and the processing of the current descriptor completes.
5 .. 31	Reserved		

Notes to Table 21–8:

(1) This bit must be cleared after a read is performed. Write one to clear this bit.

(2) This bit is updated by hardware after each DMA transfer completes. It remains set until software writes one to clear.

(3) This bit is continuously updated by the hardware.

DMA Descriptors

Table 21–9 shows the structure a DMA descriptor entry. See “Data Structure” on page 21–15 for the structure definition.

Table 21–9. DMA Descriptor Structure

Byte Offset	Field Names			
	31 24	23 16	15 8	7 0
base	source			
base + 4	Reserved			
base + 8	destination			
base + 12	Reserved			
base + 16	next_desc_ptr			
base + 20	Reserved			
base + 24	Reserved		bytes_to_transfer	
base + 28	desc_control	desc_status	actual_bytes_transferred	

Table 21–10 describes the each field in a descriptor entry.

Table 21–10. DMA Descriptor Field Description (Part 1 of 2)

Field Name	Access	Description
source	R/W	Specifies the address of data to be read. This address is set to 0 if the input interface is an Avalon-ST interface.
destination	R/W	Specifies the address to which data should be written. This address is set to 0 if the output interface is an Avalon-ST interface.
next_desc_ptr	R/W	Specifies the address of the next descriptor in the linked list.
bytes_to_transfer	R/W	Specifies the number of bytes to transfer. If this field is 0, the SG-DMA controller core continues transferring data until it encounters an EOP.

Table 21–10. DMA Descriptor Field Description (Part 2 of 2)

Field Name	Access	Description
actual_bytes_transferred	R	Specifies the number of bytes that are successfully transferred by the core. This field is updated after the core processes a descriptor.
desc_status	R/W	This field is updated after the core processes a descriptor. See Table 21–12 on page 21–14 for the bit map of this field.
desc_control	R/W	Specifies the behavior of the core. This field is updated after the core processes a descriptor. See Table 21–11 on page 21–14 for descriptions of each bit.

Table 21–1 provides a bit map for the desc_control field.

Table 21–11. DESC_CONTROL Bit Map

Bit (s)	Field Name	Access	Description
0	GENERATE_EOP	W	When this bit is set to 1,the DMA read block asserts the EOP signal on the final word.
1	READ_FIXED_ADDRESS	R/W	This bit applies only to Avalon-MM read master ports. When this bit is set to 1, the DMA read block does not increment the memory address. When this bit is set to 0, the read address increments after each read.
2	WRITE_FIXED_ADDRESS	R/W	This bit applies only to Avalon-MM write master ports. When this bit is set to 1, the DMA write block does not increment the memory address. When this bit is set to 0, the write address increments after each write. In memory-to-stream configurations, the DMA read block generates a start-of-packet (SOP) on the first word when this bit is set to 1.
[6:3]	Reserved	—	—
7	OWNED_BY_HW	R/W	This bit determines whether hardware or software has write access to the current register. When this bit is set to 1, the core can update the descriptor and software should not access the descriptor due to the possibility of race conditions. Otherwise, it is safe for software to update the descriptor.

After completing a DMA transaction, the descriptor processor block updates the desc_status field to indicate how the transaction proceeded. Table 21–1 provides the bit map of this field.

Table 21–12. DESC_STATUS Bit Map

Bit	Bit Name	Access	Description
[7:0]	ERROR_0 .. ERROR_7	R	Each bit represents an error that occurred on the Avalon-ST interface. The context of each error is defined by the component connected to the Avalon-ST interface.

Timeouts

The SG-DMA controller does not implement internal counters to detect stalls. Software can instantiate a timer component if this functionality is required.

Programming with SG-DMA Controller

This section describes the device and descriptor data structures, and the application programming interface (API) for the SG-DMA controller core.

Data Structure

Figure 21–6 shows the data structure for the device.

Figure 21–6. Device Data Structure

```
typedef struct alt_sgdma_dev
{
  alt_llist                 llist;               // Device linked-list entry
  const char                *name;               // Name of SGDMA in SOPC System
  void                      *base;               // Base address of SGDMA
  alt_u32                   *descriptor_base;    // reserved
  alt_u32                   next_index;          // reserved
  alt_u32                   num_descriptors;     // reserved
  alt_sgdma_descriptor      *current_descriptor; // reserved
  alt_sgdma_descriptor      *next_descriptor;    // reserved
  alt_avalon_sgdma_callback callback;            // Callback routine pointer
  void                      *callback_context;   // Callback context pointer
  alt_u32                   chain_control;       // Value OR'd into control reg
} alt_sgdma_dev;
```

Figure 21–7 shows the data structure for the descriptors.

Figure 21–7. Descriptor Data Structure

```
typedef struct {
    alt_u32   *read_addr;
    alt_u32   read_addr_pad;

    alt_u32   *write_addr;
    alt_u32   write_addr_pad;

    alt_u32   *next;
    alt_u32   next_pad;

    alt_u16   bytes_to_transfer;
    alt_u8    read_burst; /* Reserved field. Set to 0. */
    alt_u8    write_burst;/* Reserved field. Set to 0. */

    alt_u8    status;
    alt_u8    control;

} alt_avalon_sgdma_packed alt_sgdma_descriptor;
```

SG-DMA API

Table 21–13 lists all functions provided and briefly describes each.

Table 21–13. Function List

Name	Description
alt_avalon_sgdma_do_async_transfer()	Starts a non-blocking transfer of a descriptor chain.
alt_avalon_sgdma_do_sync_transfer()	Starts a blocking transfer of a descriptor chain. This function blocks both before transfer if the controller is busy and until the requested transfer has completed.
alt_avalon_sgdma_construct_mem_to_mem_desc()	Constructs a single SG-DMA descriptor in the specified memory for an Avalon-MM to Avalon-MM transfer.
alt_avalon_sgdma_construct_stream_to_mem_desc()	Constructs a single SG-DMA descriptor in the specified memory for an Avalon-ST to Avalon-MM transfer. The function automatically terminates the descriptor chain with a NULL descriptor.
alt_avalon_sgdma_construct_mem_to_stream_desc()	Constructs a single SG-DMA descriptor in the specified memory for an Avalon-MM to Avalon-ST transfer.
alt_avalon_sgdma_check_descriptor_status()	Reads the status of a given descriptor.
alt_avalon_sgdma_register_callback()	Associates a user-specific callback routine with the SG-DMA interrupt handler.
alt_avalon_sgdma_start()	Starts the DMA engine. This is not required when alt_avalon_sgdma_do_async_transfer() and alt_avalon_sgdma_do_sync_transfer() are used.
alt_avalon_sgdma_stop()	Stops the DMA engine. This is not required when alt_avalon_sgdma_do_async_transfer() and alt_avalon_sgdma_do_sync_transfer() are used.
alt_avalon_sgdma_open()	Returns a pointer to the SG-DMA controller with the given name.

alt_avalon_sgdma_do_async_transfer()

Prototype: int alt_avalon_do_async_transfer(alt_sgdma_dev *dev, alt_sgdma_descriptor *desc)

Thread-safe: No.

Available from ISR: Yes.

Include: <**altera_avalon_sgdma.h**>, <**altera_avalon_sgdma_descriptor.h**>, <**altera_avalon_sgdma_regs.h**>

Parameters: `*dev`—a pointer to an SG-DMA device structure.

`*desc`—a pointer to a single, constructed descriptor. The descriptor must have its “next” descriptor field initialized either to a non-ready descriptor, or to the next descriptor in the chain.

Returns: Returns 0 success. Other return codes are defined in **errno.h**.

Description: Set up and begin a non-blocking transfer of one or more descriptors or a descriptor chain. If the SG-DMA controller is busy at the time of this call, the routine immediately returns `EBUSY`; the application can then decide how to proceed without being blocked. If a callback routine has been previously registered with this particular SG-DMA controller, the transfer is set up to issue an interrupt on error, EOP, or chain completion. Otherwise, no interrupt is registered and the application developer must check for and handle errors and completion.

alt_avalon_sgdma_do_sync_transfer()

Prototype: alt_u8 alt_avalon_sgdma_do_sync_transfer(alt_sgdma_dev *dev, alt_sgdma_descriptor *desc)

Thread-safe: No.

Available from ISR: Not recommended.

Include: <**altera_avalon_sgdma.h**>, <**altera_avalon_sgdma_descriptor.h**>, <**altera_avalon_sgdma_regs.h**>

Parameters: `*dev`—a pointer to an SG-DMA device structure.

`*desc`—a pointer to a single, constructed descriptor. The descriptor must have its “next” descriptor field initialized either to a non-ready descriptor, or to the next descriptor in the chain.

Returns: Returns the contents of the `status` register.

Description: Sends a fully formed descriptor or list of descriptors to the SG-DMA controller for transfer. This function blocks both before transfer, if the SG-DMA controller is busy, and until the requested transfer has completed. If an error is detected during the transfer, it is abandoned and the controller’s `status` register contents are returned to the caller. Additional error information is available in the status bits of each descriptor that the SG-DMA processed. The user application searches through the descriptor or list of descriptors to gather specific error information.

alt_avalon_sgdma_construct_mem_to_mem_desc()

Prototype:	void alt_avalon_sgdma_construct_mem_to_mem_desc(alt_sgdma_descriptor *desc, alt_sgdma_descriptor *next, alt_u32 *read_addr, alt_u32 *write_addr, alt_u16 length, int read_fixed, int write_fixed)
Thread-safe:	Yes.
Available from ISR:	Yes.
Include:	<**altera_avalon_sgdma.h**>, <**altera_avalon_sgdma_descriptor.h**>, <**altera_avalon_sgdma_regs.h**>
Parameters:	`*desc`—a pointer to the descriptor being constructed. `*next`—a pointer to the "next" descriptor. This does not need to be a complete or functional descriptor, but must be properly allocated. `*read_addr`—the first read address for the SG-DMA transfer. `*write_addr`—the first write address for the SG-DMA transfer. `length`—the number of bytes for the transfer. `read_fixed`—if non-zero, the SG-DMA reads from a fixed address. `write_fixed`—if non-zero, the SG-DMA writes to a fixed address.
Returns:	void
Description:	This function constructs a single SG-DMA descriptor in the memory specified in `alt_avalon_sgdma_descriptor *desc` for an Avalon-MM to Avalon-MM transfer. The function sets the `OWNED_BY_HW` bit in the descriptor's control field, marking the completed descriptor as ready to run. The descriptor is processed when the SG-DMA controller receives the descriptor and the `RUN` bit is 1. The next field of the descriptor being constructed is set to the address in `*next`. The `OWNED_BY_HW` bit of the descriptor at `*next` is explicitly cleared. Once the SG-DMA completes processing of the `*desc`, it does not process the descriptor at `*next` until its `OWNED_BY_HW` bit is set. To create a descriptor chain, you can repeatedly call this function using the previous call's `*next` pointer in the *desc parameter. You must properly allocate memory for the creation of both the descriptor under construction as well as the next descriptor in the chain. Descriptors must be in a memory device mastered by the SG-DMA controller's chain read and chain write Avalon master ports. Care must be taken to ensure that both `*desc` and `*next` point to areas of memory mastered by the controller.

alt_avalon_sgdma_construct_stream_to_mem_desc()

Prototype:	void alt_avalon_sgdma_construct_stream_to_mem_desc(alt_sgdma_descriptor *desc, alt_sgdma_descriptor *next, alt_u32 *write_addr, alt_u16 length_or_eop, int write_fixed)
Thread-safe:	Yes.
Available from ISR:	Yes.
Include:	<**altera_avalon_sgdma.h**>, <**altera_avalon_sgdma_descriptor.h**>, <**altera_avalon_sgdma_regs.h**>
Parameters:	`*desc`—a pointer to the descriptor being constructed. `*next`—a pointer to the “next” descriptor. This does not need to be a complete or functional descriptor, but must be properly allocated. `*write_addr`—the first write address for the SG-DMA transfer. `length_or_eop`—the number of bytes for the transfer. If set to zero (0x0), the transfer continues until an EOP signal is received from the Avalon-ST interface. `write_fixed`—if non-zero, the SG-DMA will write to a fixed address.
Returns:	void
Description:	This function constructs a single SG-DMA descriptor in the memory specified in `alt_avalon_sgdma_descriptor *desc` for an Avalon-ST to Avalon-MM transfer. The source (read) data for the transfer comes from the Avalon-ST interface connected to the SG-DMA controller's streaming read port. The function sets the `OWNED_BY_HW` bit in the descriptor's control field, marking the completed descriptor as ready to run. The descriptor is processed when the SG-DMA controller receives the descriptor and the `RUN` bit is 1. The next field of the descriptor being constructed is set to the address in `*next`. The `OWNED_BY_HW` bit of the descriptor at `*next` is explicitly cleared. Once the SG-DMA completes processing of the `*desc`, it does not process the descriptor at `*next` until its `OWNED_BY_HW` bit is set. To create a descriptor chain, you can repeatedly call this function using the previous call's `*next` pointer in the *desc parameter. You must properly allocate memory for the creation of both the descriptor under construction as well as the next descriptor in the chain. Descriptors must be in a memory device mastered by the SG-DMA controller’s chain read and chain write Avalon master ports. Care must be taken to ensure that both `*desc` and `*next` point to areas of memory mastered by the controller.

alt_avalon_sgdma_construct_mem_to_stream_desc()

Prototype: void alt_avalon_sgdma_construct_mem_to_stream_desc(alt_sgdma_descriptor *desc, alt_sgdma_descriptor *next, alt_u32 *read_addr, alt_u16 length, int read_fixed, int generate_sop, int generate_eop, alt_u8 atlantic_channel)

Thread-safe: Yes.

Available from ISR: Yes.

Include: <**altera_avalon_sgdma.h**>, <**altera_avalon_sgdma_descriptor.h**>, <**altera_avalon_sgdma_regs.h**>

Parameters: `*desc`—a pointer to the descriptor being constructed.

`*next`—a pointer to the “next” descriptor. This does not need to be a complete or functional descriptor, but must be properly allocated.

`*read_addr`—the first read address for the SG-DMA transfer.

`length`—the number of bytes for the transfer.

`read_fixed`—if non-zero, the SG-DMA reads from a fixed address.

`generate_sop`—if non-zero, the SG-DMA generates a SOP on the Avalon-ST interface when commencing the transfer.

`generate_eop`—if non-zero, the SG-DMA generates an EOP on the Avalon-ST interface when completing the transfer.

`atlantic_channel`—an 8-bit Avalon-ST channel number. Channels are currently not supported. Set this parameter to 0.

Returns: void

Description: This function constructs a single SG-DMA descriptor in the memory specified in `alt_avalon_sgdma-descriptor *desc` for an Avalon-MM to Avalon-ST transfer. The destination (write) data for the transfer goes to the Avalon-ST interface connected to the SG-DMA controller's streaming write port. The function sets the `OWNED_BY_HW` bit in the descriptor's control field, marking the completed descriptor as ready to run. The descriptor is processed when the SG-DMA controller receives the descriptor and the `RUN` bit is 1.

The next field of the descriptor being constructed is set to the address in `*next`. The `OWNED_BY_HW` bit of the descriptor at `*next` is explicitly cleared. Once the SG-DMA completes processing of the `*desc`, it does not process the descriptor at `*next` until its `OWNED_BY_HW` bit is set. To create a descriptor chain, you can repeatedly call this function using the previous call's `*next` pointer in the *desc parameter.

You are responsible for properly allocating memory for the creation of both the descriptor under construction as well as the next descriptor in the chain. Descriptors must be in a memory device mastered by the SG-DMA controller’s chain read and chain write Avalon master ports. Care must be taken to ensure that both `*desc` and `*next` point to areas of memory mastered by the controller.

alt_avalon_sgdma_check_descriptor_status()

Prototype: int alt_avalon_sgdma_check_descriptor_status(alt_sgdma_descriptor *desc)

Thread-safe: Yes.

Available from ISR: Yes.

Include: <**altera_avalon_sgdma.h**>, <**altera_avalon_sgdma_descriptor.h**>, <**altera_avalon_sgdma_regs.h**>

Parameters: `*desc`—a pointer to the constructed descriptor to examine.

Returns: Returns 0 if the descriptor is error-free, not owned by hardware, or a previously requested transfer completed normally. Other return codes are defined in **errno.h**.

Description: Checks a descriptor previously owned by hardware for any errors reported in a previous transfer. The routine reports: errors reported by the SG-DMA controller, the buffer in use.

alt_avalon_sgdma_register_callback()

Prototype: void alt_avalon_sgdma_register_callback(alt_sgdma_dev *dev, alt_avalon_sgdma_callback callback, alt_u16 chain_control, void *context)

Thread-safe: Yes.

Available from ISR: Yes.

Include: <**altera_avalon_sgdma.h**>, <**altera_avalon_sgdma_descriptor.h**>, <**altera_avalon_sgdma_regs.h**>

Parameters: `*dev`—a pointer to the SG-DMA device structure.

`callback`—a pointer to the callback routine to execute at interrupt level.

`chain_control`—the SG-DMA control register contents.

`*context`—a pointer used to pass context-specific information to the ISR. `context` can point to any ISR-specific information.

Returns: void

Description: Associates a user-specific routine with the SG-DMA interrupt handler. If a callback is registered, all non-blocking transfers enables interrupts that causes the callback to be executed. The callback runs as part of the interrupt service routine, and care must be taken to follow the guidelines for acceptable interrupt service routine behavior as described in the *Nios II Software Developer's Handbook*.

To disable callbacks after registering one, call this routine with 0x0 as the callback argument.

alt_avalon_sgdma_start()

Prototype: void alt_avalon_sgdma_start(alt_sgdma_dev *dev)

Thread-safe: No.

Available from ISR: Yes.

Include: <**altera_avalon_sgdma.h**>, <**altera_avalon_sgdma_descriptor.h**>, <**altera_avalon_sgdma_regs.h**>

Parameters: `*dev`—a pointer to the SG-DMA device structure.

Returns: void

Description: Starts the DMA engine and processes the descriptor pointed to in the controller's next descriptor pointer and all subsequent descriptors in the chain. It is not necessary to call this function when `do_sync` or `do_async` is used.

alt_avalon_sgdma_stop()

Prototype:	void alt_avalon_sgdma_stop(alt_sgdma_dev *dev)
Thread-safe:	No.
Available from ISR:	Yes.
Include:	<**altera_avalon_sgdma.h**>, <**altera_avalon_sgdma_descriptor.h**>, <**altera_avalon_sgdma_regs.h**>
Parameters:	`*dev`—a pointer to the SG-DMA device structure.
Returns:	void
Description:	Stops the DMA engine following completion of the current buffer descriptor. It is not necessary to call this function when `do_sync` or `do_async` is used.

alt_avalon_sgdma_open()

Prototype:	alt_sgdma_dev* alt_avalon_sgdma_open(const char* name)
Thread-safe:	Yes.
Available from ISR:	No.
Include:	<**altera_avalon_sgdma.h**>, <**altera_avalon_sgdma_descriptor.h**>, <**altera_avalon_sgdma_regs.h**>
Parameters:	`name`—the name of the SG-DMA device to open.
Returns:	A pointer to the SG-DMA device structure associated with the supplied name, or NULL if no corresponding SG-DMA device structure was found.
Description:	Retrieves a pointer to a hardware SG-DMA device structure.

