Chapter Revision Dates xxi

Section I. Design Flows

Chapter 1. Design Planning with the Quartus II Software

Introduction 1-1
Creating Design Specifications 1-2
Device Selection 1-2
Device Migration Planning 1-3
Planning for Device Programming/Configuration 1-4
Early Power Estimation 1-5
Early Power Estimator File 1-5
Early Pin Planning and I/O Analysis 1-6
Creating a Top-Level Design File for I/O Analysis 1-7
Selecting Third-Party EDA Tool Flows 1-8
Synthesis Tools 1-8
Simulation Tools 1-8
Formal Verification Tools 1-9
Planning for On-Chip Debugging Options 1-9
Design Practices and HDL Coding Styles 1-11
Design Recommendations 1-11
Recommended HDL Coding Styles 1-12
Planning for Hierarchical and Team-Based Design 1-13
Flat Compilation Flow with No Design Partitions 1-13
Incremental Compilation with Design Partitions 1-13
Top-Down Versus Bottom-Up Incremental Flows 1-14
Top-Down Incremental Compilation Flow 1-14
Bottom-Up and Team-Based Incremental Compilation Flow 1-15
Mixed Incremental Compilation Flow 1-15
Planning Design Partitions 1-16
Creating a Design Floorplan 1-17
Fast Synthesis and Early Timing Estimation 1-17
Conclusion 1-18
Referenced Documents 1-18
Document Revision History 1-19

Chapter 2. Quartus II Incremental Compilation for Hierarchical and Team-Based Design

Introduction 2-1
Deciding Whether to Use an Incremental Compilation Flow 2-2
Flat Compilation Flow with No Design Partitions 2-2
Quartus II Smart Compilation 2-3
Incremental Compilation Flow with Design Partitions 2-3
Top-Down versus Bottom-Up Compilation Flows 2-6
Quick Start Guide—Summary of Incremental Compilation 2-7
Preparing a Design for Incremental Compilation 2-8
Compiling a Design Using Incremental Compilation 2-9
Deciding which Design Blocks Should Be Design Partitions 2-9
Impact of Design Partitions on Design Optimization 2-11

Partition Statistics Reports . . . 2-11
Partition Timing Reports . . . 2-13
Incremental Compilation Advisor . . . 2-13
Using Partitions with Third-Party Synthesis Tools . . . 2-15
Synopsys Synplify Pro/Premier and Mentor Graphics Precision RTL Plus . . . 2-15
Other Synthesis Tools . . . 2-15
Design Partition Assignments Compared to Physical Placement Assignments . . . 2-15
Creating Design Partition Assignments . . . 2-16
Creating Design Partitions with the Design Partition Planner . . . 2-16
Creating Design Partitions In the Design Partitions Window . . . 2-18
Creating Design Partitions in the Project Navigator . . . 2-18
Creating Design Partitions with Tcl Scripting . . . 2-19
Partition Name . . . 2-19
Setting the Netlist Type for Design Partitions . . . 2-19
Fitter Preservation Level . . . 2-21
Empty Partitions . . . 2-22
Where Are the Netlist Databases Stored? . . . 2-23
What Changes Trigger a Partition's Automatic Resynthesis? . . . 2-23
Determining Which Partitions Are Resynthesized Due to Source Code Changes . . . 2-24
Forcing Use of the Post-Fitting Netlist When a Partition has Changed . . . 2-25
Creating a Design Floorplan with LogicLock Location Assignments . . . 2-25
Taking Advantage of the Early Timing Estimator . . . 2-28
What LogicLock Changes Trigger Refitting? . . . 2-28
Exporting and Importing Partitions . . . 2-29
Quartus II Exported Partition Files (.qxp) . . . 2-30
Bottom-Up Incremental Compilation Summary . . . 2-30
Preparing a Design for Bottom-Up Incremental Compilation . . . 2-31
Creating and Compiling Lower-Level Projects . . . 2-31
Exporting Lower-Level Projects . . . 2-32
Including or Importing Lower-Level Projects into the Top-Level Project . . . 2-32
Performing an Incremental Compilation in the Top-Level Project . . . 2-32
Netlist Types for Imported Partitions . . . 2-33
Exporting a Lower-Level Partition to be Used in a Top-Level Project . . . 2-34
Exporting a Lower-Level Block within a Project . . . 2-35
Using a .qxp File as a Source File in the Top-Level Project . . . 2-36
Importing a Lower-Level Partition Into the Top-Level Project . . . 2-36
Importing Assignments and Advanced Import Settings . . . 2-38
Design Partition Properties after Importing . . . 2-38
Importing Design Partition Assignments Within the Subdesign . . . 2-38
Synopsys Design Constraint Files for the Quartus II TimeQuest Timing Analyzer . . . 2-38
Importing LogicLock Assignments . . . 2-38
Importing Other Instance Assignments . . . 2-39
Importing Global Assignments . . . 2-39
Advanced Import Settings . . . 2-39
Generating Bottom-Up Design Partition Scripts for Project Management . . . 2-40
Project Creation . . . 2-41
Excluded Partitions . . . 2-41
Assignments from the Top-Level Design . . . 2-41
Virtual Pin Assignments . . . 2-42
LogicLock Region Assignments . . . 2-43
Global Signal Promotion Assignments . . . 2-43
Makefile Generation . . . 2-44
Importing SDC Constraints from Lower-Level Partitions . . . 2-45
Creating an .sdc File with Project-Wide Constraints . . . 2-46

Creating an .sdc File with Partition-Specific Constraints 2-47
Consolidating the SDC Files in the Top-Level Design 2-48
Recommended Design Flows and Compilation Application Examples 2-49
Reducing Compilation Time When Changing a Source File for One Partition 2-49
Optimizing a Timing-Critical Partition to Achieve Timing Closure 2-50
Preserving Results for Some Partitions Before Adding Other Partitions 2-51
Debugging Incrementally with the SignalTap II Logic Analyzer 2-52
Implementing a Team-Based Bottom-Up Design Flow 2-53
Performing Design Iteration in a Bottom-Up Design Flow 2-56
Creating Hard-Wired Macros (or Precompiled Design Blocks) for IP Reuse 2-57
Using an Exported Partition to Send a Design without Including Source Files 2-59
Incremental Compilation Restrictions 2-60
Preserving Exact Timing Performance 2-61
When Placement and Routing May Not Be Preserved Exactly 2-61
Using Incremental Compilation with Quartus II Archive Files 2-61
Formal Verification Support 2-61
Importing Encrypted IP Cores in Bottom-Up Flows 2-62
SignalProbe Pins and Engineering Change Management with the Chip Planner 2-62
Linked Partitions Due to SignalProbe Pins or ECO Changes 2-62
Exported Partitions 2-63
SignalTap II Embedded Logic Analyzer in Bottom-Up Compilation Flows 2-64
Logic Analyzer Interface in Bottom-Up Compilation Flows 2-64
Migrating Projects with Design Partitions to Different Devices 2-64
HardCopy Compilation and Migration Flows 2-64
HardCopy APEX and HardCopy Stratix Devices 2-64
HardCopy ASIC Migration Flows 2-65
HardCopy ASIC Stand-Alone Compilations 2-65
Assignments Made in HDL Source Code in Bottom-Up Flows 2-65
Restrictions on Megafunction Partitions 2-65
Register Packing and Partition Boundaries 2-66
I/O Register Packing 2-66
Bottom-Up Design Partition Script Limitations 2-67
Warnings About Extra Clocks Due to Bottom-Up Design Partition Scripts 2-67
Synopsys Design Constraint Files for the TimeQuest Timing Analyzer in Bottom-Up Design Partition Scripts 2-67
Wildcard Support in Bottom-Up Design Partition Scripts 2-67
Derived Clocks and PLLs in Bottom-Up Design Partition Scripts 2-67
Pin Assignments for GXB and LVDS Blocks in Bottom-Up Design Partition Scripts 2-68
Virtual Pin Timing Assignments in Bottom-Up Design Partition Scripts 2-68
Top-Level Ports that Feed Multiple Lower-Level Pins in Bottom-Up Design Partition Scripts 2-68
Scripting Support 2-69
Preparing a Design for Incremental Compilation 2-69
Creating Design Partitions 2-69
Setting Properties of Design Partitions 2-70
Creating Floorplan Location Assignments—Excluding or Filtering Certain Device Elements (Such as RAM or DSP Blocks) 2-71
Generating Bottom-Up Design Partition Scripts 2-71
Command Line Support 2-72
Exporting a Partition to be Used in a Top-Level Project 2-73
Importing a Lower-Level Partition into the Top-Level Project 2-74
Makefiles 2-74
Recommended Design Flows and Compilation Application Examples—Scripting and Command-Line Operation 2-74
Reducing Compilation Time When Changing a Source File for One Partition—Command-Line

Example 2-75
Optimizing the Placement for a Timing-Critical Partition 2-75
Conclusion 2-76
Referenced Documents 2-76
Document Revision History 2-77

Chapter 3. Quartus II Design Flow for MAX+PLUS II Users

Introduction 3-1
Chapter Overview 3-1
Typical Design Flow 3-2
Device Support 3-2
Quartus II GUI Overview 3-3
Project Navigator 3-3
Node Finder 3-3
Tcl Console 3-4
Messages 3-4
Status 3-4
Change Manager 3-4
Setting Up MAX+PLUS II Look and Feel in the Quartus II Software 3-5
MAX+PLUS II Look and Feel 3-5
Compiler Tool 3-7
Analysis and Synthesis 3-7
Partition Merge 3-8
Fitter 3-8
Assembler 3-8
Timing Analyzer 3-9
EDA Netlist Writer 3-9
Design Assistant 3-9
MAX+PLUS II Design Conversion 3-9
Converting an Existing MAX+PLUS II Design 3-9
Converting MAX+PLUS II Graphic Design Files 3-11
Importing MAX+PLUS II Assignments 3-11
Quartus II Design Flow 3-12
Creating a New Project 3-12
Design Entry 3-13
Making Assignments 3-15
Assignment Editor 3-15
Timing Assignments 3-16
Synthesis 3-17
Functional Simulation 3-17
Place and Route 3-19
Timing Analysis 3-20
Timing Closure Floorplan 3-22
Timing Simulation 3-23
Quartus II Simulator Tool 3-23
EDA Timing Simulation 3-24
Power Estimation 3-25
Programming 3-25
Conclusion 3-26
Quartus II Command Reference for MAX+PLUS II Users 3-26
Referenced Documents 3-33
Document Revision History 3-34

Chapter 4. Quartus II Support for HardCopy Series Devices

Introduction . . . 4-1
HardCopy Series Device Support . . . 4-1
HardCopy Series Design Benefits . . . 4-2
Quartus II Features for HardCopy Planning . . . 4-2
HardCopy Development Flow . . . 4-3
Designing the FPGA First . . . 4-4
Designing the HardCopy Device First . . . 4-6
HardCopy Device Resource Guide . . . 4-7
HardCopy Companion Device Selection . . . 4-10
HardCopy Recommended Settings in the Quartus II Software . . . 4-11
Limit DSP and RAM to HardCopy Device Resources . . . 4-11
Enable Design Assistant to Run During Compile . . . 4-12
Timing Settings . . . 4-13
TimeQuest Timing Analyzer . . . 4-13
Setting Up the TimeQuest Timing Analyzer . . . 4-14
Constraints for Clock Effect Characteristics . . . 4-14
Quartus II Software Features Supported for HardCopy Designs . . . 4-16
Physical Synthesis Optimization . . . 4-16
LogicLock Regions . . . 4-16
PowerPlay Power Analyzer . . . 4-16
Incremental Compilation . . . 4-16
HardCopy Utilities Menu . . . 4-17
Companion Revisions . . . 4-18
Compiling the HardCopy Companion Revision . . . 4-19
Comparing HardCopy and FPGA Companion Revisions . . . 4-20
Generate a HardCopy Handoff Report . . . 4-20
Archive HardCopy Handoff Files . . . 4-21
HardCopy Advisor . . . 4-21
HardCopy Design Readiness Check . . . 4-23
Execution of HardCopy Design Readiness Check . . . 4-23
Stratix III Support . . . 4-24
Setting Check . . . 4-24
Summary . . . 4-25
Global Setting . . . 4-25
Instance Setting . . . 4-25
Operating Setting . . . 4-25
I/O Check . . . 4-26
Input Pin Placement for Global and Regional Clock . . . 4-26
PLL Usage Check . . . 4-27
PLL Real-Time Reconfigurable Check . . . 4-27
PLL Clock Outputs Driving Multiple Clock Network Types Check . . . 4-27
PLL with No Compensation Mode Check . . . 4-27
PLL with Normal or Source Synchronous Mode Feeding Output Pin Check . . . 4-27
RAM Usage Check . . . 4-28
Initialized Memory Dependency Testing . . . 4-28
Performing ECOs with Quartus II Engineering Change Management with the Chip Planner . . . 4-29
Migrating One-to-One Changes . . . 4-29
Migrating Changes that Must be Implemented Differently . . . 4-30
Changes that Cannot be Migrated . . . 4-31
Overall Migration Flow . . . 4-31
Preparing the Revisions . . . 4-31
Applying ECO Changes . . . 4-31
Formal Verification of FPGA and HardCopy Revisions . . . 4-32

HardCopy Floorplan View . . . 4-33
Legacy HardCopy Device Support . . . 4-34
Features . . . 4-35
HARDCOPY_FPGA_PROTOTYPE, HardCopy Stratix, and Stratix Devices . . . 4-36
HardCopy Design Flow . . . 4-37
The Design Flow Steps of the One-Step Process . . . 4-38
Compile the Design for an FPGA . . . 4-38
Migrate the Compiled Project . . . 4-38
Close the Quartus FPGA Project . . . 4-39
Open the Quartus HardCopy Project . . . 4-39
Compile for HardCopy Stratix Device . . . 4-39
How to Design HardCopy Stratix Devices . . . 4-39
HardCopy Timing Optimization Wizard . . . 4-40
Tcl Support for HardCopy Migration . . . 4-42
Design Optimization and Performance Estimation . . . 4-42
Design Optimization . . . 4-43
Performance Estimation . . . 4-43
Buffer Insertion . . . 4-46
Placement Constraints . . . 4-46
Location Constraints . . . 4-46
LAB Assignments . . . 4-47
LogicLock Assignments . . . 4-47
Checking Designs for HardCopy Design Guidelines . . . 4-48
Altera-Recommended HDL Coding Guidelines . . . 4-48
Design Assistant . . . 4-48
Design Assistant Settings . . . 4-48
Running Design Assistant . . . 4-48
Reports and Summary . . . 4-49
Generating the HardCopy Design Database . . . 4-49
Static Timing Analysis . . . 4-51
Early Power Estimation . . . 4-51
HardCopy Stratix Early Power Estimation . . . 4-51
Tcl Support for HardCopy Stratix . . . 4-52
Conclusion . . . 4-52
Referenced Documents . . . 4-52
Document Revision History . . . 4-53

Section II. Design Guidelines

Chapter 5. Design Recommendations for Altera Devices and the Quartus II Design Assistant

Introduction . . . 5-1
Synchronous FPGA Design Practices . . . 5-2
Fundamentals of Synchronous Design . . . 5-2
Hazards of Asynchronous Design . . . 5-3
Design Guidelines . . . 5-4
Combinational Logic Structures . . . 5-4
Combinational Loops . . . 5-4
Latches . . . 5-5
Delay Chains . . . 5-5
Pulse Generators and Multivibrators . . . 5-6
Clocking Schemes . . . 5-7
Internally Generated Clocks . . . 5-8
Divided Clocks . . . 5-8

Ripple Counters 5-8
Multiplexed Clocks 5-9
Gated Clocks 5-10
Synchronous Clock Enables 5-11
Recommended Clock-Gating Methods 5-11
Design Techniques to Save Power 5-12
Checking Design Violations Using the Design Assistant 5-13
Quartus II Design Flow with the Design Assistant 5-13
The Design Assistant Settings Page 5-15
Message Severity Levels 5-15
Design Assistant Rules 5-16
Summary of Rules and IDs 5-16
Design Should Not Contain Combinational Loops 5-17
Register Output Should Not Drive Its Own Control Signal Directly or through Combinational Logic 5-18
Design Should Not Contain Delay Chains 5-18
Design Should Not Contain Ripple Clock Structures 5-18
Pulses Should Not Be Implemented Asynchronously 5-18
Multiple Pulses Should Not Be Generated in the Design 5-19
Design Should Not Contain SR Latches 5-19
Design Should Not Contain Latches 5-19
Combinational Logic Should Not Directly Drive Write Enable Signal of Asynchronous RAM 5-20
Design Should Not Contain Asynchronous Memory 5-20
Gated Clocks Should Be Implemented According to Altera Standard Scheme 5-21
Logic Cell Should Not Be Used to Generate Inverted Clock 5-21
Gated Clock Is Not Feeding At Least A Pre-Defined Number Of Clock Ports to Effectively Save Power: <n> 5-21
Clock Signal Source Should Drive Only Input Clock Ports 5-22
Clock Signal Should Be a Global Signal 5-22
Clock Signal Source Should Not Drive Registers that Are Triggered by Different Clock Edges 5-23
Combinational Logic Used as a Reset Signal Should Be Synchronized 5-23
External Reset Should Be Synchronized Using Two Cascaded Registers 5-23
External Reset Should Be Synchronized Correctly 5-24
Reset Signal Generated in One Clock Domain and Used in Other Asynchronous Clock Domains Should Be Synchronized Correctly 5-25
Reset Signal Generated in One Clock Domain and Used in Other Asynchronous Clock Domains Should Be Synchronized 5-25
Output Enable and Input of the Same Tri-State Nodes Should Not Be Driven by the Same Signal Source 5-26
Synchronous Port and Asynchronous Port of the Same Register Should Not Be Driven by the Same Signal Source 5-26
More Than One Asynchronous Signal Source of the Same Register Should Not Be Driven by the Same Source 5-26
Clock Port and Any Other Signal Port of the Same Register Should Not Be Driven by the Same Signal Source 5-26
Nodes with More Than Specified Number of Fan-outs: <n> 5-27
Top Nodes with Highest Fan-out: <n> 5-27
Data Bits Are Not Synchronized When Transferred between Asynchronous Clock Domains . 5-27
Multiple Data Bits Transferred Across Asynchronous Clock Domains Are Synchronized, But Not All Bits May Be Aligned in the Receiving Clock Domain 5-28
Data Bits Are Not Correctly Synchronized When Transferred Between Asynchronous Clock Domains 5-28
Only One VREF Pin Should Be Assigned to HardCopy Test Pin in an I/O Bank 5-28

A PLL Drives Multiple Clock Network Types 5-29
Data Bits Are Not Synchronized When Transferred to the State Machine of Asynchronous Clock Domains 5-29
No Reset Signal Defined to Initialize the State Machine 5-29
State Machine Should Not Contain Unreachable State 5-29
State Machine Should Not Contain a Deadlock State 5-30
State Machine Should Not Contain a Dead Transition 5-30
Enabling and Disabling Design Assistant Rules 5-30
Using the Assignment Editor 5-30
Using Verilog HDL 5-31
Using VHDL 5-31
Using TCL Commands 5-32
Viewing Design Assistant Results 5-32
Summary Report 5-33
Settings Report 5-33
Detailed Results Report 5-34
Messages Report 5-34
HardCopy Test Pins Report 5-34
Rule Suppression Assignments Report 5-34
Ignored Design Assistant Assignments Report 5-35
Custom Rules Report 5-35
Custom Rules 5-35
XML File Format for Custom Rules 5-35
Specifying the Path to the Custom Rules File 5-37
Custom Rules Coding Examples 5-37
Targeting Clock and Register-Control Architectural Features 5-41
Clock Network Resources 5-42
Reset Resources 5-42
Register Control Signals 5-43
Targeting Embedded RAM Architectural Features 5-43
Conclusion 5-44
Referenced Documents 5-44
Document Revision History 5-45

Chapter 6. Recommended HDL Coding Styles

Introduction 6-1
Quartus II Language Templates 6-1
Using Altera Megafunctions 6-2
Instantiating Altera Megafunctions in HDL Code 6-3
Instantiating Megafunctions Using the MegaWizard Plug-In Manager 6-4
Creating a Netlist File for Other Synthesis Tools 6-5
Instantiating Megafunctions Using the Port and Parameter Definition 6-5
Inferring Multiplier and DSP Functions from HDL Code 6-6
Multipliers—Inferring the LPM_MULT Megafunction from HDL Code 6-6
Multiply-Accumulators and Multiply-Adders—Inferring ALTMULT_ACCUM and ALTMULT_ADD Megafunctions from HDL Code 6-8
Inferring Memory Functions from HDL Code 6-12
RAM Functions—Inferring ALTSYNCRAM and ALTDPRAM Megafunctions from HDL Code . 6-13
Use Synchronous Memory Blocks 6-14
Avoid Unsupported Reset and Control Conditions 6-14
Check Read-During-Write Behavior 6-16
Single-Clock Synchronous RAM with Old Data Read-During-Write Behavior 6-17
Single-Clock Synchronous RAM with New Data Read-During-Write Behavior 6-19
Simple Dual-Port, Dual-Clock Synchronous RAM 6-21

True Dual-Port Synchronous RAM 6-23
Specifying Initial Memory Contents at Power-Up 6-27
ROM Functions—Inferring ALTSYNCRAM and LPM_ROM Megafunctions from HDL Code . . 6-29
Shift Registers—Inferring the ALTSHIFT_TAPS Megafunction from HDL Code 6-32
Simple Shift Register 6-33
Shift Register with Evenly Spaced Taps 6-34
Coding Guidelines for Registers and Latches 6-36
Register Power-Up Values in Altera Devices 6-36
Secondary Register Control Signals Such as Clear and Clock Enable 6-38
Latches 6-42
Unintentional Latch Generation 6-42
Inferring Latches Correctly 6-43
General Coding Guidelines 6-46
Tri-State Signals 6-46
Clock Multiplexing 6-47
Adder Trees 6-51
Architectures with 4-Input LUTs in Logic Elements 6-51
Architectures with 6-Input LUTs in Adaptive Logic Modules 6-52
State Machines 6-53
Verilog HDL State Machines 6-54
VHDL State Machines 6-58
Multiplexers 6-60
Quartus II Software Option for Multiplexer Restructuring 6-61
Multiplexer Types 6-61
Default or Others Case Assignment 6-63
Implicit Defaults 6-63
Degenerate Multiplexers 6-65
Buses of Multiplexers 6-67
Cyclic Redundancy Check Functions 6-68
If Performance is Important, Optimize for Speed 6-68
Use Separate CRC Blocks Instead of Cascaded Stages 6-68
Use Separate CRC Blocks Instead of Allowing Blocks to Merge 6-68
Take Advantage of Latency if Available 6-69
Save Power by Disabling CRC Blocks When Not in Use 6-69
Use the Device Synchronous Load (sload) Signal to Initialize 6-69
Comparators 6-69
Counters 6-71
Designing with Low-Level Primitives 6-71
Conclusion 6-72
Referenced Documents 6-72
Document Revision History 6-73

Chapter 7. Managing Metastability with the Quartus II Software

Introduction 7-1
Metastability Analysis in the Quartus II Software 7-2
What is a Synchronization Register Chain? 7-3
Identifying Synchronizers for Metastability Analysis 7-4
Using the Global Synchronizer Identification Setting 7-4
Refining Synchronizer Identification Using the Instance-Specific Assignment 7-5
How Timing Constraints Affect Synchronizer Chain Identification and Metastability Analysis . . 7-6
Metastability and MTBF Reporting 7-6
Metastability Report 7-7
MTBF Summary Report 7-7
Synchronizer Summary 7-8

Synchronizer Chain Statistics Report in the TimeQuest Timing Analyzer 7-8
Synchronizer Data Toggle Rate in MTBF Calculation 7-9
MTBF Optimization 7-9
Synchronization Register Chain Length 7-10
Reducing Metastability Effects 7-11
Apply Complete System-Centric Timing Constraints for the TimeQuest Timing Analyzer 7-11
Force the Identification of Synchronization Registers 7-11
Set the Synchronizer Data Toggle Rate 7-12
Optimize Metastability During Fitting 7-12
Increase the Length of Synchronizers to Protect and Optimize 7-12
Set Fitter Effort to Standard Fit instead of Auto Fit 7-12
If Possible, Increase the Number of Stages Used in Synchronizers 7-12
If Possible, Select a Faster Speed Grade Device 7-13
Scripting Support 7-13
Identifying Synchronizers for Metastability Analysis 7-13
Synchronizer Data Toggle Rate in MTBF Calculation 7-13
report_metastability TimeQuest and Tcl Command 7-14
MTBF Optimization 7-14
Synchronization Register Chain Length 7-14
Conclusion 7-14
Referenced Documents 7-15
Document Revision History 7-15

Chapter 8. Best Practices for Incremental Compilation Partitions and Floorplan Assignments
Introduction 8-1
Overview: Incremental Compilation 8-1
Choosing the Netlist Type and Fitter Preservation Level 8-2
Top-Down versus Bottom-Up Compilation Flows 8-3
Generating Bottom-Up Design Partition Scripts for Project Management 8-4
Why Plan Partitions and Floorplan Assignments for Incremental Compilation? 8-4
Partition Boundaries and Optimization 8-5
Creating Design Partitions: General Partitioning Guidelines 8-6
Plan Design Hierarchy and Source Design Files 8-6
Using Partitions with Third-Party Synthesis Tools 8-7
Partition Design by Functionality and Block Size 8-8
Partition Design by Clock Domain and Timing Criticality 8-8
Consider What Is Changing 8-8
Creating Design Partitions: Design Guidelines 8-9
Register Partition Inputs and Outputs 8-9
Minimize Cross-Partition-Boundary I/O 8-10
Avoid the Need for Logic Optimization Across Partitions 8-11
Keep Logic in the Same Partition for Optimization and Merging 8-12
Keep Constants in the Same Partition as Logic 8-13
Avoid Unconnected Partition I/O 8-14
Avoid Signals That Drive Multiple Partition I/O or Connect I/O Together 8-14
Invert Clocks in Destination Partitions 8-16
Connect I/O Directly to I/O Register for Packing Across Partition Boundaries 8-16
Do Not Use Internal Tri-States 8-20
Include All Tri-State and Enable Logic in the Same Partition 8-20
Include Bidirectional I/O Registers in the Same Partition 8-21
Summary of Guidelines Related to Logic Optimization Across Partitions 8-22
Creating Design Partitions: Consider Additional Design Suggestions 8-23
Balance Logic Resources 8-23
Balance Global Routing Signals and Clock Networks if Required 8-24

Assign Virtual Pins in Bottom-Up Flows 8-25
Perform Timing Budgeting if Required 8-26
Consider a Cascaded Reset Structure 8-26
Drive Clocks Directly in Bottom-Up Flows 8-28
Recreate PLLs for Lower-Level Partitions if Required in Bottom-Up Flows 8-28
Checking Partition Quality 8-29
Incremental Compilation Advisor 8-29
Design Partition Planner 8-29
Floorplan Partition Coloring 8-31
Viewing Design Partition Planner and Floorplan Side-by-Side 8-32
Partition Statistics Report 8-33
Report Partition Timing in the TimeQuest Timing Analyzer 8-34
Ensure Partition Assignments Do Not Impact the Quality of Results 8-34
Introduction to Design Floorplans 8-35
The Difference between Logical Partitions and Physical Regions 8-35
Why Create a Floorplan? 8-36
Why Create a Floorplan in Bottom-Up Flows? 8-36
Why Create a Floorplan in Top-Down Flows? 8-36
When to Create a Floorplan 8-37
Early Floorplan 8-38
Late Floorplan 8-38
Creating a Design Floorplan: Placement Guidelines 8-38
Assigning Partitions to LogicLock Regions 8-39
How to Size and Place Regions 8-39
Modifying Region Size and Origin 8-40
I/O Connections 8-41
LogicLock Resource Exclusions 8-41
Creating Non-Rectangular Regions 8-42
Checking Floorplan Quality 8-43
Incremental Compilation Advisor 8-43
LogicLock Region Resource Estimates 8-43
LogicLock Region Properties Statistics Report 8-43
Critical Path Settings for Chip Planner 8-44
Locate the Quartus II TimeQuest Timing Analyzer Path in the Chip Planner 8-44
Inter-Region Connection Bundles 8-44
Routing Utilization 8-44
Ensure Floorplan Assignments Do Not Impact Quality of Results 8-44
Recommended Design Flows and Application Examples 8-45
Create a Floorplan for the Entire Design in a Top-Down Flow 8-45
Create a Floorplan as the Project Lead in a Bottom-Up Flow 8-46
Create a Floorplan Assignment for One Design Block with Difficult Timing 8-47
Potential Issues with Creating Partitions and Floorplan Assignments 8-47

Chapter Revision Dates

The chapters in this book, *Quartus II Handbook Version 9.0 Volume 1: Design and Synthesis*, were revised on the following dates. Where chapters or groups of chapters are available separately, part numbers are listed.

Chapter 1 Design Planning with the Quartus II Software
Revised: *March 2009*
Part Number: *QII51016-9.0.0*

Chapter 2 Quartus II Incremental Compilation for Hierarchical and Team-Based Design
Revised: *March 2009*
Part Number: *QII51015-9.0.0*

Chapter 3 Quartus II Design Flow for MAX+PLUS II Users
Revised: *March 2009*
Part Number: *QII51002-9.0.0*

Chapter 4 Quartus II Support for HardCopy Series Devices
Revised: *March 2009*
Part Number: *QII51004-9.0.0*

Chapter 5 Design Recommendations for Altera Devices and the Quartus II Design Assistant
Revised: *March 2009*
Part Number: *QII51006-9.0.0*

Chapter 6 Recommended HDL Coding Styles
Revised: *March 2009*
Part Number: *QII51007-9.0.0*

Chapter 7 Managing Metastability with the Quartus II Software
Revised: *March 2009*
Part Number: *QII51018-9.0.0*

Chapter 8 Best Practices for Incremental Compilation Partitions and Floorplan Assignments
Revised: *March 2009*
Part Number: *QII51017-9.0.0*

Chapter 9 Quartus II Integrated Synthesis
Revised: *March 2009*
Part Number: *QII51008-9.0.0*

Chapter 10 Synopsys Synplify Support
Revised: *March 2009*
Part Number: *QII51009-9.0.0*

Chapter 11 Mentor Graphics Precision Synthesis Support
Revised: *March 2009*
Part Number: *QII51011-9.0.0*

Chapter 12 Mentor Graphics LeonardoSpectrum Support
Revised: *March 2009*
Part Number: *QII51010-9.0.0*

Chapter 13 Analyzing Designs with Quartus II Netlist Viewers
Revised: *March 2009*
Part Number: *QII51013-9.0.0*

Section I. Design Flows

The Altera® Quartus® II design software provides a complete design environment that easily adapts to your specific design requirements. This handbook is arranged in chapters, sections, and volumes that correspond to the major stages in the overall design flow. For a general introduction to features and the standard design flow in the software, refer to the *Introduction to the Quartus II Software* manual.

This section starts the *Quartus II Handbook* with an introduction to design planning and a collection of various specialized design flows in the Quartus II software.

This section includes the following chapters:

- Chapter 1, Design Planning with the Quartus II Software

  This chapter discusses important FPGA design planning issues such as device selection, early power estimation, I/O pin planning, and design planning. It provides recommendations and describes various tools available for Altera FPGAs to help you improve design productivity.

  Use this chapter when starting your design for an overview of various planning considerations.

- Chapter 2, Quartus II Incremental Compilation for Hierarchical and Team-Based Design

  This chapter documents Altera's incremental design and compilation flow, which allows you to preserve the results and performance for unchanged logic in your design as you make changes elsewhere, reduces design iteration time by up to 70% so you achieve timing closure efficiently, and facilitates modular hierarchical and team-based design flows using top-down or bottom-up methodologies

  Use this chapter to learn about using the incremental compilation flow, and read about recommended incremental design flows using Quartus II features.

- Chapter 3, Quartus II Design Flow for MAX+PLUS II Users

  There are many features in the Quartus II software to help users of the legacy MAX+PLUS® II software easily transition to the Quartus II software design environment. This chapter describes how to convert MAX+PLUS II designs to Quartus II projects, and highlights the similarities and differences between the MAX+PLUS II and Quartus II design flows.

  Use this chapter if you are using the legacy MAX+PLUS II software.

- Chapter 4, Quartus II Support for HardCopy Series Devices

  Using the Quartus II software, you can leverage an FPGA device as a prototype and seamlessly migrate your design to a HardCopy ASIC to reduce cost for volume production. This chapter describes the Quartus II support for HardCopy design flows.

  Use this chapter if you want to migrate your design to a HardCopy ASIC.

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

1. Design Planning with the Quartus II Software

QII51016-9.0.0

Introduction

This chapter discusses important FPGA design planning issues, provides recommendations, and describes various tools available for Altera® FPGAs to help you improve design productivity.

The inherent flexibility of advanced FPGAs means that the pin layout, power consumption, area utilization, and timing performance for each design block are all dependent on the final design implementation. Due to the significant increase in FPGA device densities over the last few years, designs are increasingly complex and may involve multiple designers. The system architect must resolve these design issues when integrating design blocks, often leading to problems that affect the overall time to market and thereby increase cost. Many potential problems can be solved earlier in the design cycle by performing good design planning.

This chapter contains the following sections:

- "Creating Design Specifications" on page 1–2
- "Device Selection" on page 1–2
- "Planning for Device Programming/Configuration" on page 1–4
- "Early Power Estimation" on page 1–5
- "Early Pin Planning and I/O Analysis" on page 1–6
- "Selecting Third-Party EDA Tool Flows" on page 1–8
- "Planning for On-Chip Debugging Options" on page 1–9
- "Design Practices and HDL Coding Styles" on page 1–11
- "Planning for Hierarchical and Team-Based Design" on page 1–13
- "Fast Synthesis and Early Timing Estimation" on page 1–17

Before reading the design planning guidelines discussed in this chapter, consider your design priorities: What are the important factors for your design? More device features, density, or performance can increase system cost. Signal integrity and board issues may impact I/O pin locations. Power, timing performance, and area utilization affect each other, and compilation time is affected by optimizations for these factors.

The Quartus® II software optimizes designs for the best average results, but you can change settings to focus on one aspect of the design results and trade off other aspects. Certain tools or debugging options can lead to restrictions in your design flow. If you know what is important in a particular design, this knowledge will help you choose the tools, features, and methodologies that you should use with the design. This chapter cannot cover every possible consideration for planning a complex FPGA design, but once you understand your design priorities, you can use the design planning issues described here as a guide to help ensure a productive and successful FPGA design flow.

This chapter provides an introduction to various design and planning features in the Quartus II software. For a general overview of the Quartus II design flow and features, refer to the *Introduction to the Quartus II Software* manual. For more details about specific Quartus II features and methodologies, this chapter provides references to other appropriate chapters in the *Quartus II Handbook*. After you have selected a device family, you can refer to the Design Guidelines section of the device's Literature page on Altera's website to check if additional guidelines are available for your device family.

Creating Design Specifications

Before you create your logic design or complete your system design, you should have detailed design specifications. The specifications define what the system should do, specify the I/O interfaces for the FPGA, and include a block diagram of basic design functions. Taking the time to create these specifications will help improve design efficiency.

Creating a test plan at this phase can also help you design for testability and manufacturability. For example, do you want to perform any built-in self-test functions to drive interfaces? If so, you could use a UART interface with a Nios® II processor inside the FPGA device. You might require the ability to validate all the design interfaces. Refer to "Planning for On-Chip Debugging Options" on page 1–9 for guidelines related to analyzing and debugging the device after it is in the system.

It is also useful to consider a common design directory structure at this point, if your design includes multiple designers. This will ease the design integration stages. "Planning for Hierarchical and Team-Based Design" on page 1–13 provides more suggestions for team-based designs.

Device Selection

The first stage in design planning is choosing the best device for your application. The device selection affects the rest of your design cycle, including board specification and layout. Most of this planning is performed outside of the Quartus II software, but this section provides a few suggestions to aid in the planning process.

It is important to choose the device family that best suits your design requirements. Different families offer different trade-offs, including cost, performance, logic and memory density, I/O density, power utilization, and packaging. You should also consider feature requirements, such as I/O standards support, high-speed transceivers, global/regional clock networks, and the number of phase-locked loops (PLLs) available in the device. You can review important features of each device family in the Selector Guides available on the Altera website. Each device family also has a device handbook or set of data sheets that documents the device features in detail.

Determining the required device density can be a challenging part of the design planning process. Devices with more logic resources and higher I/O counts can implement larger and potentially more complex designs, but may have a higher cost. Select a device that meets your design requirements with some safety margin, in case you want to add more logic later in the design cycle or reserve logic and memory for on-chip debugging (refer to "Planning for On-Chip Debugging Options" on page 1–9). Consider requirements for specific types of dedicated logic blocks, such as memory blocks of different sizes, or digital signal processing (DSP) blocks to implement certain arithmetic functions.

If you have prior designs that target Altera devices, you can use their resource utilization as an estimate for your new design. You can compile existing designs in the Quartus II software with the device selection set to **Auto** to review the resource utilization and find out which device density fits the design.

Coding style, device architecture, and the optimization options used in the Quartus II software can significantly affect a design's resource utilization.

For resource utilization estimates for certain configurations of Altera's intellectual property (IP) designs, refer to the User Guides for Altera megafunctions and IP MegaCore® functions on the IP Megafunctions page on the Altera website (www.altera.com/literature/lit-ip.jsp). You can use these numbers to help estimate the resource utilization of your design.

Device Migration Planning

Determine whether you want the option of migrating your design to another device density to allow flexibility when the design nears completion, or whether you want to migrate to a HardCopy® ASIC when the design reaches volume production. In some cases, designers may target a smaller (and less expensive) device and then move to a larger device if necessary to fit their design. Other designers may prototype their design in a larger device to reduce optimization time and achieve timing closure more quickly, and then migrate to a final smaller device after prototyping. Similarly, many designers compile and optimize their design for an FPGA device before moving to a HardCopy ASIC when the design is complete and ready for higher-volume production. If you would like this flexibility, you should specify these migration options in the Quartus II software at the beginning of your design cycle. Specify the target migration devices in the **Migration compatibility** or **Companion device** sections of the **Device** page in the **Settings** dialog box.

Selecting a migration device has an impact on pin placement because some pins may serve different functions in different device densities or package sizes. When making pin assignments in the Quartus II software, the Pin Migration View in the Pin Planner highlights pins that change function between your migration devices. (Refer to "Early Pin Planning and I/O Analysis" on page 1–6 for more details.) Selecting a companion device may force you to restrict logic utilization to ensure that your design is compatible with a selected HardCopy device. Adding migration or companion devices later in the design cycle is possible, but requires extra effort to check pin assignments, and may require design changes to fit into the new target device. It is much easier to consider these issues early in the design cycle than at the end, when the design is near completion and ready for migration.

In addition, if you are planning to use a HardCopy ASIC, review HardCopy guidelines early in the design cycle for any Quartus II settings that should be used or other restrictions you should consider. It is especially important to use complete timing constraints if you want to migrate to a HardCopy device because of the rigorous verification requirements for ASICs.

For more information about timing requirements and analysis for HardCopy designs, refer to the *HardCopy Series Handbook*.

Planning for Device Programming/Configuration

Another important part of the device planning is determining how you want to program or configure the device in your system. Choosing your programming or configuration method early allows system and board designers to determine what companion devices, if any, are required for your system. Your board layout also depends on the type of programming or configuration method you plan to use for programmable devices. Many programming options use a JTAG interface to connect to the devices, so you may require a JTAG chain be set up on the board.

The device family handbooks describe the configuration options available for a given device family. For more details about configuration options, refer to the *Configuration Handbook*. For information about programming CPLD devices, refer to your device data sheet or handbook. Programming and configuration of Altera devices includes the following options:

- Using enhanced configuration devices—These devices combine industry-standard flash memory with a feature-rich configuration controller, including device features such as concurrent and dynamic configuration, data compression, clock division, and an external flash memory interface. You can also implement remote and local system updates with enhanced configuration devices.
- Using Flash memory devices with a memory controller, such as an Altera MAX® device—The flash memory controller can interface with a PC or microprocessor to receive configuration data via a parallel port.
- Using the Quartus II Serial Flash Loader (SFL)—This scheme allows you to configure the FPGA and program serial configuration devices using the same JTAG interface.
- Using the Quartus II Parallel Flash Loader (PFL)—This solution quickly retrieves data from a JTAG interface and generates data formatted for the receiving target flash device, significantly reducing the flash device programming time. If your system already contains a common flash interface (CFI) flash memory, you can utilize it for the FPGA configuration storage as well, because the PFL feature supports many common industry-standard flash devices. If you choose this method, check the list of supported flash devices early in your system design cycle and plan accordingly. Refer to *AN 386: Using the MAX II Parallel Flash Loader with the Quartus II Software* for the list of supported Flash devices.

Early Power Estimation

You can use the Quartus II power estimation and analysis tools to provide information to PCB board and system designers. You can perform early power estimation before you have created any source code, or when you have a preliminary version of the design, and then perform the most accurate analysis when the design is complete.

Device power consumption must be accurately estimated to develop an appropriate power budget and to design the power supplies, voltage regulators, heat sink, and cooling system. Power estimation and analysis has two significant planning requirements:

- Thermal planning—You must ensure that the cooling solution is sufficient to dissipate the heat generated by the device. In particular, the computed junction temperature must fall within normal device specifications.
- Power supply planning—Power supplies must provide adequate current to support device operation.

Power consumption in FPGA devices is dependent on the design, providing a challenge during early board specification and layout. The Altera PowerPlay Early Power Estimator spreadsheet allows you to estimate power utilization before the design is complete, by processing information about the device resources that will be used in the design, as well as the operating frequency, toggle rates, and environmental considerations.

If you have an existing design or a partially-completed design, the power estimator file generated by the Quartus II software can provide input to the spreadsheet for your current design (refer to "Early Power Estimator File").

When the design is complete, the PowerPlay Power Analyzer tool in the Quartus II software provides an accurate estimation of power to help ensure that thermal and supply budgets are not violated.

The PowerPlay Early Power Estimator spreadsheets for each supported device family are available on the PowerPlay Early Power Estimator and Power Analyzer page of the Altera website.

Estimating power consumption early in the design cycle allows planning of power budgets and avoids surprises for designers developing the PCB.

For more information about power estimation and analysis, refer to the *PowerPlay Power Analysis* chapter in volume 3 of the *Quartus II Handbook.*

Early Power Estimator File

When entering data into the Early Power Estimator spreadsheet, you must include the device resources, operating frequency, toggle rates, and other parameters. Specifying these values requires familiarity with the design. If you do not have an existing design, estimate the number of device resources used in your design and enter it manually. If you have an existing design or a partially completed design, you can generate a power estimator file.

First, compile your design in the Quartus II software. After compilation is complete, on the Project menu, click **Generate PowerPlay Early Power Estimator File**. This command instructs the Quartus II software to write out a power estimator Comma-Separated Value (**.csv**) file (or a text [**.txt**] file for older device families).

The PowerPlay Early Power Estimator spreadsheet includes the Import Data macro, which parses the information in the power estimation file and transfers it into the spreadsheet. If you do not want to use the macro, you can transfer the data into the Early Power Estimator spreadsheet manually.

If the existing Quartus II project represents only a portion of your full design, you should enter the additional resources used in the final design manually. You can edit the spreadsheet and add additional device resources after importing the power estimation file information.

Early Pin Planning and I/O Analysis

It is important to plan top-level FPGA I/O pins early, so board designers can start developing the PCB design and layout. The FPGA device's I/O capabilities influence pin locations and other types of assignments. In cases where the board design team specifies an FPGA pin-out, it is crucial that the pin locations be verified in the FPGA place-and-route software as soon as possible to avoid board design changes.

Traditionally, designers and system architects could not check the validity of FPGA pin assignments until the design was complete. You can now create a preliminary pin-out for an Altera FPGA using the Quartus II Pin Planner before the source code is designed, based on standard I/O interfaces (such as memory and bus interfaces) and any other I/O-related assignments defined by system requirements. Refer to "Creating a Top-Level Design File for I/O Analysis" on page 1–7. Quartus II I/O Assignment Analysis checks that the pin locations and assignments are supported in the target FPGA architecture. You can use **I/O Assignment Analysis** to validate I/O-related assignments that you make or modify throughout the design process.

The Pin Planner enables easy I/O pin assignment planning, assignment, and validation. Use the Pin Planner Package view to make pin location and other assignments using a device package view instead of pin numbers. The Pads view displays I/O pads in order around the silicon die to help you follow pad distance and pin placement guidelines. With the Pin Planner, you can identify I/O banks, voltage reference (VREF) groups, and differential pin pairings to help you through the I/O planning process. If migration devices are selected (including HardCopy devices) as described in "Device Migration Planning" on page 1–3, the Pin Migration view highlights pins that change function in the migration device when compared to the currently selected device. Selecting pins in the Device Migration view cross-probes to the rest of the Pin Planner, so you can use device migration information when planning your pin assignments. You can also configure board trace models of selected pins for use in "board-aware" signal integrity reports generated with the **Enable Advanced I/O Timing** option. This option ensures you get very accurate I/O timing analysis. You have the option to use a Microsoft Excel spreadsheet to start the I/O planning process if you normally use a spreadsheet in your design flow, and you can export a Comma-Separated Value (**.csv**) file containing your I/O assignments for spreadsheet use when all pins are assigned.

When planning is complete, the pin location information can be passed to PCB designers. The Pin Planner is tightly integrated with certain PCB design EDA tools, and can read pin location changes from these tools to check the suggested changes. It is important that pin assignments match between the Quartus II software and your schematic and board layout tools to ensure the design works correctly on the board where it is placed, especially if changes to the pin-out must be made. The system architect can use the Quartus II software to pass pin information to team members designing individual logic blocks, for better timing closure when they compile their design. When the design is complete, the Quartus II Fitter reports should be used for the final sign-off of pin assignments.

Starting FPGA pin planning early—before the HDL design is complete—improves the confidence in early board layouts, reduces the chance of error, and improves the design's overall time to market.

For more information about I/O assignment and analysis, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*. For more information about passing I/O information between the Quartus II software and third-party EDA tools, refer to the *Mentor Graphics PCB Design Tools Support* and *Cadence PCB Design Tools Support* chapters in the *I/O and PCB Tools* section in volume 2 of the *Quartus II Handbook*.

Creating a Top-Level Design File for I/O Analysis

Early in the design process, before the source code is created, the system architect typically has information about the I/O interfaces and IP cores that will be used in the design. You can use this information with the **Create/Import Megafunction** feature in the Pin Planner to specify details about the design I/O interfaces. Specifying these details allows you to create a top-level design file that includes all your I/O information, so you can analyze the I/O assignments in the Quartus II software.

The Pin Planner interfaces with the MegaWizard™ Plug-In Manager, and allows you to create or import custom megafunctions and IP cores that use I/O interfaces. Configure how they are connected to each other by specifying matching node names for selected ports in the **Set Up Top-Level Design File** dialog box. Make any other I/O-related assignments for these interfaces or other design I/O pins in the Pin Planner.

When you have entered as much information as possible, generate a top-level design file using the **Create Top-Level Design File** command. The Pin Planner creates virtual pin assignments for internal nodes, so internal nodes are not assigned to device pins during compilation. After analysis and synthesis of the newly generated top-level wrapper file, use the generated netlist to perform I/O Analysis with the **Start I/O Assignment Analysis** command.

You can use the I/O analysis results to change pin assignments or IP parameters and repeat the checking process until the I/O interface meets your design requirements and passes the pin checks in the Quartus II software. When this initial pin planning is complete, you can create a Quartus II Revision based on the Quartus II-generated netlist. You then have a choice for how to proceed: you can use the generated netlist to develop the top-level file for the actual design, or disregard the generated netlist and use the generated Quartus II Settings File (**.qsf**) with the actual design.

Selecting Third-Party EDA Tool Flows

Your complete FPGA design flow may include third-party EDA tools in addition to the Quartus II software. Determine which tools you want to use with the Quartus II software to ensure that they are supported and set up correctly, and that you are aware of any useful features or undesired limitations.

Synthesis Tools

You can synthesize your design using the Quartus II software's integrated synthesis tool or your preferred third-party synthesis tool. Different synthesis tools may give different results. If you want to select the best-performing tool for your application, you can experiment by synthesizing typical designs for your application and coding style and comparing the results. Be sure to perform placement and routing in the Quartus II software to get accurate timing analysis and logic utilization results. Results from synthesis are estimates before place-and-route and do not include logic that is treated as a black box for synthesis (such as megafunctions or Altera IP cores in some synthesis tools). In addition, these estimates do not take into account logic usage reduction achieved in the Quartus II Fitter through register packing or other Quartus II optimizations, such as Physical Synthesis, that may change both timing and resource utilization results.

Altera recommends that you use the most recent version of third-party synthesis tools, because tool vendors frequently add new features, fix tool issues, and enhance performance for Altera devices. The *Quartus II Software Release Notes* lists the version of each synthesis tool that is officially supported by that version of the Quartus II software.

Specify your synthesis tool in the New Project Wizard or the **EDA Tools Settings** page of the **Settings** dialog box to use the correct Library Mapping File (**.lmf**) for your synthesis netlist.

Synthesis tools may offer the capability to create a Quartus II project and pass constraints, such as the EDA tool setting, device selection, and timing requirements that you specified in your synthesis project. You can use this capability to save time when setting up your Quartus II project for placement and routing.

If you want to take advantage of an incremental compilation methodology, you should partition your design for synthesis and generate multiple output netlist files. Refer to "Incremental Compilation with Design Partitions" on page 1–13 for more information.

For more information about synthesis tool flows, refer to the appropriate chapter in the *Synthesis* section in volume 1 of the *Quartus II Handbook*.

Simulation Tools

Altera provides the ModelSim-Altera simulator with Quartus II license subscriptions, and the Quartus II software can generate timing netlist files to support other third-party simulation tools.

If you use a third-party simulation tool, ensure that you use the software version that is supported with your Quartus II version. The *Quartus II Software Release Notes* list the version of each simulation tool that is officially supported with that particular version of the Quartus II software. Also ensure that you use the model libraries provided with your Quartus II software version. Libraries can change between versions, which might cause a mismatch with your simulation netlist.

Specify your simulation tool in the **EDA Tools Settings** page of the **Settings** dialog box to generate the appropriate output simulation netlist.

For more information about simulation tool flows, refer to the appropriate chapter in the *Simulation* section in volume 3 of the *Quartus II Handbook*.

Formal Verification Tools

The Quartus II software supports some formal verification flows. Consider whether your desired formal verification flow impacts the design and compilation stages of your design.

Using a formal verification flow can impact performance results because it requires that certain logic optimizations be turned off, such as register retiming, and forces hierarchy blocks to be preserved, which can restrict optimization. Formal verification treats memory blocks as black boxes. Therefore, it is best to keep memory in a separate hierarchy block so other logic does not get incorporated into the black box for verification. There are other restrictions that may also limit your design, so consult the documentation for details. If formal verification is important to your design, it is easier to plan for limitations and restrictions in the beginning than to make changes later in the design flow.

Specify your formal verification tool in the **EDA Tools Settings** page of the **Settings** dialog box to generate the appropriate output netlist.

For more information about formal verification flows, refer to the appropriate chapter in the *Formal Verification* section in volume 3 of the *Quartus II Handbook*.

Planning for On-Chip Debugging Options

Altera’s in-system debugging tools offer different advantages and trade-offs, so a particular debugging tool may work better for different systems and designers. It is beneficial to evaluate on-chip debugging options early in your design process, to ensure that your system board, Quartus II project, and design are all set up to support the appropriate options. Planning can reduce time spent during debugging and eliminates having to make changes later to accommodate your preferred debugging methodologies.

The Quartus II portfolio of verification tools includes the following in-system debugging features:

- SignalProbe incremental routing—This feature makes design verification more efficient by quickly routing internal signals to I/O pins without affecting the design. Starting with a fully routed design, you can select and route signals for debugging to either previously reserved or currently unused I/O pins.

- SignalTap® II Embedded Logic Analyzer—This logic analyzer helps you debug an FPGA design by probing the state of the internal signals in the design without the use of external equipment or extra I/O pins, while the design is running at full speed in an FPGA device. Defining custom trigger-condition logic provides greater accuracy and improves the ability to isolate problems. The SignalTap II Embedded Logic Analyzer does not require external probes or changes to the design files to capture the state of the internal nodes or I/O pins in the design; all captured signal data is conveniently stored in device memory until you are ready to read and analyze the data.
- Logic Analyzer Interface (LAI)—This interface enables you to connect and transmit internal FPGA signals to an external logic analyzer for analysis. You can use this feature to connect a large set of internal device signals to a small number of output pins for debugging purposes, and allows you to take advantage of advanced features in your external logic analyzer or mixed signal oscilloscope.
- In-System Memory Content Editor—This feature provides read and write access to in-system FPGA memories and constants through the JTAG interface, making it easy to test changes to memory contents and constant values in the FPGA while the device is functioning in a system.
- In-System Sources and Probes—This feature sets up customized register chains to drive or sample the instrumented nodes in your logic design, providing an easy way to input simple virtual stimuli and capture the current value of instrumented nodes. You can force trigger conditions set up using the SignalTap II Logic Analyzer, create simple test vectors to exercise your design without the use of external test equipment, and dynamically control run-time control signals with the JTAG chain.
- Virtual JTAG Megafunction—The sld_virtual_jtag megafunction allows you to build your own system-level debugging infrastructure, including both processor-based debugging solutions and debugging tools in software for system-level debugging. The sld_virtual_jtag megafunction can be instantiated directly in your HDL code to provide one or more transparent communication channels to access parts of your FPGA design using the JTAG interface of the device.

For more information about debugging tools, refer to the appropriate "Referenced Documents" on page 1–18. For an overview of debugging options that will help you decide which option to use, refer to the introduction in *Section V. In-System Design Debugging* in volume 3 of the *Quartus II Handbook*.

If you intend to use any of these features, you may have to plan for the features when developing your system board, Quartus II project, and design. The following paragraphs describe various factors to consider during your design planning stages.

The SignalTap II Embedded Logic Analyzer, Logic Analyzer Interface, In-System Memory Content Editor, In-System Sources and Probes, and Virtual JTAG megafunction require JTAG connections to perform in-system debugging. Plan your system and board with JTAG ports that are available for debugging.

The JTAG debugging features also require a small amount of additional logic resources to implement the JTAG hub logic. If you set up the appropriate feature early in your design cycle, you can include these device resources in your early resource estimations to ensure you do not overfill the device with logic.

The SignalTap II Embedded Logic Analyzer uses device memory to capture data during system operation. To ensure that you have enough memory resources to take advantage of this debugging technique, consider reserving device memory to be used during debugging.

To use incremental debugging with the SignalTap II Embedded Logic Analyzer, the **Full incremental compilation** option must be turned on. This option is on by default for projects created in the Quartus II software version 6.1 or later, but is not turned on automatically for existing projects. If incremental compilation is not enabled, you must recompile the entire design when you want to add debugging functions, or when you make certain changes to SignalTap II settings. Using incremental compilation with the SignalTap II Embedded Logic Analyzer greatly reduces the compilation time required for debugging.

SignalProbe and the Logic Analyzer Interface require I/O pins for debugging. Consider reserving I/O pins for debugging so that you do not have to change the design or board to accommodate debugging signals later. Keep in mind that the Logic Analyzer Interface can multiplex signals with design I/O pins if required. Ensure that your board supports some kind of debugging mode, where debugging signals do not affect system operation.

If you want to use the Virtual JTAG megafunction for custom debugging applications, you must instantiate it and incorporate it as part of the design process.

The In-System Sources and Probes feature also requires that you instantiate a megafunction in your HDL code. In addition, you have the option to instantiate the SignalTap II Embedded Logic Analyzer as a megafunction, so you can connect it to nodes in your design manually and ensure that the tapped node names do not change during synthesis. You can add the debugging block as a separate design partition for incremental compilation to minimize recompilation times.

To use the In-System Memory Content Editor for RAM or ROM blocks or the lpm_constant megafunction, ensure that you turn on the **Allow In-System Memory Content Editor** to capture and update content independently of the system clock option when you create the memory block in the MegaWizard Plug-In Manager.

Design Practices and HDL Coding Styles

In the development of complex FPGA designs, design practices and coding styles have an enormous impact on your device's timing performance, logic utilization, and system reliability. Follow Altera's recommendations to achieve the best synthesis and fitting results.

Design Recommendations

Use synchronous design practices to consistently meet your design goals. Problems with other design techniques include reliance on propagation delays in a device, incomplete timing analysis, and possible glitches. In a synchronous design, a clock signal triggers all events. As long as all of the registers' timing requirements are met, a synchronous design behaves in a predictable and reliable manner for all process, voltage, and temperature (PVT) conditions. You can easily target synchronous designs to different device families or speed grades.

Pay particular attention to clock signals, because they have a large effect on your design's timing accuracy, performance, and reliability. Problems with clock signals can cause functional and timing problems in your design. Use dedicated clock pins and clock routing for best results, and if PLLs are available in your target device, use the PLLs for clock inversion, multiplication, and division. For clock multiplexing and gating, use the dedicated clock control block or PLL clock switchover feature instead of combinational logic if these features are available in your device. If you must use internally-generated clock signals, register the output of any combinational logic used as a clock signal to reduce glitches.

The Design Assistant in the Quartus II software is a design-rule checking tool that enables you to check for design issues early in the design flow. The Design Assistant checks your design for adherence to Altera-recommended design guidelines or design rules. To run the Design Assistant, on the Processing menu, point to **Start** and click **Start Design Assistant**. To set the Design Assistant to run automatically during compilation, turn on **Run Design Assistant during compilation** in the **Settings** dialog box. You can also use third-party "lint" tools to check your coding style.

It is also helpful to understand your device's target architecture, so you can target your design to take advantage of those features. For example, it is important that control signals use the dedicated control signals in the device architecture, so in some cases you might be required to limit the number of different control signals used in your design to achieve the best results.

For more information about design recommendations and using the Design Assistant, refer to the *Design Recommendations for Altera Devices and the Quartus II Design Assistant* chapter in volume 1 of the *Quartus II Handbook*. You can also refer to industry papers for more information about multiple clock design. For a good analysis, refer to *Synthesis and Scripting Techniques for Designing Multi-Asynchronous Clock Designs* under **Papers** at www.sunburst-design.com.

Recommended HDL Coding Styles

HDL coding styles can have a significant effect on the quality of results for programmable logic designs. Use Altera's recommended coding styles to achieve optimal synthesis results. When designing memory and DSP functions, it is helpful to understand your device's target architecture so you can take advantage of the dedicated logic block sizes and configurations. Follow the coding guidelines for inferring megafunctions and targeting dedicated device hardware, such as memory and DSP blocks.

For specific HDL coding examples and recommendations, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*. Refer to your synthesis tool's documentation for any additional tool-specific guidelines. In the Quartus II software, you can use the HDL examples in the Language Templates available from the right-click menu in the text editor.

Planning for Hierarchical and Team-Based Design

If you want to create a hierarchical design that can take advantage of the compilation-time savings and performance preservation of Quartus II incremental compilation, plan for an incremental compilation flow from the beginning of your design cycle. The following subsections describe the flat compilation flow, in which the design hierarchy is flattened without design partitions, and then the incremental compilation flows that use design partitions in top-down, bottom-up, or mixed design methodologies. Incremental compilation flows offer several advantages but require more design planning to ensure good quality of results. The last subsections discuss factors to consider when planning an incremental compilation flow: planning design partitions and creating a design floorplan.

For details about using the incremental compilation flows in the Quartus II software, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Flat Compilation Flow with No Design Partitions

In this compilation flow in the Quartus II software, the entire design is compiled together in a "flat" netlist. This flow is used if you do not create any design partitions. Your source code can have hierarchy, but the design is flattened during compilation and all of the design source code is synthesized and fit in the target device whenever the design is recompiled after any change in the design. By processing the entire design, the software performs all available logic and placement optimizations on the entire design to improve area and performance. You can use debugging tools in an incremental design flow, such as the SignalTap II Logic Analyzer, but you do not specify any design partitions to preserve design hierarchy during compilation.

The flat compilation flow is easy to use; you do not have to plan any design partitions. However, because the entire design is recompiled whenever there are any changes to the design, compilation times can be relatively long for large devices. In addition, you may find that the results for one part of the design change when you change a different part of your design.

The full incremental compilation option is turned on by default in the Quartus II software, so the project is ready for you to create design partitions for incremental compilation. If you do not create any lower-level design partitions, the entire design is considered as a single design partition, and the software uses a flat compilation flow.

Incremental Compilation with Design Partitions

In an incremental compilation flow, the system architect splits a large design into smaller partitions which can be designed separately. Team members can work on partitions independently, which can simplify the design process and reduce compilation time.

When hierarchical design partitions are well chosen and placed in the device floorplan, you can speed up your design compilation time while maintaining or even improving the quality of results.

You may want to use incremental compilation later in the design cycle when you are not interested in improving the majority of the design any further, and want to make changes to, or optimize, one specific block. In this case, you may want to preserve the performance of modules that are unmodified and reduce compilation time on subsequent iterations.

Incremental compilation may also be useful for both reducing compilation time and achieving timing closure. For example, you may want to specify which partitions should be preserved in subsequent incremental compilations and then recompile the other partitions with advanced optimizations turned on.

If a part of your design is not yet complete, you can create an empty partition for the incomplete part of the design while compiling the completed partitions. Then, save the results for the complete partitions while you work on the new part of the design.

Alternately, different designers or IP providers may be working on different blocks of the design using a team-based methodology, and you may want to combine these blocks in a bottom-up compilation flow.

When planning your design code and hierarchy, ensure that each design entity is created in a separate file so the entities remain independent when you make source code changes in the file. If you use a third-party synthesis tool, create separate Verilog Quartus Mapping (VQM) or EDIF netlists for each design partition in your synthesis tool. You may have to create separate projects within your synthesis tool, so the tool synthesizes each partition separately and generates separate output netlist files. Refer to your synthesis tool documentation for information about support for Quartus II incremental compilation. The netlists are then considered the source files for incremental compilation.

Top-Down Versus Bottom-Up Incremental Flows

The Quartus II incremental compilation feature supports both top-down and bottom-up compilation flows that are suitable for different design methodologies. You can also combine these flows in a mixed compilation flow. The following subsections briefly describe each of these compilation flows so that you can choose the flow that best meets your design requirements.

Top-Down Incremental Compilation Flow

With top-down compilation, one designer or project lead compiles the entire design in the software. Different designers or IP providers can design and verify different parts of the design, and the project lead can add design entities to the project as they are completed. You can also target optimizations on one part of the design while designating the rest of the design as “empty.” Regardless of the source for all the design logic, the project lead compiles and optimizes the top-level project as a whole.

Incremental compilation preserves the compilation results and performance of unchanged partitions in your design, greatly reducing design iteration time by focusing new compilations on changed design partitions only. New compilation results are then merged with the previous compilation results from unchanged design partitions. Additionally, you can target optimization techniques, such as physical synthesis, to specific design partitions while leaving other partitions untouched. You can also use this flow with empty partitions if parts of your design are incomplete or missing.

Bottom-Up and Team-Based Incremental Compilation Flow

Bottom-up design flows allow individual designers to complete the optimization of their design in separate projects and then integrate each lower-level project into one top-level project. Bottom-up methodologies include team-based design flows in which design partitions are created by team members in another location or by third-party IP providers.

Incremental compilation provides export and import features to enable bottom-up design methodologies. Designers of lower-level blocks can export the optimized netlist for their design, along with a set of assignments, such as LogicLock™ regions. The system architect then imports each design block as a design partition in a top-level project.

In bottom-up design flows, it is very important that the system architect provide guidance to designers of lower-level blocks to ensure that each partition uses the appropriate device resources. Because the designs are developed independently, each lower-level designer has no information about the overall design or how their partition connects with other partitions. This lack of information can lead to problems during system integration. The top-level project information, including pin locations, physical constraints, and timing requirements, should be communicated to the designers of lower-level partitions before they start their design.

The system architect can plan design partitions at the top level and use Quartus II incremental compilation to communicate information to lower-level designers through automatically-generated scripts. The **Generate bottom-up design partition scripts** option automates the process of transferring top-level project information to lower-level modules. The software provides a project manager interface for managing project information in the top-level design.

The scripts can create Quartus II projects for all the lower-level design blocks and pass all the relevant project assignments. Using these scripts makes it easier for designers of lower-level modules to implement the instructions from the project lead, and avoid conflicts between projects when importing and incorporating the projects into the top-level design. You can use this methodology to help reduce the need to further optimize the designs after integration and improve overall designer productivity and team collaboration.

Mixed Incremental Compilation Flow

You can combine top-down and bottom-up compilation flows to take advantage of top-down flows for part of your design, while importing parts of the design that are developed independently.

The top-down flow is generally simpler to perform than its bottom-up counterpart. For example, having to export and import lower-level designs is eliminated. A top-down approach also provides the design software with information about the entire design, so it can perform global placement optimizations when no part of the design is locked down to a specific location.

In a bottom-up design methodology, you must perform resource balancing and time-budgeting very carefully, because the software does not have any information about the other partitions in the top-level design when it compiles individual lower-level partitions. Using bottom-up compilation flows where required, in combination with top-down compilation flows to reduce compilation time and preserve results for other parts of the design, can be an effective way to improve your productivity.

Planning Design Partitions

Partitioning a design for an FPGA requires planning to ensure optimal results when the partitions are integrated, and ensure that each partition is placed well relative to other partitions in the device. Following Altera's recommendations for creating design partitions improves the overall quality of results. For example, registering partition I/O boundaries keeps critical timing paths inside one partition that can be optimized independently. When the design partitions are specified, you can use the Incremental Compilation Advisor to ensure that partitions meet Altera's recommendations.

Determining a timing budget before designers develop their individual blocks reduces the chance of timing problems during system integration. If you optimize lower-level partitions separately, any unregistered paths that cross between partitions are not optimized as an entire path. To ensure that the software correctly optimizes the input and output logic in each partition, you may be required to perform some manual timing budgeting. For each unregistered timing path that crosses between partitions, you should make timing assignments on the corresponding I/O path in each partition to constrain both ends of the path to the budgeted timing delay. Assigning a timing budget for each part of the connection ensures that the software optimizes paths appropriately so they meet the top-level design requirements.

It is important to plan and balance resource utilization. When performing incremental compilation, the software synthesizes each partition separately, with no data about the resources used in other partitions. Therefore, device resources can be overused in the individual partitions during synthesis, and the design may not fit in the target device when the partitions are merged.

In a bottom-up design flow in which designers optimize their lower-level designs and export them to a top-level design, the software also places and routes each partition separately. In some cases, partitions can use conflicting resources when combined at the top level. Balancing resource utilization between the design partitions avoids any problems with conflicting resources when all the partitions are integrated.

For guidelines on creating design partitions and organizing your source code, refer to the *Best Practices for Incremental Compilation Partitions and Floorplan* chapter in volume 1 of the *Quartus II Handbook*.

Creating a Design Floorplan

To take full advantage of incremental compilation, you may be required to create a design floorplan to avoid conflicts between design partitions, and to ensure that each partition is placed well relative to other partitions. Creating location assignments for each partition ensures that no conflicts occur for locations between different partitions. In addition, a design floorplan helps to avoid a situation in which the Fitter is directed to place or replace a portion of the design in an area of the device where most resources have already been claimed. Without floorplan assignments, this situation can lead to increased compilation time and reduced quality of results.

You can use the Quartus II Timing Closure Floorplan or Chip Planner, depending on your target device, to create a design floorplan using LogicLock region assignments for each design partition. With a basic design framework for the top-level design, these floorplan editors allow you to view connections between regions, estimate physical timing delays on the chip, and move regions around the device floorplan. When you have compiled the full design, you can also view logic placement and locate areas of routing congestion to improve the floorplan assignments.

Good partition and floorplan design helps lower-level designs meet top-level design requirements when integrated with the rest of the design, reducing the time spent integrating and verifying the timing of the top-level design.

For details about creating placement assignments in the design floorplan, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*. For guidelines on creating a design floorplan for incremental compilation, refer to the *Best Practices for Incremental Compilation Partitions and Floorplan Assignments* chapter in volume 1 of the *Quartus II Handbook*.

Fast Synthesis and Early Timing Estimation

It is much less costly to find design issues early in the design cycle than to find problems in the final timing closure stages. When the first version of the design source code is complete, you may want to perform a quick compilation to create a kind of silicon virtual prototype (SVP) that you can use to perform timing analysis.

If you synthesize with the Quartus II software, you can choose to perform a **Fast** synthesis, which reduces the compilation time but may give reduced quality of results. On the Assignments menu, click **Settings**. On the **Analysis & Synthesis Settings** tab, click **More Settings** and set the **Synthesis Effort**.