22. DMA Controller Core

NII51006-9.0.0

Core Overview

The direct memory access (DMA) controller core with Avalon® interface performs bulk data transfers, reading data from a source address range and writing the data to a different address range. An Avalon Memor-Mapped (Avalon-MM) master peripheral, such as a CPU, can offload memory transfer tasks to the DMA controller. While the DMA controller performs memory transfers, the master is free to perform other tasks in parallel.

The DMA controller transfers data as efficiently as possible, reading and writing data at the maximum pace allowed by the source or destination. The DMA controller is capable of performing Avalon transfers with flow control, enabling it to automatically transfer data to or from a slow peripheral with flow control (for example, UART), at the maximum pace allowed by the peripheral.

The DMA controller is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. For the Nios® II processor, device drivers are provided in the HAL system library. See “Software Programming Model” on page 22–5 for details of HAL support.

This chapter contains the following sections:

- “Functional Description”
- “Instantiating the Core in SOPC Builder” on page 22–4
- “Device Support” on page 22–5
- “Software Programming Model” on page 22–5

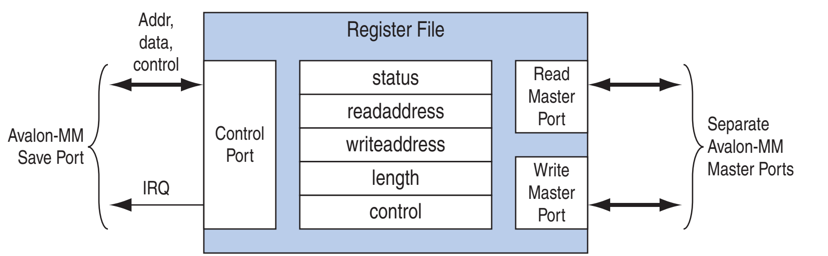
Functional Description

You can use the DMA controller to perform data transfers from a source address-space to a destination address-space. The controller has no concept of endianness and does not interpret the payload data. The concept of endianness only applies to a master that interprets payload data.

The source and destination may be either an Avalon-MM slave peripheral (for example, a constant address) or an address range in memory. The DMA controller can be used in conjunction with peripherals with flow control, which allows data transactions of fixed or variable length. The DMA controller can signal an interrupt request (IRQ) when a DMA transaction completes. A transaction is a sequence of one or more Avalon transfers initiated by the DMA controller core.

The DMA controller has two Avalon-MM master ports—a master read port and a master write port—and one Avalon-MM slave port for controlling the DMA as shown in Figure 22–1.

Figure 22–1. DMA Controller Block Diagram



A typical DMA transaction proceeds as follows:

1. A CPU prepares the DMA controller for a transaction by writing to the control port.
2. The CPU enables the DMA controller. The DMA controller then begins transferring data without additional intervention from the CPU. The DMA's master read port reads data from the read address, which may be a memory or a peripheral. The master write port writes the data to the destination address, which can also be a memory or peripheral. A shallow FIFO buffers data between the read and write ports.
3. The DMA transaction ends when a specified number of bytes are transferred (a fixed-length transaction) or an end-of-packet signal is asserted by either the sender or receiver (a variable-length transaction). At the end of the transaction, the DMA controller generates an interrupt request (IRQ) if it was configured by the CPU to do so.
4. During or after the transaction, the CPU can determine if a transaction is in progress, or if the transaction ended (and how) by examining the DMA controller's `status` register.

Setting Up DMA Transactions

An Avalon-MM master peripheral sets up and initiates DMA transactions by writing to registers via the control port. The Avalon-MM master programs the DMA engine using byte addresses which are byte aligned. The master peripheral configures the following options:

- Read (source) address location
- Write (destination) address location
- Size of the individual transfers: Byte (8-bit), halfword (16-bit), word (32-bit), doubleword (64-bit) or quadword (128-bit)
- Enable interrupt upon end of transaction
- Enable source or destination to end the DMA transaction with end-of-packet signal
- Specify whether source and destination are memory or peripheral

The master peripheral then sets a bit in the `control` register to initiate the DMA transaction.

The Master Read and Write Ports

The DMA controller reads data from the source address through the master read port, and then writes to the destination address through the master write port. You program the DMA controller using byte addresses. Read and write start addresses should be aligned to the transfer size. For example, to transfer data words, if the start address is 0, the address will increment to 4, 8, and 12. For heterogeneous systems where a number of different slave devices are of different widths, the data width for read and write masters matches the width of the widest data-width slave addressed by either the read or the write master. For bursting transfers, the burst length is set to the DMA transaction length with the appropriate unit conversion. For example, if a 32-bit data width DMA is programmed for a word transfer of 64 bytes, the length registered is programmed with 64 and the burst count port will be 16. If a 64-bit data width DMA is programmed for a doubleword transfer of 8 bytes, the length register is programmed with 8 and the burst count port will be 1.

There is a shallow FIFO buffer between the master read and write ports. The default depth is 2, which makes the write action depend on the data-available status of the FIFO, rather than on the status of the master read port.

Both the read and write master ports can perform Avalon transfers with flow control, which allows the slave peripheral to control the flow of data and terminate the DMA transaction.

For details about flow control in Avalon-MM data transfers and Avalon-MM peripherals, refer to *Avalon Interface Specifications*.

Addressing and Address Incrementing

When accessing memory, the read (or write) address increments by 1, 2, 4, 8, or 16 after each access, depending on the width of the data. On the other hand, a typical peripheral device (such as UART) has fixed register locations. In this case, the read/write address is held constant throughout the DMA transaction.

The rules for address incrementing are, in order of priority:

- If the `control` register's `RCON` (or `WCON`) bit is set, the read (or write) increment value is 0.
- Otherwise, the read and write increment values are set according to the transfer size specified in the control register, as shown in Table 22–1.

Table 22–1. Address Increment Values

Transfer Width	Increment
byte	1
halfword	2
word	4
doubleword	8
quadword	16

In systems with heterogeneous data widths, care must be taken to present the correct address or offset when configuring the DMA to access native-aligned slaves. For example, in a system using a 32-bit Nios II processor and a 16-bit DMA, the base address for the UART `txdata` register must be divided by the dma_data_width/cpu_data_width—2 in this example.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ Interface for the DMA controller in SOPC Builder to specify the core's configuration. Instantiating the DMA controller in SOPC Builder creates one slave port and two master ports. You must specify which slave peripherals can be accessed by the read and write master ports. Likewise, you must specify which other master peripheral(s) can access the DMA control port and initiate DMA transactions. The DMA controller does not export any signals to the top level of the system module.

DMA Parameters (Basic)

This section describes the parameters you can configure on the **DMA Parameters** page.

Transfer Size

The parameter **Width of the DMA Length Register** specifies the minimum width of the DMA's transaction length register, which can be between 1 and 32. The `length` register determines the maximum number of transfers possible in a single DMA transaction.

By default, the length register is wide enough to span any of the slave peripherals mastered by the read or write ports. Overriding the length register may be necessary if the DMA master port (read or write) masters only data peripherals, such as a UART. In this case, the address span of each slave is small, but a larger number of transfers may be desired per DMA transaction.

Burst Transactions

When **Enable Burst Transfers** is turned on, the DMA controller performs burst transactions on its master read and write ports. The parameter **Maximum Burst Size** determines the maximum burst size allowed in a transaction.

In burst mode, the length of a transaction must not be longer than the configured maximum burst size. Otherwise, the transaction must be performed as multiple transactions.

FIFO Implementation

This option determines the implementation of the FIFO buffer between the master read and write ports. Select **Construct FIFO from Registers** to implement the FIFO using one register per storage bit. This option has a strong impact on logic utilization when the DMA controller's data width is large. See "Advanced Options" on page 22–5.

To implement the FIFO using embedded memory blocks available in the FPGA, select **Construct FIFO from Memory Blocks**.

Advanced Options

This section describes the parameters you can configure on the **Advanced Options** page.

Allowed Transactions

You can choose the transfer datawidth(s) supported by the DMA controller hardware. The following datawidth options can be enabled or disabled:

- Byte
- Halfword (two bytes)
- Word (four bytes)
- Doubleword (eight bytes)
- Quadword (sixteen bytes)

Disabling unnecessary transfer widths reduces the number of on-chip logic resources consumed by the DMA controller core. For example, if a system has both 16-bit and 32-bit memories, but the DMA controller transfers data to the 16-bit memory, 32-bit transfers could be disabled to conserve logic resources.

Device Support

The DMA Controller Core with Avalon Interface supports all Altera device families.

Software Programming Model

This section describes the programming model for the DMA controller, including the register map and software declarations to access the hardware. For Nios II processor users, Altera provides HAL system library drivers that enable you to access the DMA controller core using the HAL API for DMA devices.

HAL System Library Support

The Altera-provided driver implements a HAL DMA device driver that integrates into the HAL system library for Nios II systems. HAL users should access the DMA controller via the familiar HAL API, rather than accessing the registers directly.

If your program uses the HAL device driver to access the DMA controller, accessing the device registers directly interferes with the correct behavior of the driver.

The HAL DMA driver provides both ends of the DMA process; the driver registers itself as both a receive channel (`alt_dma_rxchan`) and a transmit channel (`alt_dma_txchan`). The *Nios II Software Developer's Handbook* provides complete details of the HAL system library and the usage of DMA devices.

ioctl() Operations

`ioctl()` operation requests are defined for both the receive and transmit channels, which allows you to control the hardware-dependent aspects of the DMA controller. Two `ioctl()` functions are defined for the receiver driver and the transmitter driver: `alt_dma_rxchan_ioctl()` and `alt_dma_txchan_ioctl()`. Table 22–2 lists the available operations. These are valid for both the transmit and receive channels.

Table 22–2. Operations for alt_dma_rxchan_ioctl() and alt_dma_txchan_ioctl()

Request	Meaning
`ALT_DMA_SET_MODE_8`	Transfers data in units of 8 bits. The parameter `arg` is ignored.
`ALT_DMA_SET_MODE_16`	Transfers data in units of 16 bits. The parameter `arg` is ignored.
`ALT_DMA_SET_MODE_32`	Transfers data in units of 32 bits. The parameter `arg` is ignored.
`ALT_DMA_SET_MODE_64`	Transfers data in units of 64 bits. The parameter `arg` is ignored.
`ALT_DMA_SET_MODE_128`	Transfers data in units of 128 bits. The parameter `arg` is ignored.
`ALT_DMA_RX_ONLY_ON` *(1)*	Sets a DMA receiver into streaming mode. In this case, data is read continuously from a single location. The parameter `arg` specifies the address to read from.
`ALT_DMA_RX_ONLY_OFF` *(1)*	Turns off streaming mode for a receive channel. The parameter `arg` is ignored.
`ALT_DMA_TX_ONLY_ON` *(1)*	Sets a DMA transmitter into streaming mode. In this case, data is written continuously to a single location. The parameter `arg` specifies the address to write to.
`ALT_DMA_TX_ONLY_OFF` *(1)*	Turns off streaming mode for a transmit channel. The parameter `arg` is ignored.

Note to Table 22–2:

(1) These macro names changed in version 1.1 of the Nios II Embedded Design Suite (EDS). The old names (`ALT_DMA_TX_STREAM_ON`, `ALT_DMA_TX_STREAM_OFF`, `ALT_DMA_RX_STREAM_ON`, and `ALT_DMA_RX_STREAM_OFF`) are still valid, but new designs should use the new names.

Limitations

Currently the Altera-provided drivers do not support 64-bit and 128-bit DMA transactions.

This function is not thread safe. If you want to access the DMA controller from more than one thread then you should use a semaphore or mutex to ensure that only one thread is executing within this function at any time.

Software Files

The DMA controller is accompanied by the following software files. These files define the low-level interface to the hardware. Application developers should not modify these files.

- **altera_avalon_dma_regs.h**—This file defines the core's register map, providing symbolic constants to access the low-level hardware. The symbols in this file are used only by device driver functions.
- **altera_avalon_dma.h**, **altera_avalon_dma.c**—These files implement the DMA controller's device driver for the HAL system library.

Register Map

Programmers using the HAL API never access the DMA controller hardware directly via its registers. In general, the register map is only useful to programmers writing a device driver.

The Altera-provided HAL device driver accesses the device registers directly. If you are writing a device driver, and the HAL driver is active for the same device, your driver will conflict and fail to operate.

Table 22–3 shows the register map for the DMA controller. Device drivers control and communicate with the hardware through five memory-mapped 32-bit registers.

Table 22–3. DMA Controller Register Map

Offset	Register Name	Read/Write	31 13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	`status` *(1)*	RW	*(2)*									LEN	WEOP	REOP	BUSY	DONE
1	`readaddress`	RW	Read master start address													
2	`writeaddress`	RW	Write master start address													
3	`length`	RW	DMA transaction length (in bytes)													
4	—	—	Reserved *(3)*													
5	—	—	Reserved *(3)*													
6	`control`	RW	*(2)*	SOFTWARERESET	QUADWORD	DOUBLEWORD	WCON	RCON	LEEN	WEEN	REEN	I_EN	GO	WORD	HW	BYTE
7	—	—	Reserved *(3)*													

Notes to Table 22–3:

(1) Writing zero to the `status` register clears the `LEN`, `WEOP`, `REOP`, and `DONE` bits.

(2) These bits are reserved. Read values are undefined. Write zero.

(3) This register is reserved. Read values are undefined. The result of a write is undefined.

status Register

The `status` register consists of individual bits that indicate conditions inside the DMA controller. The `status` register can be read at any time. Reading the `status` register does not change its value.

The `status` register bits are shown in Table 22–4.

Table 22–4. status Register Bits (Part 1 of 2)

Bit Number	Bit Name	Read/Write/Clear	Description
0	`DONE`	R/C	A DMA transaction is complete. The `DONE` bit is set to 1 when an end of packet condition is detected or the specified transaction length is completed. Write zero to the `status` register to clear the `DONE` bit.
1	`BUSY`	R	The `BUSY` bit is 1 when a DMA transaction is in progress.

Table 22–4. status Register Bits (Part 2 of 2)

Bit Number	Bit Name	Read/Write/Clear	Description
2	REOP	R	The REOP bit is 1 when a transaction is completed due to an end-of-packet event on the read side.
3	WEOP	R	The WEOP bit is 1 when a transaction is completed due to an end of packet event on the write side.
4	LEN	R	The LEN bit is set to 1 when the length register decrements to zero.

readaddress Register

The readaddress register specifies the first location to be read in a DMA transaction. The readaddress register width is determined at system generation time. It is wide enough to address the full range of all slave ports mastered by the read port.

writeaddress Register

The writeaddress register specifies the first location to be written in a DMA transaction. The writeaddress register width is determined at system generation time. It is wide enough to address the full range of all slave ports mastered by the write port.

length Register

The length register specifies the number of bytes to be transferred from the read port to the write port. The length register is specified in bytes. For example, the value must be a multiple of 4 for word transfers, and a multiple of 2 for halfword transfers.

The length register is decremented as each data value is written by the write master port. When length reaches 0 the LEN bit is set. The length register does not decrement below 0.

The length register width is determined at system generation time. It is at least wide enough to span any of the slave ports mastered by the read or write master ports, and it can be made wider if necessary.

control Register

The control register is composed of individual bits that control the DMA's internal operation. The control register's value can be read at any time. The control register bits determine which, if any, conditions of the DMA transaction result in the end of a transaction and an interrupt request.

The control register bits are shown in Table 22–5.

Table 22–5. Control Register Bits (Part 1 of 2)

Bit Number	Bit Name	Read/ Write/ Clear	Description
0	BYTE	RW	Specifies byte transfers.
1	HW	RW	Specifies halfword (16-bit) transfers.
2	WORD	RW	Specifies word (32-bit) transfers.

 © March 2009 Altera Corporation

Table 22–5. Control Register Bits (Part 2 of 2)

Bit Number	Bit Name	Read/ Write/ Clear	Description
3	GO	RW	Enables DMA transaction. When the GO bit is set to 0, the DMA is prevented from executing transfers. When the GO bit is set to 1 and the length register is non-zero, transfers occur.
4	I_EN	RW	Enables interrupt requests (IRQ). When the I_EN bit is 1, the DMA controller generates an IRQ when the status register's DONE bit is set to 1. IRQs are disabled when the I_EN bit is 0.
5	REEN	RW	Ends transaction on read-side end-of-packet. When the REEN bit is set to 1, a slave port with flow control on the read side may end the DMA transaction by asserting its end-of-packet signal.
6	WEEN	RW	Ends transaction on write-side end-of-packet. When the WEEN bit is set to 1, a slave port with flow control on the write side may end the DMA transaction by asserting its end-of-packet signal.
7	LEEN	RW	Ends transaction when the length register reaches zero. When the LEEN bit is 1, the DMA transaction ends when the length register reaches 0. When this bit is 0, length reaching 0 does not cause a transaction to end. In this case, the DMA transaction must be terminated by an end-of-packet signal from either the read or write master port.
8	RCON	RW	Reads from a constant address. When RCON is 0, the read address increments after every data transfer. This is the mechanism for the DMA controller to read a range of memory addresses. When RCON is 1, the read address does not increment. This is the mechanism for the DMA controller to read from a peripheral at a constant memory address. For details, see "Addressing and Address Incrementing" on page 22–3.
9	WCON	RW	Writes to a constant address. Similar to the RCON bit, when WCON is 0 the write address increments after every data transfer; when WCON is 1 the write address does not increment. For details, see "Addressing and Address Incrementing" on page 22–3.
10	DOUBLEWORD	RW	Specifies doubleword transfers.
11	QUADWORD	RW	Specifies quadword transfers.
12	SOFTWARERESET	RW	Software can reset the DMA engine by writing this bit to 1 twice. Upon the second write of 1 to the SOFTWARERESET bit, the DMA control is reset identically to a system reset. The logic which sequences the software reset process then resets itself automatically.

The data width of DMA transactions is specified by the BYTE, HW, WORD, DOUBLEWORD, and QUADWORD bits. Only one of these bits can be set at a time. If more than one of the bits is set, the DMA controller behavior is undefined. The width of the transfer is determined by the narrower of the two slaves read and written. For example, a DMA transaction that reads from a 16-bit flash memory and writes to a 32-bit on-chip memory requires a halfword transfer. In this case, HW must be set to 1, and BYTE, WORD, DOUBLEWORD, and QUADWORD must be set to 0.

To successfully perform transactions of a specific width, that width must be enabled in hardware using the **Allowed Transaction** hardware option. For example, the DMA controller behavior is undefined if quadword transfers are disabled in hardware, but the QUADWORD bit is set during a DMA transaction.

Executing a DMA software reset when a DMA transfer is active may result in permanent bus lockup (until the next system reset). The SOFTWARERESET bit should therefore not be written except as a last resort.

Interrupt Behavior

The DMA controller has a single IRQ output that is asserted when the status register's DONE bit equals 1 and the control register's I_EN bit equals 1.

Writing the status register clears the DONE bit and acknowledges the IRQ. A master peripheral can read the status register and determine how the DMA transaction finished by checking the LEN, REOP, and WEOP bits.

23. Video Sync Generator and Pixel Converter Cores

QII55006-9.0.0

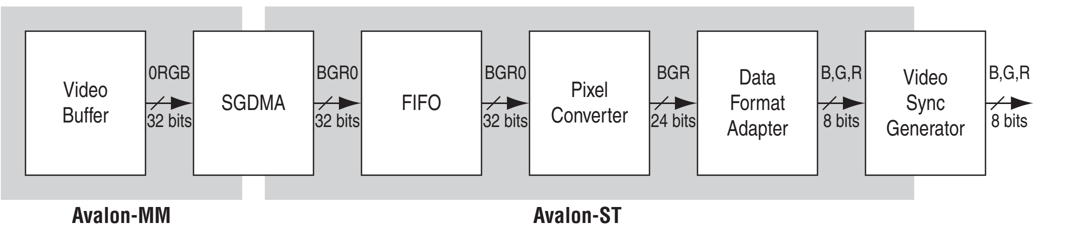
Core Overview

The video sync generator core accepts a continuous stream of pixel data in RGB format, and outputs the data to an off-chip display controller with proper timing. You can configure the video sync generator core to support different display resolutions and synchronization timings.

The pixel converter core transforms the pixel data to the format required by the video sync generator. Figure 23–1 shows a typical placement of the video sync generator and pixel converter cores in a system.

In this example, the video buffer stores the pixel data in 32-bit unpacked format. The extra byte in the pixel data is discarded by the pixel converter core before the data is serialized and sent to the video sync generator core.

Figure 23–1. Typical Placement in a System



The video sync generator and pixel converter cores are SOPC Builder-ready and integrate easily into any SOPC Builder-generated system.

These cores are deployed in the Nios II Embedded Software Evaluation Kit (NEEK), which includes an LCD display daughtercard assembly attached via an HSMC connector.

This chapter contains the following sections:

- "Video Sync Generator" on page 23–2
- "Pixel Converter" on page 23–5
- "Device Support" on page 23–6
- "Hardware Simulation Considerations" on page 23–6

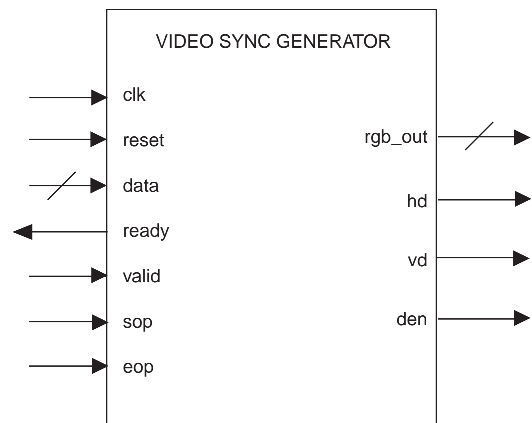
Video Sync Generator

This section describes the hardware structure and functionality of the video sync generator core.

Functional Description

The video sync generator core adds horizontal and vertical synchronization signals to the pixel data that comes through its Avalon® (Avalon-ST) input interface and outputs the data to an off-chip display controller. No processing or validation is performed on the pixel data. Figure 23–2 shows a block diagram of the video sync generator.

Figure 23–2. Video Sync Generator Block Diagram



You can configure various aspects of the core and its Avalon-ST interface to suit your requirements. You can specify the data width, number of beats required to transfer each pixel and synchronization signals. See "Instantiating the Core in SOPC Builder" on page 23–3 for more information on the available options.

To ensure incoming pixel data is sent to the display controller with correct timing, the video sync generator core must synchronize itself to the first pixel in a frame. The first active pixel is indicated by an `sop` pulse.

The video sync generator core expects continuous streams of pixel data at its input interface and assumes that each incoming packet contains the correct number of pixels (Number of rows * Number of columns). Data starvation disrupts synchronization and results in unexpected output on the display.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ interface for the video sync generator core in SOPC Builder to configure the core. Table 23–1 lists the available parameters in the MegaWizard interface.

Table 23–1. Video Sync Generator Parameters

Parameter Name	Description
Horizontal Sync Pulse Pixels	The width of the h-sync pulse in number of pixels.
Total Vertical Scan Lines	The total number of lines in one video frame. The value is the sum of the following parameters: **Number of Rows**, **Vertical Blank Lines**, and **Vertical Front Porch Lines**.
Number of Rows	The number of active scan lines in each video frame.
Horizontal Sync Pulse Polarity	The polarity of the h-sync pulse; 0 = active low and 1 = active high.
Horizontal Front Porch Pixels	The number of blanking pixels that follow the active pixels. During this period, there is no data flow from the Avalon-ST sink port to the LCD output data port.
Vertical Sync Pulse Polarity	The polarity of the v-sync pulse; 0 = active low and 1 = active high.
Vertical Sync Pulse Lines	The width of the v-sync pulse in number of lines.
Vertical Front Porch Lines	The number of blanking lines that follow the active lines. During this period, there is no data flow from the Avalon-ST sink port to the LCD output data port.
Number of Columns	The number of active pixels in each line.
Horizontal Blank Pixels	The number of blanking pixels that precede the active pixels. During this period, there is no data flow from the Avalon-ST sink port to the LCD output data port.
Total Horizontal Scan Pixels	The total number of pixels in one line. The value is the sum of the following parameters: **Number of Columns**, **Horizontal Blank Pixel**, and **Horizontal Front Porch Pixels**.
Beats Per Pixel	The number of beats required to transfer one pixel. Valid values are 1 and 3. This parameter, when multiplied by **Data Stream Bit Width** must be equal to the total number of bits in one pixel. This parameter affects the operating clock frequency, as shown in the following equation: Operating clock frequency = (**Beats per pixel**) * (Pixel_rate), where Pixel_rate (in MHz) = ((**Total Horizontal Scan Pixels**) * (**Total Vertical Scan Lines**) * (Display refresh rate in Hz))/1000000.
Vertical Blank Lines	The number of blanking lines that proceed the active lines. During this period, there is no data flow from the Avalon-ST sink port to the LCD output data port.
Data Stream Bit Width	The width of the inbound and outbound data.

Signals

Table 23–2 lists the input and output signals for the video sync generator core.

Table 23–2. Video Sync Generator Core Signals

Signal Name	Width (Bits)	Direction	Description
Global Signals			
clk	1	Input	System clock.
reset	1	Input	System reset.
Avalon-ST Signals			
data	Variable-width	Input	Incoming pixel data. The datawidth is determined by the parameter **Data Stream Bit Width**.
ready	1	Output	This signal is asserted when the video sync generator is ready to receive the pixel data.
valid	1	Input	This signal is not used by the video sync generator core because the core always expects valid pixel data on the next clock cycle after the ready signal is asserted.
sop	1	Input	Start-of-packet. This signal is asserted when the first pixel is received.
eop	1	Input	End-of-packet. This signal is asserted when the last pixel is received.
LCD Output Signals			
rgb_out	Variable-width	Output	Display data. The datawidth is determined by the parameter **Data Stream Bit Width**.
hd	1	Output	Horizontal synchronization pulse for display.
vd	1	Output	Vertical synchronization pulse for display.
den	1	Output	This signal is asserted when the video sync generator core outputs valid data for display.

Timing Diagrams

The horizontal and vertical synchronization timings are determined by the parameters setting. Figure 23–3 shows the horizontal synchronization timing when the parameters **Data Stream Bit Width** and **Beats Per Pixel** are set to 8 and 3, respectively.

Figure 23–3. Horizontal Synchronization Timing—8 Bits DataWidth and 3 Beats Per Pixel

 © March 2009 Altera Corporation

Figure 23–4 sho.ws the horizontal synchronization timing when the parameters **Data Stream Bit Width** and **Beats Per Pixel** are set to 24 and 1, respectively.

Figure 23–4. Horizontal Synchronization Timing—24 Bits DataWidth and 1 Beat Per Pixel

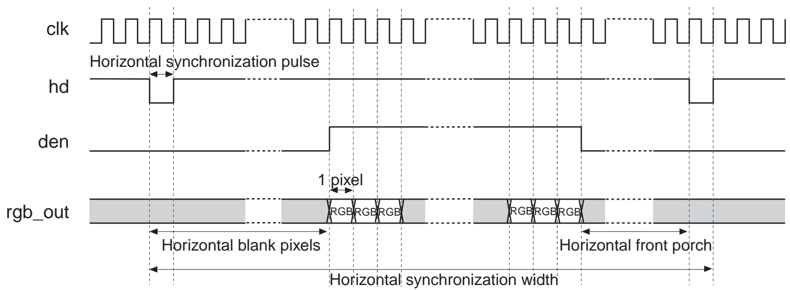


Figure 23–5 shows the vertical synchronization timing.

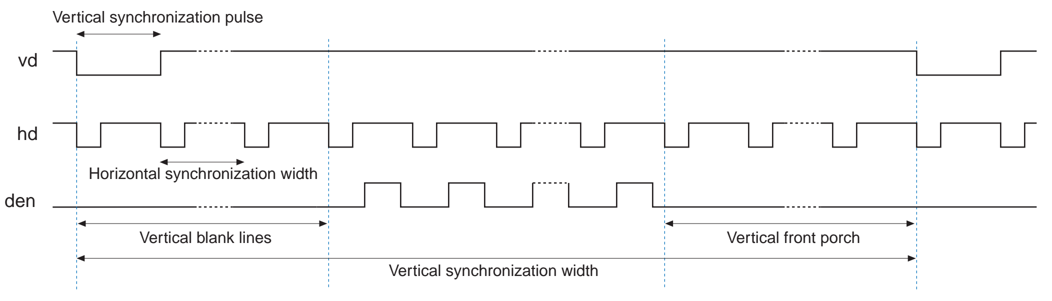
Figure 23–5. Vertical Synchronization Timing—8 Bits DataWidth and 3 Beats Per Pixel / 24 Bits DataWidth and 1 Beat Per Pixel



Pixel Converter

This section describes the hardware structure and functionality of the pixel converter core.

Functional Description

The pixel converter core receives pixel data on its Avalon-ST input interface and transforms the pixel data to the format required by the video sync generator. The least significant byte of the 32-bit wide pixel data is removed and the remaining 24 bits are wired directly to the core's Avalon-ST output interface.

Instantiating the Core in SOPC Builder

Use the MegaWizard interface for the pixel converter core in SOPC Builder to add the core to a system. You can configure the following parameter:

Source symbols per beat—The number of symbols per beat on the Avalon-ST source interface.

Signals

Table 23–3 lists the input and output signals for the pixel converter core.

Table 23–3. Pixel Converter Input Interface Signals

Signal Name	Width (Bits)	Direction	Description
Global Signals			
clk	1	Input	Not in use.
reset_n	1	Input	
Avalon-ST Signals			
data_in	32	Input	Incoming pixel data. Contains four 8-bit symbols that are transferred in 1 beat.
data_out	24	Output	Output data. Contains three 8-bit symbols that are transferred in 1 beat.
sop_in	1	Input	Wired directly to the corresponding output signals.
eop_in	1	Input	
ready_in	1	Input	
valid_in	1	Input	
empty_in	1	Input	
sop_out	1	Output	Wired directly from the input signals.
eop_out	1	Output	
ready_out	1	Output	
valid_out	1	Output	
empty_out	1	Output	

Device Support

The video sync generator and pixel converter cores support all Altera device families.

Hardware Simulation Considerations

For a typical 60 Hz refresh rate, set the simulation length for the video sync generator core to at least 16.7 µs to get a full video frame. Depending on the size of the video frame, simulation may take a very long time to complete.

24. Interval Timer Core

NII51008-9.0.0

Core Overview

The Interval Timer core with Avalon® interface is an interval timer for Avalon-based processor systems, such as a Nios® II processor system. The core provides the following features:

- 32-bit and 64-bit counters.
- Controls to start, stop, and reset the timer.
- Two count modes: count down once and continuous count-down.
- Count-down period register.
- Option to enable or disable the interrupt request (IRQ) when timer reaches zero.
- Optional watchdog timer feature that resets the system if timer ever reaches zero.
- Optional periodic pulse generator feature that outputs a pulse when timer reaches zero.
- Compatible with 32-bit and 16-bit processors.

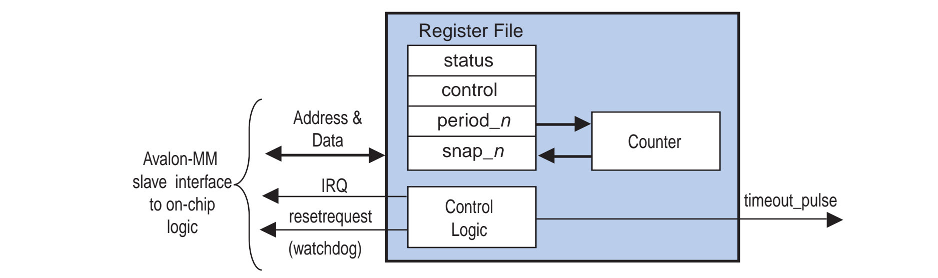
Device drivers are provided in the HAL system library for the Nios II processor. The interval timer core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- "Functional Description"
- "Device Support" on page 24–2
- "Instantiating the Core in SOPC Builder" on page 24–3
- "Software Programming Model" on page 24–5

Functional Description

Figure 24–1 shows a block diagram of the interval timer core.

Figure 24–1. Interval Timer Core Block Diagram



The intervanl timer core has two user-visible features:

- The Avalon Memory-Mapped (Avalon-MM) interface that provides access to six 16-bit registers
- An optional pulse output that can be used as a periodic pulse generator

All registers are 16-bits wide, making the core compatible with both 16-bit and 32-bit processors. Certain registers only exist in hardware for a given configuration. For example, if the core is configured with a fixed period, the period registers do not exist in hardware.

The following sequence describes the basic behavior of the interval timer core:

- An Avalon-MM master peripheral, such as a Nios II processor, writes the core's `control` register to perform the following tasks:
  - Start and stop the timer
  - Enable/disable the IRQ
  - Specify count-down once or continuous count-down mode
- A processor reads the `status` register for information about current timer activity.
- A processor can specify the timer period by writing a value to the period registers.
- An internal counter counts down to zero, and whenever it reaches zero, it is immediately reloaded from the period registers.
- A processor can read the current counter value by first writing to one of the snap registers to request a coherent snapshot of the counter, and then reading the snap registers for the full value.
- When the count reaches zero, one or more of the following events are triggered:
  - If IRQs are enabled, an IRQ is generated.
  - The optional pulse-generator output is asserted for one clock period.
  - The optional watchdog output resets the system.

Avalon-MM Slave Interface

The interval timer core implements a simple Avalon-MM slave interface to provide access to the register file. The Avalon-MM slave port uses the `resetrequest` signal to implement watchdog timer behavior. This signal is a non-maskable reset signal, and it drives the reset input of all Avalon-MM peripherals in the SOPC Builder system. When the `resetrequest` signal is asserted, it forces any processor connected to the system to reboot. For more information, refer to "Configuring the Timer as a Watchdog Timer" on page 24–4.

Device Support

The interval timer core supports all Altera® device families.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ Interface for the interval timer core in SOPC Builder to specify the hardware features. This section describes the options available in the MegaWizard Interace.

Timeout Period

The **Timeout Period** setting determines the initial value of the period registers. When the **Writeable period** option is on, a processor can change the value of the period by writing to the period registers. When the **Writeable period** option is off, the period is fixed and cannot be updated at runtime. See "Hardware Options" on page 24–3 for information on register options.

The **Timeout Period** is an integer multiple of the **Timer Frequency**. The **Timer Frequency** is fixed at the frequency setting of the system clock associated with the timer. The **Timeout Period** setting can be specified in units of **µs** (microseconds), **ms** (milliseconds), **seconds** , or **clocks** (number of cycles of the system clock associated with the timer). The actual period depends on the frequency of the system clock associated with the timer. If the period is specified in **µs**, **ms**, or **seconds**, the true period will be the smallest number of clock cycles that is greater or equal to the specified **Timeout Period** value. For example, if the associated system clock has a frequency of 30 **ns**, and the specified **Timeout Period** value is 1 **µs**, the true timeout period will be 1.020 microseconds.

Counter Size

The **Counter Size** setting determines the timer's width, which can be set to either 32 or 64 bits. A 32-bit timer has two 16-bit period registers, whereas a 64-bit timer has four 16-bit period registers. This option applies to the snap registers as well.

Hardware Options

The following options affect the hardware structure of the interval timer core. As a convenience, the **Preset Configurations** list offers several pre-defined hardware configurations, such as:

- **Simple periodic interrupt**—This configuration is useful for systems that require only a periodic IRQ generator. The period is fixed and the timer cannot be stopped, but the IRQ can be disabled.
- **Full-featured**—This configuration is useful for embedded processor systems that require a timer with variable period that can be started and stopped under processor control.
- **Watchdog—**This configuration is useful for systems that require watchdog timer to reset the system in the event that the system has stopped responding. Refer to "Configuring the Timer as a Watchdog Timer" on page 24–4.

Register Options

Table 24–1 shows the settings that affect the interval timer core's registers.

Table 24–1. Register Options

Option	Description
Writeable period	When this option is enabled, a master peripheral can change the count-down period by writing to the period registers. When disabled, the count-down period is fixed at the specified **Timeout Period**, and the period registers do not exist in hardware.
Readable snapshot	When this option is enabled, a master peripheral can read a snapshot of the current count-down. When disabled, the status of the counter is detectable only via other indicators, such as the `status` register or the IRQ signal. In this case, the snap registers do not exist in hardware, and reading these registers produces an undefined value.
Start/Stop control bits	When this option is enabled, a master peripheral can start and stop the timer by writing the START and STOP bits in the `control` register. When disabled, the timer runs continuously. When the **System reset on timeout (watchdog)** option is enabled, the START bit is also present, regardless of the **Start/Stop control bits** option.

Output Signal Options

Table 24–2 shows the settings that affect the interval timer core's output signals.

Table 24–2. Output Signal Options

Option	Description
Timeout pulse (1 clock wide)	When this option is on, the core outputs a signal `timeout_pulse`. This signal pulses high for one clock cycle whenever the timer reaches zero. When this option is off, the `timeout_pulse` signal does not exist.
System reset on timeout (watchdog)	When this option is on, the core's Avalon-MM slave port includes the `resetrequest` signal. This signal pulses high for one clock cycle whenever the timer reaches zero resulting in a system-wide reset. The internal timer is stopped at reset. Explicitly writing the START bit of the `control` register starts the timer. When this option is off, the `resetrequest` signal does not exist. Refer to "Configuring the Timer as a Watchdog Timer".

Configuring the Timer as a Watchdog Timer

To configure the core for use as a watchdog, in the MegaWizard Interface select **Watchdog** in the **Preset Configurations** list, or choose the following settings:

- Set the **Timeout Period** to the desired "watchdog" period.
- Turn off **Writeable period**.
- Turn off **Readable snapshot**.
- Turn off **Start/Stop control bits**.
- Turn off **Timeout pulse**.
- Turn on **System reset on timeout (watchdog)**.

© March 2009 Altera Corporation

A watchdog timer wakes up (comes out of reset) stopped. A processor later starts the timer by writing a 1 to the `control` register's `START` bit. Once started, the timer can never be stopped. If the internal counter ever reaches zero, the watchdog timer resets the system by generating a pulse on its `resetrequest` output. To prevent the system from resetting, the processor must periodically reset the timer's count-down value by writing one of the period registers (the written value is ignored). If the processor fails to access the timer because, for example, software stopped executing normally, the watchdog timer resets the system and returns the system to a defined state.

Software Programming Model

The following sections describe the software programming model for the interval timer core, including the register map and software declarations to access the hardware. For Nios II processor users, Altera provides hardware abstraction layer (HAL) system library drivers that enable you to access the interval timer core using the HAL application programming interface (API) functions.

HAL System Library Support

The Altera-provided drivers integrate into the HAL system library for Nios II systems. When possible, HAL users should access the core via the HAL API, rather than accessing the core's registers directly.

Altera provides a driver for both the HAL timer device models: system clock timer, and timestamp timer.