Regardless of your compilation flow, you can use the an Early Timing Estimate to perform a quick placement and routing, and a timing analysis of your design. On the Processing menu, point to **Start**, and click **Start Early Timing Estimate**. The software chooses a device automatically if required, places any LogicLock regions used to create a floorplan, finds a quick initial placement for all the design logic, and provides a useful estimate of the final design performance. If you have entered timing constraints, timing analysis reports on these constraints.

Early Timing Estimation is supported with both the TimeQuest and Classic Timing Analyzers. Use the TimeQuest Timing Analyzer with Synopsys Design Constraint (SDC) format constraints to enable advanced timing analysis capabilities that are not available in the Classic Timing Analyzer.

Designers of individual blocks in bottom-up design flows can use these features as they develop the design. Any issues highlighted in the lower level design blocks can be communicated to the system architect. Resolving these issues may require allocating additional device resources to the individual block or changing its timing budget.

A top-level designer can also use fast synthesis and early timing estimation to prototype the entire design. Incomplete partitions can be marked as empty in an incremental compilation flow, while the rest of the design is compiled to get an early timing estimate and detect any problems with design integration.

A system architect can use early timing estimation along with design partition scripts (as described in "Bottom-Up and Team-Based Incremental Compilation Flow" on page 1–15) to pass additional constraints to lower-level designers, and provide more information about the other partitions in the design. This information can be especially useful to optimize cross-partition paths. Running early timing estimations helps designers find and resolve design problems during the early design stages.

Conclusion

Modern FPGAs support large, complex designs with fast timing performance. By planning several aspects of your design early in the process, you can reduce unnecessary time spent handling issues in later stages of the process. You can use various features of the Quartus II software to quickly plan your design and achieve the best possible results. Following the guidelines presented in this chapter can improve productivity, which reduces the design cost and improves the final product's time to market.

Document Revision History

Table 1–1 shows the revision history for this chapter.

Table 1–1. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v.9.0.0	No change to content	Updated for the Quartus II 9.0 software release.
November 2008 v8.1.0	Changed to 8-1/2 x 11 page size. No change to content.	Updated for the Quartus II 8.1 software release.
May 2008 v8.0.0	■ Organization changes ■ Added “Creating Design Specifications” section ■ Added reference to new details in the *In-System Design Debugging* section of volume 3 ■ Added more details to the “Design Practices and HDL Coding Styles” section ■ Added references to the new *Best Practices for Incremental Compilation Partitions and Floorplan Assignments* chapter ■ Added reference to the Quartus II Language Templates	Updated for the Quartus II 8.0 software release and related documentation; expanded and improved organization of topic coverage.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

2. Quartus II Incremental Compilation for Hierarchical and Team-Based Design

QII51015-9.0.0

Introduction

The ability to iterate rapidly through FPGA design and debugging stages is critical. The Quartus® II software introduced the FPGA industry's first true incremental design and compilation flow, with the following benefits:

- Preserves the results and performance for unchanged logic in your design as you make changes elsewhere
- Reduces design iteration time by up to 70%, so you can perform more design iterations per day and achieve timing closure efficiently
- Integrates with third-party synthesis software's incremental synthesis flows
- Facilitates modular hierarchical and team-based design flows

"Deciding Whether to Use an Incremental Compilation Flow" on page 2–2 provides an overview of the Quartus II design flow with and without incremental compilation to help you decide if you should take advantage of optional incremental flows for your project. The remainder of the chapter includes the following sections:

- "Quick Start Guide—Summary of Incremental Compilation" on page 2–7
- "Deciding which Design Blocks Should Be Design Partitions" on page 2–9, including integration with third-party synthesis tools
- "Creating Design Partition Assignments" on page 2–16, including using the Design Partition Planner
- "Setting the Netlist Type for Design Partitions" on page 2–19
- "Creating a Design Floorplan with LogicLock Location Assignments" on page 2–25
- "Exporting and Importing Partitions" on page 2–29
- "Importing SDC Constraints from Lower-Level Partitions" on page 2–45
- "Recommended Design Flows and Compilation Application Examples" on page 2–49, including the steps required to carry out the following tasks:
  - "Reducing Compilation Time When Changing a Source File for One Partition"
  - "Preserving Results for Some Partitions Before Adding Other Partitions"
  - "Optimizing a Timing-Critical Partition to Achieve Timing Closure"
  - "Debugging Incrementally with the SignalTap II Logic Analyzer"
  - "Implementing a Team-Based Bottom-Up Design Flow"
  - "Performing Design Iteration in a Bottom-Up Design Flow"
  - "Creating Hard-Wired Macros (or Precompiled Design Blocks) for IP Reuse"
  - "Using an Exported Partition to Send a Design without Including Source Files"
- "Incremental Compilation Restrictions" on page 2–60
- "Scripting Support" on page 2–69

Quartus II incremental compilation supports the Arria® GX, Stratix®, and Cyclone® series of devices, with limited support for HardCopy® ASICs (for details, refer to "HardCopy Compilation and Migration Flows" on page 2–64.

Deciding Whether to Use an Incremental Compilation Flow

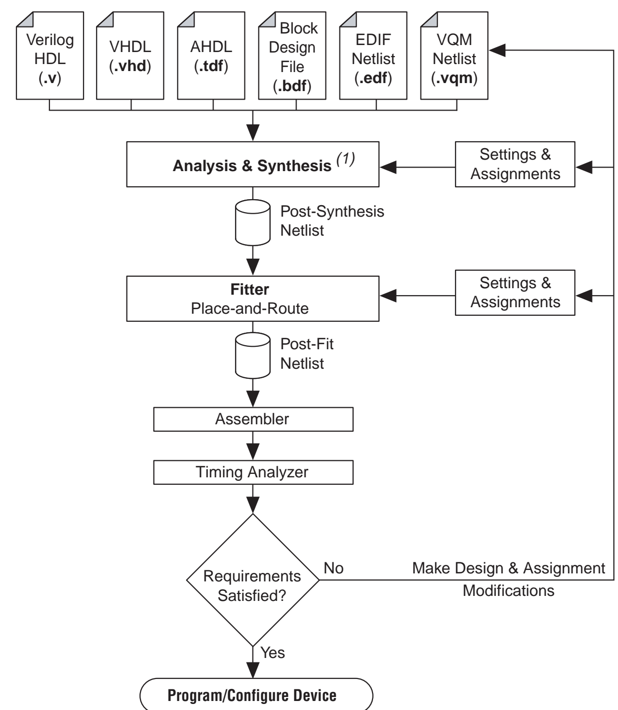
Quartus II incremental compilation enhances the standard Quartus II design flow by allowing you to preserve the satisfactory compilation results and performance of unchanged parts of your design. This section outlines the flat compilation flow with no design partitions and the incremental flow when you divide the design into partitions, and explains the differences. The section also explains when a flat compilation flow is satisfactory, and highlights some of the reasons you might want to create design partitions and use the incremental flow.

The full incremental compilation option is turned on by default in the Quartus II software, so the project is ready for you to create design partitions for incremental compilation. If you do not create any design partitions, the software uses a flat compilation flow, and you cannot make incremental changes within the design. Synthesizing and fitting the design with no partitions is similar to compiling with the Quartus II full incremental compilation option turned off. However, Altera recommends leaving the option turned on because doing so enables some incremental flows, such as debugging with the SignalTap® II Embedded Logic Analyzer, even if you do not create design partitions.

Flat Compilation Flow with No Design Partitions

Figure 2–1 shows the compilation flow with no design partitions.

Figure 2–1. Quartus II Compilation Flow with No Design Partitions



Note to Figure 2–1:

(1) When you use EDIF or VQM netlists created by third-party EDA synthesis tools, Analysis and Synthesis creates the design database, but logic synthesis and technology mapping are performed only for black boxes.

In the default flat compilation flow with no design partitions, all the source code is processed with the Analysis & Synthesis module, and all the logic is placed and routed by the Fitter module whenever the design is recompiled after a change in any part of the design. One reason for this behavior is to obtain optimal quality of results. By processing the entire design, the compiler can perform global optimizations to improve area and performance.

You can use a flat compilation flow for small designs, such as designs in CPLD devices or low-density FPGA devices, when the timing requirements are met easily with a single compilation. A flat design is satisfactory when compilation time and preserving results for timing closure are not concerns.

Quartus II Smart Compilation

The Quartus II software also includes a feature called Smart Compilation, which should not be confused with incremental compilation. In any Quartus II compilation flow, you can use Smart Compilation to allow the compiler to determine which compiler stages are required, based on the changes made to the design since the last smart compilation, and then skip any stages that are not required. For example, when Smart Compilation is on, the compiler skips the Analysis & Synthesis module if all the design source files are unchanged. Smart Compilation skips only entire compiler stages. It cannot make incremental changes within a given stage of the compilation flow. To turn on Smart Compilation, on the Assignments menu, click **Settings**. In the **Category** list, select **Compilation Process Settings** and click **Use Smart Compilation**.

Incremental Compilation Flow with Design Partitions

Using design partitions allows you to preserve the results and performance for unchanged logic in your design as you make changes elsewhere, and reduce compilation time. Incremental compilation is recommended for large designs and high resource densities, as well as designs that require high performance relative to the speed of the device architecture. The feature also facilitates team-based design environments, allowing designers to create and optimize design blocks independently.

Incremental compilation supports top-down incremental compilation, in which one designer manages a single project for the entire design, and bottom-up incremental compilation, in which each design block can be developed and optimized independently, and combinations of the two. See "Top-Down versus Bottom-Up Compilation Flows" on page 2–6 for more details. To take advantage of the incremental compilation flow, start by splitting the design along any of its hierarchical boundaries into blocks called design partitions. Refer to "Deciding which Design Blocks Should Be Design Partitions" on page 2–9 and "Creating Design Partition Assignments" on page 2–16 for more details. The Quartus II software synthesizes each individual hierarchical design partition separately, then merges the partitions into a complete netlist for subsequent stages of the compilation flow. When recompiling the design, you can use source code, post-synthesis results, or post-fitting results for each partition. If you want to preserve the Fitter results, you can keep just the placement results, or keep both the placement and routing results.

You can use incremental compilation toward the end of your design cycle when you do not have to improve the majority of the design any further and want to make changes to or optimize one specific block. In this case, you can preserve the performance of modules that meet their requirements to make timing closure easier and reduce compilation time on subsequent iterations. You can also recompile the other partitions with advanced optimizations turned on to improve their performance without affecting the preserved partitions.

Part of your design may be incomplete or developed by a different designer or IP provider. You can create an empty partition for this part of the design while compiling the completed partitions, and then save the results for the complete partitions while you optimize the imported part of the design. Alternatively, different designers or IP providers may want to develop and optimize different blocks of the design independently, and you can combine them in a bottom-up compilation flow.

For more detailed examples that describe recommended design flows to take advantage of the incremental compilation features, refer to “Recommended Design Flows and Compilation Application Examples” on page 2–49.

Table 2–1 shows a summary of the impact of incremental compilation on your compilation results.

Table 2–1. Impact Summary of Using Incremental Compilation

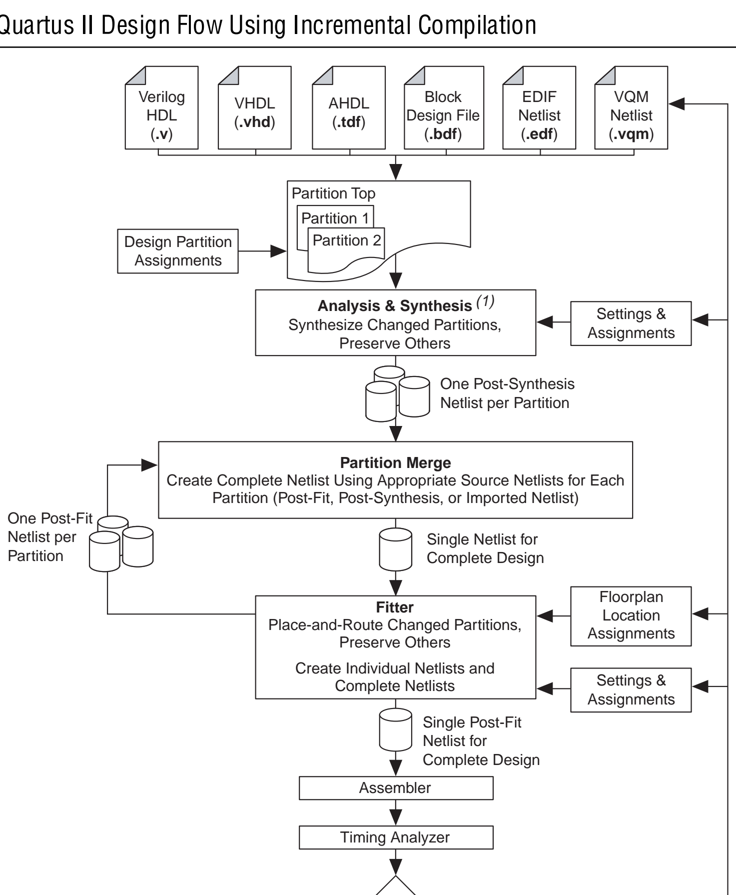
Characteristic	Impact of Incremental Compilation with Design Partitions
Compilation Time Savings	Typically saves 50-70% of compilation time when post-fit netlists are preserved; there are savings in both Quartus II integrated synthesis and the Fitter.
Performance Preservation	Excellent when critical paths are contained within a partition, because you can preserve post-fitting information for unchanged partitions.
Node Name Preservation	Preserves post-fitting node names for unchanged partitions.
Area Changes	The area (logic resource utilization) might increase because cross-boundary optimizations are no longer possible, and placement and register packing are restricted.
f_{MAX} Changes	The design’s maximum frequency might be reduced because cross-boundary optimizations are no longer possible. If the design is partitioned and the floorplan location assignments are created appropriately, there is no negative impact on f_{MAX}.
Floorplan Creation	Recommended for critical partitions to ensure the best quality of results when making design changes. Required when importing partitions from another Quartus II project to avoid placement conflicts.

If you use the incremental compilation feature at any point in your design flow, you should start planning for incremental compilation from the start of your design development. It is easier to accommodate the guidelines for partitioning and creating a floorplan if you start planning at the beginning of your design cycle.

Refer to the *Best Practices for Incremental Compilation Partitions and Floorplan Assignments* chapter in volume 1 of the *Quartus II Handbook* for more information and recommendations.

Figure 2–2 shows a block diagram of the Quartus II design flow using incremental compilation with design partitions.

Figure 2–2. Quartus II Design Flow Using Incremental Compilation



Note to Figure 2–2:

(1) When you use EDIF or VQM netlists created by third-party EDA synthesis tools, Analysis and Synthesis creates the design database, but logic synthesis and technology mapping are performed only for black boxes.

The diagram in Figure 2–2 shows a top-level partition and two lower-level partitions. If any part of the design changes, Analysis and Synthesis processes the changed partitions and keeps the existing netlists for the unchanged partitions. After completion of Analysis and Synthesis, there is one post-synthesis netlist for each partition.

The Partition Merge step creates a single, complete netlist that consists of post-synthesis netlists, post-fit netlists, and netlists imported from other Quartus II projects, depending on the netlist type you specify for each partition.

The Fitter then processes the merged netlist, preserving the placement or placement and routing of unchanged partitions, refitting only those partitions that have changed. The Fitter generates the complete netlist for use in further stages of the compilation flow, including timing analysis and programming file generation. It also generates individual netlists for each partition so the Partition Merge stage can use the post-fit netlist to preserve the placement and routing of a partition if you specify to do so in future compilations. The Quartus II software does not resynthesize or refit unchanged partitions that have a netlist type assignment that specifies the use of a post-synthesis or post-fit netlist, respectively.

For more information about using the incremental compilation feature, refer to the “Quick Start Guide—Summary of Incremental Compilation” on page 2–7.

Quartus II software versions before version 8.1 included an “incremental synthesis only” option that did not preserve placement results. This option was removed beginning with version 8.1. You can use a post-synthesis netlist to preserve synthesis results with full incremental compilation.

Top-Down versus Bottom-Up Compilation Flows

With top-down compilation, one designer compiles the entire design in the software. You can use a top-down flow to optimize all blocks of the design together, or to optimize one or more critical design blocks or IP cores before adding the rest of the design. You can preserve fitting results and performance for completed blocks while other parts of the design are changing, which also reduces the compilation times for each design iteration. Different designers or IP providers can create and verify HDL code separately, but one person (generally the project lead or system architect) compiles and optimizes the design as a single top-level Quartus II project.

With bottom-up design flows, individual designers or IP providers can complete the development and optimization of their design in separate Quartus II projects and then integrate each lower-level project into one top-level project. Incremental compilation provides export and import features to enable this design methodology. Designers of lower-level blocks can export the optimized placed and routed netlist for their design, along with a set of assignments such as LogicLock™ regions. The project lead then imports each design block as a design partition in a top-level project.

A bottom-up design flow permits the reuse of compilation results from another project, with the ultimate goals of performance preservation and compilation time reduction in a multiple-designer environment.

A bottom-up design flow also has the following potential drawbacks that require careful planning:

- Achieving timing closure for the full design may be more difficult if you compile the lower-level blocks independently without any information about each other. This problem may be avoided by careful timing budgeting and special design rules, such as always registering the ports at the module boundaries.
- For the same reason, resource budgeting and allocation may be required to avoid resource conflicts and overuse. Floorplan creation is typically very important in a bottom-up flow.

 © March 2009 Altera Corporation

In a bottom-up design flow, the top-level project lead can do much of the design planning, and then pass constraints on to the designers of lower-level blocks using Quartus II-generated design partition scripts.

When using the full incremental compilation flow, users who traditionally relied on a bottom-up approach for the sole reason of performance preservation can now employ a top-down approach to achieve the same goal. This ability is important for the following two reasons:

- A top-down flow is generally simpler to perform than its bottom-up counterpart. For example, having to export and import lower-level designs is eliminated.
- A top-down approach provides the design software with information about the entire design so it can perform some global placement and routing optimizations. Therefore, it is often easier to ensure good quality of results with a top-down flow than with a bottom-up flow.

The Quartus II incremental compilation feature is very flexible and supports numerous design methodologies. You can mix top-down and bottom-up flows within a single project. If the top-level design includes one or more design blocks that are optimized by different designers or IP providers, you can import those blocks (using a bottom-up methodology) into a project that also includes partitions for a top-down incremental methodology. In addition, as you perform timing closure for a design, you can create a subproject for one block of the design to be optimized by another designer in a separate Quartus II project, and pass information about the rest of the design to the subproject to obtain the best results. By following a mixed design methodology, you can take advantage of the team-based capabilities of a bottom-up flow while maintaining the advantages of a top-down flow for most of the design logic.

Importing partitions is not supported in HardCopy or FPGA companion device compilations when there is a migration device setting. You cannot use a bottom-up methodology if you migrate to a HardCopy ASIC. For details, refer to “HardCopy Compilation and Migration Flows” on page 2–64.

The following Quick Start Guide describes the top-down compilation flow because it is the more commonly used and easy-to-use incremental compilation flow. For more information about exporting design partitions from separate Quartus II projects and importing them as part of a bottom-up design flow, refer to “Exporting and Importing Partitions” on page 2–29.

Quick Start Guide—Summary of Incremental Compilation

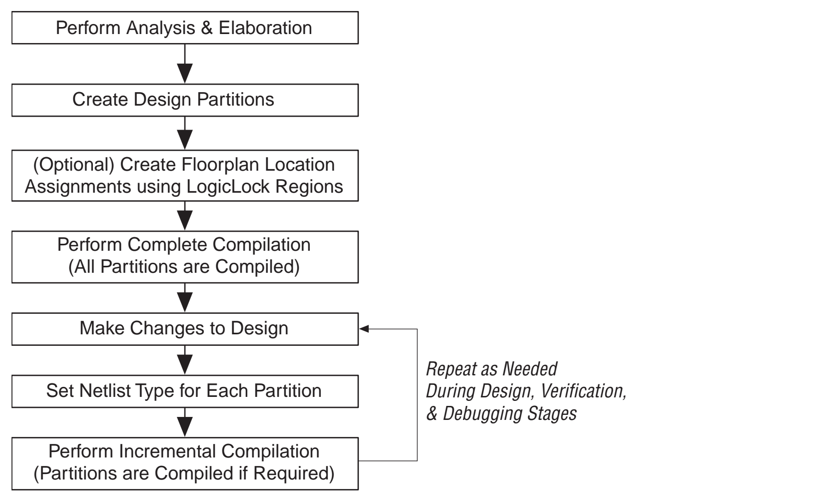
This section provides a summary of the steps required to perform a simple incremental compilation flow. Detailed descriptions for many of these steps are included in later sections of this chapter. For specific examples of design flows that take advantage of the incremental compilation features, refer to “Recommended Design Flows and Compilation Application Examples” on page 2–49.

For a step-by-step introduction to implementing an incremental compilation flow in the Quartus II software, on the Help menu, click **Tutorial**. After the introduction, choose **Module 7: Incremental Compilation** to view design flows for incremental compilation.

The flow chart in Figure 2–3 illustrates the incremental compilation flow when all partitions are contained in one top-level project. The following subsections describe the steps in the flow.

First, prepare the design for incremental compilation and perform a full compilation. Then proceed to verify or debug your design and make design changes as required. When you perform additional design iterations, choose which netlists to reuse and perform incremental compilations.

Figure 2–3. Summary of Incremental Compilation Flow



Preparing a Design for Incremental Compilation

To set up your design for incremental compilation, perform the following steps:

1. Elaborate the design. On the Processing menu, point to **Start** and click **Start Analysis & Elaboration**, or run any compilation flow (such as a full compilation) that includes this step. Elaboration is the part of the synthesis process that identifies your design's hierarchy.
2. Create partitions in your design by designating specific instances as design partitions. In the user interface, you can right-click an instance in the Project Navigator, point to **Design Partition**, and click **Set as Design Partition**. Alternatively, on the Tools menu you can open the Design Partition Planner and right-click on a design block to use the Auto-Partition feature that creates partitions based on the size and connectivity of the hierarchical design blocks. Refer to "Creating Design Partition Assignments" on page 2–16 for details.

   Refer to "Deciding which Design Blocks Should Be Design Partitions" on page 2–9 for an explanation of design partitions and what part of your design can be specified as a design partition.
3. If required for your design flow, use LogicLock regions to make location assignments for each partition to create a design floorplan. If timing-critical design blocks change with future compilations, assigning the partition to a physical region on the device can improve results. Refer to the section "Creating a Design Floorplan with LogicLock Location Assignments" on page 2–25 for details about these assignments.

4. Compile the design. The first compilation after making partition assignments is a complete compilation that prepares the design for subsequent incremental compilations.

Compiling a Design Using Incremental Compilation

After compiling the design once and then making changes, take advantage of incremental compilation to recompile only the changed parts of the design. To do this, perform the following general steps:

1. Choose which of the following compilation results you intend to reuse for each partition.
   - To preserve previous placement results for a partition, set the Netlist Type assignment for that partition to **Post-Fit**.
     - To preserve routing information as well, set the **Fitter Preservation Level** to **Placement and Routing**.
   - To save only the synthesis results, set the Netlist Type assignment for that partition to **Post-Synthesis**.

   Partitions with design changes are recompiled automatically with these Netlist Type settings. You can also direct the software to recompile from the source code by choosing the **Source File** netlist type.

   If you do not want to compile a specific partition at all, set its Netlist Type to **Empty**.

   For details about setting these partition properties, refer to "Setting the Netlist Type for Design Partitions" on page 2–19.

2. Compile the design. The Quartus II software preserves the results you specified in step 1.

Deciding which Design Blocks Should Be Design Partitions

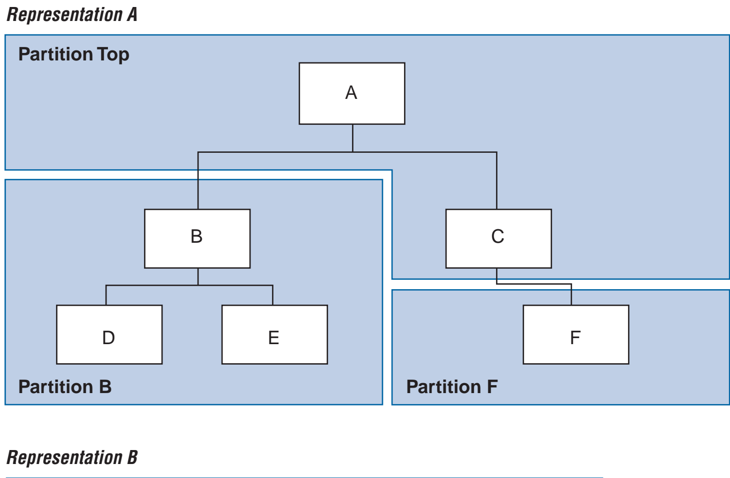
It is a common design practice to create modular or hierarchical designs in which you develop each design entity separately, and then instantiate them in a higher-level entity, forming a complete design. The Quartus II software does not consider each design entity or instance to be a design partition for incremental compilation automatically; instead, you must designate one or more design hierarchies below the top-level project as a design partition. Creating partitions prevents the compiler from performing optimizations across partition boundaries, as discussed in "Impact of Design Partitions on Design Optimization" on page 2–11. However, this allows for separate synthesis and placement for each partition, making incremental compilation possible.

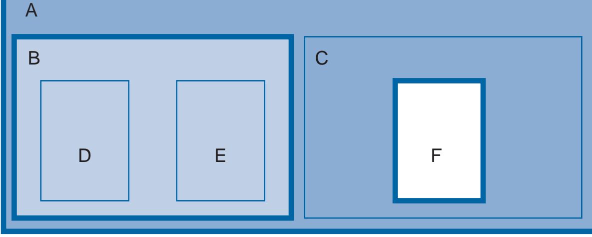
Partitions must have the same boundaries as hierarchical blocks in the design because a partition cannot be a portion of the logic within a hierarchical entity. When you declare a partition, every hierarchical instance within that partition becomes part of the same partition. You can create new partitions for hierarchical instances within an existing partition, in which case the instances within the new partition are no longer included in the higher-level partition, as described in the following example.

In Figure 2–5, hierarchical instances **B** and **F** form partitions in the complete design, which is made up of instances **A**, **B**, **C**, **D**, **E**, and **F**. The shaded boxes in Representation A indicate design partitions in a "tree" representation of the hierarchy. In Representation B, the lower-level instances are represented inside the higher-level instances, and the partitions are illustrated with different colored shading. The top-level partition, called Top, automatically contains the top-level entity in the design, and contains any logic not defined as part of another partition. The design file for the top level may be just a wrapper for the hierarchical instances below it, or it may contain its own logic. In this example, the partition for top-level entity **A** also includes the logic in one of its lower-level instances, **C**. Because instance **F** is contained in its own partition, it is not treated as part of the top-level partition. Another separate partition, **B**, contains the logic in instances **B**, **D**, and **E**.

Figure 2–4. Partitions in a Hierarchical Design

Representation A





You can make partition assignments to any design instance. The instance can be defined in HDL or schematic design, or come from a third-party synthesis tool as a VQM or EDIF netlist instance.

To take advantage of incremental compilation when source files change, create separate design files for each partition. If you define two different entities as separate partitions but they are in the same design file, you cannot maintain incremental compilation because the software would have to recompile both partitions if you changed either entity in the design file. Similarly, if two partitions rely on the same lower-level entity definition, changes in that lower-level affect both partitions.

The remainder of this section provides information to help you choose which design blocks you should assign as partitions.

Impact of Design Partitions on Design Optimization

The boundaries of your design partitions can impact the design's quality of results. Creating partitions prevents the compiler from performing logic optimizations across partition boundaries, which allows the software to synthesize and place each partition separately in an incremental flow. Therefore, consider partitioning guidelines to help reduce the effect of partition boundaries.

Whenever possible, register all inputs and outputs of each partition. This helps avoid any delay penalty on signals that cross partition boundaries and keeps each register-to-register timing path within one partition for optimization. In addition, minimize the number of paths that cross partition boundaries. If there are timing-critical paths that cross partition boundaries, rework the partitions to avoid these inter-partition paths. Including as many of the timing-critical connections as possible inside a partition allows you to effectively apply optimizations to that partition to improve timing, while leaving the rest of the design unchanged. In addition, avoid constant partition inputs and outputs, because to maintain incremental behavior, the software cannot use the constants to optimize logic on either side of the partition boundary.

The Design Partition Planner can help you make good assignments, as described in "Creating Design Partition Assignments" on page 2–16. The following sections describe tools you can use after compilation to analyze the partition assignments.You can view "Partition Statistics Reports", including information about the number of I/O connections and how many are unregistered or driven by a constant value, in the partition statistics reports. You can also create "Partition Timing Reports" and refer to the "Incremental Compilation Advisor"for analysis and guidelines.

If critical timing paths cross partition boundaries, you can perform timing budgeting and make timing assignments to constrain the logic in each partition so the entire timing path meets its requirements. In addition, because each partition is optimized independently during synthesis, you may have to perform some resource balancing to ensure that each partition uses an appropriate number of device resources. With bottom-up compilation flows in which design partitions are compiled separately from the top level, there may be conflicts related to global routing resources for clock signals when the design is imported into the top. You can use the ALTCLK_CTRL megafunction to instantiate a clock control block and connect it appropriately in both the bottom and top-level projects, or find the compiler-generated clock control node in your design and make clock control location assignments in the Assignment Editor.

For more partitioning guidelines and specific recommendations for fixing common design issues, as well as information on resource balancing, global signal usage, and timing budgeting, refer to the *Best Practices for Incremental Compilation Partitions and Floorplan Assignments* chapter in volume 1 of the *Quartus II Handbook*.

Partition Statistics Reports

After compilation, you can view statistics about design partitions in the Partition Merge Partition Statistics compilation report and the **Statistics** tab in the **Design Partitions Properties** dialog box.

The **Partition Statistics** page under the **Partition Merge** folder of the Compilation Report lists statistics about each partition. The statistics for each partition (each row in the table) include the number of logic cells it contains, as well as the number of input and output pins it contains and how many are registered or unconnected. This report is useful when optimizing your design partitions in a top-down compilation flow, or when you are compiling the top-level design in a bottom-up compilation flow, ensuring that the partitions meet the guidelines presented in the *Best Practices for Incremental Compilation Partitions and Floorplan Assignments* chapter in volume 1 of the *Quartus II Handbook*. Figure 2–5 shows the report window.

Figure 2–5. Partition Merge Partition Statistics Report

	Partition Name	Total combinational functions	normal mode	arithmetic mode	Total registers	Input Ports	Output Ports	Registered Input Ports
1	Top	16	4	12	26	12	10	1
2	mult:inst6	42	24	18	0	11	11	0
3	taps:inst	8	8	0	32	13	8	11
4	hvalues:inst2	3	3	0	0	2	3	0

You can also view statistics about the resource and port connections for a particular partition on the **Statistics** tab of the **Design Partition Properties** dialog box. On the Assignments menu, click **Design Partitions Window**. Right-click on a partition and click **Properties** to open the dialog box. Click **Show All Partitions** to view all the partitions in the same report (Figure 2–6).

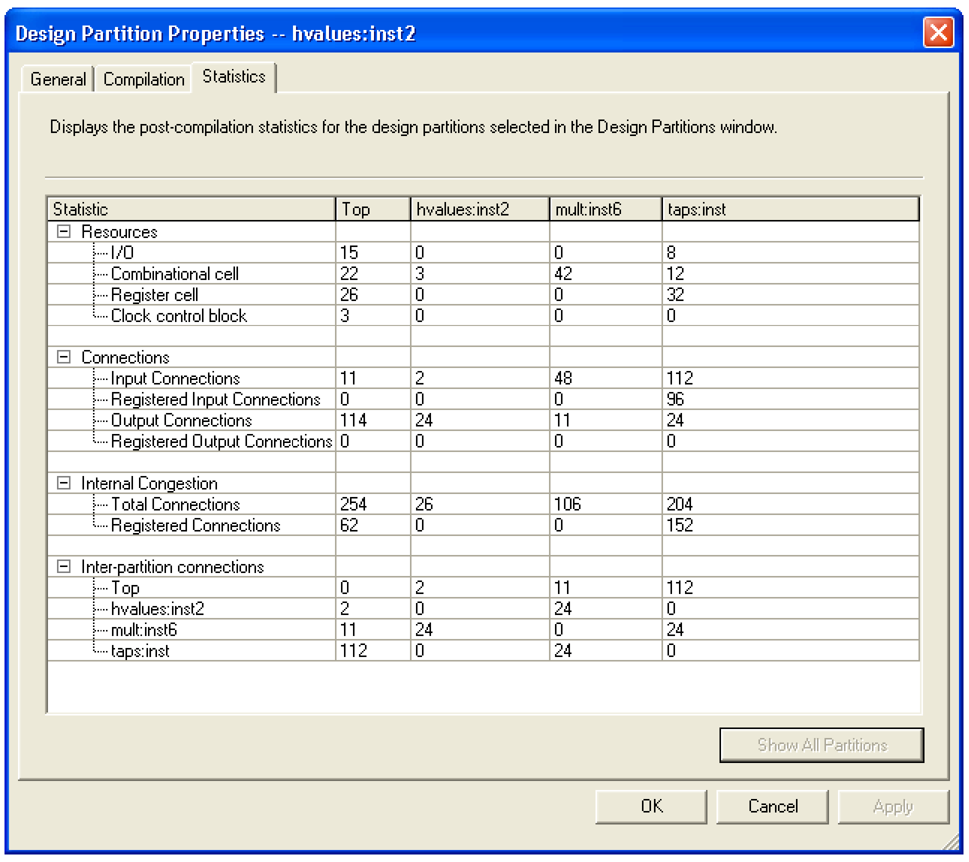
Figure 2–6. Statistics Tab in the Design Partitions Properties Dialog Box



Partition Timing Reports

You can generate a Partition Timing Overview report and a Partition Timing Details report by clicking **Report Partitions** in the Tasks pane in the TimeQuest Timing Analyzer or using the `report_partitions` Tcl command.

The Partition Timing Overview report shows the total number of failing paths for each partition and the worst-case slack for any path involving the partition.