System Clock Driver

When configured as the system clock, the interval timer core runs continuously in periodic mode, using the default period set in SOPC builder. The system clock services are then run as a part of the interrupt service routine for this timer. The driver is interrupt-driven, and therefore must have its interrupt signal connected in the system hardware.

The Nios II integrated development environment (IDE) allows you to specify system library properties that determine which timer device will be used as the system clock timer.

Timestamp Driver

The interval timer core may be used as a timestamp device if it meets the following conditions:

- The timer has a writeable `period` register, as configured in SOPC Builder.
- The timer is not selected as the system clock.

The Nios II IDE allows you to specify system library properties that determine which timer device will be used as the timestamp timer.

If the timer hardware is not configured with writeable `period` registers, calls to the `alt_timestamp_start()` API function will not reset the timestamp counter. All other HAL API calls will perform as expected.

For more information about using the system clock and timestamp features that use these drivers, refer to the *Nios II Software Developer's Handbook*. The Nios II Embedded Design Suite (EDS) also provides several example designs that use the interval timer core.

Limitations

The HAL driver for the interval timer core does not support the watchdog reset feature of the core.

Software Files

The interval timer core is accompanied by the following software files. These files define the low-level interface to the hardware, and provide the HAL drivers. Application developers should not modify these files.

- **altera_avalon_timer_regs.h—**This file defines the core's register map, providing symbolic constants to access the low-level hardware.
- **altera_avalon_timer.h**, **altera_avalon_timer_sc.c, altera_avalon_timer_ts.c, altera_avalon_timer_vars.c—**These files implement the timer device drivers for the HAL system library.

Register Map

You do not need to access the interval timer core directly via its registers if using the standard features provided in the HAL system library for the Nios II processor. In general, the register map is only useful to programmers writing a device driver.

The Altera-provided HAL device driver accesses the device registers directly. If you are writing a device driver, and the HAL driver is active for the same device, your driver will conflict and fail to operate correctly.

Table 24–3 shows the register map for the 32-bit timer.

Table 24–3. Register Map—32-bit Timer

Offset	Name	R/W	Description of Bits						
			15	...	4	3	2	1	0
0	`status`	RW	*(1)*					`RUN`	`TO`
1	`control`	RW	*(1)*			`STOP`	`START`	`CONT`	`ITO`
2	`periodl`	RW	Timeout Period – 1 (bits [15:0])						
3	`periodh`	RW	Timeout Period – 1 (bits [31:16])						
4	`snapl`	RW	Counter Snapshot (bits [15:0])						
5	`snaph`	RW	Counter Snapshot (bits [31:16])						

Note to Table 24–3:

(1) Reserved. Read values are undefined. Write zero.

Table 24–4 shows the register map for the 64-bit timer.

Table 24–4. Register Map—64-bit Timer

Offset	Name	R/W	Description of Bits						
			15	...	4	3	2	1	0
0	status	RW	*(1)*					RUN	TO
1	control	RW	*(1)*			STOP	START	CONT	ITO
2	period_0	RW	Timeout Period – 1 (bits [15:0])						
3	period_1	RW	Timeout Period – 1 (bits [31:16])						
4	period_2	RW	Timeout Period – 1 (bits [47:32])						
5	period_3	RW	Timeout Period – 1 (bits [63:48])						
6	snap_0	RW	Counter Snapshot (bits [15:0])						
7	snap_1	RW	Counter Snapshot (bits [31:16])						
8	snap_2	RW	Counter Snapshot (bits [47:32])						
9	snap_3	RW	Counter Snapshot (bits [63:48])						

Note to Table 24–4:

(1) Reserved. Read values are undefined. Write zero.

status Register

The status register has two defined bits, as shown in Table 24–5.

Table 24–5. status Register Bits

Bit	Name	R/W/C	Description
0	TO	RC	The TO (timeout) bit is set to 1 when the internal counter reaches zero. Once set by a timeout event, the TO bit stays set until explicitly cleared by a master peripheral. Write zero to the status register to clear the TO bit.
1	RUN	R	The RUN bit reads as 1 when the internal counter is running; otherwise this bit reads as 0. The RUN bit is not changed by a write operation to the status register.

control Register

The control register has four defined bits, as shown in Table 24–6.

Table 24–6. control Register Bits (Part 1 of 2)

Bit	Name	R/W/C	Description
0	ITO	RW	If the ITO bit is 1, the interval timer core generates an IRQ when the status register's TO bit is 1. When the ITO bit is 0, the timer does not generate IRQs.
1	CONT	RW	The CONT (continuous) bit determines how the internal counter behaves when it reaches zero. If the CONT bit is 1, the counter runs continuously until it is stopped by the STOP bit. If CONT is 0, the counter stops after it reaches zero. When the counter reaches zero, it reloads with the value stored in the period registers, regardless of the CONT bit.
2	START *(1)*	W	Writing a 1 to the START bit starts the internal counter running (counting down). The START bit is an event bit that enables the counter when a write operation is performed. If the timer is stopped, writing a 1 to the START bit causes the timer to restart counting from the number currently stored in its counter. If the timer is already running, writing a 1 to START has no effect. Writing 0 to the START bit has no effect.

Table 24–6. control Register Bits (Part 2 of 2)

Bit	Name	R/W/C	Description
3	STOP *(1)*	W	Writing a 1 to the `STOP` bit stops the internal counter. The `STOP` bit is an event bit that causes the counter to stop when a write operation is performed. If the timer is already stopped, writing a 1 to `STOP` has no effect. Writing a 0 to the stop bit has no effect. If the timer hardware is configured with **Start/Stop control bits** off, writing the `STOP` bit has no effect.

Note to Table 24–6:

(1) Writing 1 to both `START` and `STOP` bits simultaneously produces an undefined result.

period_n Registers

The `period_`*n* registers together store the timeout period value. The internal counter is loaded with the value stored in these registers whenever one of the following occurs:

- A write operation to one of the `period_`*n* register
- The internal counter reaches 0

The timer's actual period is one cycle greater than the value stored in the `period_`*n* registers because the counter assumes the value zero for one clock cycle.

Writing to one of the `period_`*n* registers stops the internal counter, except when the hardware is configured with **Start/Stop control bits** off. If **Start/Stop control bits** is off, writing either register does not stop the counter. When the hardware is configured with **Writeable period** disabled, writing to one of the `period_`*n* registers causes the counter to reset to the fixed **Timeout Period** specified at system generation time.

snap_n Registers

A master peripheral may request a coherent snapshot of the current internal counter by performing a write operation (write-data ignored) to one of the `snap_`*n* registers. When a write occurs, the value of the counter is copied to `snap_`*n* registers. The snapshot occurs whether or not the counter is running. Requesting a snapshot does not change the internal counter's operation.

Interrupt Behavior

The interval timer core generates an IRQ whenever the internal counter reaches zero and the `ITO` bit of the `control` register is set to 1. Acknowledge the IRQ in one of two ways:

- Clear the `TO` bit of the `status` register
- Disable interrupts by clearing the `ITO` bit of the `control` register

Failure to acknowledge the IRQ produces an undefined result.

25. System ID Core

NII51014-9.0.0

Core Overview

The system ID core with Avalon® interface is a simple read-only device that provides SOPC Builder systems with a unique identifier. Nios® II processor systems use the system ID core to verify that an executable program was compiled targeting the actual hardware image configured in the target FPGA. If the expected ID in the executable does not match the system ID core in the FPGA, it is possible that the software will not execute correctly.

This chapter contains the following sections:

- "Functional Description"
- "Device Support" on page 25–2
- "Instantiating the Core in SOPC Builder" on page 25–2
- "Software Programming Model" on page 25–2

Functional Description

The system ID core provides a read-only Avalon Memory-Mapped (Avalon-MM) slave interface. This interface has two 32-bit registers, as shown in Table 25–1. The value of each register is determined at system generation time, and always returns a constant value.

Table 25–1. System ID Core Register Map

Offset	Register Name	R/W	Description
0	`id`	R	A unique 32-bit value that is based on the contents of the SOPC Builder system. The id is similar to a check-sum value; SOPC Builder systems with different components, different configuration options, or both, produce different id values.
1	`timestamp`	R	A unique 32-bit value that is based on the system generation time. The value is equivalent to the number of seconds after Jan. 1, 1970.

There are two basic ways to use the system ID core:

- Verify the system ID before downloading new software to a system. This method is used by software development tools, such as the Nios II integrated development environment (IDE). There is little point in downloading a program to a target hardware system, if the program is compiled for different hardware. Therefore, the Nios II IDE checks that the system ID core in hardware matches the expected system ID of the software before downloading a program to run or debug.
- Check system ID after reset. If a program is running on hardware other than the expected SOPC Builder system, the program may fail to function altogether. If the program does not crash, it can behave erroneously in subtle ways that are difficult to debug. To protect against this case, a program can compare the expected system ID against the system ID core, and report an error if they do not match.

Device Support

The system ID core supports all Altera® device families.

Instantiating the Core in SOPC Builder

The System ID core has no user-configurable features. The `id` and `timestamp` register values are determined at system generation time based on the configuration of the SOPC Builder system and the current time. You can add only one system ID core to an SOPC Builder system, and its name is always `sysid`.

After system generation, you can examine the values stored in the `id` and `timestamp` registers by opening the MegaWizard™ Interface for the System ID core. Hovering the mouse over the component in SOPC Builder also displays a tool-tip showing the values.

Software Programming Model

This section describes the software programming model for the system ID core. For Nios II processor users, Altera provides the HAL system library header file that defines the system ID core registers.

The System ID core comes with the following software files. These files provide low-level access to the hardware. Application developers should not modify these files.

- **alt_avalon_sysid_regs.h**—Defines the interface to the hardware registers.
- **alt_avalon_sysid.c, alt_avalon_sysid.h**—Header and source files defining the hardware access functions.

Altera provides one access routine, `alt_avalon_sysid_test()`, that returns a value indicating whether the system ID expected by software matches the system ID core.

alt_avalon_sysid_test()

Prototype:	`alt_32 alt_avalon_sysid_test(void)`
Thread-safe:	No.
Available from ISR:	Yes.
Include:	**<altera_avalon_sysid.h>**
Description:	Returns 0 if the values stored in the hardware registers match the values expected by software. Returns 1 if the hardware timestamp is greater than the software timestamp. Returns -1 if the software timestamp is greater than the hardware timestamp.

26. Mutex Core

NII51020-9.0.0

Core Overview

Multiprocessor environments can use the mutex core with Avalon® interface to coordinate accesses to a shared resource. The mutex core provides a protocol to ensure mutually exclusive ownership of a shared resource.

The mutex core provides a hardware-based atomic test-and-set operation, allowing software in a multiprocessor environment to determine which processor owns the mutex. The mutex core can be used in conjunction with shared memory to implement additional interprocessor coordination features, such as mailboxes and software mutexes.

The mutex core is designed for use in Avalon-based processor systems, such as a Nios® II processor system. Altera provides device drivers for the Nios II processor to enable use of the hardware mutex.

The mutex core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- "Functional Description"
- "Device Support" on page 26–2
- "Instantiating the Core in SOPC Builder" on page 26–2
- "Software Programming Model" on page 26–2
- "Mutex API" on page 26–4

Functional Description

The mutex core has a simple Avalon Memory-Mapped (Avalon-MM) slave interface that provides access to two memory-mapped, 32-bit registers. Table 26–1 shows the registers.

Table 26–1. Mutex Core Register Map

Offset	Register Name	R/W	Bit Description		
			31 … 16	15 … 1	0
0	`mutex`	RW	`OWNER`	`VALUE`	
1	`reset`	RW	Reserved		`RESET`

The mutex core has the following basic behavior. This description assumes there are multiple processors accessing a single mutex core, and each processor has a unique identifier (ID).

- When the `VALUE` field is `0x0000`, the mutex is unlocked and available. Otherwise, the mutex is locked and unavailable.
- The `mutex` register is always readable. Avalon-MM master peripherals, such as a processor, can read the `mutex` register to determine its current state.

- The mutex register is writable only under specific conditions. A write operation changes the mutex register only if one or both of the following conditions are true:
  - The VALUE field of the mutex register is zero.
  - The OWNER field of the mutex register matches the OWNER field in the data to be written.
- A processor attempts to acquire the mutex by writing its ID to the OWNER field, and writing a non-zero value to the VALUE field. The processor then checks if the acquisition succeeded by verifying the OWNER field.
- After system reset, the RESET bit in the reset register is high. Writing a one to this bit clears it.

Device Support

The mutex core supports all Altera device families.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ Interface for the mutex core in SOPC Builder to specify the core's hardware features. The MegaWizard Interface provides the following options:

- **Initial Value**—the initial contents of the VALUE field after reset. If the **Initial Value** setting is non-zero, you must also specify **Initial Owner**.
- **Initial Owner**—the initial contents of the OWNER field after reset. When **Initial Owner** is specified, this owner must release the mutex before it can be acquired by another owner.

Software Programming Model

The following sections describe the software programming model for the mutex core. For Nios II processor users, Altera provides routines to access the mutex core hardware. These functions are specific to the mutex core and directly manipulate low-level hardware. The mutex core cannot be accessed via the HAL API or the ANSI C standard library. In Nios II processor systems, a processor locks the mutex by writing the value of its cpuid control register to the OWNER field of the mutex register.

Software Files

Altera provides the following software files accompanying the mutex core:

- **altera_avalon_mutex_regs.h**—Defines the core's register map, providing symbolic constants to access the low-level hardware.
- **altera_avalon_mutex.h**—Defines data structures and functions to access the mutex core hardware.
- **altera_avalon_mutex.c**—Contains the implementations of the functions to access the mutex core

Hardware Access Routines

This section describes the low-level software constructs for manipulating the mutex core. The file **altera_avalon_mutex.h** declares a structure `alt_mutex_dev` that represents an instance of a mutex device. It also declares routines for accessing the mutex hardware structure, listed in Table 26–2.

Table 26–2. Hardware Access Routines

Function Name	Description
`altera_avalon_mutex_open()`	Claims a handle to a mutex, enabling all the other functions to access the mutex core.
`altera_avalon_mutex_trylock()`	Tries to lock the mutex. Returns immediately if it fails to lock the mutex.
`altera_avalon_mutex_lock()`	Locks the mutex. Will not return until it has successfully claimed the mutex.
`altera_avalon_mutex_unlock()`	Unlocks the mutex.
`altera_avalon_mutex_is_mine()`	Determines if this CPU owns the mutex.
`altera_avalon_mutex_first_lock()`	Tests whether the mutex has been released since reset.

These routines coordinate access to the software mutex structure using a hardware mutex core. For a complete description of each function, see section "Mutex API" on page 26–4.

The code shown in Example 26–1 demonstrates opening a mutex device handle and locking a mutex.

Example 26–1. Opening and Locking a mutex

```
#include <altera_avalon_mutex.h>
/* get the mutex device handle */
alt_mutex_dev* mutex = altera_avalon_mutex_open( "/dev/mutex" );
/* acquire the mutex, setting the value to one */
altera_avalon_mutex_lock( mutex, 1 );
/*
 * Access a shared resource here.
 */
/* release the lock */
altera_avalon_mutex_unlock( mutex );
```

Mutex API

This section describes the application programming interface (API) for the mutex core.

altera_avalon_mutex_is_mine()

Prototype:	`int altera_avalon_mutex_is_mine(alt_mutex_dev* dev)`
Thread-safe:	Yes.
Available from ISR:	No.
Include:	<**altera_avalon_mutex.h**>
Parameters:	`dev`—the mutex device to test.
Returns:	Returns non zero if the mutex is owned by this CPU.
Description:	`altera_avalon_mutex_is_mine()` determines if this CPU owns the mutex.

altera_avalon_mutex_first_lock()

Prototype:	`int altera_avalon_mutex_first_lock(alt_mutex_dev* dev)`
Thread-safe:	Yes.
Available from ISR:	No.
Include:	<**altera_avalon_mutex.h**>
Parameters:	`dev`—the mutex device to test.
Returns:	Returns 1 if this mutex has not been released since reset, otherwise returns 0.
Description:	`altera_avalon_mutex_first_lock()` determines whether this mutex has been released since reset.

altera_avalon_mutex_lock()

Prototype:	`void altera_avalon_mutex_lock(alt_mutex_dev* dev, alt_u32 value)`
Thread-safe:	Yes.
Available from ISR:	No.
Include:	<**altera_avalon_mutex.h**>
Parameters:	`dev`—the mutex device to acquire. `value`—the new value to write to the mutex.
Returns:	—
Description:	`altera_avalon_mutex_lock()` is a blocking routine that acquires a hardware mutex, and at the same time, loads the mutex with the `value` parameter.

altera_avalon_mutex_open()

Prototype:	`alt_mutex_dev* alt_hardware_mutex_open(const char* name)`
Thread-safe:	Yes.
Available from ISR:	No.
Include:	<**altera_avalon_mutex.h**>
Parameters:	`name`—the name of the mutex device to open.
Returns:	A pointer to the mutex device structure associated with the supplied name, or NULL if no corresponding mutex device structure was found.
Description:	`altera_avalon_mutex_open()` retrieves a pointer to a hardware mutex device structure.

altera_avalon_mutex_trylock()

Prototype:	`int altera_avalon_mutex_trylock(alt_mutex_dev* dev, alt_u32 value)`
Thread-safe:	Yes.
Available from ISR:	No.
Include:	<**altera_avalon_mutex.h**>
Parameters:	`dev`—the mutex device to lock. `value`—the new value to write to the mutex.
Returns:	`0` = The mutex was successfully locked. Others = The mutex was not locked.
Description:	`altera_avalon_mutex_trylock()` tries once to lock the hardware mutex, and returns immediately.

altera_avalon_mutex_unlock()

Prototype:	`void altera_avalon_mutex_unlock(alt_mutex_dev* dev)`
Thread-safe:	Yes.
Available from ISR:	No.
Include:	<**altera_avalon_mutex.h**>
Parameters:	`dev`—the mutex device to unlock.
Returns:	Null.
Description:	`altera_avalon_mutex_unlock()` releases a hardware mutex device. Upon release, the value stored in the mutex is set to zero. If the caller does not hold the mutex, the behavior of this function is undefined.

27. Mailbox Core

NII53001-9.0.0

Core Overview

Multiprocessor environments can use the mailbox core with Avalon® interface to send messages between processors.

The mailbox core contains mutexes to ensure that only one processor modifies the mailbox contents at a time. The mailbox core must be used in conjunction with a separate shared memory that is used for storing the actual messages.

The mailbox core is designed for use in Avalon-based processor systems, such as a Nios® II processor system. Altera provides device drivers for the Nios II processor. The mailbox core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- "Functional Description"
- "Device Support" on page 27–2
- "Instantiating the Core in SOPC Builder" on page 27–2
- "Software Programming Model" on page 27–3
- "Mailbox API" on page 27–5

Functional Description

The mailbox core has a simple Avalon Memory-Mapped (Avalon-MM) slave interface that provides access to four memory-mapped, 32-bit registers. Table 27–1 shows the registers.

Table 27–1. Mutex Core Register Map

Offset	Register Name	R/W	Bit Description		
			31 … 16	15 … 1	0
0	`mutex0`	RW	`OWNER`	`VALUE`	
1	`reset0`	RW	Reserved		`RESET`
2	`mutex1`	RW	`OWNER`	`VALUE`	
3	`reset1`	RW	Reserved		`RESET`

The mailbox component contains two mutexes: One to ensure unique write access to shared memory and one to ensure unique read access from shared memory. The mailbox core is used in conjunction with a separate memory in the system that is shared among multiple processors.

Mailbox functionality using the mutexes and memory is implemented entirely in the software. Refer to "Software Programming Model" on page 27–3 for details about how to use the mailbox core in software.

For a detailed description of the mutex hardware operation, refer to the *Mutex Core* chapter in volume 5 of the *Quartus II Handbook*.

Device Support

The mailbox core supports all Altera® device families.

Instantiating the Core in SOPC Builder

You can instantiate and configure the mailbox core in an SOPC Builder system using the following process:

1. Decide which processors share the mailbox.
2. On the SOPC Builder **System Contents** tab, instantiate a memory component to serve as the mailbox buffer. Any RAM can be used as the mailbox buffer. The mailbox buffer can share space in an existing memory, such as program memory; it does not require a dedicated memory.
3. On the SOPC Builder **System Contents** tab, instantiate the mailbox component. The mailbox MegaWizard™ Interface presents the following options:
   - **Memory module**—Specifies which memory to use for the mailbox buffer. If the **Memory module** list does not contain the desired shared memory, the memory is not connected in the system correctly. Refer to Step 4 on page 27–2.
   - **CPUs available with this memory**—Shows all the processors that can share the mailbox. This field is always read-only. Use it to verify that the processor connections are correct. If a processor that needs to share the mailbox is missing from the list, refer to Step 4 on page 27–2.
   - **Shared mailbox memory offset**—Specifies an offset into the memory. The mailbox message buffer starts at this offset.
   - **Mailbox size (bytes)**—Specifies the number of bytes to use for the mailbox message buffer. The Nios II driver software provided by Altera uses eight bytes of overhead to implement the mailbox functionality. For a mailbox capable of passing only one message at a time, **Mailbox size (bytes)** must be at least 12 bytes.
   - **Maximum available bytes**—Specifies the number of bytes in the selected memory available for use as the mailbox message buffer. This field is always read-only.
4. If not already connected, make component connections on the SOPC Builder **System Contents** tab.
   a. Connect each processor’s data bus master port to the mailbox slave port.
   b. Connect each processor’s data bus master port to the shared mailbox memory.

Software Programming Model

The following sections describe the software programming model for the mailbox core. For Nios II processor users, Altera provides routines to access the mailbox core hardware. These functions are specific to the mailbox core and directly manipulate low-level hardware.

The mailbox software programming model has the following characteristics and assumes there are multiple processors accessing a single mailbox core and a shared memory:

- Each mailbox message is one 32-bit word.
- There is a predefined address range in shared memory dedicated to storing messages. The size of this address range imposes a maximum limit on the number of messages pending.
- The mailbox software implements a message FIFO between processors. Only one processor can write to the mailbox at a time, and only one processor can read from the mailbox at a time, ensuring message integrity.
- The software on both the sending and receiving processors must agree on a protocol for interpreting mailbox messages. Typically, processors treat the message as a pointer to a structure in shared memory.
- The sending processor can post messages in succession, up to the limit imposed by the size of the message address range.
- When messages exist in the mailbox, the receiving processor can read messages. The receiving processor can block until a message appears, or it can poll the mailbox for new messages.
- Reading the message removes the message from the mailbox.

Software Files

Altera provides the following software files accompanying the mailbox core hardware:

- **altera_avalon_mailbox_regs.h**—Defines the core's register map, providing symbolic constants to access the low-level hardware.
- **altera_avalon_mailbox.h**—Defines data structures and functions to access the mailbox core hardware.
- **altera_avalon_mailbox.c**—Contains the implementations of the functions to access the mailbox core.

Programming with the Mailbox Core

This section describes the software constructs for manipulating the mailbox core hardware.

The file **altera_avalon_mailbox.h** declares a structure `alt_mailbox_dev` that represents an instance of a mailbox device. It also declares functions for accessing the mailbox hardware structure, listed in Table 27–2. For a complete description of each function, refer to "Mailbox API" on page 27–5.

Table 27–2. Mailbox API Functions

Function Name	Description
altera_avalon_mailbox_close()	Closes the handle to a mailbox.
altera_avalon_mailbox_get()	Returns a message if one is present, but does not block waiting for a message.
altera_avalon_mailbox_open()	Claims a handle to a mailbox, enabling all the other functions to access the mailbox core.
altera_avalon_mailbox_pend()	Blocks waiting for a message to be in the mailbox.
altera_avalon_mailbox_post()	Posts a message to the mailbox.

Example 27–1 demonstrates writing to and reading from a mailbox. For this example, assume that the hardware system has two processors communicating via mailboxes. The system includes two mailbox cores, which provide two-way communication between the processors.

Example 27–1. Writing to and Reading from a Mailbox

```
#include <stdio.h>
#include "altera_avalon_mailbox.h"

int main()
{
  alt_u32 message = 0;
  alt_mailbox_dev* send_dev, recv_dev;
  /* Open the two mailboxes between this processor and another */
  send_dev = altera_avalon_mailbox_open("/dev/mailbox_0");
  recv_dev = altera_avalon_mailbox_open("/dev/mailbox_1");

  while(1)
  {
    /* Send a message to the other processor */
    altera_avalon_mailbox_post(send_dev, message);

    /* Wait for the other processor to send a message back */
    message = altera_avalon_mailbox_pend(recv_dev);
  }
  return 0;
}
```

Mailbox API

This section describes the application programming interface (API) for the mailbox core.

altera_avalon_mailbox_close()

Prototype:	`void altera_avalon_mailbox_close (alt_mailbox_dev* dev);`
Thread-safe:	Yes.
Available from ISR:	No.
Include:	<**altera_avalon_mailbox.h**>
Parameters:	`dev`—the mailbox to close.
Returns:	Null.
Description:	`altera_avalon_mailbox_close()` closes the mailbox.

altera_avalon_mailbox_get()

Prototype:	`alt_u32 altera_avalon_mailbox_get (alt_mailbox_dev* dev, int* err);`
Thread-safe:	Yes.
Available from ISR:	No.
Include:	<**altera_avalon_mailbox.h**>
Parameters:	`dev`—the mailbox handle. `err`—pointer to an error code that is returned.
Returns:	Returns a message if one is available in the mailbox, otherwise returns 0. The value pointed to by `err` is 0 if the message was read correctly, or `EWOULDBLOCK` if there is no message to read.
Description:	`altera_avalon_mailbox_get()` returns a message if one is present, but does not block waiting for a message.

altera_avalon_mailbox_open()

Prototype:	`alt_mailbox_dev* altera_avalon_mailbox_open (const char* name);`
Thread-safe:	Yes.
Available from ISR:	No.
Include:	<**altera_avalon_mailbox.h**>
Parameters:	`name`—the name of the mailbox device to open.
Returns:	Returns a handle to the mailbox, or NULL if this mailbox does not exist.
Description:	`altera_avalon_mailbox_open()` opens a mailbox.

altera_avalon_mailbox_pend()

Prototype:	`alt_u32 altera_avalon_mailbox_pend (alt_mailbox_dev* dev);`
Thread-safe:	Yes.
Available from ISR:	No.
Include:	<**altera_avalon_mailbox.h**>
Parameters:	`dev`—the mailbox device to read a message from.
Returns:	Returns the message.
Description:	`altera_avalon_mailbox_pend()` is a blocking routine that waits for a message to appear in the mailbox and then reads it.

altera_avalon_mailbox_post()

Prototype:	`int altera_avalon_mailbox_post (alt_mailbox_dev* dev, alt_u32 msg);`
Thread-safe:	Yes.
Available from ISR:	No.
Include:	<**altera_avalon_mailbox.h**>
Parameters:	`dev`—the mailbox device to post a message to. `msg`—the value to post.
Returns:	Returns 0 on success, or `EWOULDBLOCK` if the mailbox is full.
Description:	`altera_avalon_mailbox_post()` posts a message to the mailbox.

Section V. Test and Debug Peripherals

This section describes test and debug peripherals provided by Altera for SOPC Builder systems.

This section includes the following chapters:

- Chapter 28, Cyclone III Remote Update Controller Core
- Chapter 29, Performance Counter Core
- Chapter 30, Avalon Streaming Test Pattern Generator and Checker Cores

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

28. Cyclone III Remote Update Controller Core

QII55017-9.0.0

Core Overview

The Cyclone® III Remote Update Controller core provides a method to control the Cyclone III remote update block from SOPC Builder systems. The core allows you to access all features of the ALTREMOTE_UPDATE megafunction through a simple Avalon® Memory-Mapped (Avalon-MM) slave interface. The slave interface allows Avalon-MM master peripherals, such as a Nios® II processor, to communicate with the core simply by reading and writing the registers.

The Cyclone III Remote Update Controller core is a thin Avalon interface layer on top of the ALTREMOTE_UPDATE megafunction. Every function of the core maps directly to a function of the megafunction. Altera recommends that you familiarize yourself with the ALTREMOTE_UPDATE megafunction before using the core.

For more information about the ALTREMOTE_UPDATE megafunction, refer to the *altremote_update Megafunction User Guide*. For more information about remote system upgrade in Cyclone III devices, refer to the *Remote System Upgrade With Cyclone III Devices* chapter in volume 1 of the *Cyclone III Device Handbook*.

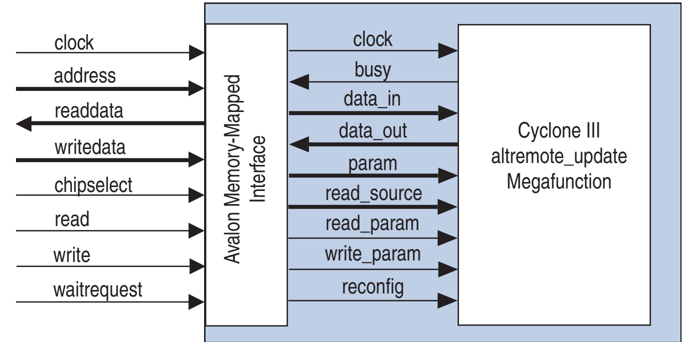
The Cyclone III Remote Update Controller core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- "Functional Description"
- "Device Support" on page 28–2
- "Instantiating the Core in SOPC Builder" on page 28–2

Functional Description

Figure 28–1 shows a block diagram of the Cyclone III Remote Update Controller core.

Figure 28–1. Cyclone III Remote Update Controller Core Block Diagram



Avalon-MM Slave Interface and Registers

The `address` bus on the core's Avalon-MM interface is 6 bits wide. The lower three bits of the `address` bus map directly to the `param` signal of the ALTREMOTE_UPDATE megafunction whereas the upper three bits map to the `read_source` signal.

Reading or writing to address offsets 0x00 – 0x1F of the Cyclone III Remote Update Controller core is equivalent to performing read or write operations to the ALTREMOTE_UPDATE megafunction using the `param` and `read_source` signals.

Table 28–1 shows the mapping of the 5 lowest order Remote Update Controller address bits to the ALTREMOTE_UPDATE megafunction signals.

Table 28–1. Avalon-MM Address Bits to Megafunction Signals Mapping

Address Bit	Megafunction Signal
address[0]	param[0]
address[1]	param[1]
address[2]	param[2]
address[3]	read_source[0]
address[4]	read_source[1]

The highest order address bit [5] is used to access a single `control/status` register. Reading or writing any address offset from 0x20 – 0x3F accesses the `control/status` register.

Table 28–2 shows the bit map of the `control/status` register.

Table 28–2. Bit Map of Control/Status Register

Bit(s)	Field	Access	Description
0	RECONFIG	RW	Set this bit to 1 to reset the FPGA and trigger reconfiguration.
1	RESET_TIMER	RW	Set this bit to 1 to reset the watchdog timer. Then, set this bit to 0 to allow the watchdog timer to continue.
2..31	Reserved		

Device Support

The Cyclone III Remote Update Controller core can only target Cyclone III device family. Both CFI flash and EPCS configuration devices are supported as non-volatile storage for configuration images.

Instantiating the Core in SOPC Builder

The Cyclone III Remote Update Controller core has no user-configurable parameters.

Software Programming Model

Software programs can operate the Cyclone III Remote Update Controller core by reading from and writing to the core's registers.

You can only reconfigure the FPGA to an application image from the factory image. Any attempt to reconfigure from an already reconfigured application image causes the FPGA to return to the factory image.

This section describes the most common types of operations using the Cyclone III Remote Update Controller core.

Setting the Configuration Offset

Before you reconfigure the FPGA, you must first specify the offset within the memory device from which you want to execute a reconfiguration. The offset is the relative address within the memory device where the configuration image is located. Write the offset value to address 0x04 of the core to set the configuration offset.

For example, if your system contains a CFI flash memory mapped at address 0x04000000, and the configuration image is located at address 0x100000 in the flash memory, the offset to set in the Cyclone III Remote Update Controller core is 0x100000.

Shifting the Configuration Offset Value

The ALTREMOTE_UPDATE megafunction requires that you provide only the 22 highest-order bits of a 24-bit address offset. To translate the address, right shift the offset by two bits. This results in a properly oriented 22-bit address offset.

If you are using a CFI flash device, you must also take into account the data width of the flash. If the data width of your flash device is 16 bits, you must provide a 16-bit address offset to the Cyclone III Remote Update Controller core. This requires an additional 1-bit right shift of the byte address offset. No translation is necessary if the data width of your flash is 8 bits.

If you are using an EPCS serial configuration device, consider the data width of the device to be 8 bits. Even though the EPCS device is a serial device, it uses byte addressing internally.

For example, an FPGA is set up to configure itself using active parallel mode from a 16-bit CFI flash memory mapped at address 0x04000000 in an SOPC Builder system, and the configuration image is located at byte offset 0x100000 within the flash memory. To derive the correct configuration offset, you must first right shift the byte offset 0x100000 by one bit to obtain the 16-bit address. Then, right shift by another two bits to obtain the highest 22 bits of the 24-bit offset. The result is a configuration offset of 0x20000 (0x100000 >> 3 = 0x20000), to be written to address 0x04 of the core.

Setting up the Watchdog Timer

You can set up the watchdog timer by writing the upper 12 bits of the 29-bit timeout value to address 0x02 of the core. To reset the watchdog timer, set the `RESET_TIMER` bit of the `control/status` register to 1 and immediately set the bit to 0.

Ensure that you don't accidentally set bit 0 of the `control/status` register to 1. Otherwise, you will trigger a reconfiguration of the FPGA.

For more information on watchdog timer, refer to the *ALTREMOTE_UPDATE Megafunction User Guide*.

If you do not use the watchdog timer feature of the ALTREMOTE_UPDATE megafunction, it must be disabled before a reconfiguration is performed. To disable the watchdog timer, write `0x00` to address 0x03 of the core.

Triggering a Reconfiguration

You can trigger a reconfiguration once you have set the reconfiguration offset in the Cyclone III Remote Update Controller core, and you have either setup or disabled the watchdog timer. To trigger a reconfiguration, set the `RECONFIG` bit in the `control/status` register to 1. Consequently, the FPGA performs a reset and reconfigures itself from the configuration image specified.

Code Example

Example 28–1 shows a C function that can be used to operate the Cyclone III Remote Update Controller core from a processor such as Nios II.

Example 28–1. FPGA Reconfiguration Function

```
/*******************************************************************************
 * Function: CycloneIII_Reconfig
 * Purpose: Uses the ALT_REMOTE_UPDATE megafunction to reconfigure a Cyclone III FPGA.
 * Parameters:
 *    remote_update_base -  base address of the remote update controller
 *    flash_base         -  base address of flash device
 *    reconfig_offset    -  offset in flash from which to reconfigure
 *    watchdog_timeout   -  29-bit watchdog timeout value
 *    width_of_flash     -  data-width of flash device
 * Returns: 0 ( but never exits since it reconfigures the FPGA )
 ****************************************************************************/
int CycloneIII_Reconfig( int remote_update_base,
                         int flash_base,
                         int reconfig_offset,
                         int watchdog_timeout,
                         int width_of_flash )
{int offset_shift;

  // Obtain upper 12 bits of 29-bit watchdog timeout value
  watchdog_timeout = watchdog_timeout >> 17;

  // Only enable the watchdog timer if its timeout value is greater than 0.
  if( watchdog_timeout > 0 )
  {
    // Set the watchdog timeout value
    IOWR( remote_update_base, 0x2, watchdog_timeout );
  }
  else
  {
   // Disable the watchdog timer
   IOWR( remote_update_base, 0x3, 0 );
  }

  // Calculate how much to shift the reconfig offset location:
  //  width_of_flash == 8->offset_shift = 2.
  //  width_of_flash == 16->offset_shift = 3
  offset_shift = (( width_of_flash / 8 ) + 1 );

  // Write the offset of the desired reconfiguration image in flash
  IOWR( remote_update_base, 0x4, reconfig_offset >> offset_shift );

  // Perform the reconfiguration by setting bit 0 in the
  // control/status register
  IOWR( remote_update_base, 0x20, 0x1 );

  return( 0 );
}
```

29. Performance Counter Core

QII55001-9.0.0

Core Overview

The performance counter core with Avalon® interface enables relatively unobtrusive, real-time profiling of software programs. With the performance counter, you can accurately measure execution time taken by multiple sections of code. You need only add a single instruction at the beginning and end of each section to be measured.

The main benefit of using the performance counter core is the accuracy of the profiling results. Alternatives include the following approaches:

- GNU profiler, `gprof`—`gprof` provides broad low-precision timing information about the entire software system. It uses a substantial amount of RAM, and degrades the real-time performance. For many embedded applications, `gprof` distorts real-time behavior too much to be useful.
- Interval timer peripheral—The interval timer is less intrusive than `gprof`. It can provide good results for narrowly targeted sections of code.

The performance counter core is unobtrusive, requiring only a single instruction to start and stop profiling, and no RAM. It is appropriate for high-precision measurements of narrowly targeted sections of code.

For further discussion of all three profiling methods, refer to *AN 391: Profiling Nios II Systems*.

The performance counter core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. The core is designed for use in Avalon-based processor systems, such as a Nios® II processor system. Altera® device drivers enable the Nios II processor to use the performance counters.

This chapter contains the following sections:

- "Functional Description" on page 29–2
- "Device and Tools Support" on page 29–3
- "Instantiating the Core in SOPC Builder" on page 29–3
- "Hardware Simulation Considerations" on page 29–4
- "Software Programming Model" on page 29–4
- "Performance Counter API" on page 29–6

Functional Description

The performance counter core is a set of counters which track clock cycles, timing multiple sections of your software. You can start and stop these counters in your software, individually or as a group. You can read cycle counts from hardware registers.

The core contains two counters for every section:

- Time: A 64-bit clock cycle counter.
- Events: A 32-bit event counter.

Section Counters

Each 64-bit time counter records the aggregate number of clock cycles spent in a section of code. The 32-bit event counter records the number of times the section executes.

The performance counter core can have up to seven section counters.

Global Counter

The global counter controls all section counters. The section counters are enabled only when the global counter is running.

The 64-bit global clock cycle counter tracks the aggregate time for which the counters were enabled. The 32-bit global event counter tracks the number of global events, that is, the number of times the performance counter core has been enabled.

Register Map

The performance counter core has a simple Avalon Memory-Mapped (Avalon-MM) slave interface that provides access to memory-mapped registers. Reading from the registers retrieves the current times and event counts. Writing to the registers starts, stops and resets the counters. Table 29–1 shows the registers in detail.