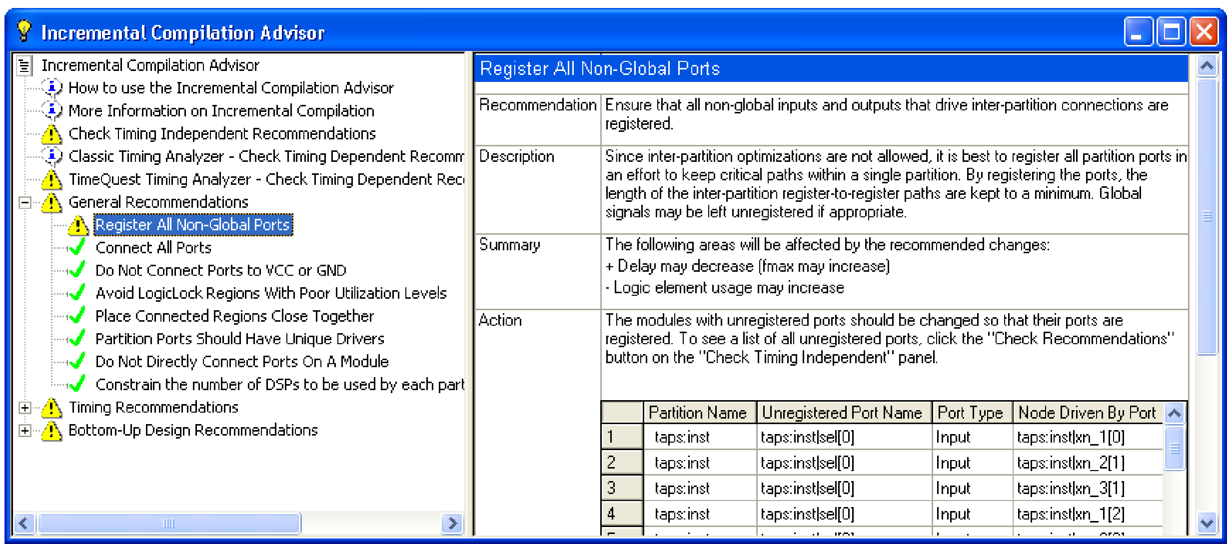
The Partition Timing Details report shows the number of failing partition-to-partition paths and worst-case slack for partition-to partition paths to provide a more detailed breakdown of where the critical paths in the design are with respect to design partitions.

Incremental Compilation Advisor

You can use the Incremental Compilation Advisor to check that your design follows Altera's recommendations presented for creating design partitions and floorplan location assignments. On the Tools menu, point to **Advisors** and click **Incremental Compilation Advisor**.

As shown in Figure 2–7, recommendations are split into **General Recommendations** that apply to all compilation flows and **Bottom-Up Design Recommendations** that apply to advanced bottom-up design methodologies. Each recommendation provides an explanation, describes the effect of the recommendation, and provides the action required to make the suggested change. In some cases, there is a link to the appropriate Quartus II settings page where you can make a suggested change to assignments or settings. The relevant timing-independent recommendations for the design are also listed in the Design Partitions Window and the LogicLock Regions Window.

Figure 2–7. Incremental Compilation Advisor



To check whether the design follows the recommendations, go to the **Timing Independent Recommendations** page or the **Timing Dependent Recommendations** page, and click **Check Recommendations**. For large designs, these operations can take a few minutes. After you perform a check operation, symbols appear next to each recommendation, as shown in Figure 2–8, to indicate whether the design or project setting follows the recommendations, or if some or all of the design or project settings do not follow the recommendations. Refer to the Legend on the **How to use the Incremental Compilation Advisor** page in the advisor for more information.

For some items in the Advisor, if your design does not follow the recommendation, the **Check Recommendations** operation lists any parts of the design that could be improved. For example, if not all of the partition I/O ports follow the **Register All Ports** recommendation, the advisor displays a list of unregistered ports with the partition name and the node name associated with for the port.

When the advisor provides a list of nodes, you can right-click on a node and click **Locate** to cross-probe to other Quartus II features such as the RTL Viewer, Chip Planner, or the design source code in the text editor.

Opening a new TimeQuest report resets the Incremental Compilation Advisor results, so you must rerun the Check Recommendations process.

Using Partitions with Third-Party Synthesis Tools

If you are using a third-party synthesis tool, set up your tool to create a separate VQM or EDIF netlist for each hierarchical partition. In the Quartus II software, assign the top-level entity from each netlist to be a design partition. The VQM or EDIF netlist file is treated as the source file for the partition in the Quartus II software.

Synopsys Synplify Pro/Premier and Mentor Graphics Precision RTL Plus

The Synplify Pro and Synplify Premier software include the MultiPoint synthesis feature to perform incremental synthesis for each design block assigned as a Compile Point in the user interface or a script. The Precision RTL Plus software includes an incremental synthesis feature that performs block-based synthesis based on Partition assignments in the source HDL code. These features provide automated block-based incremental synthesis flows and create different output netlist files for each block when set up for an Altera device.

Using incremental synthesis within your synthesis tool ensures that only those sections of a design that have been updated are resynthesized when the design is compiled, reducing synthesis run time and preserving the results for the unchanged blocks. You can change and resynthesize one section of a design without affecting other sections of the design.

For more information about these incremental synthesis flows, refer to your tool vendor's documentation, or the appropriate chapter in volume 1 of the *Quartus II Handbook*: *Synopsys Synplify Support* or *Mentor Graphics Precision Synthesis Support*.

Other Synthesis Tools

You can also partition your design and create different netlist files manually with the basic Synplify software (non-Pro/Premier), the basic Precision RTL software (non-Plus), or any other supported synthesis tool by creating a separate project or implementation for each partition, including the top level. Set up each higher-level project to instantiate the lower-level VQM/EDIF netlists as black boxes. Synplify, Precision, and most synthesis tools automatically treat a design block as a black box if the logic definition is missing from the project. Each tool also includes options or attributes to specify that the design block should be treated as a black box, which you can use to avoid warnings about the missing logic.

Design Partition Assignments Compared to Physical Placement Assignments

Design partitions for incremental compilation are logical partitions, different from physical placement assignments in the device floorplan. A logical design partition does not refer to a physical area of the device and does not directly control the placement of instances. A logical design partition sets up a virtual boundary between design hierarchies so each is compiled separately, preventing logical optimizations from occurring between them. When the software compiles the design source code, the logic in each partition can be placed anywhere in the device unless you make additional placement assignments. The software creates a separate post-synthesis and post-fitting netlist for each partition, which allows the software to reuse the synthesis results or reuse the fitting results (including placement and routing information) in subsequent compilations.

If you preserve the compilation results using a Post-Fit netlist, it is not necessary for you to back-annotate or make any location assignments for specific logic nodes. You should not use the incremental compilation and assignment back-annotation features in the same Quartus II project. The incremental compilation feature does not use placement "assignments" to preserve placement results; it simply reuses the netlist database that includes the placement information.

You can assign design partitions to physical regions in the device floorplan using LogicLock assignments. In the Quartus II software, LogicLock regions are used to constrain blocks of a design to a particular region of the device. Altera recommends using LogicLock regions to improve the quality of results and avoid placement conflicts in some cases when performing incremental compilation. Creating floorplan location assignments for design partitions using LogicLock regions is discussed in "Creating a Design Floorplan with LogicLock Location Assignments" on page 2–25.

For more information about when and why to create a design floorplan, refer to the *Best Practices for Incremental Compilation Partitions and Floorplan Assignments* chapter in volume 1 of the *Quartus II Handbook*.

Creating Design Partition Assignments

There are several ways to designate a design instance as a design partition, as described in the following subsections. If the full incremental compilation option is not turned on when you specify your first design partition, a dialog box appears that asks whether you want to enable incremental compilation.

To turn on incremental compilation, on the Assignments menu, click **Settings**. In the **Category** list, select **Compilation Process Settings**. Under **Compilation Process Settings**, select **Incremental Compilation**. On the **Incremental Compilation** page, turn on **Full incremental compilation**. Turning off the **Full incremental compilation** option does not remove any partition assignments. Partition assignments have no effect on the design if incremental compilation is turned off.

Creating Design Partitions with the Design Partition Planner

The Design Partition Planner allows you to view design connectivity and hierarchy, and can assist you in creating effective design partitions that follow Altera's guidelines.

To view a design and create design partitions, first compile the design, or perform at least Analysis and Synthesis. On the Tools menu, click **Design Partition Planner**. The design is displayed as a single top-level design block, containing its lower-level instances as boxes.

To show connectivity between blocks, extract instances from the top-level design block. Click on a design block and drag it into the surrounding white space, or right-click an entity and click **Extract from Parent** on the Shortcut menu. When you extract entities, connection bundles are drawn between entities, showing the number of connections existing between pairs of entities. When you have extracted a design block that you want to set as a design partition, right-click on that design block and choose **Create Design Partition**.

The Design Partition Planner also has an **Auto-Partition** feature that creates partitions based on the size and connectivity of the hierarchical design blocks. Right-click on the design block you want to partition (such as the top-level design hierarchy), and choose **Auto-Partition**. You can then analyze and adjust the partition assignments as required.

Figure 2–8 shows the Design Partition Planner after making a design partition assignment to one instance (in the pale red shaded box), and dragging another instance away from the top-level block within the same partition (two design blocks in the pale blue shaded box). The figure shows the number of connections between each partition and information about the size of each design instance.

Figure 2–8. Design Partition Planner

To switch between connectivity display mode and hierarchical display mode, click **Hierarchy Display** on the View menu. Alternately, to switch temporarily to a view-only hierarchy display, click and hold the hierarchy icon in the top-left corner of any entity.

To control the way the connection bundles are displayed, right-click in the white space and choose **Bundle Configuration**. For example, you can remove the connection lines between partitions and I/O banks by turning off **Display connections to I/O banks**. You can also use the settings on the **Connection Counting** tab to adjust how the connections are counted in the bundles.

For more details about how to use the Design Partition Planner, refer to Using the Design Partition Planner in the Quartus II Help.

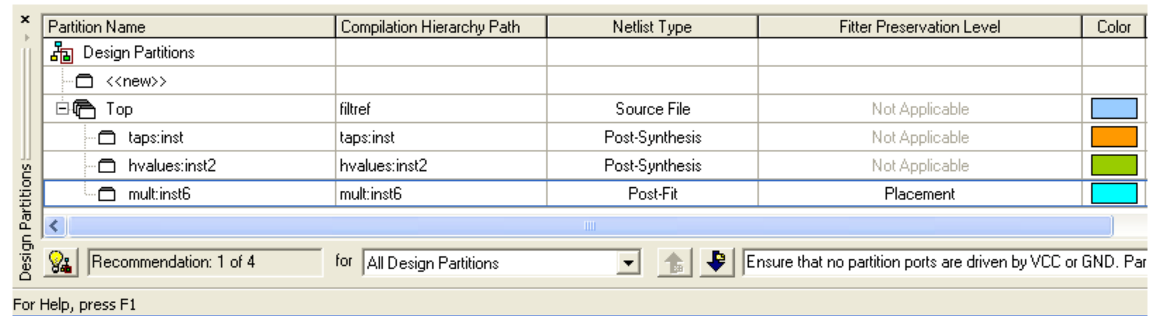
Creating Design Partitions In the Design Partitions Window

The Design Partitions Window allows you to create and delete partitions, and is the main window for setting the Netlist Type and Fitter Preservation Level described in "Setting the Netlist Type for Design Partitions" on page 2–19. First, perform Analysis and Elaboration, or any compilation flow that includes this step. Elaboration is the part of the synthesis process that identifies your design's hierarchy. On the Assignments menu, click **Design Partitions Window** (Figure 2–9). In this window, you can create your partitions in one of the following ways:

- Create new partitions for one or more instances by dragging and dropping them from the **Hierarchy** tab of the **Project Navigator** into the **Design Partitions Window**. Using this method, you can create multiple partitions at once.
- Create new partitions by double-clicking the <<*new*>> cell in the **Partition Name** column. In the **Create New Partitions** dialog box, select the design instance and click **OK**.

To delete partitions in the Design Partitions Window, right-click a partition and click **Delete**, or select the partition and press the Delete key.

Figure 2–9. Design Partitions Window



The Design Partitions Window lists recommendations at the bottom of the window, as well as a link to the Incremental Compilation Advisor, where you can view additional recommendations about the partitions.

The **Color** column indicates the color of each partition in the Partition Planner view of the Chip Planner floorplan. The **Source File Status** column lists the date that the source code was changed and bold font indicates that it has changed since the last compilation. The other status columns indicate which post-compilation netlists are available.

Creating Design Partitions in the Project Navigator

You can use the list of instances under the **Hierarchy** tab in the **Project Navigator** to create and delete design partitions. First, elaborate the design or run any compilation flow that includes this step. Right-click an instance in the **Project Navigator**, point to **Design Partition,** and click **Set as Design Partition**. A design partition icon appears next to each instance that is set as a partition (Figure 2–10).

To remove an existing partition assignment, click **Set as Design Partition** again. (This process turns off the option.)

Figure 2–10. Project Navigator Showing Design Partitions

Creating Design Partitions with Tcl Scripting

You can also create partitions with Tcl scripting commands. For details about the command line and scripting flow, refer to “Scripting Support” on page 2–69.

Partition Name

When you create a partition, the Quartus II software automatically generates a name based on the instance name and hierarchy path. To change the name, double-click on the partition name in the Design Partitions window, or right-click the partition and click **Rename**. Alternatively, right-click the partition in the Design Partitions window and click **Properties** to open the **Design Partition Properties** dialog box. On the **General** tab, enter the new name in the **Name** field.

By renaming your partitions, you can avoid referring to them by their hierarchy path, which can sometimes be long. This is especially important when using command-line commands or assignments. Partition names can be from 1 to 1024 characters in length and must be unique. The name can only contain alphanumeric characters and the pipe (|), colon (:), and underscore (_) characters.

Setting the Netlist Type for Design Partitions

The Netlist Type is a property of each design partition that allows you to specify the type of netlist or source file that the compiler should use as the input for each partition. The Netlist Type property controls the incremental compilation process, as described in “Compiling a Design Using Incremental Compilation” on page 2–9. This property determines which netlist the Partition Merge stage uses in the next compilation.

To view and modify the Netlist Type, on the Assignments menu, click **Design Partitions Window**. Double-click the Netlist Type for an entry. Alternatively, right-click on an entry, click **Design Partition Properties**, then modify the Netlist Type on the **Compilation** tab.

Table 2–2 and Table 2–3 describe the standard and advanced settings for the Netlist Type property, explains the behavior of the Quartus II software for each setting, and provides guidance on when to use each setting. For examples that describe how to use these settings to accomplish various design goals, refer to "Recommended Design Flows and Compilation Application Examples" on page 2–49.

Table 2–2. Standard Netlist Type Settings

Partition Netlist Type	Quartus II Behavior for Partition During Compilation
Source File	Always compiles the partition using the associated design source file(s). Use this netlist type to recompile a partition from the source code using new synthesis or Fitter settings.
Post-Synthesis	Preserves post-synthesis results for the partition and reuses the post-synthesis netlist as long as the following conditions are true: ■ A post-synthesis netlist is available from a previous synthesis ■ No change that triggers an automatic resynthesis has been made to the partition since the previous synthesis. For details, refer to "What Changes Trigger a Partition's Automatic Resynthesis?" on page 2–23. Compiles the partition from the source files if resynthesis is triggered or if a post-synthesis netlist is not available. Use this netlist type to preserve the synthesis results unless you make design changes, but allow the Fitter to refit the partition using any new Fitter settings.
Post-Fit	Preserves post-fit results for the partition and reuses the post-fit netlist as long as the following conditions are true: ■ A post-fit netlist is available from a previous fitting ■ No change that triggers an automatic resynthesis has been made to the partition since the previous fitting. For details, refer to "What Changes Trigger a Partition's Automatic Resynthesis?" on page 2–23. When a post-fit netlist is not available, the software reuses the post-synthesis netlist if it is available, or otherwise compiles from the source files. Compiles the partition from the source files if resynthesis is triggered. The Fitter Preservation Level specifies what level of information is preserved from the post-fit netlist. For details, refer to "Fitter Preservation Level" on page 2–21. Use this netlist type to preserve the Fitter results unless you make design changes. You can also use this netlist type to apply global optimizations, such as Physical Synthesis optimizations that occur in the Fitter, to certain partitions while preserving the fitting results for other partitions.

Table 2–3. Advanced Netlist Type Settings

Partition Netlist Type	Quartus II Behavior for Partition During Compilation
Post-Fit (Strict)	Preserves post-fit results for the partition even if changes have been made to the associated source files since the previous fitting. Misuse of the **Post-Fit (Strict)** Netlist Type can result in the generation of a functionally incorrect netlist when source design files change. Use caution when applying this assignment. For more information, refer to “Forcing Use of the Post-Fitting Netlist When a Partition has Changed” on page 2–25. When a post-fit netlist is not available, the software reuses the post-synthesis netlist if it is available, or otherwise compiles from the source files. The Fitter Preservation Level specifies what level of information is preserved from the post-fit netlist. For details, refer to “Fitter Preservation Level” on page 2–21.
Empty	Uses an empty placeholder netlist for the partition and automatically adds virtual pins at the partition boundaries. You can use this netlist type to skip the compilation of a partition. For more details on the **Empty** setting, refer to “Empty Partitions” on page 2–22.

Fitter Preservation Level

The **Fitter Preservation Level** property specifies which information the compiler uses from a post-fit netlist.

On the Assignments menu, click **Design Partitions Window**. To view and modify the Fitter Preservation Level, double-click an entry. Alternatively, right-click and click **Properties**, then edit the F**itter Preservation Level** on the **Compilation** tab.

Table 2–4 describes the Fitter Preservation Level settings.

Table 2–4. Fitter Preservation Level Settings (Part 1 of 2)

Fitter Preservation Level	Quartus II Behavior for Partition During Compilation
Placement	Preserves the netlist atoms and their placement in the design partition. Re-routes the design partition. This setting saves significant compilation time because the Fitter does not need to re-fit the nodes in the partition.
Placement and Routing	Preserves the design partition’s netlist atoms and their placement and routing. The minimum preservation level required to preserve Engineering Change Order (ECO) changes made to the post-fitting netlist and SignalProbe pins added to the design. This setting reduces compilation times compared to Placement only, but provides less flexibility to the router to make changes if there are changes in other parts of the design.

Table 2–4. Fitter Preservation Level Settings (Part 2 of 2)

Fitter Preservation Level	Quartus II Behavior for Partition During Compilation
Placement, Routing, and High-Speed Tiles	Preserves the design partition's netlist atoms and their placement and routing in the design partition, as well as the high-speed power tile settings. This setting maximizes performance preservation for timing-critical paths, while allowing low-power tiles to be switched to high-speed if required as the rest of the design is changed. This setting is available only for devices with configurable power tiles.
Netlist Only	Preserves the netlist atoms of the design partition, but replaces and reroutes the design partition. A post-fit netlist with the atoms preserved can be different than the Post-Synthesis netlist because it contains Fitter optimizations; for example, Physical Synthesis changes made during a previous Fitting. You can use this setting to: ■ Preserve Fitter optimizations but allow the software to perform placement and routing again ■ Reapply certain Fitter optimizations (such as Fitter, physical synthesis) that would otherwise be impossible when the placement is locked down ■ Resolve resource conflicts between two imported partitions in a bottom-up design flow

Empty Partitions

You can use the **Empty** setting to skip the compilation of a partition that is incomplete or missing from the top-level design. You can also use it if you want to compile only some partitions in the design, such as during optimization or if the compilation time is large for one partition and you want to exclude it. This is useful if you want to optimize the placement of a timing-critical block such as an IP core, and then lock its placement before adding the rest of your custom logic in a top-down design flow.

To set the Netlist Type to **Empty**, on the Assignments menu, click **Design Partitions Window**, double-click an entry, or right-click an entry and click **Design Partition Properties** and select **Empty**. This setting specifies that the Quartus II Compiler should use an empty placeholder netlist for the partition.

When a partition Netlist Type is defined as **Empty**, virtual pins are automatically created at the boundary of the partition. This means that the software temporarily maps I/O pins in the lower-level design entity to internal cells instead of pins during compilation.

Any child partitions below an empty partition in the design hierarchy are also automatically treated as empty, regardless of their settings.

If you plan to take full advantage of the **Empty** setting, it is important to keep the design logic in the leaves of the hierarchy tree to provide the most flexibility. If you have logic at one hierarchy level and additional logic in a child hierarchy, you cannot isolate the top-level logic in an empty partition without the lower-level partition being treated as empty as well.

You can use a design flow in which some partitions are set to **Empty** in a variation of a bottom-up design flow, where you develop pieces of the design separately and then combine them at the top level at a later time.

When you implement part of the design without information about the rest of the project, it is impossible for the Compiler to perform global placement optimizations. To reduce this effect, follow good partitioning guidelines by ensuring the input and output ports of the partitions are registered whenever possible, and minimizing cross-partition I/O.

When you set a design partition to **Empty**, a design file is required in Analysis and Synthesis to specify the port interface information so it can connect the partition correctly to other logic and partitions in the design. If a partition is imported from another project, the Quartus II Exported Partition (**.qxp**) file contains this information. For more information about these files, refer to "Quartus II Exported Partition Files (.qxp)" on page 2–30. If there is no **.qxp** file or design file to represent the design entity, you must create a wrapper file (called a black box, stub, or hollow-body file) that defines the design block and specifies the input, output, and bidirectional ports. For example, in Verilog HDL, you should include a module declaration, and in VHDL, you should include an entity and architecture declaration.

If the project database includes a previously generated post-synthesis or post-fit netlist for an unchanged **Empty** partition, you can set the Netlist Type from **Empty** directly to **Post-Synthesis** or **Post-Fit**. In this case, the software reuses the previous netlist information and does not have to recompile from the source code.

Where Are the Netlist Databases Stored?

The incremental compilation database folder (**\incremental_db**) includes all the netlist information from previous compilations. To avoid unnecessary recompilations, these database files must not be altered or deleted.

If you archive or reproduce the project in another location, you can use a Quartus II Archive File (**.qar)**. Include the compilation database to preserve post-synthesis or post-fit compilation results. For details, refer to "Using Incremental Compilation with Quartus II Archive Files" on page 2–61.

To manually create a project archive that preserves compilation results without keeping the incremental compilation database, you can keep all source and settings files, and create and save a **.qxp** file for each partition in the design that can be imported into the project to import the compilation results. Refer to "Exporting a Lower-Level Block within a Project" on page 2–35 for more details about how to create a **.qxp** file for a partition within your design.

What Changes Trigger a Partition's Automatic Resynthesis?

A partition is synthesized from its source files if there is no post-synthesis netlist available from a previous synthesis, or if the Netlist Type is set to **Source File**. In addition, certain changes to a design partition trigger an automatic resynthesis of the partition when the Netlist Type is **Post-Synthesis** or **Post-Fit**. The software resynthesizes the partition in these cases to ensure that the design description matches the post-place-and-route programming files. If you don't want this resynthesis to occur automatically, set the Netlist Type to **Post-Fit (Strict)**. Refer to "Forcing Use of the Post-Fitting Netlist When a Partition has Changed" on page 2–25.

The following list explains the changes that trigger a partition's automatic resynthesis when the Netlist Type is set to **Post-Synthesis** or **Post-Fit**:

- The device family setting has changed.

- Any dependent source design file has changed. Refer to "Determining Which Partitions Are Resynthesized Due to Source Code Changes" on page 2–24 for details.
- The partition boundary was changed by an addition, removal, or change to the port boundaries of a lower-level partition (that is, a partition defined for a lower-level instance within this partition).
- A dependent source file was compiled into a different library (so it has a different `-library` argument).
- A dependent source file was added or removed; that is, the partition depends on a different set of source files.
- The partition's root instance has a different entity binding. In VHDL, an instance may be bound to a specific entity and architecture. If the target entity or architecture changes, it triggers resynthesis.
- The partition has different parameters on its root hierarchy or on an internal AHDL hierarchy (AHDL automatically inherits parameters from its parent hierarchies). This occurs if you modified the parameters on the hierarchy directly, or if you modified them indirectly by changing the parameters in a parent design hierarchy.

The software reuses the post-synthesis results but re-fits the design if you change the device setting within the same device family. The software reuses the post-fitting netlist if you change only the device speed grade.

Synthesis and Fitter assignments such as optimization settings, timing assignments, or Fitter location assignments including pin assignments, do not trigger automatic recompilation in the incremental compilation flow. For details about how you can affect placement with LogicLock regions, refer to "What LogicLock Changes Trigger Refitting?" on page 2–28. To recompile a partition with new assignments, change the Netlist Type assignment for that partition to one of the following:

- **Source File** to recompile with all new settings
- **Post-Synthesis** to recompile using existing synthesis results but new Fitter settings
- **Post-Fit** with the **Fitter Preservation Level** set to **Placement** to rerun routing using existing placement results, but new routing settings (such as delay chain settings)

Determining Which Partitions Are Resynthesized Due to Source Code Changes

The Quartus II software uses an internal checksum algorithm to determine whether the contents of a source file have changed. Source files are the design files used to create the design, and consist of VHDL files, Verilog HDL files, AHDL files, Block Design Files (**.bdf**), EDIF netlists, VQM netlists, memory initialization files, as well as **.qxp** files from exported partitions. Changes in other files, such as vector waveform files for simulation, do not trigger recompilation. When design files in a partition have dependencies on other files, changing one file may trigger an automatic recompilation of another file. The Partition Dependent Files table in the Analysis and Synthesis report lists the design files that contribute to each design partition. You can use this table to determine which partitions are recompiled when a specific file is changed.

For example, if a design has file **A.v** that contains entity a, **B.v** that contains entity **B**, and **C.v** that contains entity **C**, then the Partition Dependent Files table for the partition containing entity a lists file **A.v**, the table for the partition containing entity **B** lists file **B.v**, and the table for the partition containing entity **C** lists file **C.v**. Any dependencies are transitive, so if file **A.v** depends on **B.v**, and **B.v** depends on **C.v**, the entities in file **A.v** depend on files **B.v** and **C.v**. In this case, files **B.v** and **C.v** are listed in the report table as dependent files for the partition containing entity **A**.

If you define module parameters in a higher-level module, the Quartus II software checks the parameter values when determining which partitions require resynthesis. If you change a parameter in a higher-level module that affects a lower-level module, the lower-level module is resynthesized. Parameter dependencies are tracked separately from source file dependencies; therefore, parameter definitions are not listed in the Partition Dependent Files list.

If a design contains common files, such as an **includes.v** file that is referenced in each entity by the command `` `include includes.v``, all partitions are dependent on this file. A change to **includes.v** causes the entire design to be recompiled. The VHDL statement `use work.all` also typically results in unnecessary recompilations, because it makes all entities in the work library visible in the current entity, which results in the current entity being dependent on all other entities in the design.

To avoid this type of problem, ensure that files common to all entities, such as a common include file, contain only the set of information that is truly common to all entities. Remove `use work.all` statements in your VHDL file or replace them by including only the specific design units needed for each entity.

Forcing Use of the Post-Fitting Netlist When a Partition has Changed

Forcing the use of the post-fitting netlist when the contents of a source file has changed is recommended only for advanced users who understand when a partition must be recompiled. You might use this assignment, for example, if you are making source code changes but do not want to recompile the partition until you finish debugging a different partition. To force the Fitter to use a previously generated post-fit netlist even when there are changes to the source files, you can use the **Post-Fit (Strict)** Netlist Type assignment.

Misuse of the **Post-Fit (Strict)** Netlist Type can result in the generation of a functionally incorrect netlist when source design files change. Use caution when applying this assignment.

Creating a Design Floorplan with LogicLock Location Assignments

A floorplan represents the layout of the physical resources on the device. The expressions “creating a design floorplan” and “floorplanning” describe the process of mapping the logical design hierarchy onto physical regions in the device floorplan. After you have partitioned the design, you can create floorplan location assignments for the design as discussed in this section to improve the quality of results when using the full incremental compilation flow. Creating a design floorplan is not a requirement to use an incremental compilation flow, but it is highly recommended in certain cases. Floorplan location planning can be important for a design that uses incremental compilation for the following reasons:

- To avoid resource conflicts between partitions, predominantly when partitions are imported from another Quartus II project

- To ensure a good quality of results when recompiling individual partitions in top-down flows

In top-down flows, design floorplan assignments prevent the situation in which the Fitter must place a partition in an area of the device where most resources are already used by other partitions. A physical region assignment provides a reasonable region to re-place logic after a change, so the Fitter does not have to scatter logic throughout the available space in the device.

Floorplan assignments are not required for non-critical partitions in a top-down flow. The logic for partitions that are not timing-critical (such as simple top-level glue logic) can be placed anywhere in the device on each recompilation, if that is best for your design.

The simplest way to create a floorplan for a partitioned design is to create one LogicLock region per partition (including the top-level partition). Initially, you can leave each region with the default settings of **Auto** size and **Floating** location to allow the Quartus II software to determine the optimal size and location for the regions. Then, after compilation, use the Fitter-determined size and origin location as a starting point for your design floorplan. Check the quality of results obtained for your floorplan location assignments and make changes to the regions as needed. Alternately, you can perform synthesis, and then set the regions to the required size based on resource estimates. In this case, use your knowledge of the connections between partitions to place the regions in the floorplan.

Once you have created an initial floorplan, you can refine the region using tools in the Quartus II software. You can also use advanced techniques such as creating non-rectangular regions by nesting child LogicLock regions.

For more information about when creating a design floorplan can be important, as well as guidelines for creating the floorplan, refer to the *Best Practices for Incremental Compilation Partitions and Floorplan Assignments* chapter in volume 1 of the *Quartus II Handbook*.

You can use the Incremental Compilation Advisor to check that your LogicLock regions meet Altera's guidelines, described in "Incremental Compilation Advisor" on page 2–13.

To create a LogicLock region for each design partition, use the following general methodology:

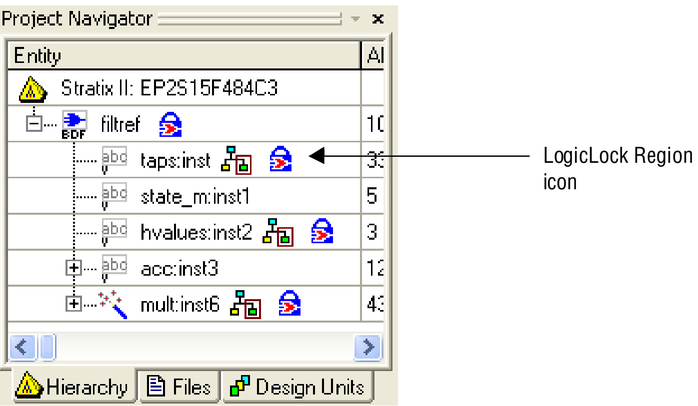
1. On the Assignments menu, click **Design Partitions Window** and ensure that all partitions have their Netlist Type set to **Source File** or **Post-Synthesis**. If the Netlist Type is set to **Post-Fit**, floorplan location assignments are not used when recompiling the design.

2. Create a LogicLock region for each partition (including the top-level entity, which is automatically considered a partition) using one of the following methods:
   - On the Tools menu, click **Design Partition Planner**. Right-click within the colored box that represents a partition and click **Create LogicLock Region**. In the Design Partitions Window, right-click on a partition and click **Create New LogicLock Region**.
   - Under **Compilation Hierarchy** in the **Project Navigator**, right-click each instance that is denoted as a partition and click **Create New LogicLock Region**. In the Design Partitions Window, right click on the row for a partition and choose **Create New LogicLock Region**.

With any of these methods, you can highlight multiple (or all) partitions by holding down the Ctrl key and clicking each partition. Then you can choose the option to create a separate LogicLock region for each highlighted partition.

A LogicLock icon appears in the Project Navigator next to each instance that is set as a LogicLock region (Figure 2–11).

Figure 2–11. Project Navigator Showing LogicLock Regions



3. To place auto-sized, floating-location LogicLock regions, on the Processing menu, point to **Start** and click **Start Early Timing Estimate**.

You must perform Analysis and Synthesis and Partition Merge before performing an Early Timing Estimate.

   To run a full compilation instead of the Early Timing Estimate, on the Processing menu, click **Start Compilation**.

4. On the Assignments menu, click **LogicLock Regions Window**, and while holding the Ctrl key, click each LogicLock region to select all regions (including the top-level region).
5. Right-click the last selected LogicLock region, and click **Set Size and Origin to Previous Fitter Results**.

Use the Fitter-chosen locations only as a starting point to make the regions of a fixed size and location. Generally, regions with fixed size and location yield better f_{MAX} than auto-sized regions.

Do not back-annotate the contents of the region, just save the size and origin. Placement is preserved using the post-fit netlist, not back-annotated content assignments.

6. If required, modify the size and location via the **LogicLock Regions Window** or the **Chip Planner**. For example, make the regions bigger to fill up the device and allow for future logic changes.
7. To estimate the timing performance of your design with these LogicLock regions, on the Processing menu, point to **Start** and click **Start Early Timing Estimate**.
8. Repeat steps 6 and 7 until you are satisfied with the quality of results for your design floorplan.
9. On the Processing menu, click **Start Compilation** to run a full compilation.

If you do not use auto-sized and floating-location regions, you can estimate the size of the regions after synthesis in steps 3–5. On the Processing menu, point to **Start** and click **Start Analysis & Synthesis**. Right-click a region in the **LogicLock Regions** dialog box, and choose **Set to Estimated Size**. Then continue with step 6 to modify the size and origin of each region as appropriate.

Taking Advantage of the Early Timing Estimator

The methodology for creating a floorplan takes advantage of the Early Timing Estimator to enable quick compilations of the design while creating assignments. The Early Timing Estimator feature provides a timing estimate for a design as much as 45 times faster than running a full compilation, yet estimates are, on average, within 11% of final design timing. You can use the Chip Planner to view the "placement estimate" created by this feature, identify critical paths by locating from the timing analyzer reports, and, if necessary, add or modify floorplan constraints. You can then rerun the Early Timing Estimator to quickly assess the impact of any floorplan location assignments or logic changes, enabling rapid iterations on design variants to help you find the best solution. This faster placement has an impact on the quality of results. If getting the best quality of results is important in a given design iteration, perform a full compilation with the Fitter instead of using the Early Timing Estimate feature.

What LogicLock Changes Trigger Refitting?

As described in "What Changes Trigger a Partition's Automatic Resynthesis?" on page 2–23, most assignment changes do not trigger recompilation of a partition if the Netlist Type and Fitter Preservation Level settings specify that Fitter results should be preserved. For example, changing a pin assignment does not trigger recompilation; therefore, the design does not use the new pin assignment unless you change the Netlist Type to **Post-Synthesis** or **Source File**.

Similarly, if a partition's placement is preserved, and the partition is assigned to a LogicLock region, the Fitter always reuses the corresponding LogicLock region size specified in the post-fit netlist. That is, changes to the LogicLock **Size** setting do not trigger refitting if a partition's placement is preserved with the **Post-Fit** Netlist Type setting or with an imported partition that includes post-fit information.

However, you can use the LogicLock **Origin** location assignment to change or fine-tune the previous Fitter results. When you change the **Origin** setting for a region, the Fitter can move the region in the following manner, depending upon how the placement is preserved for that region's members:

- When you set a new region Origin, the Fitter uses the new origin and re-places the logic, preserving the relative placement of the member logic.
- When you set the region Origin to **Floating**, the following conditions apply:
  - If the region's member placement is preserved with an Imported partition: The Fitter chooses a new Origin and re-places the logic, preserving the relative placement of the member logic within the region.
  - If the region's member placement is preserved with a **Post-Fit** Netlist Type: The Fitter does not change the Origin location, and reuses the previous placement results.

Exporting and Importing Partitions

A bottom-up compilation flow refers to the design methodology in which a project is first divided into smaller subdesigns that are implemented as separate projects, potentially by different designers. The compilation results of these lower-level projects are then exported and given to the designer (or the project lead) who is responsible for importing them into the top-level project to obtain a fully functional design. This type of design flow is required only if lower-level designers want to optimize their placement and routing independently, and pass their design to the project lead to reuse placement and routing results. Otherwise, a project lead can integrate source HDL from several designers in a single Quartus II project, and use the standard incremental compilation flow described previously.

In a bottom-up design flow, the top-level project lead can do much of the design planning, and then pass constraints on to the designers of lower-level blocks. The bottom-up design partition scripts generated by the Quartus II software can make it easier to plan a bottom-up design, and limit the difficulties that can arise when integrating separate designs. Refer to "Generating Bottom-Up Design Partition Scripts for Project Management" on page 2–40 for details.

For examples of using team-based and bottom-up design to achieve design goals, refer to "Recommended Design Flows and Compilation Application Examples" on page 2–49. There are some additional restrictions related to bottom-up flows in the Quartus II software, described in "Incremental Compilation Restrictions" on page 2–60.

This section describes the export and import features provided to support bottom-up compilation flows.

The section covers the following topics:

- "Quartus II Exported Partition Files (.qxp)" on page 2–30
- "Bottom-Up Incremental Compilation Summary"
- "Preparing a Design for Bottom-Up Incremental Compilation" on page 2–31
- "Exporting a Lower-Level Partition to be Used in a Top-Level Project" on page 2–34

- "Exporting a Lower-Level Block within a Project" on page 2–35
- "Using a .qxp File as a Source File in the Top-Level Project" on page 2–36
- "Importing a Lower-Level Partition Into the Top-Level Project" on page 2–36
- "Importing Assignments and Advanced Import Settings" on page 2–38
- "Generating Bottom-Up Design Partition Scripts for Project Management" on page 2–40
- "Importing SDC Constraints from Lower-Level Partitions" on page 2–45

Quartus II Exported Partition Files (.qxp)

The bottom-up incremental compilation flow uses a **.qxp** file to represent lower-level design partitions. A **.qxp** file is a binary file that contains compilation results describing the exported design partition and includes a post-fit or post-synthesis netlist, and a set of assignments typically including LogicLock placement constraints. The **.qxp** file does not contain the original source design files from the lower-level design.

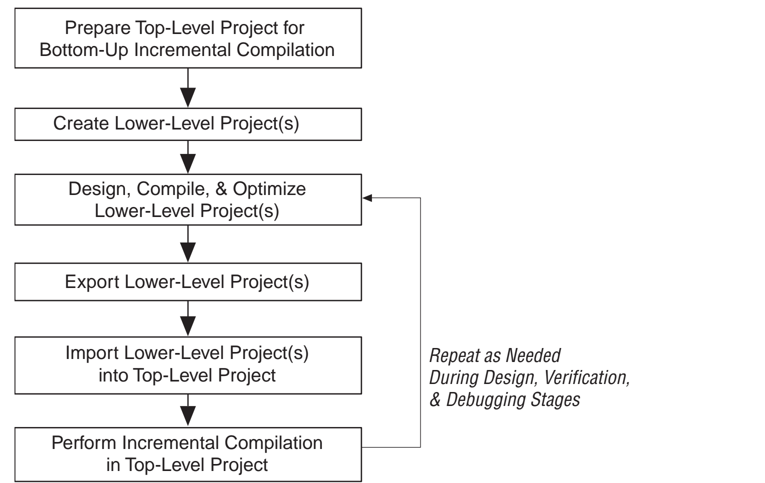
The following sections provide an overview of a bottom-up incremental compilation flow, and describe how to generate a **.qxp** file for a lower-level design partition, and how to import the **.qxp** file into the top-level project.

Bottom-Up Incremental Compilation Summary

The flow chart in Figure 2–12 illustrates the incremental compilation flow using a bottom-up methodology in which lower-level partitions are compiled separately before being imported into the top-level project. The following subsections describe the steps involved in the flow.

First, prepare the top-level design for incremental compilation. Then design, optimize, verify, and debug the lower-level projects. Export the design hierarchy of each lower-level project as a Quartus II **.qxp**, and import the **.qxp** files into the top-level design. Finally, compile the entire top-level design.

Figure 2–12. Summary of Bottom-Up Incremental Compilation Flow



Preparing a Design for Bottom-Up Incremental Compilation

To prepare the design for a bottom-up design methodology, the project lead or top-level designer should perform the following steps:

1. Create the top-level Quartus II project, and apply project-wide settings and global assignments.

   a. Create source code for a "skeleton" of the entire design that includes the hierarchy and the port interfaces for the lower-level designs. The top-level design file instantiates the lower-level blocks you plan to compile in separate Quartus II projects. If you want to compile the design with the lower-level blocks missing, create empty black box wrapper files for each design block to define the design entity and ports.

   b. Create all global assignments, including the device assignment, pin location assignments, and timing assignments, so the final design meets its requirements. Lower-level project designers can add their own constraints for their partitions as needed, and later provide them to the top-level designer, but the project-wide constraints that affect more than one lower-level project constraint should be provided by the top-level designer or project lead to avoid any conflicts and ensure that lower-level projects use the correct assignments.

2. For each lower-level design block imported to the top-level project, designate the instance as a design partition with an Empty Netlist Type. Refer to "Creating Design Partition Assignments" on page 2–16 and "Setting the Netlist Type for Design Partitions" on page 2–19 for details.

3. If the project lead plans to import placement information from the lower-level projects, create LogicLock regions for each of the lower-level partitions to create a design floorplan. Refer to "Creating a Design Floorplan with LogicLock Location Assignments" on page 2–25.

4. Optional: Perform a full compilation of the skeleton design. On the Project menu, click **Generate Bottom-Up Design Partition Scripts**. Provide each lower-level designer with the generated Tcl file to create their project with the appropriate constraints. If you use makefiles in your design environment, provide the makefile for each partition. Refer to "Generating Bottom-Up Design Partition Scripts for Project Management" on page 2–40 for details.

Creating and Compiling Lower-Level Projects

The designer of each lower-level design should create a separate Quartus II project.

If you create the project manually, create a new Quartus II project for the subdesign with all of the required settings. Create with LogicLock region assignments and global assignments (including clock settings) as specified by the project lead, as well as virtual pin assignments for ports which represent connections to core logic instead of external device pins in the top-level module.

If you have a bottom-up design partition script from the top-level designer, source the Tcl script to create the Quartus II project with all the required settings and assignments from the top-level design.

If you use makefiles, use the **make** command and the makefile provided by the project lead to create a Quartus II project with all of the required settings and assignments, and compile the project. Specify the dependencies in the makefile to indicate which source file should be associated with which partition.

Compile and optimize each lower-level design as a separate Quartus II project.

Exporting Lower-Level Projects

When you achieve the design requirements for the lower-level design, export each design as a partition for the top-level design.

If you are not using makefiles, on the Project menu, use the **Export Design Partition** dialog box to export each lower-level design. Refer to "Exporting a Lower-Level Partition to be Used in a Top-Level Project" on page 2–34. If you want to export only a portion of the design in the lower-level project, refer to "Exporting a Lower-Level Block within a Project" on page 2–35 for instructions. Each lower-level designer must provide the **.qxp** file to the project lead.

If your design team uses makefiles, the project lead can use the **make** command with the **master_makefile** to export the lower-level partitions and create **.qxp** files, and then import them into the top-level design.

Including or Importing Lower-Level Projects into the Top-Level Project

After exporting lower-level projects, the project lead then incorporates the **.qxp** files sent in by the designers of each lower-level subdesign partition.

If you want to use the exported **.qxp** file information as a design file in the top-level design, simply add the **.qxp** file as a source file in the project. In this case, the instance in the **.qxp** file does not have to be a partition in the top-level design. Refer to "Using a .qxp File as a Source File in the Top-Level Project" on page 2–36 for details.

If you want to import any placement information, on the Project menu, click **Import Design Partition** and specify the partition in the top-level project that is represented by the subdesign **.qxp** file. Refer to "Importing a Lower-Level Partition Into the Top-Level Project" on page 2–36 for details. Repeat the process for each partition in the design that you want to import.

You can automate the import process by using makefiles: the **master_makefile** command imports each partition into the top-level design. Be sure to specify which source files should be associated with which partition so that the software can rebuild the project if source files change.

For details about which assignments are imported and how to avoid conflicts, refer to "Importing Assignments and Advanced Import Settings" on page 2–38.

Performing an Incremental Compilation in the Top-Level Project

After you have imported the design partitions that make up the top-level project, you can perform a full compilation. The software compiles imported partitions in the same way as partitions defined in the top-level project. The software recompiles an imported partition only if it has been imported since the last compilation.

Netlist Types for Imported Partitions

Partitions that are imported from another project use two additional netlist types and the top-level project uses the **Empty** Netlist Type to create a placeholder for partitions until the associated **.qxp** files from other designers have been imported. These Netlist Types are described in Table 2–5.

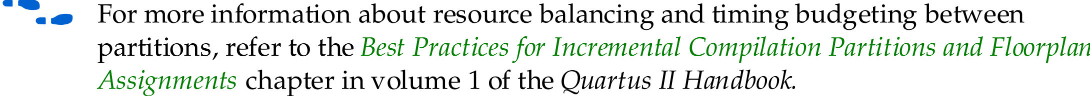
Table 2–5. Netlist Types for Imported Partitions

Partition Netlist Type	Quartus II Behavior for Partition During Compilation
Imported	Compiles the partition using a netlist imported from a **.qxp** file. The software does not modify or overwrite the original imported netlist during compilation. To preserve changes made to the imported netlist (such as movement of an imported LogicLock region), use the **Post-Fit (Import-based)** setting following a successful compilation with the imported netlist. For additional details, refer to "Exporting and Importing Partitions" on page 2–29. To remove the imported netlist and recompile from the source code, set the Netlist Type to **Source File**. The Fitter Preservation Level specifies what level of information is preserved from the imported netlist. Refer to "Fitter Preservation Level" on page 2–21 for details. If you have not imported a netlist for this partition using the **Import Design Partition** command, this setting is not available.
Post-Fit (Import-based)	Preserves post-fit results for the partition and reuses the post-fit netlist as long as the following conditions are true: ■ A post-fit netlist is available from a previous fitting ■ No change has been made to the associated imported netlist since the previous fitting Compiles the partition from the imported netlist if the imported netlist changes (which means it has been reimported) or if a post-fit netlist is not available. Changes to assignments do not cause recompilation. The Fitter Preservation Level specifies what level of information is preserved from the post-fit netlist. Refer to "Fitter Preservation Level" on page 2–21 for details. You can use this netlist type to preserve changes to the placement and routing of an imported netlist. If you have not imported a netlist for this partition using the **Import Design Partition** command, this setting is not available.
Empty	Uses an empty placeholder netlist for the partition and automatically adds virtual pins at the partition boundaries. You can use this netlist type to skip the compilation of a lower-level partition to be imported later. For more details on the Empty setting, refer to "Empty Partitions" on page 2–22.

Exporting a Lower-Level Partition to be Used in a Top-Level Project

Each lower-level subdesign is compiled as a separate Quartus II project. In each project, use the following guidelines to improve the exporting and importing process:

- If you have a bottom-up design partition script from the top level, source the Tcl script to create the project and all the assignments from the top-level design. Doing so may create many of the assignments described below. Ensure that the LogicLock region uses only the resources allocated by the top-level project lead.
- Ensure that you know which clocks should be allocated to global routing resources so that there are no resource conflicts in the top-level design.
  - Set the **Global Signal** assignment to **On** for the high fan-out signals that should be routed on global routing lines.
  - To avoid other signals being placed on global routing lines, on the Assignments menu, click **Settings** and turn off **Auto Global Clock and Auto Global Register Controls** under **More Settings** on the Fitter page of the **Settings** dialog box.
  - Alternatively, you can set the **Global Signal** assignment to **Off** for signals that should not be placed on global routing lines. Placement for LABs depends on whether the inputs to the logic cells within the LAB use a global clock. You may encounter problems if signals do not use global lines in the lower-level design, but use global routing in the top level.
- Use the Virtual Pin assignment to indicate pins of a subdesign that do not drive pins in the top-level design. This is critical when a subdesign has more output ports than the number of pins available in the target device. Using virtual pins also helps optimize cross-partition paths for a complete design by enabling you to provide more information about the subdesign ports, such as location and timing assignments.
- Because subdesigns are compiled independently without any information about each other, you should provide more information about the timing paths that may be affected by other partitions in the top-level design. You can apply location assignments for each pin to indicate the port location after incorporation in the top-level design. You can also apply timing assignments to the I/O ports of the subdesign to perform timing budgeting.



For more information about resource balancing and timing budgeting between partitions, refer to the *Best Practices for Incremental Compilation Partitions and Floorplan Assignments* chapter in volume 1 of the *Quartus II Handbook.*

When your subdesign partition has been compiled using these guidelines, and is ready to be incorporated into the top-level design, export a subdesign as a partition using the following steps:

1. In the subdesign project, use one of the following methods to open the **Export Design Partition** dialog box.
   - In the Design Partition Planner (available from the Tools menu), right-click within the colored box that represents a partition and click **Export Design Partition**.
   - On the Project menu, click **Export Design Partition**.

2. In the **Export file** box, type the name of the **.qxp** file. By default, the directory path and file name are the same as the current project.
3. You can also select the **Partition hierarchy to export**. By default, the Top partition (the entire project) is exported, but you can choose to export the compilation result of any partition hierarchy in the project, as described in "Exporting a Lower-Level Block within a Project" on page 2–35. Choose the partition hierarchy from the pull-down list.
4. Under **Netlist to export**, select either **Post-fit netlist** or **Post-synthesis netlist**. The default is **Post-fit netlist**. For post-fit netlists, turn on or off the **Export routing** option as required.
5. Click **OK**. The Quartus II software creates the **.qxp** file in the specified directory.

Alternatively, you can set up your project so that the export process is performed every time you compile the design:

1. On the Assignments menu, click **Settings**.
2. In the **Settings** dialog box, under **Compilation Process Settings**, select the **Incremental Compilation** page.
3. Turn on **Automatically export design partition after compilation**.
4. If you want to view or change the default export settings, click the **Export Design Partition Settings** button.
5. In the **Export Design Partition Settings** dialog box, change the settings, if required, as in steps 2-4 in the preceding export procedure. Click **OK**.
6. Click **OK** to close the **Settings** dialog box. During the next full compilation, the software creates the **.qxp** file in the specified directory.

Exporting a Lower-Level Block within a Project

Step 3 in "Exporting a Lower-Level Partition to be Used in a Top-Level Project" on page 2–34 enables you to create a **.qxp** file for a lower-level block within a Quartus II project. When you do this, the command exports the entire hierarchy under the specified partition into the **.qxp** file.

You can use this feature to add test logic around a lower-level block to be exported as a design partition for a top-level design. You can also instantiate additional design components in a lower-level project so it matches the top-level design environment. For example, you can include a top-level PLL in your lower-level project so that you can optimize the design with information about the frequency multipliers, phase shifts, compensation delays, and any other PLL parameters. The software then captures timing and resource requirements more accurately while ensuring that the timing analysis in the lower-level project is complete and accurate. You can export the lower-level partition, without exporting any auxiliary components to the top-level design.

In addition, you can use this feature in a top-down design flow to create **.qxp** files for specific design partitions that are complete. You can then import the **.qxp** file back into the project and use the **Imported** netlist type, as described in the following section. In this usage, the **.qxp** file acts as an archive for the partition, including the netlist and placement and routing information in one file. If you change the source code for the partition, you must change the netlist type back to **Source File** to use the source instead of the imported information.

Using a .qxp File as a Source File in the Top-Level Project

To include the design netlist from a **.qxp** file, you can simply use the **.qxp** file as a source file in your design (just like a Verilog or VHDL source file).

The **.qxp** file contains the design block exported from the subdesign project and has the same name as the partition. When you instantiate the design block in a top-level design and include the **.qxp** file as a source file in the project, the software adds the exported netlist to the database for the top-level project. The **.qxp** port names are case sensitive if the original HDL of the lower-level partition were case sensitive.

The software also filters the assignments from the subdesign to bring the appropriate assignments into the top-level project. Refer to the sections in "Importing Assignments and Advanced Import Settings" on page 2–38 that describe which assignments are included in the top-level project. The assignments in the **.qxp** file are treated like assignments made in an HDL source file, and can be overridden by assignments in the top-level project.

When you use a **.qxp** file as a source file in this way, you cannot currently import any post-fit database information into your project. If you want to import post-fit information from the exported netlist, refer to the following section, "Importing a Lower-Level Partition Into the Top-Level Project".

When you use a **.qxp** file as a source file, you can choose whether you want the file to be a partition in the top-level project. If you do not designate the **.qxp** instance as a partition, the software removes unconnected ports and unused logic just like a regular source file. If you do assign the instance as a design partition, the partition boundary is always preserved, as discussed in "Impact of Design Partitions on Design Optimization" on page 2–11.

If you use the **Locate** command into the **.qxp** file or try to open the **.qxp** file in the Quartus II software, the software opens an exported partition information file that explains the contents of the file and provides the port list. Because the **.qxp** file is a binary file, you cannot view the design netlist itself.

Importing a Lower-Level Partition Into the Top-Level Project

The import process imports the design netlist from the **.qxp** file into a particular design partition and adds the netlist to the database for the top-level project. Importing allows you to re-use the post-fitting results from the exported partition. Importing also filters the assignments from the subdesign to create the appropriate assignments in the top-level project. Before you can import a partition, you must have performed an elaboration of the design hierarchy and assigned the design partitions. If you elaborate the design with Empty partitions and have not created a black box wrapper file to define the port connections, Analysis and Elaboration generates error messages about undefined ports but you can still proceed with the import process.

To import a subdesign partition into a top-level design, perform the following steps:

1. In the top-level project, use one of the following methods to open the **Import Design Partition** dialog box:
   - In the Design Partition Planner right-click within the colored box that represents a partition and click **Import Design Partition**.
   - In the Design Partitions window, right-click on the partition that you want to import and click **Import Design Partition**.
   - On the Project menu, click **Import Design Partition**.
2. In the Partition(s) box, browse to the desired partition if required. To choose a partition, highlight the partition name in the **Select Partition(s)** dialog box and use the appropriate buttons to select or deselect the desired partitions.

   ☞ You can select multiple partitions if your top-level design has multiple instances of the subdesign partition and you want to use the same imported netlist.

3. Under **Import file**, type the name of the **.qxp** file or browse for the file that you want to import into the selected partition. This file is required only during importation, and is not used during subsequent compilations unless you reimport the partition.

   ☞ If you have already imported the **.qxp** file for this partition at least once, you can use the same location as the previous import instead of specifying the file name again. To do so, turn on **Reimport using the latest import files at previous locations**. This option is especially useful when you import the new **.qxp** files for several partitions that you have already imported at least once. You can select all the partitions to be imported in the Partition(s) box and then use the **Reimport using latest import files at previous locations** option to import all partitions using their previous locations, without specifying individual file names.

4. Optional: To view the contents of the selected **.qxp** file, click **Load Properties**. The properties displayed include the Netlist Type, Entity name, Device, and statistics about the partition size and ports.
5. Optional: Click **Advanced Import Settings** and make selections, as appropriate, to control how assignments and regions are integrated from a subdesign into a top-level design partition. During importation, some regions may be resized or slightly moved. Click **OK** to apply the settings.

   For more information about the advanced settings, refer to "Importing Assignments and Advanced Import Settings" on page 2–38.

6. To start importation, in the **Import Design Partition** dialog box, click **OK**. The specified **.qxp** file is imported into the database for the current top-level project.

Importing Assignments and Advanced Import Settings

When you import a subdesign partition into a top-level design, the software sets certain assignments by default and also imports relevant assignments from the subdesign into the top-level design.

Design Partition Properties after Importing

When you import a subdesign partition, the import process sets the partition's Netlist Type to **Imported**.

If you compile the design and make changes to the place-and-route results, use the **Post-Fit (Import-based)** Netlist Type on the subsequent compilation. To discard an imported netlist and recompile from source code, compile the partition with netlist type set to **Source File** and be sure to include the relevant source code with the top-level project.

The import process sets the partition's Fitter Preservation Level to the setting with the highest degree of preservation supported by the imported netlist. For example, if a post-fit netlist is imported with placement information, the level is set to **Placement**, but you can change it to the **Netlist Only** value.

Refer to "Setting the Netlist Type for Design Partitions" on page 2–19 for details about the Netlist Type and Fitter Preservation Level setting.

Importing Design Partition Assignments Within the Subdesign

Design partition assignments defined within the subdesign project are not imported into the top-level project. All logic in the subdesign is imported as one partition in the **.qxp** file.

Synopsys Design Constraint Files for the Quartus II TimeQuest Timing Analyzer

Timing assignments made for the Quartus II TimeQuest Timing Analyzer in a Synopsys Design Constraint (**.sdc**) file are not imported into the top-level project. Ensure that the top-level project includes all of the timing requirements for the entire project.

Refer to "Importing SDC Constraints from Lower-Level Partitions" on page 2–45 for recommendations about managing the SDC constraints for the top-level and lower-level projects.

Importing LogicLock Assignments

LogicLock regions are set to a fixed size when imported. If you instantiate multiple instances of a subdesign in the top-level design, the imported LogicLock regions are set to a Floating location. Otherwise, they are set to a Fixed location. You can change the location of LogicLock regions after they are imported, or change them to a Floating location to allow the software to place each region but keep the relative locations of nodes within the region wherever possible. To preserve changes made to a partition after compilation, use the Netlist Type **Post-Fit (Import-Based)**.

The LogicLock Member State assignment is set to **Locked** to signify that it is a preserved region.

LogicLock back-annotation and node location data is not imported because the **.qxp** file contains all of the relevant placement information. Altera strongly recommends that you do not add to or delete members from an imported LogicLock region.

Importing Other Instance Assignments

All instance assignments are imported, with the exception of design partition assignments, SDC constraints, and LogicLock assignments, as described previously.

Importing Global Assignments

Global assignments are not imported. The project lead should make global assignments in the top-level design. Note that clock settings for the Quartus II Classic Timing Analyzer are global assignments, and are not imported. When it is possible for a particular constraint, the global assignment is converted to an instance-specific assignment for the target design partition.

Advanced Import Settings

The **Advanced Import Settings** dialog box allows you to specify the options that control how assignments and regions are integrated and how to resolve assignment conflicts when importing a subdesign partition into a top-level design. The following subsections describe each of these options.

Allow Creation of New Assignments

Allows the import command to add new assignments from the imported project to the top-level project.

When this option is turned off, it imports updates to existing assignments, but no new assignments are allowed.

Promote Assignments to all Instances of the Imported Entity

Converts and promotes entity-level assignments from the subdesign into instance-level assignments in the top-level design.

Assignment Conflict Resolution: LogicLock Regions

Choose one of the following options to determine how to handle conflicting LogicLock assignments (that is, subdesign assignments that do not match the top-level assignments):

- **Always replace regions in the current project** (default)—Deletes existing regions and replaces them with the new subdesign region. Any changes made to the LogicLock region after the assignments were imported are also deleted.
- **Always update regions in the current projects—**Overwrites existing region assignments to reflect any new subdesign assignments with the exception of the LogicLock Origin, in case the project lead has made floorplan location assignments in the top-level design.
- **Skip conflicting regions—**Ignores and does not import subdesign assignments that conflict with any assignments that exist in the top-level design.

Assignment Conflict Resolution: Other Assignments

Choose one of the following options to determine how to handle conflicts with other types of assignments (that is, the subdesign assignments do not match the top-level assignments):

- **Always replace assignments in the current project** (default)—Overwrites or updates existing instance assignments with the new subdesign assignments.
- **Skip conflicting assignments**—Ignores and does not import subdesign assignments that conflict with any assignments that exist in the top-level design.

Generating Bottom-Up Design Partition Scripts for Project Management

The bottom-up design partition scripts automate the process of transferring top-level project information to lower-level design blocks. The Quartus II software provides an interface for managing resources and timing budgets in the top-level design. This makes it easier for designers of lower-level modules to implement the instructions from the project lead, and avoid conflicts between projects when importing and incorporating the projects into the top-level design. This helps reduce the need to further optimize the designs after integration, and improves overall designer productivity and team collaboration.

Generating bottom-up design partition scripts is optional.

For example design scenarios using these scripts, refer to "Implementing a Team-Based Bottom-Up Design Flow" on page 2–53. In a typical bottom-up design flow, the project lead must perform some or all of the following tasks to ensure successful integration of the subprojects:

- Manually determine which assignments should be propagated from the top level to the bottom levels. This requires detailed knowledge of which Quartus II assignments are required to set up low-level projects.
- Manually communicate the top-level assignments to the low-level projects. This requires detailed knowledge of Tcl or other scripting languages to efficiently communicate project constraints.
- Manually determine appropriate timing and location assignments that help overcome the limitations of bottom-up design. This requires examination of the logic in the lower levels to determine appropriate timing constraints.
- Perform final timing closure and resource conflict avoidance at the top level. Because the low-level projects have no information about each other, meeting constraints at the lower levels does not guarantee they are met when integrated at the top-level. It then becomes the project lead's responsibility to resolve the issues, even though information about the low-level implementation may not be available.

Using the Quartus II software to generate bottom-up design partition scripts from the top level of the design makes these tasks much easier and eliminates the chance of error when communicating between the project lead and lower-level designers. Partition scripts pass on assignments made in the top-level design, and create some new assignments that guide the placement and help the lower-level designers see how their design connects to other partitions. If necessary, you can exclude specific design partitions.

 © March 2009 Altera Corporation

Generate design partition scripts after a successful compilation of the top-level design. On the Project menu, click **Generate Bottom-Up Design Partition Scripts**. The design can have empty partitions as placeholders for lower-level blocks, and you can perform an Early Timing Estimation instead of a full compilation to reduce compilation time.

The following subsections describe the information that can be included in the bottom-up design partition Tcl scripts. Use the options in the **Generate Bottom-Up Design Partition Scripts** dialog box to choose which types of assignments you want to pass down and create in the lower-level partition projects. Each time you rerun the script generation process, the Quartus II software recreates the files and replaces older versions.

For information about current limitations in the bottom-up partition scripts, refer to "Register Packing and Partition Boundaries" on page 2–66.

Project Creation

You can use the **Create lower-level project if one does not exist** option for the partition scripts to create lower-level projects if they are required. The Quartus II Project File for each lower-level project has the same name as the entity name of its corresponding design partition.

With this project creation feature, the scripts work by themselves to create a new project, or can be sourced to make assignments in an existing project.

Excluded Partitions

Use the **Excluded partition(s)** option at the bottom of the dialog box to exclude specific partitions from the Tcl script generation process. Use the browse button, then highlight the partition name in the **Select Partition(s)** dialog box and use the appropriate buttons to select or deselect the desired partitions.

Assignments from the Top-Level Design

By default, any assignments made at the top level (not including default assignments or project information assignments) are passed down to the appropriate lower-level projects in the scripts. The software uses the assignment variables and determines the logical partition(s) to which the assignment pertains. This includes global assignments, instance assignments, and entity-level assignments. The software then changes the assignments so that they are syntactically valid in a project with its target partition's logic as the top-level entity.

The names of the design files that apply to the specific partition are added to each lower-level project.

The script uses the file name(s) specified in the top-level project. If the top-level project used a placeholder wrapper file with a different name than the design file in the lower-level project, be sure to add the appropriate file to the lower-level project.

The scripts process wildcard assignments correctly, provided there is only one wildcard. Assignments with more than one wildcard are ignored and warning messages are issued.

Use the following options to specify which types of assignments to pass down to the lower-level projects:

- **Timing assignments**—When this option is turned on, all Classic Timing Analyzer global timing assignments for the lower-level projects are included in the script, including t_{CO}, t_{SU}, and f_{MAX} constraints. In addition, after you've compiled a design using TimeQuest constraints, a separate Tcl script is generated to create an **.sdc** file for each lower-level project that provides the clock constraints and any minimum or maximum delays. This option may also include timing constraints on internal partition connections.
- **Design partition assignments**—When this option is turned on, script assignments related to design partitions in the lower-level projects are included, as well as assignments associated with LogicLock regions.
- **Pin location assignments**—When this option is turned on, all pin location assignments for lower-level project ports that connect to pins in the top-level design are included in the script, controlling the overuse of I/Os at the top-level during the integration phase and preserving placement.

Virtual Pin Assignments

When **Create virtual pins at low-level ports connected to other design units** is turned on, the Quartus II software searches partition netlists and identifies all ports that have cross-partition dependencies. For each lower-level project pin associated with an internal port in another partition or in the top-level project, the script generates a virtual pin assignment, ensuring more accurate placement, because virtual pins are not directly connected to I/O ports in the top-level project. These pins are removed from a lower-level netlist when it is imported into the top-level design.

Virtual Pin Timing and Location Assignments

One of the main issues in bottom-up design methodologies is that each individual design block includes no information about how it is connected to other design blocks. If you turn on the option to write virtual pin assignments, you can also turn on options to constrain these virtual pins to achieve better timing performance after the lower-level partitions are integrated at the top level.

When **Place created virtual pins at location of top-level source/sink** is turned on, the script includes location constraints for each virtual pin created. Virtual output pins are assigned to the location of the connection's destination in the top-level project, and virtual input pins are assigned to the location of the connection's source in the top-level project. If the top-level design uses Empty partitions, the final location of the connection is not known, but the pin is still assigned to the LogicLock region that contains its source or destination.

As a result, these virtual pins are no longer placed inside the LogicLock region of the lower-level project, but at their location in the top-level design, eliminating resource consumption in the lower-level project and providing more information about lower-level projects and their port dependencies. These location constraints are not imported into the top-level project.

When **Add maximum delay to created virtual input pins**, **Add maximum delay from created virtual output pins**, or both are turned on, the script includes timing constraints for each virtual pin created. The value you enter in the dialog box is the maximum delay allowed to or from all paths between virtual pins to help meet the timing requirements for the complete design. The software uses the `INPUT_MAX_DELAY` assignment or `OUTPUT_MAX_DELAY` assignment to apply the constraint.

This option allows the project lead to specify a general timing budget for all lower-level internal pin connections. The lower-level designer can override these constraints by applying individual node-level assignments on any specific pin as needed.

LogicLock Region Assignments

When **Copy LogicLock region assignments from top-level** is turned on, the script includes assignments identifying the LogicLock assignment for the partition.

The script can also pass assignments to create the LogicLock regions for all other partitions. When **Include all LogicLock regions in lower-level projects** is turned on, the script for each partition includes all LogicLock region assignments for the top-level project and each lower-level partition, revealing the floorplan for the complete design in each partition. Regions that do not belong to other partitions contain virtual pins representing the source and destination ports for cross-partition connections. This allows each designer to view the connectivity between their partition and other partitions in the top-level design more easily, and helps ensure that resource conflicts at the top level are minimized.

When **Remove existing LogicLock regions from lower-level projects** is turned on, the script includes commands to remove LogicLock regions defined in the lower-level project prior to running the script. This ensures that LogicLock regions not part of the top-level project do not become part of the complete design, and avoids any location conflicts by ensuring lower-level designs use the LogicLock regions specified at the top level.

Global Signal Promotion Assignments

To help prevent conflicts in global signal usage when importing projects into the top-level design, you can choose to write assignments that control how signals are promoted to global routing resources in the lower-level partitions. These options can help resource balancing of global routing resources.

When **Promote top-level global signals in lower-level projects** is turned on, the Quartus II software searches partition netlists and identifies global resources, including clock signals. For the relevant partitions, the script then includes a global signal promotion assignment, providing information to the lower-level projects about global resource allocation.

When **Disable automatic global promotion in lower-level projects** is turned on, the script includes assignments that turn off all automatic global promotion settings in the lower-level projects. These settings include the **Auto Global Memory Control Signals** logic option, output enable logic options, and clock and register control promotions. If you select the **Disable automatic global promotion in lower-level projects** option in conjunction with the **Promote top-level global signals in lower-level projects** option, you can ensure that only signals promoted to global resources in the top-level are promoted in the lower-level projects.

Makefile Generation

Makefiles allow you to use **make** commands to ensure that a bottom-up project is up-to-date if you have a make utility installed on your computer. The **Generate makefiles to maintain lower-level and top-level projects option** creates a makefile for each design partition in the top-level design, as well as a master makefile that can run the lower-level project makefiles. The Quartus II software places the master makefiles in the top-level directory, and the partition makefiles in their corresponding lower-level project directories.

You must specify the dependencies in the makefiles to indicate which source file should be associated with which partition. The makefiles use the directory locations generated using the **Create lower-level project if one does not exist** option. If you created your lower-level projects without using this option, you must modify the variables at the top of the makefile to specify the directory location for each lower-level project.

To run the makefiles, use a command such as `make -f master_makefile.mak` from the script output directory. The master makefile first runs each lower-level makefile, which sources its Tcl script and then generates a **.qxp** file to export the project as a design partition. Next, run the top-level makefile that specifies these newly generated **.qxp** files as the import files for their respective partitions in the top-level project. The top-level makefile then imports the lower-level results and performs a full compilation, producing a final design.

To exclude a certain partition from being compiled, edit the `EXCLUDE_FLAGS` section of **master_makefile.mak** according to the instructions in the file, and specify the appropriate options. You can also exclude some partitions from being built, exported, or imported using **make** commands. To exclude a partition, run the makefile using a command such as the one for the GNU **make** utility shown in the following example:

```
gnumake -f master_makefile.mak exclude_<partition directory>=1 ↵
```

This command instructs that the partition whose output files are in <*partition directory*> are not built. Multiple directories can be excluded by adding multiple `exclude_`<*partition directory*> commands. Command-line options override any options in the makefile.