Table 29–1. Performance Counter Core Register Map (Part 1 of 2)

Offset	Register Name	Bit Description

4*n* + 0	$T[n]_{lo}$	section *n* clock cycle counter [31:0]	*(1)*	0 = STOP
4*n* + 1	$T[n]_{hi}$	section *n* clock cycle counter [63:32]	*(1)*	0 = START
4*n* + 2	`Ev[n]`	section *n* event counter	*(1)*	*(1)*
4*n* + 3	—	*(1)*	*(1)*	*(1)*

Note to Table 29–1:

(1) Reserved. Read values are undefined. When writing, set reserved bits to zero.

System Reset Considerations

After system reset, the performance counter core is stopped and disabled, and all counters contain zero.

Device and Tools Support

The performance counter core supports all Altera device families supported by SOPC Builder, and provides device drivers for the Nios II hardware abstraction layer (HAL) system library.

Instantiating the Core in SOPC Builder

Use the MegaWizard™ interface for the performance counter core in SOPC Builder to specify the core's hardware features.

Define Counters

Choose the number of section counters you want to generate by selecting from the **Number of simultaneously-measured sections** list. The performance counter core may have up to seven sections. If you require more that seven sections, you can instantiate multiple performance counter cores.

Multiple Clock Domain Considerations

If your SOPC Builder system uses multiple clocks, place the performance counter core in the same clock domain as the CPU. Otherwise, it is not possible to convert cycle counts to seconds correctly.

Hardware Simulation Considerations

You can use this core in simulation with no special considerations.

Software Programming Model

The following sections describe the software programming model for the performance counter core.

Software Files

Altera provides the following software files for Nios II systems. These files define the low-level access to the hardware and provide control and reporting functions. Do not modify these files.

- **altera_avalon_performance_counter.h, altera_avalon_performance_counter.c**—The header and source code for the functions and macros needed to control the performance counter core and retrieve raw results.
- **perf_print_formatted_report.c**—The source code for simple profile reporting.

Using the Performance Counter

In a Nios II system, you can control the performance counter core with a set of highly efficient C macros, and extract the results with C functions.

API Summary

The Nios II application program interface (API) for the performance counter core consists of functions, macros and constants.

Functions and macros

Table 29–2 lists macros and functions for accessing the performance counter hardware structure.

Table 29–2. Performance Counter Macros and Functions

Name	Summary
`PERF_RESET()`	Stops and disables all counters, resetting them to 0.
`PERF_START_MEASURING()`	Starts the global counter and enables section counters.
`PERF_STOP_MEASURING()`	Stops the global counter and disables section counters.
`PERF_BEGIN()`	Starts timing a code section.
`PERF_END()`	Stops timing a code section.
`perf_print_formatted_report()`	Sends a formatted summary of the profiling results to `stdout`.
`perf_get_total_time()`	Returns the aggregate global profiling time in clock cycles.
`perf_get_section_time()`	Returns the aggregate time for one section in clock cycles.
`perf_get_num_starts()`	Returns the number of counter events.
`alt_get_cpu_freq()`	Returns the CPU frequency in Hz.

For a complete description of each macro and function, see "Performance Counter API" on page 29–6.

 © March 2009 Altera Corporation

Hardware Constants

You can get the performance counter hardware parameters from constants defined in **system.h**. The constant names are based on the performance counter instance name, specified on the **System Contents** tab in SOPC Builder. Table 29–3 lists the hardware constants.

Table 29–3. Performance Counter Constants

Name *(1)*	Meaning
PERFORMANCE_COUNTER_BASE	Base address of core
PERFORMANCE_COUNTER_SPAN	Number of hardware registers
PERFORMANCE_COUNTER_HOW_MANY_SECTIONS	Number of section counters

Note to Table 29–3:

(1) Example based on instance name `performance_counter`.

Startup

Before using the performance counter core, invoke `PERF_RESET` to stop, disable and zero all counters.

Global Counter Usage

Use the global counter to enable and disable the entire performance counter core. For example, you might choose to leave profiling disabled until your software has completed its initialization.

Section Counter Usage

To measure a section in your code, surround it with the macros `PERF_BEGIN()` and `PERF_END()`. These macros consist of a single write to the performance counter core.

You can simultaneously measure as many code sections as you like, up to the number specified in SOPC Builder. See “Define Counters” on page 29–3 for details. You can start and stop counters individually, or as a group.

Typically, you assign one counter to each section of code you intend to profile. However, in some situations you may wish to group several sections of code in a single section counter. As an example, to measure general interrupt overhead, you can measure all interrupt service routines (ISRs) with one counter.

To avoid confusion, assign a mnemonic symbol for each section number.

Viewing Counter Values

Library routines allow you to retrieve and analyze the results. Use `perf_print_formatted_report()` to list the results to `stdout`, as shown in Example 29–1.

Example 29–1.

```
perf_print_formatted_report(
     (void *)PERFORMANCE_COUNTER_BASE, // Peripheral's HW base address
     alt_get_cpu_freq(),               // defined in "system.h"
     3,                                // How many sections to print
     "1st checksum_test",              // Display-names of sections
     "pc_overhead",
     "ts_overhead");
```

Example 29–2 creates a table similar to this result.

Example 29–2.

```
--Performance Counter Report--
Total Time: 2.07711 seconds (103855534 clock-cycles)
+-----------------+--------+-----------+--------------+-----------+
| Section         |    %   | Time (sec)| Time (clocks) |Occurrences|
+-----------------+--------+-----------+--------------+-----------+
|1st checksum_test|     50 |   1.03800 |      51899750 |         1 |
+-----------------+--------+-----------+--------------+-----------+
| pc_overhead     |1.73e-05|   0.00000 |            18 |         1 |
+-----------------+--------+-----------+--------------+-----------+
| ts_overhead     |4.24e-05|   0.00000 |            44 |         1 |
+-----------------+--------+-----------+--------------+-----------+
```

For full documentation of `perf_print_formatted_report()`, see "Performance Counter API" on page 29–6.

Interrupt Behavior

The performance counter core does not generate interrupts.

You can start and stop performance counters, and read raw performance results, in an interrupt service routine (ISR). Do not call the `perf_print_formatted_report()` function from an ISR.

If an interrupt occurs during the measurement of a section of code, the time taken by the CPU to process the interrupt and return to the section is added to the measurement time. The same applies to context switches in a multithreaded environment. Your software must take appropriate measures to avoid or handle these situations.

Performance Counter API

This section describes the application programming interface (API) for the performance counter core.

For Nios II processor users, Altera provides routines to access the performance counter core hardware. These functions are specific to the performance counter core and directly manipulate low level hardware. The performance counter core cannot be accessed via the HAL API or the ANSI C standard library.

PERF_RESET()

Prototype:	`PERF_RESET(p)`
Thread-safe:	Yes.
Available from ISR:	Yes.
Include:	**<altera_avalon_performance_counter.h>**
Parameters:	`p`—performance counter core base address.
Returns:	—
Description:	Macro `PERF_RESET()` stops and disables all counters, resetting them to 0.

PERF_START_MEASURING()

Prototype:	`PERF_START_MEASURING(p)`
Thread-safe:	Yes.
Available from ISR:	Yes.
Include:	**<altera_avalon_performance_counter.h>**
Parameters:	`p`—performance counter core base address.
Returns:	—
Description:	Macro `PERF_START_MEASURING()` starts the global counter, enabling the performance counter core. The behavior of individual section counters is controlled by `PERF_BEGIN()` and `PERF_END()`. `PERF_START_MEASURING()` defines the start of a global event, and increments the global event counter. This macro is a single write to the performance counter core.

PERF_STOP_MEASURING()

Prototype:	`PERF_STOP_MEASURING(p)`
Thread-safe:	Yes.
Available from ISR:	Yes.
Include:	**<altera_avalon_performance_counter.h>**
Parameters:	`p`—performance counter core base address.
Returns:	—
Description:	Macro `PERF_STOP_MEASURING()` stops the global counter, disabling the performance counter core. This macro is a single write to the performance counter core.

PERF_BEGIN()

Prototype:	`PERF_BEGIN(p,n)`
Thread-safe:	Yes.
Available from ISR:	Yes.
Include:	**<altera_avalon_performance_counter.h>**
Parameters:	`p`—performance counter core base address. `n`—counter section number. Section counter numbers start at 1. Do not refer to counter 0 in this macro.

Returns: —

Description: Macro PERF_BEGIN() starts the timer for a code section, defining the beginning of a section event, and incrementing the section event counter. If you subsequently use PERF_STOP_MEASURING() and PERF_START_MEASURING() to disable and re-enable the core, the section counter will resume. This macro is a single write to the performance counter core.

PERF_END()

Prototype: PERF_END(p,n)

Thread-safe: Yes.

Available from ISR: Yes.

Include: **<altera_avalon_performance_counter.h>**

Parameters: p—performance counter core base address.

n—counter section number. Section counter numbers start at 1. Do not refer to counter 0 in this macro.

Returns: —

Description: Macro PERF_END() stops timing a code section. The section counter does not run, regardless whether the core is enabled or not. This macro is a single write to the performance counter core.

perf_print_formatted_report()

Prototype:
```
int perf_print_formatted_report (
    void* perf_base,
    alt_u32 clock_freq_hertz,
    int num_sections,
    char* section_name_1, ...
    char* section_name_n)
```

Thread-safe: No.

Available from ISR: No.

Include: **<altera_avalon_performance_counter.h>**

Parameters: `perf_base`—Performance counter core base address.

`clock_freq_hertz`—Clock frequency.

`num_sections`—The number of section counters to display. This must not exceed *<instance_name>*_HOW_MANY_SECTIONS.

`section_name_1 ... section_name_n`—The section names to display. The number of section names varies depending on the number of sections to display.

Returns: 0

Description: Function `perf_print_formatted_report()` reads the profiling results from the performance counter core, and prints a formatted summary table.

This function disables all counters. However, for predictable results in a multi-threaded or interrupt environment, invoke `PERF_STOP_MEASURING()` when you reach the end of the code to be measured, rather than relying on `perf_print_formatted_report()`.

This function requires the C standard library. Do not use the small C library with this function.

perf_get_total_time()

Prototype: `alt_u64 perf_get_total_time(void* hw_base_address)`

Thread-safe: No.

Available from ISR: Yes.

Include: **<altera_avalon_performance_counter.h>**

Parameters: `hw_base_address`—base address of performance counter core.

Returns: Aggregate global time in clock cycles.

Description: Function `perf_get_total_time()` reads the raw global time. This is the aggregate time, in clock cycles, that the performance counter core has been enabled. This function has the side effect of stopping the counters.

perf_get_section_time()

Prototype: `alt_u64 perf_get_section_time (void* hw_base_address, int which_section)`

Thread-safe: No.

Available from ISR: Yes.

Include: **<altera_avalon_performance_counter.h>**

Parameters: `hw_base_address`—performance counter core base address.
`which_section`—counter section number.

Returns: Aggregate section time in clock cycles.

Description: Function `perf_get_section_time()` reads the raw time for a given section. This is the time, in clock cycles, that the section has been running. This function has the side effect of stopping the counters.

perf_get_num_starts()

Prototype: `alt_u32 perf_get_num_starts (void* hw_base_address, int which_section)`

Thread-safe: Yes.

Available from ISR: Yes.

Include: **<altera_avalon_performance_counter.h>**

Parameters: `hw_base_address`—performance counter core base address.
`which_section`—counter section number.

Returns: Number of counter events.

Description: Function `perf_get_num_starts()` retrieves the number of counter events (or times a counter has been started). If `which_section` = 0, it retrieves the number of global events (times the performance counter core has been enabled). This function does not stop the counters.

alt_get_cpu_freq()

Prototype: `alt_u32 alt_get_cpu_freq()`

Thread-safe: Yes.

Available from ISR: Yes.

Include: **<altera_avalon_performance_counter.h>**

Parameters:

Returns: CPU frequency in Hz.

Description: Function `alt_get_cpu_freq()` returns the CPU frequency in Hz.

30. Avalon Streaming Test Pattern Generator and Checker Cores

QII55007-9.0.0

Core Overview

The data generation and monitoring solution for Avalon® Streaming (Avalon-ST) consists of two components: a test pattern generator core that generates packetized or non-packetized data and sends it out on an Avalon-ST data interface, and a test pattern checker core that receives the same data and checks it for correctness.

The test pattern generator core can insert different error conditions, and the test pattern checker reports these error conditions to the control interface, each via an Avalon Memory-Mapped (Avalon-MM) slave.

Both cores are SOPC Builder-ready and integrate easily into any SOPC Builder-generated system.

This chapter contains the following sections:

- "Resource Utilization and Performance"
- "Test Pattern Generator" on page 30–3
- "Test Pattern Checker" on page 30–5
- "Device Support" on page 30–6
- "Hardware Simulation Considerations" on page 30–6
- "Software Programming Model" on page 30–7
- "Test Pattern Generator API" on page 30–12
- "Test Pattern Checker API" on page 30–16

Resource Utilization and Performance

Resource utilization and performance for the test pattern generator and checker cores depend on the data width, number of channels, and whether the streaming data uses the optional packet protocol.

Table 30–1 provides estimated resource utilization and performance for the test pattern generator core.

Table 30–1. Test Pattern Generator Estimated Resource Utilization and Performance

No. of Channels	Datawidth (No. of 8-bit Symbols Per Beat)	Packet Support	Stratix® II and Stratix II GX			Cyclone® II			Stratix

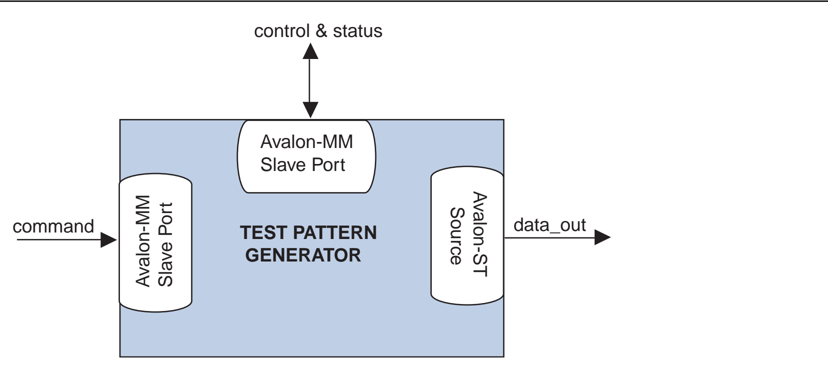
Test Pattern Generator

This section describes the hardware structure and functionality of the test pattern generator core.

Functional Description

The test pattern generator core accepts commands to generate data via an Avalon-MM command interface, and drives the generated data to an Avalon-ST data interface. You can parameterize most aspects of the Avalon-ST data interface such as the number of error bits and data signal width, thus allowing you to test components with different interfaces. Figure 30–1 shows a block diagram of the test pattern generator core.

Figure 30–1. Test Pattern Generator Core Block Diagram



The data pattern is determined by the following equation:
Symbol Value = Symbol Position in Packet XOR Data Error Mask. Non-packetized data is one long stream with no beginning or end.

The test pattern generator core has a throttle register that is set via the Avalon-MM control interface. The value of the throttle register is used in conjunction with a pseudo-random number generator to throttle the data generation rate.

Command Interface

The command interface is a 32-bit Avalon-MM write slave that accepts data generation commands. It is connected to a 16-element deep FIFO, thus allowing a master peripheral to drive a number of commands into the test pattern generator core.

The command interface maps to the following registers: `cmd_lo` and `cmd_hi`. The command is pushed into the FIFO when the register `cmd_lo` (address 0) is written to. When the FIFO is full, the command interface asserts the `waitrequest` signal. You can create errors by writing to the register `cmd_hi` (address 1). The errors are only cleared when 0 is written to this register or its respective fields. See page "Test Pattern Generator Command Registers" on page 30–9 for more information on the register fields.

Control and Status Interface

The control and status interface is a 32-bit Avalon-MM slave that allows you to enable or disable the data generation as well as set the throttle.

This interface also provides useful generation-time information such as the number of channels and whether or not packets are supported.

Output Interface

The output interface is an Avalon-ST interface that optionally supports packets. You can configure the output interface to suit your requirements.

Depending on the incoming stream of commands, the output data may contain interleaved packet fragments for different channels. To keep track of the current symbol's position within each packet, the test pattern generator core maintains an internal state for each channel.

Instantiating the Test Pattern Generator in SOPC Builder

Use the MegaWizard™ interface for the test pattern generator core in SOPC Builder to configure the core. The following sections list the available options in the MegaWizard interface.

Functional Parameter

The functional parameter allows you to configure the test pattern generator as a whole: **Throttle Seed**—The starting value for the throttle control random number generator. Altera recommends a value which is unique to each instance of the test pattern generator and checker cores in a system.

Output Interface

You can configure the output interface of the test pattern generator core using the following parameters:

- **Number of Channels**—The number of channels that the test pattern generator core supports. Valid values are 1 to 256.
- **Data Bits Per Symbol**—The number of bits per symbol for the input and output interfaces. Valid values are 1 to 256. Example—For typical systems that carry 8-bit bytes, set this parameter to 8.
- **Data Symbols Per Beat**—The number of symbols (words) that are transferred per beat. Valid values are 1 to 256.
- **Include Packet Support**—Indicates whether or not packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.
- **Error Signal Width (bits)**—The width of the `error` signal on the output interface. Valid values are 0 to 31. A value of 0 indicates that the `error` signal is not used.

Test Pattern Checker

This section describes the hardware structure and functionality of the test pattern checker core.

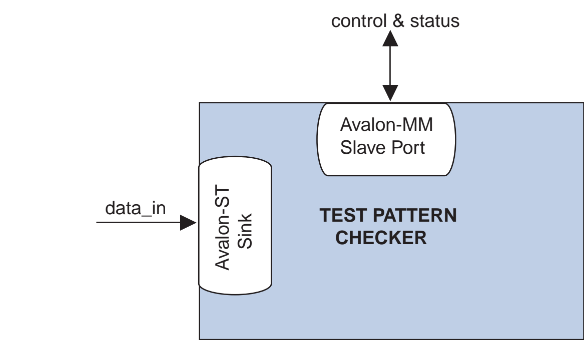
Functional Description

The test pattern checker core accepts data via an Avalon-ST interface, checks it for correctness against the same predetermined pattern used by the test pattern generator core to produce the data, and reports any exceptions to the control interface. You can parameterize most aspects of the test pattern checker's Avalon-ST interface such as the number of error bits and the data signal width, thus allowing you to test components with different interfaces.

The test pattern checker has a throttle register that is set via the Avalon-MM control interface. The value of the throttle register controls the rate at which data is accepted.

Figure 30–2 shows a block diagram of the test pattern checker core.

Figure 30–2. Test Pattern Checker



The test pattern checker core detects exceptions and reports them to the control interface via a 32-element deep internal FIFO. Possible exceptions are data error, missing start-of-packet (SOP), missing end-of-packet (EOP) and signalled error.

As each exception occurs, an exception descriptor is pushed into the FIFO. If the same exception occurs more than once consecutively, only one exception descriptor is pushed into the FIFO. All exceptions are ignored when the FIFO is full. Exception descriptors are deleted from the FIFO after they are read by the control and status interface.

Input Interface

The input interface is an Avalon-ST interface that optionally supports packets. You can configure the input interface to suit your requirements.

Incoming data may contain interleaved packet fragments. To keep track of the current symbol's position, the test pattern checker core maintains an internal state for each channel.