Another feature of makefiles is the ability to have the master makefile invoke the low-level makefiles in parallel on systems with multiple processors. This option can help designers working with multiple CPUs greatly improve their compilation time. For the GNU make utility, add the `-j`<*N*> flag to the **make** command. The value <*N*> is the number of processors that can be used to run the build.

The makefile does not include a make clean option, so the design may recompile when **make** is run again and a **.qxp** file already exists.

Importing SDC Constraints from Lower-Level Partitions

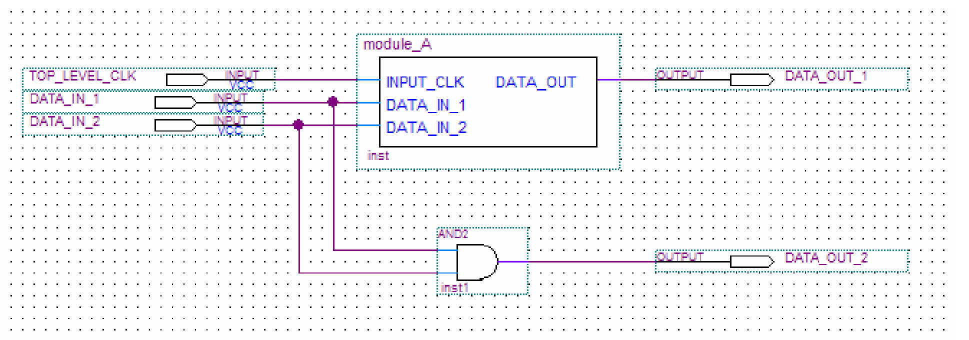
The bottom-up design partition scripts described in the previous section automate the process of transferring top-level project information and constraints to lower-level projects, so that lower-level designers each have a consistent view of the constraints that apply to the entire design. The lower-level partition designers might have to transfer new constraints back to the project lead, so that these constraints are included in final timing sign-off of the entire design. The **Import** command can be used to import assignments from lower-level partition projects into the top-level project; however, the automatic import does not include SDC format constraints for the TimeQuest Timing Analyzer.

Passing additional timing constraints to the top-level project must be managed carefully. This section provides recommendations for managing the timing constraints in a bottom-up incremental compilation flow.

To ensure that there are no conflicts between the project lead's top-level constraints and those added by the lower-level designer, use two Synopsys Design Constraint (**.sdc**) files for each lower-level project: an **.sdc** file created by the project lead that includes project-wide constraints and an **.sdc** file created by the lower-level partition designer that includes partition-specific constraints.

This section uses the example design shown in Figure 2–13 to illustrate these recommendations. The top-level design instantiates a lower-level design block called `module_A` that is set as a design partition and developed by another designer in a separate Quartus II project.

Figure 2–13. Example Design to Illustrate SDC Constraints



In this top-level project, there is a single clock setting called `clk` associated with the FPGA input called `top_level_clk`. The top-level **.sdc** file contains the following constraint for the clock:

```
create_clock -name {clk} -period 3.000 -waveform { 0.000 1.500 }
[get_ports {TOP_LEVEL_CLK}]
```

Creating an .sdc File with Project-Wide Constraints

The **.sdc** file with project-wide constraints for the lower-level project should contain all constraints that are not completely localized to the lower-level partition. This file should be maintained by the top-level project lead. The project lead must ensure that these timing constraints are delivered to the individual partition owners and that they are syntactically correct for each of the lower-level projects. This can be challenging when the design is in flux and hierarchies change. The project lead can use the Generate Bottom-Up Design Partition Scripts tool to automatically generate some of these constraints, as described in the previous section.

The **.sdc** file with project-wide constraints is used in the lower-level project, but is not exported back to the top-level project lead. The lower-level partition designer should not modify this file. If changes are necessary, they should be communicated to the top-level project lead, who can then update the SDC constraints and distribute new files to all lower-level partition designers as required.

The **.sdc** file should include clock creation and clock constraints for any clock used by more than one lower-level project. This is particularly important when dealing with complex clocking structures, such as the following:

- Cascaded clock multiplexers
- Cascaded PLLs
- Multiple independent clocks on the same clock pin
- Redundant clocking structures required for secure applications
- Virtual clocks and generated clocks which are consistently used for source synchronous interfaces
- Clock uncertainties

In addition, the **.sdc** file with project-wide constraints should contain all project-wide timing exception assignments, such as the following:

- Multicycle assignments, `set_multicycle_path`
- False path assignments, `set_false_path`
- Maximum delay assignments, `set_max_delay`
- Minimum delay assignments, `set_min_delay`

The project-wide **.sdc** file can also contain any `set_input_delay` or `set_output_delay` constraints on a lower-level project's ports, because these represent delays external to a given partition. If a lower-level designer wants to set these constraints within the lower-level project, the team must ensure that the I/O port names are identical in the two projects so the assignments can be imported successfully without any changes.

Similarly, a constraint on a path that crosses a partition boundary should be in the project-wide **.sdc** file, because it is not completely localized in a single lower-level project.

Example Step 1: Project Lead Produces .sdc File with Project-Wide Constraints for Lower-Level Project

The device input `top_level_clk` in Figure 2–13 drives the `input_clk` port of `module_A`. To make sure the clock constraint is passed correctly to the lower-level project, the project lead creates an **.sdc** file with project-wide constraints for `module_A` that contains the following command:

```
create_clock -name {clk} -period 3.000 -waveform { 0.000 1.500 }
[get_ports {INPUT_CLK}]
```

The designer of `module_A` includes this **.sdc** file as part of the lower-level project.

Creating an .sdc File with Partition-Specific Constraints

The **.sdc** file with partition-specific constraints should contain all constraints that affect only the lower-level partition. For instance, a `set_false_path` or `set_multicycle_path` constraint for a path entirely within the lower-level partition should be in the partition-specific **.sdc** file. These constraints are required for correct compilation of the partition, but need not be present in any other lower-level projects.

The partition-specific **.sdc** file should be maintained by the individual partition designer; it is their responsibility to add any constraints required to properly compile and analyze their partition.

The partition-specific **.sdc** file is used in the lower-level project and must be exported back to the project lead for the top-level design. The project lead must use the partition-specific constraints to properly constrain the placement, routing, or both if the partition logic is fit at the top level, and to ensure that final timing sign-off is accurate. Use the following guidelines in the partition-specific **.sdc** file to simplify this export/import step:

- Create a hierarchy variable for this partition (such as `module_A_hierarchy`) and set it to an empty string because the partition is the top-level instance in the separate project. The project lead modifies this variable for the top-level hierarchy, reducing the effort of translating constraints on lower-level design hierarchies into constraints that apply in the top-level hierarchy. Use the following Tcl command first to check if the variable is already defined in the project, so that the top-level project does not use this empty hierarchy path: `if {![info exists module_A_hierarchy]}`.
- Use the hierarchy variable in the partition-specific **.sdc** file as a prefix for assignments in the project. For example, instead of naming a particular instance of a register `reg:inst`, use `${module_A_hierarchy}reg:inst`. Also use the hierarchy variable as a prefix to any wildcard characters (such as '`*`').
- Be careful with assignments to I/O ports of the partition. Generally, these assignments should be specified in the **.sdc** file with project-wide constraints because the partition's interface depends on the top-level design. If you want to set I/O constraints within the lower-level project, the team must ensure that the I/O port names are identical in the two projects so the assignments can be imported successfully without any changes.

- Be careful with the `derive_clocks` and `derive_pll_clocks` commands. In most cases, the **.sdc** file with project-wide constraints should call these commands. Because these commands impact the entire design, importing them unexpectedly into the top-level design could cause problems.

If the team follows these recommendations, the project lead should be able to include the **.sdc** file with partition-specific constraints directly in the top-level project to add the **.sdc** constraints provided by the lower-level designer.

Example Step 2: Partition Designer Creates .sdc File with Partition-Specific Constraints

The lower-level designer compiles the design with the **.sdc** file with project-wide constraints and might want to add some additional constraints. In this example, the designer realizes that they must specify a false path between the register called `reg_in_1` and all destinations in this design block using the wildcard character `*`. This constraint applies entirely within the partition and must be exported to the top-level design, so it qualifies for inclusion in the **.sdc** file with partition-specific constraints. The designer first defines the `module_A_hierarchy` variable and uses it when writing the constraint as follows:

```
if {![info exists module_A_hierarchy]} {
   set module_A_hierarchy ""
}
set_false_path -from [get_registers ${module_A_hierarchy}reg_in_1] -to
[get_registers ${module_A_hierarchy}*]
```

Consolidating the SDC Files in the Top-Level Design

When the lower-level designers complete their designs, they export the results to the top-level project lead. The project lead receives the exported **.qxp** file and a copy of the **.sdc** file with partition-specific constraints.

To set up the top-level **.sdc** constraint file to accept the **.sdc** files from the lower-level projects, the top-level **.sdc** file should define the hierarchy variables specified in the lower-level **.sdc** files. List the variable for each lower-level partition and set it to the hierarchy path, up to and including the instantiation of the lower-level partition in the top-level project, including the final '`|`' hierarchy character.

To ensure that the **.sdc** files are used in the correct order, the project lead can use the Tcl Source command to load each **.sdc** file.

Example Step 3: Project Lead Performs Final Timing Analysis and Sign-off

With these commands, the project lead’s top-level **.sdc** file looks like the following example:

```
create_clock -name {clk} -period 3.000 -waveform { 0.000 1.500 }
[get_ports {TOP_LEVEL_CLK}]
# Include the lower-level SDC file
set module_A_hierarchy "module_A:inst|"  # Note the final '|' character
source <partition-specific constraint file such as
..\module_A\module_A_constraints>.sdc
```

When the project lead performs top-level timing analysis, the false path assignment from the lower-level `module_A` project expands to the following:

```
set_false_path -from module_A:inst|reg_in_1 -to module_A:inst|*
```

Adding the hierarchy path as a prefix to the SDC command makes the constraint legal in the top-level project, and ensures that the wildcard does not affect any nodes outside of the partition that it was intended to target.

By following the guidelines in this section, constraint propagation between the projects has been managed effectively.

Recommended Design Flows and Compilation Application Examples

This section provides design flows for solving common timing closure and team-based design issues using incremental compilation. Each flow describes the situation in which it should be used, and gives a step-by-step description of the commands required to implement the flow.

The following top-down incremental design flow examples reduce compilation time while making incremental changes to the design. The examples also allow you to achieve timing closure more quickly by optimizing or preserving the results for some of your design partitions:

- "Reducing Compilation Time When Changing a Source File for One Partition"
- "Preserving Results for Some Partitions Before Adding Other Partitions" on page 2–51
- "Optimizing a Timing-Critical Partition to Achieve Timing Closure" on page 2–50
- "Debugging Incrementally with the SignalTap II Logic Analyzer" on page 2–52

All examples assume you have set up the project to use the full incremental compilation flow, using the steps described in "Quick Start Guide—Summary of Incremental Compilation" on page 2–7.

The following bottom-up design flow examples illustrate team-based design methodologies and design reuse:

- "Implementing a Team-Based Bottom-Up Design Flow" on page 2–53
- "Performing Design Iteration in a Bottom-Up Design Flow" on page 2–56
- "Creating Hard-Wired Macros (or Precompiled Design Blocks) for IP Reuse" on page 2–57
- "Using an Exported Partition to Send a Design without Including Source Files" on page 2–59

Reducing Compilation Time When Changing a Source File for One Partition

Use this flow to update the source file in one partition without having to recompile the other parts of the design. To reduce the compilation time, keep the post-fit netlists for the unchanged partitions. This also preserves the performance for these blocks, which reduces additional timing closure efforts.

Example background: You have just performed a lengthy, complete compilation of a design that consists of multiple partitions. An error is found in the HDL source file for one partition and it is being fixed. Because the design is currently meeting timing requirements and the fix is not expected to affect timing performance, it makes sense to compile only the affected partition and preserve the rest of the design.

Perform the following steps to update the single source file:

1. Apply and save the fix to the HDL source file.
2. On the Assignments menu, click **Design Partitions Window**.
3. For the partitions that should be preserved, change the Netlist Type to **Post-Fit**. You can set the **Fitter Preservation Level** to either **Placement** or **Placement and Routing**. For the partition that contains the fix, you can change the netlist type to **Source File**. (Making the **Source File** setting is optional because the Quartus II software recompiles partitions by default if changes are detected in a source file.)
4. Click **Start Compilation** to incrementally compile the fixed HDL code. This compilation should take much less time than the initial full compilation.
5. Run simulation again to ensure that the error is fixed, and use the Timing Analyzer report to ensure that timing results have not degraded.

Optimizing a Timing-Critical Partition to Achieve Timing Closure

Use this flow to optimize the results of one partition when the other partitions in the design already meet their requirements. You can use this flow iteratively to lock down the performance of one partition and then move on to optimization of another partition.

Example background: You have just performed a lengthy full compilation of a design that consists of multiple partitions. The Timing Analyzer reports that the clock timing requirement is not met and you have to optimize one particular partition. You want to try optimization techniques such as raising the Placement Effort Multiplier, enabling Physical Synthesis, and running the Design Space Explorer. Because these techniques all involve significant compilation time, it makes sense to apply them to only the partition in question.

Perform the following steps to preserve the results for partitions that meet their timing requirements, and recompile a timing-critical partition with new optimization settings:

1. On the Assignments menu, click **Design Partitions Window**.
2. For the partition in question, set the Netlist Type to **Post-Synthesis** if you are changing a Fitter setting, such as raising the Placement Effort Multiplier. This causes the partition to be placed and routed with the new Fitter settings (but not resynthesized) during the next compilation. Set the Netlist Type to **Source File** if you are changing an optimization setting that affects synthesis, such as certain Physical Synthesis optimizations.
3. For the remaining partitions (including the top-level entity), set the Netlist Type to **Post-Fit**. Set the **Fitter Preservation Level** to **Placement** to allow for the most flexibility during routing. These partitions are preserved during the next compilation.
4. Apply the desired optimization settings.

5. Click **Start Compilation** to perform incremental compilation on the design with the new settings. During this compilation, the Partition Merge stage automatically merges the critical partition's netlist with the post-fit netlists of the remaining partitions. The Fitter then refits only the required partition. Because the effort is reduced as compared to the initial full compilation, the compilation time is also reduced.

To use the Design Space Explorer, perform the following steps:

1. Repeat steps 1–3 of the previous set of steps.
2. Save the project and run the Design Space Explorer.

Preserving Results for Some Partitions Before Adding Other Partitions

Use this flow to compile one set of partitions in isolation and lock the placement to preserve the results while you complete the rest of your design.

Example background: To reduce compilation time and help achieve timing closure, you decide to use one of the following compilation flows:

In the first variation, a timing-critical partition is placed and routed by itself, with extra optimizations turned on (manually or with the Design Space Explorer). After timing closure is achieved for this partition, its content and placement are preserved and the remaining partitions are fit with normal or reduced optimization levels so that the compilation time can be reduced. For example, you can compile an IP block that comes with instructions to perform optimization before you incorporate the rest of your custom logic.

In the second variation, only the quick-compiling partitions are placed and routed initially with normal or reduced optimization levels, using floorplan location assignments to reserve space in the floorplan for the partitions to be added in the future. These quick-compiling partitions are then preserved so they do not have to be compiled again when the last partitions are introduced, with extra optimizations turned on (manually or with the Design Space Explorer).

To implement this design flow, perform the following steps:

1. Partition the design and create floorplan location assignments.
2. For the partitions to be compiled first, on the Assignments menu, click **Design Partitions Window and** set Netlist Type to **Source File**.
3. For the remaining partitions (other than any direct or indirect parents of partitions in step 2), set the Netlist Type to **Empty**.
4. To compile with the desired optimizations turned on, click **Start Compilation**.
5. Check Timing Analyzer reports to ensure that timing requirements are met. If so, proceed to step 6. Otherwise, repeat steps 4 and 5 until the requirements are met.
6. In the **Design Partitions Window**, set the Netlist Type to **Post-Fit** for the first partitions. Set the **Fitter Preservation Level to Placement and Routing** only if necessary to preserve results of the timing-critical blocks; otherwise, use **Placement** to allow for the most flexibility during routing.
7. Change the Netlist Type from **Empty** to **Source File** for the remaining partitions.

8. Set the appropriate level of optimizations and compile the design. Changing the optimizations at this point does not affect any fitted partitions, because each partition has its Netlist Type set to **Post-Fit**.
9. Check Timing Analyzer reports to ensure that timing requirements are met. If not, make design or option changes and repeat step 8 and step 9 until the requirements are met.

This flow is similar to a bottom-up design flow in which a module is implemented separately and is merged into the rest of the design afterwards. Generally, optimization in this flow works only if each critical path is contained within a single partition. This is one reason why both the inputs and outputs of each partition should be registered. Ensure that if there are any partitions representing a design file that is missing from the project, you create a placeholder wrapper file that defines the port interface. Refer to "Empty Partitions" on page 2–22 for more information.

Debugging Incrementally with the SignalTap II Logic Analyzer

Incremental compilation enables you to preserve the synthesis and fitting results of your original design and add the SignalTap II Logic Analyzer to your design without recompiling your original source code.

Use this flow to reduce compilation times when adding the logic analyzer to debug your design, or when you want to modify the configuration of the SignalTap II file without modifying your logic design or its placement.

It is not necessary to create any design partitions to use the SignalTap II Incremental Compilation feature. When your project has the default **Full incremental compilation** option turned on, the SignalTap II Logic Analyzer acts as its own separate design partition.

Perform the following steps to use the SignalTap II Embedded Logic Analyzer in an incremental compilation flow:

1. On the Assignments menu, click **Design Partitions Window**.
2. Set the Netlist Type to **Post-fit** for all partitions to preserve their placement.

The netlist type for the top-level partition defaults to **Source File**, so be sure to change this Top partition in addition to any design partitions that you created.

3. If you have not already compiled the design with the current set of partitions, perform a full compilation. If the design has already been compiled with the current set of partitions, the design is ready to add the SignalTap II Logic Analyzer.
4. Set up your SignalTap II file using the **SignalTap II: post-fitting** filter in the **Node Finder** to add signals for logic analysis. This allows the Fitter to add the SignalTap II logic to the post-fit netlist without modifying the design results.

   To add signals from the pre-synthesis netlist, set the partition's Netlist Type to **Source File** and use the **SignalTap II: pre-synthesis** filter in the **Node Finder**. This allows the software to resynthesize the partition and tap directly to the pre-synthesis node names that you choose. In this case, the partition is refit, so the placement is typically different from previous fitting results.

Do not use the netlist type **Post-Synthesis** with the SignalTap II Logic Analyzer.

For more information about setting up the SignalTap II Logic Analyzer, refer to the *Design Debugging Using the SignalTap II Embedded Logic Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Implementing a Team-Based Bottom-Up Design Flow

This example describes how to use incremental compilation in a bottom-up design flow.

Example background: A project consists of several lower-level subdesigns that are implemented separately by different designers. The top-level project instantiates each of these subdesigns exactly once. The subdesign designers want to optimize their designs independently and pass on the results to the project lead.

As the project lead in this scenario, perform the following steps to prepare the design for a successful bottom-up design methodology:

1. Create a new Quartus II project to ultimately contain the full implementation of the entire design.
2. To prepare for the bottom-up methodology, create a "skeleton" of the design that defines the hierarchy for the subdesigns implemented by separate designers. The top-level design implements the top-level entity in the design and instantiates wrapper files that represent each subdesign by defining only the port interfaces but not the implementation.
3. Make project-wide settings. Select the device, make global assignments for clocks and device I/O ports, and make any global signal constraints to specify which signals can use global routing resources.
4. Make design partition assignments for each subdesign and set the Netlist Type for each design partition to be imported to **Empty** in the Design Partitions window.
5. Create LogicLock regions for each of the lower-level partitions to create a design floorplan. This floorplan should consider the connectivity between partitions and estimates of the size of each partition based on any initial implementation numbers and knowledge of the design specifications.
6. On the Project menu, click **Generate Bottom-Up Design Partition Scripts**, or launch the script generator from Tcl or the command prompt.
7. Make any changes to the default script options as desired. Altera recommends that you pass all the default constraints, including LogicLock region, for all partitions and virtual pin location assignments. Altera further recommends that you add a maximum delay timing constraint for the virtual I/O connections in each partition to help timing closure during integration at the top level. If lower-level projects have not already been created by the other designers, use the partition script to set up the projects so that you can easily take advantage of makefiles.
8. Provide all lower-level designers with the Tcl file to create their project with the appropriate constraints. If you are using makefiles, provide the makefile for each partition.

As the designer of a lower-level subdesign in this example, perform the appropriate set of steps to successfully export your design, whether your design team is using makefiles or exporting and importing the design manually.

If you are using makefiles, perform the following steps:

1. Use the **make** command and the makefile provided by the project lead to create a Quartus II project with all design constraints, and compile the project.
2. The information about which source file should be associated with which partition is not available to the software automatically, so you must specify this information in the makefile. You must specify the dependencies before the software rebuilds the project after the initial call to the makefile.
3. When you have achieved the desired compilation results and the design is ready to be imported into the top-level design, the project lead can use the `master_makefile` command to export this lower-level partition and create a **.qxp** file, and then import it into the top-level design.

If you are not using makefiles, perform the following steps:

1. Create a new Quartus II project for the subdesign.
2. Make LogicLock region assignments and global assignments (including clock settings) as specified by the project lead.
3. Make Virtual Pin assignments for ports which represent connections to core logic instead of external device pins in the top-level module.
4. Make floorplan location assignments to the Virtual Pins so they are placed in their corresponding regions as determined by the top-level module. This provides the Fitter with more information about the timing constraints between modules. Alternatively, you can apply timing I/O constraints to the paths that connect to virtual pins.
5. Proceed to compile and optimize the design as needed.
6. When you have achieved the desired compilation results, on the Project menu, click **Export Design Partition**. The **Export Design Partition** dialog box appears.
7. Under **Netlist to export**, select the netlist type **Post-fit netlist** to preserve the placement and performance of the subdesign, and turn on **Export routing** to include the routing information if required. You can export **Post-synthesis netlist** instead if placement or performance preservation is not required.
8. Provide the **.qxp** file to the project lead.

Finally, as the project lead in this example, perform the appropriate set of steps to import the files sent in by the designers of each lower-level subdesign partition.

If you are using makefiles, perform the following steps:

1. Use the `master_makefile` command to export each lower-level partition and create **.qxp** files, and then import them into the top-level design.
2. The software does not have all the information about which source files should be associated with which partition, so you must specify this information in the makefile. The software cannot rebuild the project if source files change unless you specify the dependencies.

If you are not using makefiles, perform the following steps:

1. After you obtain the **.qxp** file for each subdesign from the other designers on the team, on the Project menu, click **Import Design Partition** and specify the partition in the top-level project that is represented by the subdesign **.qxp** file.
2. Repeat the import process described in step 1 for each partition in the design. After you have imported each partition once, select all the design partitions and use the **Reimport using latest import files at previous locations** option to import all of the files from their previous locations at one time.

Resolving Assignment Conflicts During Import

When importing the subdesigns, the project lead may notice some assignment conflicts. This can occur, for example, if the subdesign designers changed their LogicLock regions to account for additional logic or placement constraints, or if the designers applied I/O port timing constraints that differ from constraints added to the top-level project by the project lead. To address these conflicts, the project lead can take one or both of the following actions:

- Allow new assignments to be imported.
- Allow existing assignments to be replaced or updated.

When LogicLock region assignment conflicts occur, the project lead may take one of the following actions:

- Allow the imported region to replace the existing region.
- Allow the imported region to update the existing region.
- Skip assignment import for regions with conflicts.

The project lead can address all of these situations using **Advanced Import Settings** as described in "Importing Assignments and Advanced Import Settings" on page 2–38.

If the placement of different subdesigns conflict, the project lead can also set the set the partition's **Fitter Preservation Level** to **Netlist Only**, which allows the software to re-perform placement and routing with the imported netlist.

Importing a Partition to be Instantiated Multiple Times

In this variation of the scenario, one of the subdesigns is instantiated more than once in the top-level design. The designer of the subdesign may want to compile and optimize the entity once under a lower-level project, and then import the results as multiple partitions in the top-level project.

In this case, placement conflict resolution as described in "Resolving Assignment Conflicts During Import" on page 2–55 is mandatory because the top-level partitions share the same imported post-fit netlist. If you import multiple instances of a subdesign in the top-level design, the imported LogicLock regions are automatically set to Floating status.

If you resolve conflicts manually, you can use the import options and manual LogicLock assignments to specify the placement of each instance in the top-level design.

Performing Design Iteration in a Bottom-Up Design Flow

Use this flow if you re-optimize lower-level partitions in a bottom-up compilation by incorporating additional constraints from the integrated top-level design.

Example background: A project consists of several lower-level subdesigns that have been exported from separate Quartus II projects and imported into the top-level design in a bottom-up compilation flow. In this example, integration at the top level has failed because the timing requirements are not met. The timing requirements are met in each individual lower-level project, but critical inter-partition paths in the top level are causing timing requirements to fail.

After trying various optimizations at the top level, the project lead determines that the design cannot meet the timing requirements given the current lower-level partition placements that were imported. The project lead decides to pass additional constraints to the lower-level projects to improve the placement.

To implement this design flow, perform the following steps:

1. In the top-level design, on the Project menu, click **Generate Bottom-Up Design Partition Scripts**, or launch the script generator from Tcl or the command line.
2. Because lower-level projects have already been created for each partition, turn off **Create lower-level project if one does not exist**.
3. Make any additional changes to the default script options as desired. Altera recommends that you pass all the default constraints, including LogicLock regions, for all partitions and virtual pin location assignments. Altera also recommends that you add a maximum delay timing constraint for the virtual I/O connections in each partition.
4. The Quartus II software generates Tcl scripts for all partitions, but in this scenario, you would focus on the partitions that make up the cross-partition critical paths. The following assignments are important in the script:
   - Virtual pin assignments for module pins not connected to device I/O ports in the top-level design.
   - Location constraints for the virtual pins that reflect the initial top-level placement of the pin's source or destination. These help make the lower-level placement "aware" of its surroundings in the top level, leading to a greater chance of timing closure during integration at the top level.
   - `INPUT_MAX_DELAY` and `OUTPUT_MAX_DELAY` timing constraints on the paths to and from the I/O pins of the partition. These constrain the pins to optimize the timing paths to and from the pins.
5. The lower-level designers source the file provided by the project lead.
   - To source the Tcl script from the Quartus II GUI, on the Tools menu, click **Utility Windows** and open the Tcl console. Navigate to the script's directory, and type the following command:

     ```
     source <filename> ↵
     ```
   - To source the Tcl script at the system command prompt, type the following command:

     ```
     quartus_cdb -t <filename>.tcl ↵
     ```

6. The lower-level designers recompile their designs with the new assignments and ensure that the internal timing requirements are met.
7. The lower-level designers re-export their results.
8. The top-level designer re-imports the results.
9. You can now analyze the design to determine whether the timing requirements have been achieved. Because the lower-level partitions were compiled with more information about connectivity at the top level, it is more likely that the inter-partition paths have improved placement which helps to meet the timing requirements.

Creating Hard-Wired Macros (or Precompiled Design Blocks) for IP Reuse

Use this design flow to create a hard-wired macro or precompiled IP block that can be instantiated in a top-level design. This flow provides the ability to export a design block with post-synthesis or placement (and, optionally, routing) information and to import any number of copies of this pre-compiled macro into another design.

Example background: An IP provider wants to produce and sell an IP core for a component to be used in higher-level systems. The IP provider wants to optimize the placement of their block for maximum performance in a specific Altera device and then deliver the placement information to their end customer. To preserve their IP, they also prefer to send a compiled netlist instead of providing the HDL source code to their customer.

The customer first specifies which Altera device is being used for this project and provides the design specifications.

As the IP provider in this example, perform the following steps to export a preplaced IP core (or hard macro):

1. Create a black box wrapper file that defines the port interface for the IP core and provide the file to the customer to instantiate as an empty partition in the top-level design.
2. Create a Quartus II project for the IP core.
3. Create a LogicLock region for the design hierarchy to be exported.

Altera recommends creating a floorplan using LogicLock regions, although it is not required for the generation and use of **.qxp** files. Using a LogicLock region for the IP core allows the customer to create an empty placeholder region to reserve space for the IP in the design floorplan. This ensures there are no conflicts with the top-level design logic, and that the IP core does not affect the timing performance of other logic in the top-level design.

LogicLock regions can be effective to reduce resource utilization conflicts and to enable performance preservation. In addition, without LogicLock regions, placement can be preserved only in an absolute manner. With LogicLock regions, you can preserve placement absolutely or relative to the origin of the associated regions. This is important when a **.qxp** file is imported for multiple partition hierarchies in the same project, because in this case, the location of at least one instance in the top-level project does not match the location used by the IP provider.

4. If required, add any logic (such as PLLs or other logic defined in the customer's top-level design) around the design hierarchy to be exported. If you do so, create a design partition for the design hierarchy that is to be exported as an IP core.

   For more information, refer to "Exporting a Lower-Level Block within a Project" on page 2–35.

5. Optimize the design and close timing to meet the design specifications.

6. Export the appropriate level of hierarchy into a single **.qxp** file. Following a successful compilation of the project, you can generate a **.qxp** file from the GUI, the command-line, or with Tcl commands:

   - If you are using the Quartus II GUI, use the **Export Design Partition** command.
   - If you are using command-line executables, run **quartus_cdb** with the `--incremental_compilation_export` option.
   - If you are using Tcl commands, use the following command: `execute_flow -incremental_compilation_export`.

7. Provide the **.qxp** file to the customer. Note that you do not have to send any of your design source code to the customer; the design netlist and placement and routing information is contained within this single file.

As the customer in this example, incorporate the IP core in your design by performing the following steps:

1. Create a Quartus II project for the top-level design that targets the same device and instantiate a copy or multiple copies of the IP core. Use a black box wrapper file to define the port interface of the IP core.

2. On the Processing menu, point to **Start** and click **Perform Analysis & Elaboration** to identify the design hierarchy.

3. Create a design partition for each instance of the IP core (refer to "Creating Design Partitions" on page 2–69) with the Netlist Type set to **Empty** (refer to "Setting the Netlist Type for Design Partitions" on page 2–19).

4. You can now continue work on your part of the design and accept the IP core from the IP provider whenever it is ready.

5. Import the **.qxp** file from the IP provider for the appropriate partition hierarchy. You can import a **.qxp** file from the GUI, the command-line, or with Tcl commands.

   - If you are using the Quartus II GUI, use the **Import Design Partition** command.
   - If you are using command-line executables, run **quartus_cdb** with the `--incremental_compilation_import` option.
   - If you are using Tcl commands, use the following command: `execute_flow -incremental_compilation_import`.

6. You can set the imported LogicLock regions to floating or move them to a new location, with the relative locations of the region contents preserved. Routing information is preserved whenever possible.

The Fitter ignores relative placement assignments if the LogicLock region's location in the top-level design is not compatible with the locations exported in the **.qxp** file.

7. You can control whether to preserve the imported netlist only, placement, or placement and routing (if the placement or placement and routing information was exported in the **.qxp** file) with the Fitter Preservation Level.

By default, the software preserves the absolute placement and routing of all nodes in the imported netlist if you choose to preserve placement and routing. However, if you use the same **.qxp** files for multiple partitions in the same project, the software preserves the relative placement for each of the imported modules (relative to the origin of the LogicLock region).

If the IP provider did not define a LogicLock region in the exported partition, the software preserves absolute placement locations and this leads to placement conflicts if the partition is imported for more than one instance.

Using an Exported Partition to Send a Design without Including Source Files

Use this flow to package a full design as a single file to send to an end customer or another design location.

Example background: A designer wants to produce a design block and needs to send out their design, but to preserve their IP, they prefer to send a synthesized netlist instead of providing the HDL source code to the recipient.

As the sender in this example, perform the following steps to export a design block:

1. Provide the device family name to the sender. If you send placement information with the synthesized netlist, also provide the exact device selection so they can set up their project to match.
2. Create a black box wrapper file that defines the port interface for the design block and provide it to the recipient for instantiating the block as an empty partition in the top-level design.
3. Create a Quartus II project for the design block, and complete the design.
4. Export the appropriate level of hierarchy into a single **.qxp** file. If you use the Quartus II GUI, use the **Export Design Partition** command (refer to "Exporting a Lower-Level Partition to be Used in a Top-Level Project" on page 2–34").
5. Select the option to include just the **Post-synthesis netlist** if you do not have to send placement information. If the recipient wants to reproduce your exact Fitter results, you can select the **Post-fitting netlist** option, and optionally enable **Export routing**.
6. Provide the **.qxp** file to the recipient. Note that you do not have to send any of your design source code.

As the recipient in this example, first create a Quartus II project for your top-level design and ensure that your project targets the same device (or at least the same device family if the **.qxp** file does not include placement information), as specified by the IP provider sending the design block. Instantiate the design block using the port information provided. Then incorporate the design block into a top-level design by performing one of the following procedures.

To use the **.qxp** file as a design file in your design, simply add the **.qxp** file from the IP provider as a source file in your Quartus II project. When you use a **.qxp** file as a source file in this way, you cannot import any post-fit netlist information. You can choose whether you want the file to be a partition in the top-level project.

To import the design instance from the **.qxp** file as a design partition and optionally include the post-fit netlist information, perform the following steps:

1. On the Processing menu, point to **Start** and click **Perform Analysis & Elaboration** to identify the design hierarchy.
2. Create a design partition for the design instance from the **.qxp** file (refer to "Creating Design Partition Assignments" on page 2–16) with the Netlist Type set to **Empty** (refer to "Setting the Netlist Type for Design Partitions" on page 2–19).
3. Import the **.qxp** file from the IP provider for the appropriate partition hierarchy. If you are using the Quartus II GUI, use the **Import Design Partition** command and browse to the **.qxp** file provided (refer to "Using a .qxp File as a Source File in the Top-Level Project" on page 2–36).
4. If the sender provides Fitter information, you can control whether to preserve the imported netlist only, placement, or placement and routing, with the Fitter Preservation Level.

Incremental Compilation Restrictions

This section documents the restrictions and limitations that you may encounter when using incremental compilation, including interactions with other Quartus II features. Some restrictions apply to both top-down and bottom-up design flows, while some additional restrictions apply only to bottom-up design flows.

The following restrictions and limitations are covered:

- "Preserving Exact Timing Performance" on page 2–61
- "When Placement and Routing May Not Be Preserved Exactly" on page 2–61
- "Using Incremental Compilation with Quartus II Archive Files" on page 2–61
- "Formal Verification Support" on page 2–61
- "Importing Encrypted IP Cores in Bottom-Up Flows" on page 2–62
- "SignalProbe Pins and Engineering Change Management with the Chip Planner" on page 2–62
- "SignalTap II Embedded Logic Analyzer in Bottom-Up Compilation Flows" on page 2–64
- "Logic Analyzer Interface in Bottom-Up Compilation Flows" on page 2–64
- "Migrating Projects with Design Partitions to Different Devices" on page 2–64
- "HardCopy Compilation and Migration Flows" on page 2–64
- "Assignments Made in HDL Source Code in Bottom-Up Flows" on page 2–65
- "Restrictions on Megafunction Partitions" on page 2–65
- "Register Packing and Partition Boundaries" on page 2–66
- "I/O Register Packing" on page 2–66

Preserving Exact Timing Performance

Timing performance might change slightly in a partition with placement and routing preserved when other partitions are incorporated or re-placed and routed. Timing changes are due to changes in parasitic loading or crosstalk introduced by the other (changed) partitions. These timing changes are very small, typically less than 30 ps on a timing path. Additional fan-out on routing lines when partitions are added can also degrade timing performance.

To ensure that a partition continues to meet its timing requirements when other partitions change, a very small timing margin might be required. The Fitter automatically works to achieve such margin when compiling any design, so you do not need to take any action.

When Placement and Routing May Not Be Preserved Exactly

The Fitter may have to refit affected nodes if the two nodes are assigned to the same location, due to imported netlists or empty partitions set to re-use a previous post-fit netlist. There are two cases in which routing information cannot be preserved exactly. First, when multiple partitions are imported, there might be routing conflicts because two lower-level blocks could be using the same routing wire, even if the floorplan assignments of the lower-level blocks do not overlap. These routing conflicts are automatically resolved by the Quartus II Fitter re-routing on the affected nets. Second, if an imported LogicLock region is moved in the top-level design, the relative placement of the nodes is preserved but the routing cannot be preserved, because the routing connectivity is not perfectly uniform throughout a device.

Using Incremental Compilation with Quartus II Archive Files

The post-synthesis and post-fitting netlist information for each design partition is stored in the project database, the **incremental_db** directory. When you archive a project, the database information is not included in the archive unless you include the compilation database in the **.qar** file.

Altera recommends that you include the database files in the **Archive Project** dialog box so compilation results are preserved. Click **Advanced**, and choose a file set that includes the compilation database, or turn on **Compilation database files** to create a Custom file set.

When you include the database, the file size of the **.qar** archive file may be significantly larger than an archive without the database.

The netlist information for imported partitions is already saved in the corresponding **.qxp** file. Imported **.qxp** files are automatically saved in a subdirectory called **imported_partitions**, so you do not need to archive the project database to keep the results for imported partitions. When you restore a project archive, the partition is automatically reimported from the **.qxp** file in this directory if it is available.

Formal Verification Support

You cannot use design partitions for incremental compilation if you are creating a netlist for a formal verification tool.

Importing Encrypted IP Cores in Bottom-Up Flows

Proper license information is required to compile encrypted IP cores. If an IP core is imported as a **.qxp** file from another Quartus II project in a bottom-up compilation flow, the top-level designer must have the correct license. That is, you require a full license to generate an unrestricted programming file. If you do not have a license, but the IP in the **.qxp** file was compiled with OpenCore Plus hardware evaluation support, you can generate an evaluation programming file without a license. If the IP supports OpenCore simulation only, you can fully compile the design and generate a simulation netlist, but you cannot create programming files unless you have a full license.

SignalProbe Pins and Engineering Change Management with the Chip Planner

When you create SignalProbe pins or use the Resource Property Editor to make changes due to engineering change orders (ECOs) after performing a full compilation, recompiling the entire design is not necessary. These changes are made directly to the netlist without performing a new placement and routing. You can preserve these changes using a post-fit netlist with placement and routing. When a partition is recompiled, SignalProbe pins and ECO changes in unaffected partitions are preserved.

For more information about using the SignalProbe feature to debug your design, refer to the *Quick Design Debugging Using SignalProbe* chapter in volume 3 of the *Quartus II Handbook*. For more information about using the Chip Planner and the Resource Property Editor to make ECOs, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

To preserve SignalProbe pins or ECO changes, the partition netlist type should be set to **Post-Fit** with the Fitter Preservation Level set to **Placement and Routing**. If any partitions with SignalProbe pins or ECO changes are set to **Post-Fit** without Routing or to **Netlist Only**, the software issues a warning and internally uses the Post-fit netlist with **Placement and Routing**. If the partitions are set to use the source code or a Post-synthesis netlist, the software issues a warning and the Post-fit SignalProbe pins or ECO changes are not included in the new compilation. However, partitions can become linked due to the SignalProbe pins or ECO changes, as described below, in which case all linked partitions inherit the netlist type from the linked partition with the highest level of preservation.

Linked Partitions Due to SignalProbe Pins or ECO Changes

If ECO changes affect more than one partition or the connection between any partitions, the partitions become linked. All of the higher-level “parent” partitions up to their nearest common parent are also linked. In this case, the connection between the partitions is actually defined outside of the two partitions immediately affected, so all the partitions must be compiled together. All linked partitions use the same netlist type, and they inherit the netlist type from the linked partition with the highest level of preservation.

When a SignalProbe pin is created, it affects the partition that contains the node being probed. In addition, any pipeline registers are created in the same partition as the node being probed. The SignalProbe output pin is assigned to the top-level partition. Therefore, there is a new connection formed between the top-level partition and the lower-level partition that is being probed. Because of this connection, the lower-level partition being probed and all of the higher-level "parent" partitions up to the top level become linked. All linked partitions use the same netlist type, and they inherit the netlist type from the linked partition with the highest level of preservation.

When partitions are linked, they can change which netlists are preserved when you recompile the design, as follows:

- If all the linked partitions are set to use the source code or a post-synthesis netlist, the partitions are refit as normal. In this case, the SignalProbe pins or ECO changes are not included in the new netlists, so you must reapply the changes in the Change Manager.
- If any of the linked partitions are set to the **Post-Fit** netlist type, and there are no source code changes, the software issues a warning and internally uses the post-fit netlist with placement and routing for all linked partitions. By preserving the appropriate post-fit netlists, the software can preserve the SignalProbe pins or ECO changes.
- If any of the linked partitions are set to the **Post-Fit (Strict)** netlist type, the software issues a warning and internally uses the post-fit netlist with placement and routing for all linked partitions, regardless of any source code changes. By preserving the appropriate post-fit netlists, the software can preserve the SignalProbe pins or ECO changes. Note that in this case, source code changes in any of the linked partitions are not included in the new netlist.
- If any of the linked partitions are recompiled due to a change in source code, the software issues a warning and recompiles the other linked partitions as well. When this occurs, the SignalProbe pins or ECO changes are not included in the new netlist, so you must reapply the changes in the Change Manager.

Exported Partitions

In a bottom-up incremental compilation, the exported netlist includes all currently saved SignalProbe pins and ECO changes. This might require flattening and combining lower-level partitions in the child project to avoid partition boundary violations at the top level. After importing this netlist, changes made in the lower-level partition do not appear in the Change Manager at the top level.

If you make any ECO changes that affect the interface to the lower-level partition, the software issues a warning message during the export process that this netlist does not work in the top-level design without modifying the top-level HDL code to reflect the lower-level change.

SignalTap II Embedded Logic Analyzer in Bottom-Up Compilation Flows

You can use the SignalTap II Embedded Logic Analyzer in any project that you can compile and program into an Altera device.

You cannot export a lower-level project that uses a SignalTap II File (**.stp**) for the SignalTap II Logic Analyzer in a bottom-up incremental compilation flow. You must disable the SignalTap II feature and recompile the design before you export the design as a partition.

You can instantiate the SignalTap II megafunction directly in your lower-level design (instead of using an **.stp** file) and export the entire design to the top level in a bottom-up flow.

You can tap any nodes in a Quartus II project, including nodes imported from other projects. Use the appropriate filter in the Node Finder to find your node names. Use **SignalTap II: post-fitting** if the Netlist Type is **Post-Fit** to incrementally tap node names in the post-fit netlist database. Use **SignalTap II: pre-synthesis** if the Netlist Type is **Source File** to make connections to the source file (pre-synthesis) node names when you synthesize the partition from the source code.

For details about using the SignalTap II logic analyzer in an incremental design flow, refer to the *Design Debugging Using the SignalTap II Embedded Logic Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Logic Analyzer Interface in Bottom-Up Compilation Flows

You can use the Logic Analyzer Interface in any project that you can compile and program into an Altera device. You cannot export a lower-level project that uses the Logic Analyzer Interface in a bottom-up incremental compilation flow. You must disable the Logic Analyzer Interface feature and recompile the design before you export the design as a partition.

For more information about the Logic Analyzer Interface, refer to the *In-System Debugging Using External Logic Analyzers* chapter in volume 3 of the *Quartus II Handbook*.

Migrating Projects with Design Partitions to Different Devices

Partition assignments are still valid if you migrate to a different device density or family. LogicLock region size is valid if you migrate to a device in the same family, but the origin location is not valid. Specific floorplan assignments are not valid for different devices or families because the location coordinates change between devices.

Post-synthesis netlists are valid if you migrate to a different-sized device in the same family. Post-fit netlists are not valid if you migrate to a different device density or family.

HardCopy Compilation and Migration Flows

HardCopy APEX and HardCopy Stratix Devices

Incremental compilation with the Quartus II software is not supported for HardCopy APEX or HardCopy Stratix design flows.

HardCopy ASIC Migration Flows

Top-down incremental compilation is supported for the base family in HardCopy migration flows for both the FPGA first and HardCopy first flows. Design partition assignments are migrated to the companion device. However, you can not make changes to the design after migration because the design would not match the compilation results for the base family. Therefore, you can perform top-down incremental compilation on one device family, but cannot perform any incremental compilations after migration.

The Netlist Only preservation level is not supported for Post-fit netlists for FPGA or HardCopy ASIC device compilations when a migration device is specified (that is, for HardCopy ASIC device compilations with a FPGA migration device, or FPGA device compilations with a HardCopy ASIC migration device).

Bottom-up incremental compilation is not supported in HardCopy ASIC or FPGA device compilations when there is a migration device setting. The Revision Compare feature requires that the HardCopy ASIC and FPGA netlists are the same. Therefore, all operations performed on one revision must also occur on the other revision. This is accomplished by logging all operations and replaying them on the other revision. Using the bottom-up flow and importing partitions does not support this requirement. You can often use a top-down flow with **Empty** partitions to implement behavior similar to a bottom-up flow, as long as you do not change any global assignments between compilations. All global assignments must be the same for all compiled partitions, so the assignments can be reproduced in the companion device after migration.

HardCopy ASIC Stand-Alone Compilations

You can use both top-down and bottom-up incremental compilation for stand-alone HardCopy ASIC compilations.

Routing preservation is not supported for HardCopy ASICs. Therefore, the **Placement and Routing** preservation level is not available, and routing cannot be exported in the bottom-up flow.

Assignments Made in HDL Source Code in Bottom-Up Flows

Assignments made with I/O primitives or the `altera_attribute` HDL synthesis attribute in lower-level partitions are passed to the top-level design, but do not appear in the top-level QSF file or Assignment Editor. These assignments are considered part of the source netlist files. You can override assignments made in these source files by changing the value with an assignment in the top-level design.

Restrictions on Megafunction Partitions

The Quartus II software does not support partitions for megafunction instantiations. If you use the MegaWizard™ Plug-In Manager to customize a megafunction variation, the MegaWizard-generated wrapper file instantiates the megafunction. You can create a partition for the MegaWizard-generated megafunction custom variation wrapper file.

The Quartus II software does not support creating a partition for inferred megafunctions (that is, where the software infers a megafunction to implement logic in your design). If you have a module or entity for the logic that is inferred, you can create a partition for that hierarchy level in the design.

The Quartus II software does not support creating a partition for any Quartus II internal hierarchy that is dynamically generated during compilation to implement the contents of a megafunction.

Register Packing and Partition Boundaries

The Quartus II software performs register packing during compilation automatically. However, when incremental compilation is enabled, logic in different partitions cannot be packed together because partition boundaries prevent cross-boundary optimization. This restriction applies to all types of register packing, including I/O cells, DSP blocks, sequential logic, and unrelated logic. Similarly, logic from two partitions cannot be packed into the same ALM.

I/O Register Packing

Cross-partition register packing of I/O registers is allowed in certain cases where your input and output pins exist in the top-level hierarchy (and the Top partition), but the corresponding I/O registers exist in other partitions.

The following specific circumstances are required for input pin cross-partition register packing:

- The input pin feeds exactly one register.
- The path between the input pin and register includes only input ports of partitions that have one fan-out each.

The following specific circumstances are required for output register cross-partition register packing:

- The register feeds exactly one output pin.
- The output pin is fed by only one signal.
- The path between the register and output pin includes only output ports of partitions that have one fan-out each.

Output pins with an output enable signal cannot be packed into the device I/O cell if the output enable logic is part of a different partition from the output register. To allow register packing for output pins with an output enable signal, structure your HDL code or design partition assignments so that the register and tri-state logic are defined in the same partition.

Bidirectional pins are handled in the same way as output pins with an output enable signal. If the registers that need to be packed are in the same partition as the tri-state logic, you can perform register packing.

The restrictions on tri-state logic exist because the I/O atom (device primitive) is created as part of the partition that contains tri-state logic. If an I/O register and its tri-state logic are contained in the same partition, the register can always be packed with tri-state logic into the I/O atom. The same cross-partition register packing restrictions also apply to I/O atoms for input and output pins. The I/O atom must

feed the I/O pin directly with exactly one signal. The path between the I/O atom and the I/O pin must include only ports of partitions that have one fan-out each. Refer to the *Best Practices for Incremental Compilation Partitions and Floorplan Assignments* chapter in volume 1 of the *Quartus II Handbook* for more information and examples of cross-partition boundary I/O packing.

Bottom-Up Design Partition Script Limitations

The Quartus II software has some limitations related to bottom-up design partition scripts.

Warnings About Extra Clocks Due to Bottom-Up Design Partition Scripts

The generated scripts include applicable clock information for all clock signals in the top-level project. Some of those clocks may not exist in the lower-level projects, so you may see warning messages related to clocks that do not exist in the project. You can ignore these warnings or edit your constraints so the messages are not generated.

Synopsys Design Constraint Files for the TimeQuest Timing Analyzer in Bottom-Up Design Partition Scripts

As described in "Generating Bottom-Up Design Partition Scripts for Project Management" on page 2–40, design partition scripts include only clock constraints and minimum and maximum delay settings for the TimeQuest Timing Analyzer.

PLL settings and timing exceptions are not passed to lower-level designs in the scripts. Refer to"Importing SDC Constraints from Lower-Level Partitions" on page 2–45 for suggestions on managing SDC constraints between top-level and lower-level projects.

Wildcard Support in Bottom-Up Design Partition Scripts

When applying constraints with wildcards, note that wildcards are not analyzed across hierarchical boundaries. For example, an assignment could be made to these nodes: `Top|A:inst|B:inst|*`, where `A` and `B` are lower-level partitions, and hierarchy `B` is a child of `A`, that is `B` is instantiated in hierarchy `A`. This assignment is applied to modules `A`, `B`, and all children instances of `B`. However, the assignment `Top|A:inst|B:inst*` is applied to hierarchy `A`, but is not applied to the `B` instances because the single level of hierarchy represented by `B:inst*` is not expanded into multiple levels of hierarchy. To avoid this issue, ensure that you apply the wildcard to the hierarchical boundary if it should represent multiple levels of hierarchy.

When using the wildcard to represent a level of hierarchy, only single wildcards are supported. This means assignments such as `Top|A:inst|*|B:inst|*` are not supported. The Quartus II software issues a warning in these cases.

Derived Clocks and PLLs in Bottom-Up Design Partition Scripts

If a clock in the top level is not directly connected to a pin of a lower-level partition, the lower-level partition does not receive assignments and constraints from the top-level pin in the design partition scripts.

This issue is of particular importance for clock pins that require timing constraints and clock group settings. Problems can occur if your design uses logic or inversion to derive a new clock from a clock input pin. Make appropriate timing assignments in your lower-level Quartus II project to ensure that clocks are not unconstrained.

In addition, if you use a PLL in your top-level design and connect it to lower-level partitions, the lower-level partitions do not have information about the multiplication or phase shift factors in the PLL. Make appropriate timing assignments in your lower-level Quartus II project to ensure that clocks are not unconstrained or constrained with the incorrect frequency. Alternately, manually duplicate the top-level derived clock logic or PLL in the lower-level design file to ensure that you have the correct multiplication or phase-shift factors, compensation delays and other PLL parameters for complete and accurate timing analysis. Create a design partition for the rest of the lower-level design logic for export to the top level. When the lower-level design is complete, export only the partition that contains the relevant logic with the feature described in "Exporting a Lower-Level Block within a Project" on page 2–35.

Pin Assignments for GXB and LVDS Blocks in Bottom-Up Design Partition Scripts

Pin assignments for high-speed GXB transceivers and hard LVDS blocks are not written in the scripts. You must add the pin assignments for these hard IP blocks in the lower-level projects manually.

Virtual Pin Timing Assignments in Bottom-Up Design Partition Scripts

Design partition scripts use `INPUT_MAX_DELAY` and `OUTPUT_MAX_DELAY` assignments to specify inter-partition delays associated with input and output pins, which would not otherwise be visible to the project. These assignments require that the software specify the clock domain for the assignment and set this clock domain to '*'.

This clock domain assignment means that there may be some paths constrained and reported by the timing analysis engine that are not required.

To restrict which clock domains are included in these assignments, edit the generated scripts or change the assignments in your lower-level Quartus II project. In addition, because there is no known clock associated with the delay assignments, the software assumes the worst-case skew, which makes the paths seem more timing critical than they are in the top-level design. To make the paths appear less timing-critical, lower the delay values from the scripts. If required, enter negative numbers for input and output delay values.

Top-Level Ports that Feed Multiple Lower-Level Pins in Bottom-Up Design Partition Scripts

When a single top-level I/O port drives multiple pins on a lower-level module, it unnecessarily restricts the quality of the synthesis and placement at the lower-level. This occurs because in the lower-level design, the software must maintain the hierarchical boundary and cannot use any information about pins being logically equivalent at the top level. In addition, because I/O constraints are passed from the top-level pin to each of the children, it is possible to have more pins in the lower level than at the top level. These pins use top-level I/O constraints and placement options

that might make them impossible to place at the lower level. The software avoids this situation whenever possible, but it is best to avoid this design practice to avoid these potential problems. Restructure your design so that the single I/O port feeds the design partition boundary and the single connection is split into multiple signals within the lower-level partition.

Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ↵
```

The *Quartus II Scripting Reference Manual* includes the same information in PDF form.

For more information about Tcl scripting, refer to the *Tcl Scripting chapter* in volume 2 of the *Quartus II Handbook*. Refer to the *Quartus II Settings File Reference Manual* for information about all settings and constraints in the Quartus II software. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Preparing a Design for Incremental Compilation

To set or modify the current mode of incremental compilation, use the following command:

```
set_global_assignment -name INCREMENTAL_COMPILATION <value> ↵
```

The incremental compilation *<value>* setting must be one of the following values:

- FULL_INCREMENTAL_COMPILATION—Full incremental compilation (this is the default)
- OFF—No incremental compilation is performed

Creating Design Partitions

To create a partition, use the following command:

```
set_instance_assignment -name PARTITION_HIERARCHY \
<file name> -to <destination> -section_id <partition name>
```

The *<destination>* should be the entity's short hierarchy path. A short hierarchy path is the full hierarchy path without the top-level name (including quotation marks), for example:

```
"ram:ram_unit|altsyncram:altsyncram_component"
```

For the top-level partition, you can use the pipe (|) symbol to represent the top-level entity.

For more information about hierarchical naming conventions, refer to the *Node-Naming Conventions in Quartus II Integrated Synthesis* section in the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*.

The <*partition name*> is the user-designated partition name, which must be unique and less than 1024 characters. The name can consist only of alphanumeric characters, and the pipe (|), colon (:), and underscore (_) characters. Altera recommends enclosing the name in double quotation marks (" ").

The <*file name*> is the name used for internally generated netlists files during incremental compilation. Netlists are named automatically by the Quartus II software based on the instance name if you create the partition in the user interface. If you are using Tcl to create your partitions, you must assign a custom file name that is unique across all partitions. For the top-level partition, the specified file name is ignored; you can use any dummy value. To ensure the names are safe and platform independent, file names must be unique regardless of case. For example, if a partition uses the file name `my_file`, no other partition can use the file name `MY_FILE`. For simplicity, Altera recommends that you base each file name on the corresponding instance name for the partition.

The software stores all netlists in the **\incremental_db** compilation database directory.

Setting Properties of Design Partitions

After a partition is created, set its Netlist Type with the following command:

```
set_global_assignment -name PARTITION_NETLIST_TYPE <value> \
-section_id <partition name>
```

The netlist type <*value*> setting is one of the following values:

- `SOURCE`—Source File
- `POST_SYNTH`—Post-Synthesis
- `POST_FIT`—Post-Fit
- `STRICT_POST_FIT`—Post-Fit (Strict)
- `IMPORTED`—Imported
- `IMPORT_BASED_POST_FIT`—Post-Fit (Import-based)
- `EMPTY`—Empty

Set the Fitter Preservation Level for a post-fit or imported netlist using the following command:

```
set_global_assignment -name PARTITION_FITTER_PRESERVATION_LEVEL \
<value> -section_id <partition name>
```

The Fitter Preservation Level <*value*> setting is one of the following values:

- `NETLIST_ONLY`—Netlist only
- `PLACEMENT`—Placement
- `PLACEMENT_AND_ROUTING`—Placement and routing
- `PLACEMENT_AND_ROUTING_AND_TILE`—Placement and routing, as well as the high-speed power tile settings

For details about these partition properties, refer to "Setting the Netlist Type for Design Partitions" on page 2–19.

Creating Floorplan Location Assignments—Excluding or Filtering Certain Device Elements (Such as RAM or DSP Blocks)

Resource filtering uses the optional Tcl argument `-exclude_resources` in the `set_logiclock_contents` function of the `incremental_compilation` Tcl package. If left unspecified, no resource filter is created.

The argument takes a list of resources-to-be-excluded as input. The list is a colon-delimited string of the keywords in Table 2–6.

Table 2–6. Resources-to-be-Excluded Keywords

Keyword	Resource
`REGISTER`	Any registers in the logic cells
`COMBINATIONAL`	Any combinational elements in the logic cells
`SMALL_MEM`	The small TriMatrix memory blocks (M512 or MLAB)
`MEDIUM_MEM`	The medium TriMatrix memory blocks (M4K or M9K)
`LARGE_MEM`	The large TriMatrix memory blocks (M-RAM or M144K)
`DSP`	Any DSP blocks
`VIRTUAL_PIN`	Any virtual pins

For example, the following command assigns everything under **alu:alu_unit** to the ALU region, excluding all the DSP and M512 blocks:

```
set_logiclock_contents -region ALU -to alu:alu_unit -exceptions \
"DSP:SMALL_MEM"
```

In the **.qsf** file, resource filtering uses an extra LogicLock membership assignment called `LL_MEMBER_RESOURCE_EXCLUDE`. For example, the following line in the **.qsf** file is used to specify a resource filter for the `alu:alu_unit` entity assigned to the ALU region. The value of the assignment takes the same format as the resource listing string taken by the previous Tcl command.

```
set_instance_assignment -name LL_MEMBER_RESOURCE_EXCLUDE \
"DSP:SMALL_MEM" -to "alu:alu_unit" -section_id ALU
```

Generating Bottom-Up Design Partition Scripts

To generate scripts, type the following Tcl command at a Tcl prompt:

```
generate_bottom_up_scripts <options> ↵
```

The command is part of the `database_manager` package, which must be loaded using the following command before the command can be used:

```
load_package database_manager
```

You must open a project before you can generate scripts.

The Tcl options are the same as those available in the GUI. The exact format of each option is specified in Table 2–7.

Table 2–7. Options for Generating Bottom-Up Partition Scripts with Tcl Commands (Part 1 of 2)

Option	Default
`-include_makefiles` <*on*|*off*>	On
`-include_project_creation` <*on*|*off*>	On

Table 2–7. Options for Generating Bottom-Up Partition Scripts with Tcl Commands (Part 2 of 2)

Option	Default
-include_virtual_pins <*on*|*off*>	On
-include_virtual_pin_timing <*on*|*off*>	On
-include_virtual_pin_locations <*on*|*off*>	On
-include_logiclock_regions <*on*|*off*>	On
-include_all_logiclock_regions <*on*|*off*>	On
-include_global_signal_promotion <*on*|*off*>	Off
-include_pin_locations <*on*|*off*>	On
-include_timing_assignments <*on*|*off*>	On
-include_design_partitions <*on*|*off*>	On
-remove_existing_regions <*on*|*off*>	On
-disable_auto_global_promotion <*on*|*off*>	Off
-bottom_up_scripts_output_directory <*output directory*>	Current project directory
-virtual_pin_delay <*delay in ns*>	*(1)*

Note to Table 2–7:

(1) No default.

The following example shows how to use the Tcl command:

```
load_package database_manager
set project test_proj
project_open $project
generate_bottom_up_scripts -bottom_up_scripts_output_directory test \
    -include_virtual_pin_timing on -virtual_pin_delay 1.2
project_close
```

Command Line Support

To generate scripts at the command prompt, type the following command:

```
quartus_cdb <project name> --generate_bottom_up_scripts=on <options> ↵
```

Once again, the options map to the same as those in the GUI. To add an option, append "--<*option_name*>=<*val*>" to the command line call.

The command prompt options are the same as those available in the GUI. They are listed in Table 2–8.

Table 2–8. Options for Generating Bottom-Up Partition Scripts (Part 1 of 2)

Option	Default
--include_makefiles_with_bottom_up_scripts=<*on*|*off*>	On
--include_project_creation_in_bottom_up_scripts=<*on*|*off*>	On
--include_virtual_pins_in_bottom_up_scripts=<*on*|*off*>	On
--include_virtual_pin_timing_in_bottom_up_scripts=<*on*|*off*>	On
--bottom_up_scripts_virtual_pin_delay=<*delay in ns*>	*(1)*
--include_virtual_pin_locations_in_bottom_up_scripts=<*on*|*off*>	On
--include_logiclock_regions_in_bottom_up_scripts=<*on*|*off*>	On
--include_all_logiclock_regions_in_bottom_up_scripts=<*on*|*off*>	On

Table 2–8. Options for Generating Bottom-Up Partition Scripts (Part 2 of 2)

Option	Default
`--include_global_signal_promotion_in_bottom_up_scripts=`<*on*|*off*>	Off
`--include_pin_locations_in_bottom_up_scripts=`<*on*|*off*>	On
`--include_timing_assignments_in_bottom_up_scripts=`<*on*|*off*>	On
`--include_design_partitions_in_bottom_up_scripts=`<*on*|*off*>	On
`--remove_existing_regions_in_bottom_up_scripts=`<*on*|*off*>	On
`--disable_auto_global_promotion_in_bottom_up_scripts=`<*on*|*off*>	Off
`--bottom_up_scripts_output_directory=`<*output directory*>	Current project directory

Note to Table 2–8:

(1) No default. You must provide this option if you are including virtual pin timing.

Exporting a Partition to be Used in a Top-Level Project

Use the `quartus_cdb` executable to export a file for a bottom-up incremental compilation flow with the following command:

```
quartus_cdb --INCREMENTAL_COMPILATION_EXPORT=<file> \
[--incremental_compilation_export_netlist_type=<POST_SYNTH|POST_FIT>]
\
[--incremental_compilation_export_partition_name=<partition name>] \
[--incremental_compilation_export_routing=<on|off>]
```

The <*file*> argument is the file path to the exported file. The <*partition name*> is the name of the partition, not its hierarchical path. If you do not specify the options, the executable uses any settings in the **.qsf** file, or it uses default values. The default partition is the top-level partition in the project, the default netlist type is post-fit, and the default for routing is on (for all device families that support exported routing).

The command reads the assignment `INCREMENTAL_COMPILATION_EXPORT_NETLIST_TYPE` to determine which netlist type to export; the default is post-fit.

You can also use the flow `INCREMENTAL_COMPILATION_EXPORT` in the `execute_flow` Tcl command contained in the `flow` Tcl package.

Use the following commands to export a **.qxp** file for a given partition, choose the netlist type, and specify whether to export routing:

```
load_package flow
set_global_assignment -name INCREMENTAL_COMPILATION_EXPORT_FILE \
<filename>
set_global_assignment -name
INCREMENTAL_COMPILATION_EXPORT_NETLIST_TYPE \
<POST_FIT|POST_SYNTH>
set_global_assignment -name \
INCREMENTAL_COMPILATION_EXPORT_PARTITION_NAME <partition name>
set_global_assignment -name INCREMENTAL_COMPILATION_EXPORT_ROUTING \
<on|off>
execute_flow -INCREMENTAL_COMPILATION_EXPORT
```

The default partition is the top-level partition in the project, the default netlist type is post-fit, and the default for routing is on (for all device families that support exported routing).

To turn on the option to always perform exportation following compilation, use the following Tcl command:

```
set_global_assignment -name AUTO_EXPORT_INCREMENTAL_COMPILATION ON
```

Importing a Lower-Level Partition into the Top-Level Project

Use the `quartus_cdb` executable to import a lower-level partition with the following command:

```
quartus_cdb -- INCREMENTAL_COMPILATION_IMPORT ↵
```

You can also use the flow called `INCREMENTAL_COMPILATION_IMPORT` in the `execute_flow` Tcl command contained in the `flow` Tcl package.

The following example script shows how to import a partition using a Tcl script:

```
load_package flow
# commands to set the import-related assignments for each partition
execute_flow --INCREMENTAL_COMPILATION_IMPORT
```

Specify the location for the imported file with the `PARTITION_IMPORT_FILE` assignment. Note that the file specified by this assignment is read only during importation. For example, the project is completely independent from any files from the lower-level projects after importing. In the command-line and Tcl flow, any partition that has this assignment set to a non-empty value is imported.

The following assignments specify how the partition should be imported:

```
PARTITION_IMPORT_PROMOTE_ASSIGNMENTS = <on|off>
PARTITION_IMPORT_NEW_ASSIGNMENTS = <on|off>
PARTITION_IMPORT_EXISTING_ASSIGNMENTS = \
replace_conflicting | skip_conflicting
PARTITION_IMPORT_EXISTING_LOGICLOCK_REGIONS = \
replace_conflicting | update_conflicting | skip_conflicting
```

Makefiles

For an example of how to use incremental compilation with a `makefile` as part of the bottom-up design flow, refer to the **read_me.txt** file that accompanies the `incr_comp` example located in the **/qdesigns/incr_comp_makefile** subdirectory. When using a bottom-up incremental compilation flow, the Generate Bottom-Up Design Partition Scripts feature can write makefiles that automatically export lower-level design partitions and import them into the top-level project whenever design files change.

Recommended Design Flows and Compilation Application Examples—Scripting and Command-Line Operation

This section provides scripting examples that cover some of the topics discussed in the main section of the chapter.

The script shown in Example 2–1 opens a project called `AB_project`, sets up two partitions, entities A and B, for the first time, and performs an initial complete compilation.

Example 2–1. AB_project

```
set project AB_project

package require ::quartus::flow
project_open $project

# Ensure that incremental compilation is turned on
set_global_assignment -name INCREMENTAL_COMPILATION \
FULL_INCREMENTAL_COMPILATION

# Set up the partitions
set_instance_assignment -name PARTITION_HIERARCHY \
 incremental_db/A_inst -to A -section_id "Partition_A"
set_instance_assignment -name PARTITION_HIERARCHY \
 incremental_db/B_inst -to B -section_id "Partition_B"

# Set the netlist types to post-fit for subsequent
# compilations (all partitions are compiled during the
# initial compilation since there are no post-fit
# netlists)
set_global_assignment -name PARTITION_NETLIST_TYPE \
 POST_FIT -section_id "Partition_A"
set_global_assignment -name PARTITION_NETLIST_TYPE \
 POST_FIT -section_id "Partition_B"

# Run initial compilation:
export_assignments
execute_flow -full_compile

project_close
```

Reducing Compilation Time When Changing a Source File for One Partition—Command-Line Example

Example background: You have run the initial compilation shown in the example script in the previous section. You have modified the HDL source file for partition **A** and want to recompile it.

Run the standard flow compilation command in your Tcl script:

```
execute_flow -full_compile
```

Or, type the following command at a system command prompt:

```
quartus_sh --flow compile AB_project↵
```

Assuming the source files for partition **B** do not depend on **A**, only **A** is recompiled. The placement of **B** and its timing performance is preserved, which also saves significant compilation time.

Optimizing the Placement for a Timing-Critical Partition

Example background: You have run the initial compilation shown in the example script under "Recommended Design Flows and Compilation Application Examples—Scripting and Command-Line Operation" on page 2–74. You would like to apply Fitter optimizations, such as physical synthesis, only to partition **A**. No changes have been made to the HDL files.

To ensure the previous compilation result for partition **B** is preserved, and to ensure that Fitter optimizations are applied to the post-synthesis netlist of partition **A**, set the netlist type of **B** to **Post-Fit** (which was already done in the initial compilation, but is repeated here for safety), and the netlist type of **A** to **Post-Synthesis**, as shown in Example 2–2:

Example 2–2. AB_project (2)

```
set project AB_project

package require ::quartus::flow
project_open $project

# Turn on Physical Synthesis Optimization
set_global_assignment -name \
PHYSICAL_SYNTHESIS_REGISTER_RETIMING ON

# For A, set the netlist type to post-synthesis
set_global_assignment -name PARTITION_NETLIST_TYPE POST_SYNTH \
-section_id "Partition_A"

# For B, set the netlist type to post-fit
set_global_assignment -name PARTITION_NETLIST_TYPE POST_FIT \
-section_id "Partition_B"