Control and Status Interface

The control and status interface is a 32-bit Avalon-MM slave that allows you to enable or disable data acceptance as well as set the throttle. This interface provides useful generation-time information such as the number of channels and whether the test pattern checker supports packets.

The control and status interface also provides information on the exceptions detected by the test pattern checker core. The interface obtains this information by reading from the exception FIFO.

Instantiating the Test Pattern Checker in SOPC Builder

Use the MegaWizard interface for the test pattern checker core in SOPC Builder to configure the core. The following sections list the available options in the MegaWizard interface.

Functional Parameter

The functional parameter allows you to configure the test pattern checker as a whole: **Throttle Seed**—The starting value for the throttle control random number generator. Altera recommends a unique value to each instance of the test pattern generator and checker cores in a system.

Input Parameters

You can configure the input interface of the test pattern checker core using the following parameters:

- **Data Bits Per Symbol**—The number of bits per symbol for the input interface. Valid values are 1 to 256.
- **Data Symbols Per Beat**—The number of symbols (words) that are transferred per beat. Valid values are 1 to 32.
- **Include Packet Support**—Indicates whether or not packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.
- **Number of Channels**—The number of channels that the test pattern checker core supports. Valid values are 1 to 256.
- **Error Signal Width (bits)**—The width of the `error` signal on the input interface. Valid values are 0 to 31. A value of 0 indicates that the `error` signal is not in use.

Device Support

The test pattern generator and checker cores support all Altera© device families.

Hardware Simulation Considerations

The test pattern generator and checker cores do not provide a simulation testbench for simulating a stand-alone instance of the component. However, you can use the standard SOPC Builder simulation flow to simulate the component design files inside an SOPC Builder system.

Software Programming Model

This section describes the software programming model for the test pattern generator and checker cores.

HAL System Library Support

For Nios II processor users, Altera provides HAL system library drivers that enable you to initialize and access the test pattern generator and checker cores. Altera recommends you to use the provided drivers to access the cores instead of accessing the registers directly.

For Nios II IDE users, copy the provided drivers from the following installation folders to your software application directory:

- *<IP installation directory>* **/ip /sopc_builder_ip /altera_avalon_data_source/HAL**
- *<IP installation directory>***/ip/sopc_builder_ip/ altera_avalon_data_sink/HAL**

This instruction does not apply if you use the Nios II command-line tools.

Software Files

The following software files define the low-level access to the hardware, and provide the routines for the HAL device drivers. Application developers should not modify these files.

- Software files provided with the test pattern generator core:
  - **data_source_regs.h**—The header file that defines the test pattern generator's register maps.
  - **data_source_util.h, data_source_util.c**—The header and source code for the functions and variables required to integrate the driver into the HAL system library.
- Software files provided with the test pattern checker core:
  - **data_sink_regs.h**—The header file that defines the core's register maps.
  - **data_sink_util.h, data_sink_util.c**—The header and source code for the functions and variables required to integrate the driver into the HAL system library.

Register Maps

This section describes the register maps for the test pattern generator and checker cores.

Test Pattern Generator Control and Status Registers

Table 30–3 shows the offset for the test pattern generator control and status registers. Each register is 32 bits wide.

Table 30–3. Test Pattern Generator Control and Status Register Map

Offset	Register Name
base + 0	status
base + 1	control
base + 2	fill

Table 30–4 describes the status register bits.

Table 30–4. Status Field Descriptions

Bit(s)	Name	Access	Description
[15:0]	ID	RO	A constant value of 0x64.
[23:16]	NUMCHANNELS	RO	The configured number of channels.
[30:24]	NUMSYMBOLS	RO	The configured number of symbols per beat.
[31]	SUPPORTPACKETS	RO	A value of 1 indicates packet support.

Table 30–5 describes the control register bits

Table 30–5. Control Field Descriptions

Bit(s)	Name	Access	Description
[0]	ENABLE	RW	Setting this bit to 1 enables the test pattern generator core.
[7:1]	Reserved		
[16:8]	THROTTLE	RW	Specifies the throttle value which can be between 0–256, inclusively. This value is used in conjunction with a pseudorandom number generator to throttle the data generation rate. Setting THROTTLE to 0 stops the test pattern generator core. Setting it to 256 causes the test pattern generator core to run at full throttle. Values between 0–256 result in a data rate proportional to the throttle value.
[17]	SOFT RESET	RW	When this bit is set to 1, all internal counters and statistics are reset. Write 0 to this bit to exit reset.
[31:18]	Reserved		

Table 30–6 describes the fill register bits.

Table 30–6. Fill Field Descriptions (Part 1 of 2)

Bit(s)	Name	Access	Description
[0]	BUSY	RO	A value of 1 indicates that data transmission is in progress, or that there is at least one command in the command queue.
[6:1]	Reserved		

Table 30–6. Fill Field Descriptions (Part 2 of 2)

Bit(s)	Name	Access	Description
[15:7]	FILL	RO	The number of commands currently in the command FIFO.
[31:16]	Reserved		

Test Pattern Generator Command Registers

Table 30–7 shows the offset for the command registers. Each register is 32 bits wide.

Table 30–7. Test Pattern Command Register Map

Offset	Register Name
base + 0	cmd_lo
base + 1	cmd_hi

Table 30–8 describes the cmd_lo register bits. The command is pushed into the FIFO only when the cmd_lo register is written to.

Table 30–8. cmd_lo Field Descriptions

Bit(s)	Name	Access	Description
[15:0]	SIZE	RW	The segment size in symbols. Except for the last segment in a packet, the size of all segments must be a multiple of the configured number of symbols per beat. If this condition is not met, the test pattern generator core inserts additional symbols to the segment to ensure the condition is fulfilled.
[29:16]	CHANNEL	RW	The channel to send the segment on. If the channel signal is less than 14 bits wide, the low order bits of this register are used to drive the signal.
[30]	SOP	RW	Set this bit to 1 when sending the first segment in a packet. This bit is ignored when packets are not supported.
[31]	EOP	RW	Set this bit to 1 when sending the last segment in a packet. This bit is ignored when packets are not supported.

Table 30–9 describes the cmd_hi register bits.

Table 30–9. cmd_hi Field Descriptions

Bit(s)	Name	Access	Description
[15:0]	SIGNALLED ERROR	RW	Specifies the value to drive the error signal. A non-zero value creates a signalled error.
[23:16]	DATA ERROR	RW	The output data is XORed with the contents of this register to create data errors. To stop creating data errors, set this register to 0.
[24]	SUPRESS SOP	RW	Set this bit to 1 to suppress the assertion of the startofpacket signal when the first segment in a packet is sent.
[25]	SUPRESS EOP	RW	Set this bit to 1 to suppress the assertion of the endofpacket signal when the last segment in a packet is sent.

Test Pattern Checker Control and Status Registers

Table 30–10 shows the offset for the control and status registers. Each register is 32 bits wide.

Table 30–10. Test Pattern Checker Control and Status Register Map

Offset	Register Name
base + 0	`status`
base + 1	`control`
base + 2	Reserved
base + 3	
base + 4	
base + 5	`exception_descriptor`
base + 6	`indirect_select`
base + 7	`indirect_count`

Table 30–11 describes the `status` register bits.

Table 30–11. Status Field Descriptions

Bit(s)	Name	Access	Description
[15:0]	`ID`	RO	Contains a constant value of `0x65`.
[23:16]	`NUMCHANNELS`	RO	The configured number of channels.
[30:24]	`NUMSYMBOLS`	RO	The configured number of symbols per beat.
[31]	`SUPPORTPACKETS`	RO	A value of 1 indicates packet support.

Table 30–12 describes the `control` register bits.

Table 30–12. Control Field Descriptions

Bit(s)	Name	Access	Description
[0]	`ENABLE`	RW	Setting this bit to 1 enables the test pattern checker.
[7:1]	Reserved		
[16:8]	`THROTTLE`	RW	Specifies the throttle value which can be between 0–256, inclusively. This value is used in conjunction with a pseudorandom number generator to throttle the data generation rate. Setting `THROTTLE` to 0 stops the test pattern generator core. Setting it to 256 causes the test pattern generator core to run at full throttle. Values between 0–256 result in a data rate proportional to the throttle value.
[17]	`SOFT RESET`	RW	When this bit is set to 1, all internal counters and statistics are reset. Write 0 to this bit to exit reset.
[31:18]	Reserved		

Table 30–13 describes the `exception_descriptor` register bits. If there is no exception, reading this register returns 0.

Table 30–13. exception_descriptor Field Descriptions

Bit(s)	Name	Access	Description
[0]	DATA ERROR	RO	A value of 1 indicates that an error is detected in the incoming data.
[1]	MISSINGSOP	RO	A value of 1 indicates missing start-of-packet.
[2]	MISSINGEOP	RO	A value of 1 indicates missing end-of-packet.
[7:3]	Reserved		
[15:8]	SIGNALLED ERROR	RO	The value of the `error` signal.
[23:16]	Reserved		
[31:24]	CHANNEL	RO	The channel on which the exception was detected.

Table 30–14 describes the `indirect_select` register bits.

Table 30–14. indirect_select Field Descriptions

Bit	Bits Name	Access	Description
[7:0]	INDIRECT CHANNEL	RW	Specifies the channel number that applies to the INDIRECT PACKET COUNT, INDIRECT SYMBOL COUNT, and INDIRECT ERROR COUNT registers.
[15:8]	Reserved		
[31:16]	INDIRECT ERROR	RO	The number of data errors that occurred on the channel specified by INDIRECT CHANNEL.

Table 30–15 describes the `indirect_count` register bits.

Table 30–15. indirect_count Field Descriptions

Bit	Bits Name	Access	Description
[15:0]	INDIRECT PACKET COUNT	RO	The number of packets received on the channel specified by INDIRECT CHANNEL.
[31:16]	INDIRECT SYMBOL COUNT	RO	The number of symbols received on the channel specified by INDIRECT CHANNEL.

Test Pattern Generator API

This section describes the application programming interface (API) for the test pattern generator core. All API functions are currently not available from the interrupt service routine (ISR).

data_source_reset()

Prototype: `void data_source_reset(alt_u32 base);`

Thread-safe: No.

Include: **<data_source_util.h>**

Parameters: `base`—The base address of the control and status slave.

Returns: `void`.

Description: This function resets the test pattern generator core including all internal counters and FIFOs. The control and status registers are not reset by this function.

data_source_init()

Prototype: `int data_source_init(alt_u32 base, alt_u32 command_base);`

Thread-safe: No.

Include: **<data_source_util.h>**

Parameters: `base`—The base address of the control and status slave.

`command_base`—The base address of the command slave.

Returns: 1—Initialization is successful.

0—Initialization is unsuccessful.

Description: This function performs the following operations to initialize the test pattern generator core:

- Resets and disables the test pattern generator core.
- Sets the maximum throttle.
- Clears all inserted errors.

data_source_get_id()

Prototype: `int data_source_get_id(alt_u32 base);`

Thread-safe: Yes.

Include: **<data_source_util.h>**

Parameters: `base`—The base address of the control and status slave.

Returns: The test pattern generator core’s identifier.

Description: This function retrieves the test pattern generator core’s identifier.

data_source_get_supports_packets()

Prototype:	`int data_source_init(alt_u32 base);`
Thread-safe:	Yes.
Include:	**<data_source_util.h>**
Parameters:	`base`—The base address of the control and status slave.
Returns:	1—Packets are supported. 0—Packets are not supported.
Description:	This function checks if the test pattern generator core supports packets.

data_source_get_num_channels()

Prototype:	`int data_source_get_num_channels(alt_u32 base);`
Thread-safe:	Yes.
Include:	**<data_source_util.h>**
Parameters:	`base`—The base address of the control and status slave.
Returns:	The number of channels supported.
Description:	This function retrieves the number of channels supported by the test pattern generator core.

data_source_get_symbols_per_cycle()

Prototype:	`int data_source_get_symbols(alt_u32 base);`
Thread-safe:	Yes.
Include:	**<data_source_util.h>**
Parameters:	`base`—The base address of the control and status slave.
Returns:	The number of symbols transferred in a beat.
Description:	This function retrieves the number of symbols transferred by the test pattern generator core in each beat.

data_source_set_enable()

Prototype:	`void data_source_set_enable(alt_u32 base, alt_u32 value);`
Thread-safe:	No.
Include:	**<data_source_util.h>**
Parameters:	`base`—The base address of the control and status slave. `value`—The `ENABLE` bit is set to the value of this parameter.
Returns:	`void.`
Description:	This function enables or disables the test pattern generator core. When disabled, the test pattern generator core stops data transmission but continues to accept commands and stores them in the FIFO.

data_source_get_enable()

Prototype:	`int data_source_get_enable(alt_u32 base);`
Thread-safe:	Yes.
Include:	**<data_source_util.h>**
Parameters:	`base`—The base address of the control and status slave.
Returns:	The value of the `ENABLE` bit.
Description:	This function retrieves the value of the `ENABLE` bit.

data_source_set_throttle()

Prototype:	`void data_source_set_throttle(alt_u32 base, alt_u32 value);`
Thread-safe:	No.
Include:	**<data_source_util.h>**
Parameters:	`base`—The base address of the control and status slave. `value`—The throttle value.
Returns:	`void.`
Description:	This function sets the throttle value, which can be between 0–256 inclusively. The throttle value, when divided by 256 yields the rate at which the test pattern generator sends data.

data_source_get_throttle()

Prototype:	`int data_source_get_throttle(alt_u32 base);`
Thread-safe:	Yes.
Include:	**<data_source_util.h>**
Parameters:	`base`—The base address of the control and status slave.
Returns:	The throttle value.
Description:	This function retrieves the current throttle value.

data_source_is_busy()

Prototype:	`int data_source_is_busy(alt_u32 base);`
Thread-safe:	Yes.
Include:	**<data_source_util.h>**
Parameters:	`base`—The base address of the control and status slave.
Returns:	1—The test pattern generator core is busy. 0—The core is not busy.
Description:	This function checks if the test pattern generator is busy. The test pattern generator core is busy when it is sending data or has data in the command FIFO to be sent.

data_source_fill_level()

Prototype: `int data_source_fill_level(alt_u32 base);`

Thread-safe: Yes.

Include: **<data_source_util.h>**

Parameters: `base`—The base address of the control and status slave.

Returns: The number of commands in the command FIFO.

Description: This function retrieves the number of commands currently in the command FIFO.

data_source_send_data()

Prototype: `int data_source_send_data(alt_u32 cmd_base, alt_u32 channel, alt_u32 size, alt_u32 flags, alt_u32 error, alt_u32 data_error_mask);`

Thread-safe: No.

Include: **<data_source_util.h>**

Parameters: `cmd_base`—The base address of the command slave.

`channel`—The channel to send the data on.

`size`—The data size.

`flags`**—**Specifies whether to send or suppress SOP and EOP signals. Valid values are `DATA_SOURCE_SEND_SOP`, `DATA_SOURCE_SEND_EOP`, `DATA_SOURCE_SEND_SUPRESS_SOP` and `DATA_SOURCE_SEND_SUPRESS_EOP`.

`error`—The value asserted on the `error` signal on the output interface.

`data_error_mask`—This parameter and the data are `XOR`ed together to produce erroneous data.

Returns: Always returns 1.

Description: This function sends a data fragment to the specified channel.

If packets are supported, user applications must ensure the following conditions are met:

SOP and EOP are used consistently in each channel.

Except for the last segment in a packet, the length of each segment is a multiple of the data width.

If packets are not supported, user applications must ensure the following conditions are met:

No SOP and EOP indicators in the data.

The length of each segment in a packet is a multiple of the data width.

Test Pattern Checker API

This section describes the API for the test pattern checker core. The API functions are currently not available from the ISR.

data_sink_reset()

Prototype: `void data_sink_reset(alt_u32 base);`

Thread-safe: No.

Include: **<data_sink_util.h>**

Parameters: `base`—The base address of the control and status slave.

Returns: `void`.

Description: This function resets the test pattern checker core including all internal counters.

data_sink_init()

Prototype: `int data_source_init(alt_u32 base);`

Thread-safe: No.

Include: **<data_sink_util.h>**

Parameters: `base`—The base address of the control and status slave.

Returns: 1—Initialization is successful.

0—Initialization is unsuccessful.

Description: This function performs the following operations to initialize the test pattern checker core:

- Resets and disables the test pattern checker core.
- Sets the throttle to the maximum value.

data_sink_get_id()

Prototype: `int data_sink_get_id(alt_u32 base);`

Thread-safe: Yes.

Include: **<data_sink_util.h>**

Parameters: `base`—The base address of the control and status slave.

Returns: The test pattern checker core's identifier.

Description: This function retrieves the test pattern checker core's identifier.

data_sink_get_supports_packets()

Prototype: `int data_sink_init(alt_u32 base);`

Thread-safe: Yes.

Include: **<data_sink_util.h>**

Parameters: `base`—The base address of the control and status slave.

Returns: 1—Packets are supported.

0—Packets are not supported.

Description: This function checks if the test pattern checker core supports packets.

data_sink_get_num_channels()

Prototype:	`int data_sink_get_num_channels(alt_u32 base);`
Thread-safe:	Yes.
Include:	**<data_sink_util.h>**
Parameters:	`base`—The base address of the control and status slave.
Returns:	The number of channels supported.
Description:	This function retrieves the number of channels supported by the test pattern checker core.

data_sink_get_symbols_per_cycle()

Prototype:	`int data_sink_get_symbols(alt_u32 base);`
Thread-safe:	Yes.
Include:	**<data_sink_util.h>**
Parameters:	`base`—The base address of the control and status slave.
Returns:	The number of symbols received in a beat.
Description:	This function retrieves the number of symbols received by the test pattern checker core in each beat.

data_sink_set enable()

Prototype:	`void data_sink_set_enable(alt_u32 base, alt_u32 value);`
Thread-safe:	No.
Include:	**<data_sink_util.h>**
Parameters:	`base`—The base address of the control and status slave. `value`—The `ENABLE` bit is set to the value of this parameter.
Returns:	`void.`
Description:	This function enables the test pattern checker core.

data_sink_get_enable()

Prototype:	`int data_sink_get_enable(alt_u32 base);`
Thread-safe:	Yes.
Include:	**<data_sink_util.h>**
Parameters:	`base`—The base address of the control and status slave.
Returns:	The value of the `ENABLE` bit.
Description:	This function retrieves the value of the `ENABLE` bit.

data_sink_set_throttle()

Prototype: `void data_sink_set_throttle(alt_u32 base, alt_u32 value);`

Thread-safe: No.

Include: **<data_sink_util.h>**

Parameters: `base`—The base address of the control and status slave.
`value`—The throttle value.

Returns: `void.`

Description: This function sets the throttle value, which can be between 0–256 inclusively. The throttle value, when divided by 256 yields the rate at which the test pattern checker receives data.

data_sink_get_throttle()

Prototype: `int data_sink_get_throttle(alt_u32 base);`

Thread-safe: Yes.

Include: **<data_sink_util.h>**

Parameters: `base`—The base address of the control and status slave.

Returns: The throttle value.

Description: This function retrieves the throttle value.

data_sink_get_packet_count()

Prototype: `int data_sink_get_packet_count(alt_u32 base, alt_u32 channel);`

Thread-safe: No.

Include: **<data_sink_util.h>**

Parameters: `base`—The base address of the control and status slave.
`channel`—Channel number.

Returns: The number of packets received on the given channel.

Description: This function retrieves the number of packets received on a given channel.

data_sink_get_symbol_count()

Prototype: `int data_sink_get_symbol_count(alt_u32 base, alt_u32 channel);`

Thread-safe: No.

Include: **<data_sink_util.h>**

Parameters: `base`—The base address of the control and status slave.
`channel`—Channel number.

Returns: The number of symbols received on the given channel.

Description: This function retrieves the number of symbols received on a given channel.

data_sink_get_error_count()

Prototype: `int data_sink_get_error_count(alt_u32 base, alt_u32 channel);`

Thread-safe: No.

Include: <**data_sink_util.h**>

Parameters: `base`—The base address of the control and status slave.
`channel`—Channel number.

Returns: The number of errors received on the given channel.

Description: This function retrieves the number of errors received on a given channel.

data_sink_get_exception()

Prototype: `int data_sink_get_exception(alt_u32 base);`

Thread-safe: Yes.

Include: **<data_sink_util.h>**

Parameters: `base`—The base address of the control and status slave.

Returns: The first exception descriptor in the exception FIFO.
0—No exception descriptor found in the exception FIFO.

Description: This function retrieves the first exception descriptor in the exception FIFO and pops it off the FIFO.

data_sink_exception_is_exception()

Prototype: `int data_sink_exception_is_exception(int exception);`

Thread-safe: Yes.

Include: **<data_sink_util.h>**

Parameters: `exception`—Exception descriptor

Returns: 1—Indicates an exception.
0—No exception.

Description: This function checks if a given exception descriptor describes a valid exception.

data_sink_exception_has_data_error()

Prototype: `int data_sink_exception_has_data_error(int exception);`

Thread-safe: Yes.

Include: **<data_sink_util.h>**

Parameters: `exception`—Exception descriptor.

Returns: 1—Data has errors.
0—No errors.

Description: This function checks if a given exception indicates erroneous data.

data_sink_exception_has_missing_sop()

Prototype: `int data_sink_exception_has_missing_sop(int exception);`

Thread-safe: Yes.

Include: **<data_sink_util.h>**

Parameters: `exception`—Exception descriptor.

Returns: 1—Missing SOP.

0—Other exception types.

Description: This function checks if a given exception descriptor indicates missing SOP.

data_sink_exception_has_missing_eop()

Prototype: `int data_sink_exception_has_missing_eop(int exception);`

Thread-safe: Yes.

Include: **<data_sink_util.h>**

Parameters: `exception`—Exception descriptor.

Returns: 1—Missing EOP.

0—Other exception types.

Description: This function checks if a given exception descriptor indicates missing EOP.

data_sink_exception_signalled_error()

Prototype: `int data_sink_exception_signalled_error(int exception);`

Thread-safe: Yes.

Include: **<data_sink_util.h>**

Parameters: `exception`—Exception descriptor.

Returns: The signalled error value.

Description: This function retrieves the value of the signalled error from the exception.

data_sink_exception_channel()

Prototype: `int data_sink_exception_channel(int exception);`

Thread-safe: Yes.

Include: **<data_sink_util.h>**

Parameters: `exception`—Exception descriptor.

Returns: The channel number on which the given exception occurred.

Description: This function retrieves the channel number on which a given exception occurred.

Document Revision History

Table 30–16 shows the revision history for this chapter.

Table 30–16. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	No change from previous release.	—
November 2008 v8.1.0	Changed to 8-1/2 x 11 page size. No change to content.	—
May 2008 v8.0.0	Updated the section on HAL System Library Support.	Updates made to comply with the Quartus II software version 8.0 release.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

Section VI. Clock Control Peripherals

This section describes clock control peripherals provided by Altera for SOPC Builder systems.

This section includes the following chapter:

- Chapter 31, PLL Cores

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

31. PLL Cores

NII53002-9.0.0

Core Overview

The PLL cores, Avalon ALTPLL and PLL, provide a means of accessing the dedicated on-chip PLL circuitry in the Altera® Stratix® and Cyclone® series FPGAs. Both cores are a component wrapper around the Altera ALTPLL megafunction.

The Avalon ALTPLL core is a newer generation of the PLL cores. Altera recommends that you use this new core in your design as the older PLL core will be phased out in the near future.

The core takes an SOPC Builder system clock as its input and generates PLL output clocks locked to that reference clock.

The PLL cores support the following features:

- All PLL features provided by Altera's ALTPLL megafunction. The exact feature set depends on the device family.
- Access to status and control signals via Avalon Memory-Mapped (Avalon-MM) registers or top-level signals on the SOPC Builder system module.

The PLL output clocks are made available in two ways:

- As sources to system-wide clocks in your SOPC Builder system.
- As output signals on your SOPC Builder system module.

For details about the ALTPLL megafunction, refer to the *ALTPLL Megafunction User Guide*.

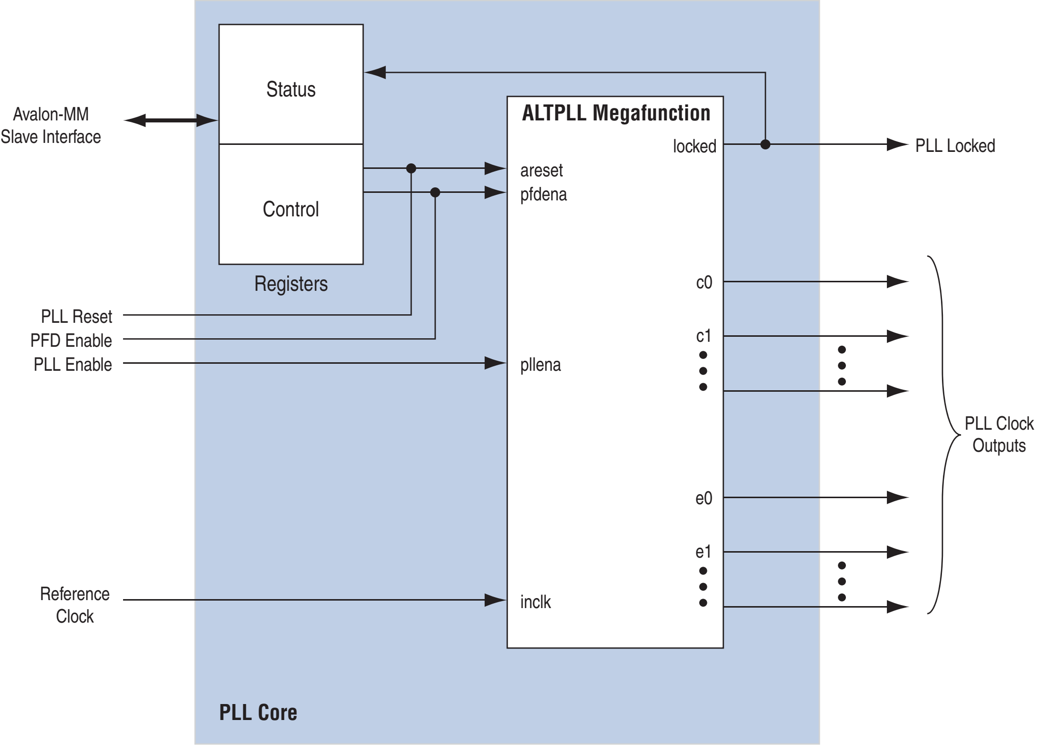
The PLL core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- "Functional Description"
- "Device Support" on page 31–3
- "Instantiating the Cores in SOPC Builder" on page 31–3
- "Hardware Simulation Considerations" on page 31–5
- "Register Definitions and Bit List" on page 31–5

Functional Description

Figure 31–1 shows a block diagram of the PLL cores and their connection to the PLL circuitry inside an Altera FPGA. The following sections describe the components of the core.

Figure 31–1. PLL Core Block Diagram



ALTPLL Megafunction

The PLL cores consist of an ALTPLL megafunction instantiation and an Avalon-MM slave interface. This interface can optionally provide access to status and control registers within the cores. The ALTPLL megafunction takes an SOPC Builder system clock as its reference, and generates one or more phase-locked output clocks.

Clock Outputs

Depending on the target device family, the ALTPLL megafunction can produce two types of output clock:

- internal (c)—clock outputs that can drive logic either inside or outside the SOPC Builder system module. Internal clock outputs can also be mapped to top-level FPGA pins. Internal clock outputs are available on all device families.
- external (e)—clock outputs that can only drive dedicated FPGA pins. They cannot be used as on-chip clock sources. External clock outputs are not available on all device families.

The Avalon ALTPLL core, however, doesn't differentiate the internal and external clock outputs and allows the external clock outputs to be used as on-chip clock sources.

To determine the exact number and type of output clocks available on your target device, refer to the *ALTPLL Megafunction User Guide*.

PLL Status and Control Signals

Depending on how the ALTPLL megafunction is parameterized, there can be a variable number of status and control signals. You can choose to export certain status and control signals to the top-level SOPC Builder system module. Alternatively, Avalon-MM registers can provide access to the signals. Any status or control signals which are not mapped to registers are exported to the top-level module. For details, refer to the "Instantiating the Cores in SOPC Builder" on page 31–3.

System Reset Considerations

At FPGA configuration, the PLL cores reset automatically. PLL-specific reset circuitry guarantees that the PLL locks before releasing reset for the overall SOPC Builder system module.

Resetting the PLL resets the entire SOPC Builder system module.

Device Support

The PLL cores support all Altera device families.

Instantiating the Cores in SOPC Builder

The PLL cores contain an instantiation of the ALTPLL megafunction. The MegaWizard™ interface for the PLL cores allows you to configure the ALTPLL megafunction, and specify connections to selected status and control signals of the megafunction.

For details about using the ALTPLL MegaWizard Plug-In Manager, refer to the *ALTPLL Megafunction User Guide*.

Instantiating the Avalon ALTPLL Core

When you instantiate the Avalon ALTPLL core, the MegaWizard Plug-In Manager is automatically launched for you to parameterize the ALTPLL megafunction. There are no additional parameters that you can configure in SOPC Builder.

The `pfdena` signal of the ALTPLL megafunction is not exported to the top level of the SOPC Builder module. You can drive this port by writing to the `PFDENA` bit in the `control` register.

The `locked`, `pllena/extclkena`, and `areset` signals of the megafunction are always exported to the top level of the SOPC Builder module. You can read the `locked` signal and reset the core by manipulating respective bits in the registers. See "Register Definitions and Bit List" on page 31–5 for more information on the registers.

Instantiating the PLL Core

This section describes the options available in the MegaWizard interface for the PLL core in SOPC Builder.

PLL Settings Page

The **PLL Settings** page contains a button that launches the ALTPLL MegaWizard Plug-In Manager. Use the MegaWizard Plug-In Manager to parameterize the ALTPLL megafunction. The set of available parameters depends on the target device family.

You cannot click **Finish** in the PLL wizard nor configure the PLL interface until you parameterize the ALTPLL megafunction.

Interface Page

The **Interface** page configures the access modes for the optional advanced PLL status and control signals.

For each advanced signal present on the ALTPLL megafunction, you can select one of the following access modes:

- **Export**—Exports the signal to the top level of the SOPC builder system module.
- **Register**—Maps the signal to a bit in a status or control register.

The advanced signals are optional. If you choose not to create any of them in the ALTPLL MegaWizard Plug-In, the PLL's default behavior is as shown in Table 31–1.

You can specify the access mode for the advanced signals shown in Table 31–1. The ALTPLL core signals, not displayed in this table, are automatically exported to the top level of the SOPC Builder system module.

Table 31–1. ALTPLL Advanced Signal

ALTPLL Name	Input / Output	Avalon-MM PLL Wizard Name	Default Behavior	Description
`areset`	input	PLL Reset Input	The PLL is reset only at device configuration.	This signal resets the entire SOPC Builder system module, and restores the PLL to its initial settings.
`pllena`	input	PLL Enable Input	The PLL is enabled.	This signal enables the PLL. `pllena` is always exported.
`pfdena`	input	PFD Enable Input	The phase-frequency detector is enabled.	This signal enables the phase-frequency detector in the PLL, allowing it to lock on to changes in the clock reference.
`locked`	output	PLL Locked Output	—	This signal is asserted when the PLL is locked to the input clock.

Asserting `areset` resets the entire SOPC Builder system module, not just the PLL.

Finish

Click **Finish** to insert the PLL into the SOPC Builder system. The PLL clock output(s) appear in the clock settings table on the SOPC Builder **System Contents** tab.

If the PLL has external output clocks, they appear in the clock settings table like other clocks; however, you cannot use them to drive components within the SOPC Builder system.

For details about using external output clocks, refer to the *ALTPLL Megafunction User Guide*.

The SOPC Builder automatically connects the PLL's reference clock input to the first available clock in the clock settings table.

If there is more than one SOPC Builder system clock available, verify that the PLL is connected to the appropriate reference clock.

Hardware Simulation Considerations

The HDL files generated by SOPC Builder for the PLL cores are suitable for both synthesis and simulation. The PLL cores support the standard SOPC Builder simulation flow, so there are no special considerations for hardware simulation.

Register Definitions and Bit List

Table 31–2 shows the register map for the PLL cores. Device drivers can control and communicate with the cores through two memory-mapped registers, `status` and `control`. The width of these registers are 32 bits in the Avalon ALTPLL core but only 16 bits in the PLL core.

In the PLL core, the `status` and `control` bits shown in Table 31–2 are present only if they have been created in the ALTPLL MegaWizard Plug-In Manager, and set to **Register** on the **Interface** page in the PLL wizard. These registers are always created in the Avalon ALTPLL core.

Table 31–2. PLL Cores Register Map

Offset	Register Name	R/W	Bit Description				
			31/15 *(2)*	...	2	1	0
0	`status`	R/O	*(1)*				`LOCKED`
1	`control`	R/W	*(1)*			`PFDENA`	`ARESET`

Note to Table 31–2:

(1) Reserved. Read values are undefined. When writing, set reserved bits to zero.

(2) The registers are 32-bit wide in the Avalon ALTPLL core and 16-bit wide in the PLL core.

Status Register

Embedded software can access the PLL status via the `status` register. Writing to `status` has no effect. Table 31–3 describes the function of each bit.

Table 31–3. Status Register Bits

Bit Number	Bit Name	Value after reset	Description
0	`LOCKED`	1	Connects to the `locked` signal on the ALTPLL. The `LOCKED` bit is high when valid clocks are present on the output of the PLL.

Table 31–3. Status Register Bits

Bit Number	Bit Name	Value after reset	Description
1 .. 15/31 *(1)*	—	—	Reserved. Read values are undefined.

Note to Table 31–3:

(1) The `status` register is 32-bit wide in the Avalon ALTPLL core and 16-bit wide in the PLL core.

Control Register

Embedded software can control the PLL via the `control` register. Software can also read back the status of control bits. Table 31–4 describes the function of each bit.

Table 31–4. Control Register Bits

Bit Number	Bit Name	Value after reset	Description
[0]	`ARESET`	0	Connects to the `areset` signal on the ALTPLL. Writing a 1 to this bit asserts the `areset` signal for one clock cycle.
[1]	`PFDENA`	1	Connects to the `pfdena` signal on the ALTPLL.
[2:15/31] *(1)*	—	—	Reserved. Read values are undefined. When writing, set reserved bits to zero.

Note to Table 31–3:

(1) The `control` register is 32-bit wide in the Avalon ALTPLL core and 16-bit wide in the PLL core.

Referenced Documents

This chapter references the *ALTPLL Megafunction User Guide*.

Document Revision History

Table 31–5 shows the revision history for this chapter.

Table 31–5. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009	Added information on the new Avalon ALTPLL core.	A new PLL core, Avalon ALTPLL, is released and the chapter is updated accordingly to include the new core.
November 2008 v8.1.0	Changed to 8-1/2 x 11 page size. No change to content.	—
May 2008 v8.0.0	No change from previous release.	—

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

About this Handbook

This handbook provides comprehensive information about the Altera® Quartus® II design software, version 9.0.

How to Contact Altera

For the most up-to-date information about Altera products, see the following table.

Contact (Note 1)	Contact Method	Address
Technical support	Website	www.altera.com/support
Technical training	Website	www.altera.com/training
	Email	custrain@altera.com
Altera literature services	Email	literature@altera.com
Non-technical support (General)	Email	nacomp@altera.com
(Software Licensing)	Email	authorization@altera.com

Note:

(1) You can also contact your local Altera sales office or sales representative.

Third-Party Software Product Information

Third-party software products described in this handbook are not Altera products, are licensed by Altera from third parties, and are subject to change without notice. Updates to these third-party software products may not be concurrent with Quartus II software releases. Altera has assumed responsibility for the selection of such third-party software products and its use in the Quartus II 9.0 software release. To the extent that the software products described in this handbook are derived from third-party software, no third party warrants the software, assumes any liability regarding use of the software, or undertakes to furnish you any support or information relating to the software. EXCEPT AS EXPRESSLY SET FORTH IN THE APPLICABLE ALTERA PROGRAM LICENSE SUBSCRIPTION AGREEMENT UNDER WHICH THIS SOFTWARE WAS PROVDED TO YOU, ALTERA AND THIRD-PARTY LICENSORS DISCLAIM ALL WARRANTIES WITH RESPECT TO THE USE OF SUCH THIRD-PARTY SOFTWARE CODE OR DOCUMENTATION IN THE SOFTWARE, INCLUDING, WITHOUT LIMITATION, ANY WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, TITLE, AND NONINFRINGEMENT. For more information, including the latest available version of specific third-party software products, refer to the documentation for the software in question.

Typographic Conventions

The following table shows the typographic conventions that this document uses.

Visual Cue	Meaning
Bold Type with Initial Capital Letters	Command names, dialog box titles, checkbox options, and dialog box options are shown in bold, initial capital letters. Example: **Save As** dialog box.
bold type	External timing parameters, directory names, project names, disk drive names, file names, file name extensions, and software utility names are shown in bold type. Examples: $\mathbf{f_{MAX}}$, **\qdesigns** directory, **d:** drive, **chiptrip.gdf** file.
Italic Type with Initial Capital Letters	Document titles are shown in italic type with initial capital letters. Example: *AN 75: High-Speed Board Design.*
Italic type	Internal timing parameters and variables are shown in italic type. Examples: t_{PIA}, $n + 1$. Variable names are enclosed in angle brackets (< >) and shown in italic type. Example: *<file name>*, *<project name>*.**pof** file.
Initial Capital Letters	Keyboard keys and menu names are shown with initial capital letters. Examples: Delete key, the Options menu.
"Subheading Title"	References to sections within a document and titles of on-line help topics are shown in quotation marks. Example: "Typographic Conventions."
`Courier type`	Signal and port names are shown in lowercase Courier type. Examples: `data1`, `tdi`, `input`. Active-low signals are denoted by suffix `n`, e.g., `resetn`. Anything that must be typed exactly as it appears is shown in Courier type. For example: `c:\qdesigns\tutorial\chiptrip.gdf`. Also, sections of an actual file, such as a Report File, references to parts of files (e.g., the AHDL keyword `SUBDESIGN`), as well as logic function names (e.g., `TRI`) are shown in Courier.
1., 2., 3., and a., b., c., etc.	Numbered steps are used in a list of items when the sequence of the items is important, such as the steps listed in a procedure.
■ ■	Bullets are used in a list of items when the sequence of the items is not important.
✓	The checkmark indicates a procedure that consists of one step only.
	The hand points to information that requires special attention.
CAUTION	A caution calls attention to a condition or possible situation that can damage or destroy the product or the user's work.
WARNING	A warning calls attention to a condition or possible situation that can cause injury to the user.
↵	The angled arrow indicates you should press the Enter key.
	The feet direct you to more information on a particular topic.