# Run incremental compilation:
export_assignments
execute_flow -full_compile

project_close
```

Conclusion

With the Quartus II incremental compilation feature described in this chapter, you can preserve the results and performance of unchanged logic in your design as you make changes elsewhere. The various applications of incremental compilation enable you to improve your productivity while designing for high-density FPGAs, using either top-down or bottom-up design methodologies.

Document Revision History

Table 2–9 shows the revision history for this chapter.

Table 2–9. Document Revision History (Part 1 of 2)

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Split up Netlist Types table ■ Moved "Quartus II Exported Partition Files (.qxp)" and "Bottom-Up Incremental Compilation Summary" into the "Exporting and Importing Partitions" section. ■ Added new section "Preparing a Design for Bottom-Up Incremental Compilation" on page 2–31 ■ Removed "Exporting a Lower-Level Partition that Uses a JTAG Feature" restriction ■ Other edits throughout chapter	Updated for Quartus II software version 9.0.
November 2008 v8.1.0	■ Added new section "Importing SDC Constraints from Lower-Level Partitions" on page 2–44 ■ Removed the Incremental Synthesis Only option ■ Removed section "OpenCore Plus Feature for MegaCore Functions in Bottom-Up Flows" ■ Removed section "Compilation Time with Physical Synthesis Optimizations" ■ Added information about using a **.qxp** file as a source design file without importing ■ Reorganized several sections ■ Updated Figure 2–10	Updated for Quartus II software version 8.1.

Table 2–9. Document Revision History (Part 2 of 2)

Date and Document Version	Changes Made	Summary of Changes
May 2008 v8.0.0	■ Added several references to the *Best Practices for Incremental Compilation Partitions and Floorplan Assignments* chapter ■ Simplified “Choosing a Quartus II Compilation Flow” section ■ Clarified material in “Quartus II software versions before version 8.1 included an “incremental synthesis only” option that did not preserve placement results. This option has been removed beginning with version 8.1. You can use a post-synthesis netlist to preserve synthesis results with full incremental compilation.” section, added information about “mixed” design flows, and added a note about HardCopy ASIC flows ■ Removed “When Design is Resynthesized” and “When Design is Refit” from Table 2–1. ■ Reorganized “Choosing Design Partitions” section ■ Added instructions for using the Design Partition Planner ■ Added information about design changes to Table 2–2 in “Setting the Netlist Type for Design Partitions” ■ Removed requirement for HDL wrapper file for Empty partitions that are Imported ■ Added details to “What Changes Trigger a Partition’s Automatic Resynthesis?” section ■ Added “What LogicLock Changes Trigger Refitting?” section ■ Removed existing section “Guidelines for Creating Good Design Partitions and LogicLock Regions” because it is covered in the *Best Practices for Incremental Compilation Partitions and Floorplan Assignments* chapter and moved some of the material to other sections of the document ■ Renamed and reorganized Application Examples ■ Removed example Placing All but One Critical Partition in a Multiple-Partition Design in a Top-Down Compilation Flow and combined it with previous example ■ Added recommendation to use a version-compatible database when archiving ■ Clarified HardCopy ASIC restrictions for bottom-up flows ■ Clarified export and import of SDC constraints in bottom-up flows ■ Added “Optimizing the Placement for a Timing-Critical Partition” section ■ Added “Using an Exported Partition to Send a Design without Including Source Files” section	Updated for Quartus II software version 8.0.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

3. Quartus II Design Flow for MAX+PLUS II Users

QII51002-9.0.0

Introduction

The feature-rich Quartus® II software helps you shorten your design cycles and reduce time-to-market. With support for FLEX®, ACEX®, and MAX® device families, as well as all of Altera's newest devices, the Quartus II software is the most widely accepted Altera® design software tool today.

This chapter describes how to convert MAX+PLUS® II designs to Quartus II projects, as well as the similarities and differences between the MAX+PLUS II and Quartus II design flows. This discussion includes supported device families, GUI comparisons, and the advantages of the Quartus II software.

There are many features in the Quartus II software to help MAX+PLUS II users easily transition to the Quartus II software design environment. These include a customizable **Look & Feel** feature, which changes the GUI to display menus, toolbars, and utility windows as they appear in the MAX+PLUS II software without sacrificing Quartus II software functionality.

Chapter Overview

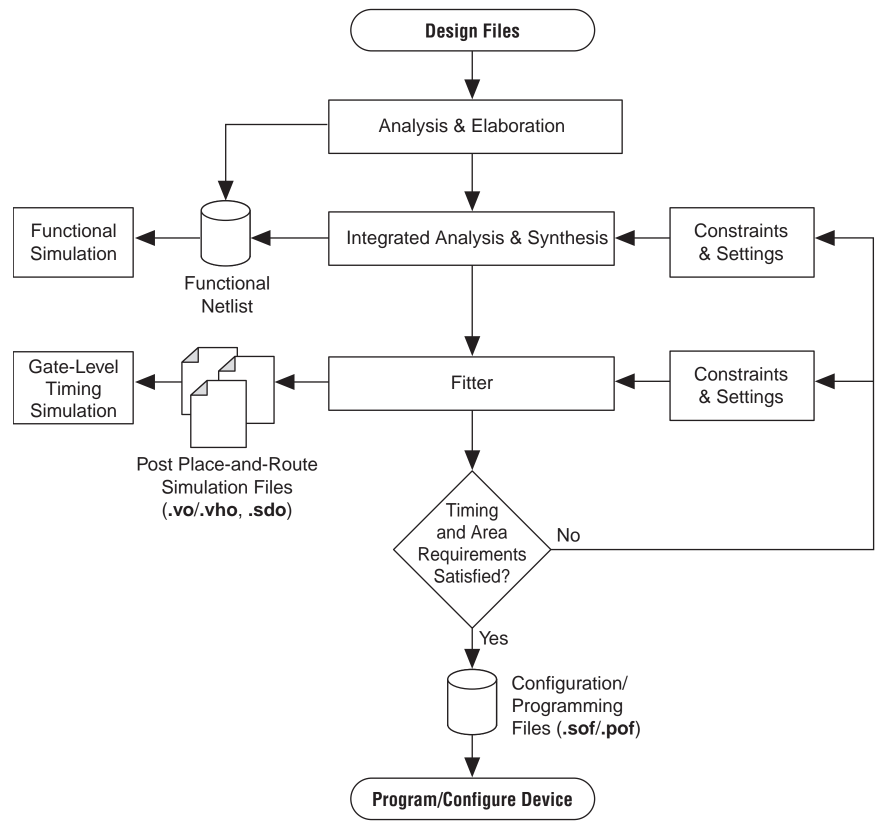
This chapter covers the following topics:

- "Typical Design Flow" on page 3–2
- "Device Support" on page 3–2
- "Quartus II GUI Overview" on page 3–3
- "Setting Up MAX+PLUS II Look and Feel in the Quartus II Software" on page 3–5
- "Compiler Tool" on page 3–7
- "MAX+PLUS II Design Conversion" on page 3–9
- "Quartus II Design Flow" on page 3–12

Typical Design Flow

Figure 3–1 shows a typical design flow with the Quartus II software.

Figure 3–1. Quartus II Software Design Flow



Device Support

The Quartus II software supports most of the devices supported in the MAX+PLUS II software, but it does not support any obsolete devices or packages. The devices supported by these two software packages are shown in Table 3–1.

Table 3–1. Device Support Comparison (Part 1 of 2)

Device Supported	Quartus II	MAX+PLUS II
Arria® GX	✓	—
Stratix® Series	✓	—
Cyclone® Series	✓	—
HardCopy® Series	✓	—
MAX® II	✓	—
Classic™	—	✓
MAX 3000A	✓	✓
MAX 7000S/AE/B	✓	✓
MAX 7000E	—	✓

Table 3–1. Device Support Comparison (Part 2 of 2)

Device Supported	Quartus II	MAX+PLUS II
MAX 9000	—	✓
ACEX® 1K	✓	✓
FLEX® 6000	✓	✓
FLEX 8000	—	✓
FLEX 10K	✓ *(1)*	✓
FLEX 10KA	✓	✓
FLEX 10KE	✓ *(2)*	✓
APEX™ II	✓	—
APEX 20K	✓	—

Notes to Table 3–1:

(1) PGA packages (represented as package type G in the ordering code) are not supported in the Quartus II software.

(2) Some packages are not supported.

Quartus II GUI Overview

The Quartus II software provides the following utility windows to assist in the development of your designs:

- Project Navigator
- Node Finder
- Tcl Console
- Messages
- Status
- Change Manager

Project Navigator

The **Hierarchy** tab of the Project Navigator window is similar to the MAX+PLUS II Hierarchy Display and provides additional information such as logic cell, register, and memory bit resource utilization. The **Files** and **Design Units** tabs of the Project Navigator window provide a list of project files and design units.

Node Finder

The Node Finder window provides the equivalent functionality of the MAX+PLUS II **Search Node Database** dialog box and allows you to find and use any node name stored in the project database.

Tcl Console

The Tcl Console window allows access to the Quartus II Tcl shell from within the GUI. You can use the Tcl Console window to enter Tcl commands and source Tcl scripts to make assignments, perform customized timing analysis, view information about devices, or fully automate and customize the way you run all components of the Quartus II software. There is no equivalent functionality in the MAX+PLUS II software.

For more information about using Tcl with the Quartus II software, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Messages

The Messages window is similar to the Message Processor window in the MAX+PLUS II software, providing detailed information, warnings, and error messages.You also can use it to locate a node from a message to various windows in the Quartus II software.

Status

The Status window displays information similar to the MAX+PLUS II Compiler window. Progress and elapsed time are shown for each stage of the compilation.

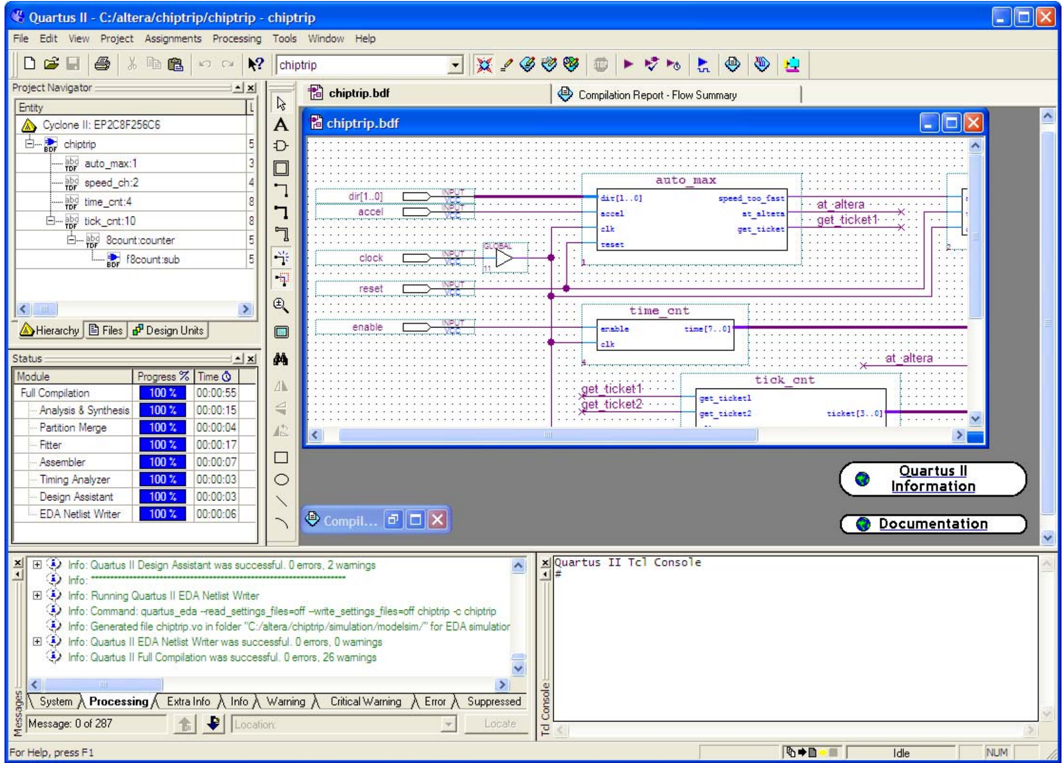
Change Manager

The Change Manager provides detailed tracking information about all design changes made with the Chip Planner.

For more information about the Engineering Change Manager and the Chip Editor, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

Figure 3–2 shows a typical Quartus II software display.

Figure 3–2. Quartus II Look and Feel



Setting Up MAX+PLUS II Look and Feel in the Quartus II Software

You can choose the MAX+PLUS II look and feel by selecting MAX+PLUS II in the **Look & Feel** box of the **General** tab of the **Customize** dialog box on the Tools menu.

Any changes to the look and feel do not become effective until you restart the Quartus II software.

By default, when you select the MAX+PLUS II look and feel, the **MAX+PLUS II** quick menu appears on the left side of the menu bar. You can turn the Quartus II and MAX+PLUS II quick menus on or off. You also can change the preferred positions of the two quick menus. To change these options, perform the following steps:

1. On the Tools menu, click **Customize**. The **Customize** dialog box appears.
2. Click the **General** tab.
3. Under **Quick menus**, select your preferred options.

MAX+PLUS II Look and Feel

The MAX+PLUS II look and feel in the Quartus II software closely resembles the MAX+PLUS II software. Figure 3–3 and 3–6 compare the MAX+PLUS II software appearance with the Quartus II MAX+PLUS II look and feel.

Figure 3–3. MAX+PLUS II Software GUI

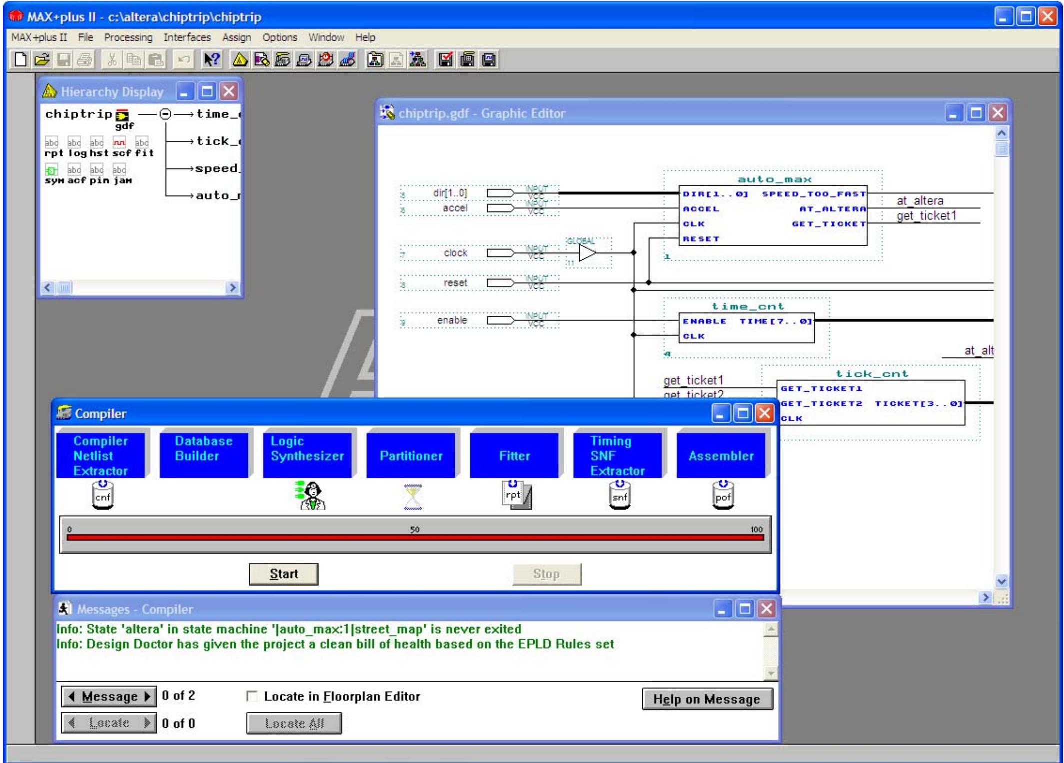


Figure 3–4. Quartus II Software with MAX+PLUS II Look and Feel

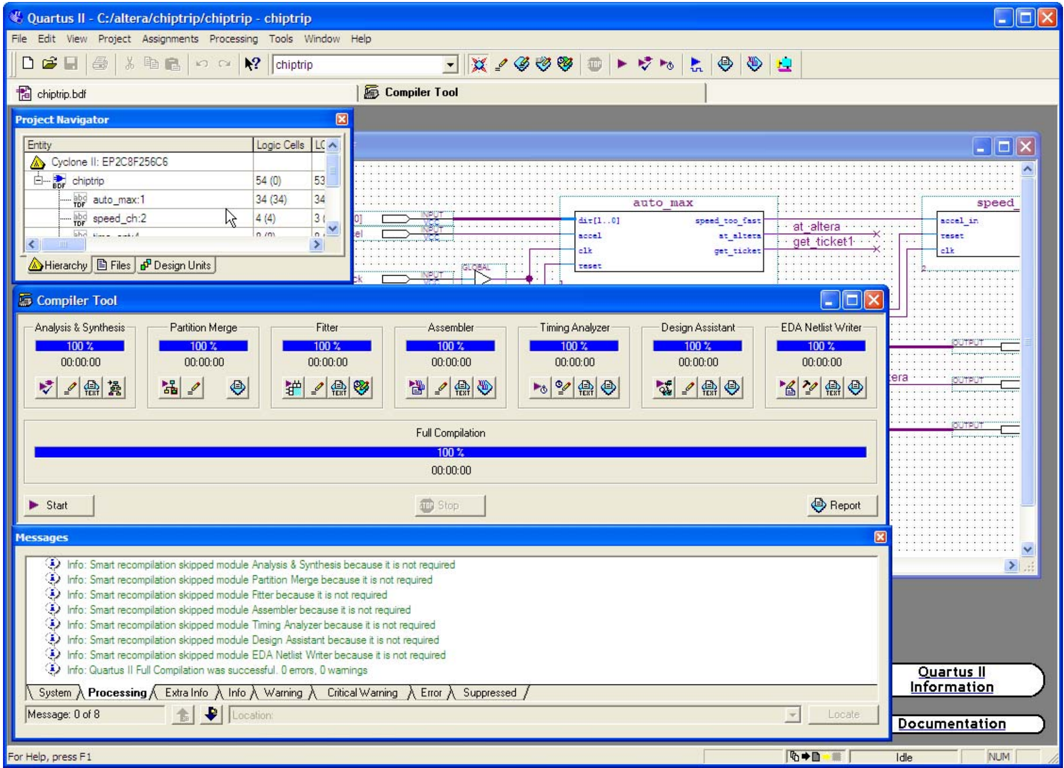


The standard MAX+PLUS II toolbar is also available in the Quartus II software with the MAX+PLUS II look and feel in the Quartus II software (Figure 3–5).

Figure 3–5. Standard MAX+PLUS II Toolbar

Compiler Tool

The Quartus II Compiler Tool provides an intuitive MAX+PLUS II style interface. You can edit the settings and view result files for the following modules:

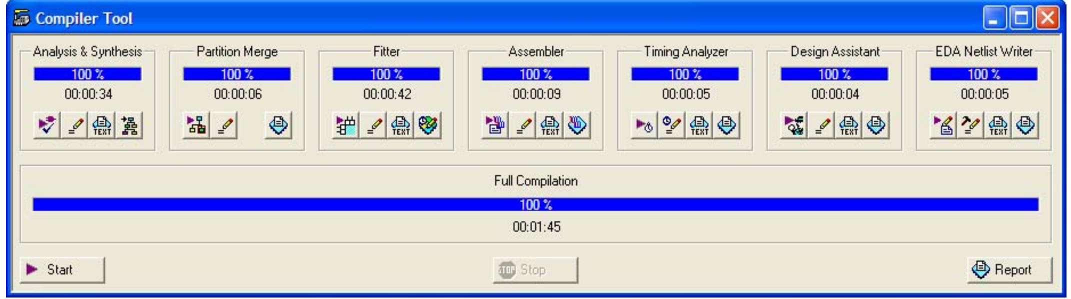
- Analysis and Synthesis
- Partition Merge
- Fitter
- Assembler
- Timing Analyzer
- EDA Netlist Writer
- Design Assistant

Each of these modules is described later in this section.

To start a compilation using the Compiler Tool, click **Compiler Tool** from either the MAX+PLUS II menu or the Tools menu and click **Start** in the Compiler Tool. The Compiler Tool, shown in Figure 3–6, displays all modules, including optional modules such as Partition Merge, Assembler, EDA Netlist Writer, and the Design Assistant.

For information about using the Quartus II software modules at the command line, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Figure 3–6. Running a Full Compilation with the Compiler Tool



Analysis and Synthesis

The Quartus II Analysis and Synthesis module analyzes your design, builds the design database, optimizes the design for the targeted architecture, and maps the technology to the design logic.

In MAX+PLUS II software, these functions are performed by the Compiler Netlist Extractor, Database Builder, and Logic Synthesizer. There is no module in the Quartus II software similar to the MAX+PLUS II Partitioner module.

Partition Merge

The optional Quartus II Partition Merge module merges the partitions to create a flattened netlist for further stages of the Quartus II compilation flow. The Partition Merge module is not similar to the MAX+PLUS II Partitioner. This tool is available only if you turn on incremental compilation. You can turn on incremental compilation by performing the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, click the **+** icon to expand **Compilation Process Settings**, and select **Incremental Compilation**. The **Full Incremental Compilation** page appears.
3. Under **Incremental compilation**, turn on **Incremental Compilation**.

Fitter

The Quartus II Fitter module uses the PowerFit Fitter to fit your design into the available resources of the targeted device. The Fitter places and routes the design. The Fitter module is similar to the Fitter stage of the MAX+PLUS II software.

Assembler

The optional Quartus II Assembler module creates a device programming image of your design so that you can configure your device. You can select from the following types of programming images:

- Programmer Object File (.**pof**)
- SRAM Output File (.**sof)**
- Hexadecimal (Intel-Format) Output File (.**hexout**)
- Tabular Text File (.**ttf)**
- Raw Binary File (.**rbf**)
- Jam™ STAPL Byte Code 2.0 File (.**jbc)**
- JEDEC STAPL Format File (.**jam**)

You can turn off the Assembler module during compilation by turning off **Run assembler** in the **Compilation Process Settings** page in the **Settings** dialog box. You also can turn off the Assembler by right-clicking in the Compiler Tool window. The Assembler module is similar to the Assembler stage of the MAX+PLUS II software.

Timing Analyzer

The Quartus II Timing Analyzer allows you to analyze more complex clocking schemes than is possible with the MAX+PLUS II Timing Analyzer. The Quartus II Timing Analyzer analyzes all clock domains in your design, including paths that cross clock domains, and also reports both f_{MAX} and slack. Slack is the margin by which the timing requirement is met or is not met. For more information on the Timing Analyzer, refer to "Timing Analysis" on page 3–20.

EDA Netlist Writer

The optional Quartus II EDA Netlist Writer module generates a netlist for simulation with an EDA simulation tool. The EDA Netlist Writer module is comparable to the VHDL and Verilog Netlist Writer in the MAX+PLUS II software.

Design Assistant

The optional Quartus II Design Assistant module checks the reliability of your design based on a set of design rules. The Design Assistant analyzes and generates messages for a design targeting any Altera device and is especially useful for checking the reliability of a design to be converted to HardCopy series devices. The Design Assistant is similar to the Design Doctor in the MAX+PLUS II software.

In the Quartus II software, you can reduce subsequent compilation time significantly by turning **Use smart compilation** on before compiling your design. The Smart Compilation feature skips any compilation stages which are not required and which may use more disk space. This Quartus II smart compilation option is similar to the MAX+PLUS II **Smart Recompile** command. To turn the **Use smart compilation** option on, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Compilation Process Settings**. The **Compilation Process Settings** page appears.
3. Turn on **Use smart compilation**.

MAX+PLUS II Design Conversion

With the Quartus II software, you can open MAX+PLUS II designs and convert MAX+PLUS II assignments and files.

The Quartus II software is project based. All the files for your design (HDL input, simulation vectors, assignments, and other relevant files) are associated with a project file. For more information about creating a new project, refer to "Creating a New Project" on page 3–12.

Converting an Existing MAX+PLUS II Design

You can easily convert an existing MAX+PLUS II design for use with the Quartus II software with the **Convert MAX+PLUS II Project** command in the Quartus II software or the **Open Project** command. You can find these commands on the File menu.

If you use the **Convert MAX+PLUS II Project** command, browse to the MAX+PLUS II Assignments and Configuration File (**.acf**) or top-level design file (Figure 3–7) and click **Open**. The **Convert MAX+PLUS II Project** command generates a Quartus II Project File (**.qpf**) and a Quartus II Settings File (**.qsf**). The Quartus II software stores project and design assignments in the **.qsf** file, which is equivalent to the Assignments and Configuration File in the MAX+PLUS II software.

You also can open and convert a MAX+PLUS II design with the **Open Project** command. In the **Open Project** dialog box, browse to the Assignments and Configuration File or the top-level design file. Click **Open** to display the **Convert MAX+PLUS II Project** dialog box.

The Quartus II software can import all MAX+PLUS II-generated files, but it cannot save files in the MAX+PLUS II format. You cannot open a Quartus II project in the MAX+PLUS II software, nor can you convert a Quartus II project to a MAX+PLUS II project.

Figure 3–7. Convert MAX+PLUS II Project Dialog Box

 © March 2009 Altera Corporation

The conversion process performs the following actions:

- Converts the MAX+PLUS II Assignments and Configuration File into a **.qsf** file (equivalent to importing all MAX+PLUS II assignments)
- Creates a **.qpf** file
- Displays all errors and warnings in the Quartus II message window

The Quartus II software can read MAX+PLUS II generated Graphic Design Files (**.gdf**) and Simulation Channel Files (**.scf**) without converting them. These files are not modified during a MAX+PLUS II design conversion.

Converting MAX+PLUS II Graphic Design Files

The Quartus II Block Editor (similar to the MAX+PLUS II Graphic Editor) saves files as Block Design Files (**.bdf**). You can convert your MAX+PLUS II Graphic Design File into a Quartus II Block Design File using one of the following methods:

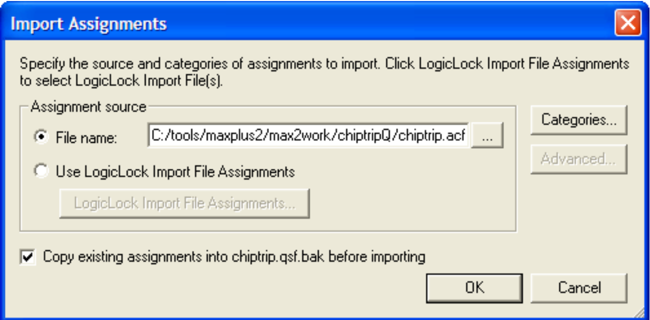
1. Open the Graphic Design File and on the File menu, click **Save As**. The **Save As** dialog box appears.
2. In the **Save as type** list, select **Block Diagram/Schematic File** (*.**bdf**).
3. Run the **quartus_g2b.exe** command line executable located in the \<*Quartus II installation*>**bin** directory. For example, to convert the **chiptrip.gdf** file to a Block Design File, type the following command at a command prompt:

```
quartus_g2b.exe chip_trip.gdf ↵
```

Importing MAX+PLUS II Assignments

You can import MAX+PLUS II assignments into an existing Quartus II project. Open the project, and on the Assignments menu, click **Import Assignments**. Browse to the Assignments and Configuration File (Figure 3–8). You can also import **.qsf** files and Entity Setting Files (**.esf**).

Figure 3–8. Import Assignments Dialog Box



The Quartus II software accepts most MAX+PLUS II assignments. However, some assignments can be imported incorrectly from the MAX+ PLUS II software into the Quartus II software due to differences in node naming conventions and the advanced Quartus II integrated synthesis algorithms.

The differing node naming conventions in the Quartus II and MAX+PLUS II software can cause improper mapping when importing your design from MAX+PLUS II software into the Quartus II software. Improper node names can interfere with the design logic if you are unaware of these node name differences and do not take appropriate steps to prevent improper node name mapping. Table 3–2 compares the differences between the naming conventions used by the Quartus II and MAX+PLUS II software.

Table 3–2. Quartus II and MAX+PLUS II Node and Pin Naming Conventions

Feature	Quartus II Format	MAX+PLUS II Format
Node name	auto_max:auto|q0	|auto_max:auto|q0
Pin name	d[0], d[1], d[2]	d0, d1, d2

When you import MAX+PLUS II assignments containing node names that use numbers, such as `signal0` or `signal1`, the Quartus II software imports the original assignment and also creates an additional copy of the assignment. The additional assignment has square brackets inserted around the number, resulting in `signal[0]` or `signal[1]`. The square bracket format is legal for signals that are part of a bus, but creates illegal signal names for signals that are not part of a bus in the Quartus II software. If your MAX+PLUS II design contains node names that end in a number and are not part of a bus, you can edit the **.qsf** file to remove the square brackets from the node names after importing them.

You can remove obsolete assignments in the **Remove Assignments** dialog box. Open this dialog box on the Assignments menu by clicking **Remove Assignments**.

The Quartus II software may not recognize valid MAX+PLUS II node names, or may split MAX+PLUS II nodes into two different nodes. As a result, any assignments made to synthesized nodes are not recognized during compilation.

For more information about Quartus II node naming conventions, refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*.

Quartus II Design Flow

The following sections include information to help you get started using the Quartus II software. They describe the similarities and differences between the Quartus II software and the MAX+PLUS II software. The following sections highlight improvements and benefits in the Quartus II software.

For an overview of the Quartus II software features and design flow, refer to the *Introduction to the Quartus II Software* manual.

Creating a New Project

The Quartus II software provides a wizard to help you create new projects. On the File menu, click **New Project Wizard** to start the New Project Wizard. The New Project Wizard generates the **.qpf** file and **.qsf** file for your project.

Design Entry

The Quartus II software supports the following design entry methods:

- Altera HDL (AHDL) Text Design File (.**tdf**)
- Block Diagram File
- EDIF Netlist File (.**edf**)
- Verilog Quartus Mapping Netlist File (.**vqm**)
- VHDL (.**vhd**)
- Verilog HDL (.**v**)

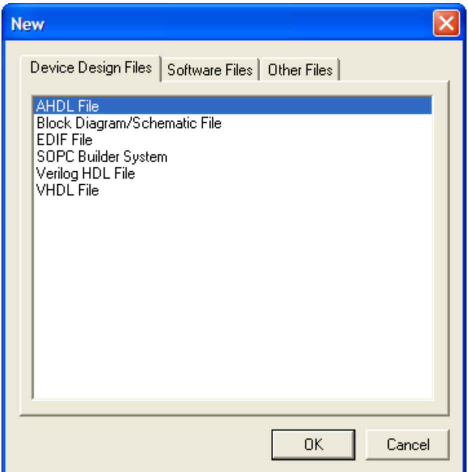
The Quartus II software has an advanced integrated synthesis engine that fully supports the Verilog HDL and VHDL languages and provides options to control the synthesis process.

For more information, refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*.

To create a new design file, perform the following steps:

1. On the File menu, click **New**. The **New** dialog box appears.
2. Click the **Device Design Files** tab.
3. Select a design entry type.
4. Click **OK** (see Figure 3–9).

Figure 3–9. New Dialog Box



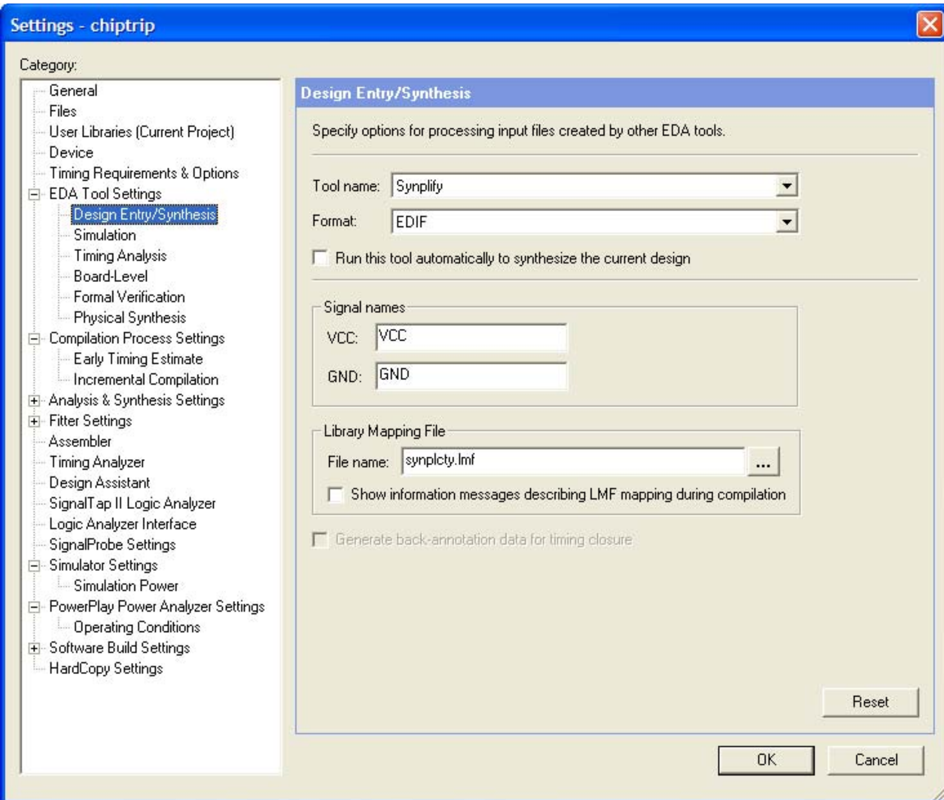
You can create other files from the **Software Files** tab and **Other Files** tab of the New dialog box on the File menu. For example, the Vector Waveform File (**.vwf**) is located in the **Other Files** tab.

To analyze a netlist file created by an EDA tool, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.

2. In the **Category** list, select **Design Entry & Synthesis**. The **Design Entry & Synthesis** page appears.
3. In the **Tool name** list, select the synthesis tool used to generate the netlist (Figure 3–10).

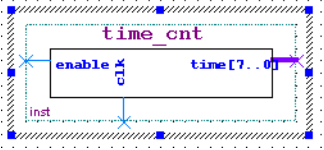
Figure 3–10. Settings Dialog Box Specifying Design Entry Tool



The Quartus II Block Editor has many advantages over the MAX+PLUS II Graphic Editor. The Block Editor offers an unlimited sheet size, multiple region selections, an enhanced Symbol Editor, and conduits.

The Symbol Editor allows you to change the positions of the ports in a symbol (refer to Figure 3–11). You can reduce wire congestion around a symbol by changing the positions of the ports.

Figure 3–11. Various Port Positions for a Symbol



To make changes to a symbol in a Block Design File, right-click a symbol in the Block Editor and select **Properties** to display the **Symbol Properties** dialog box. This dialog box allows you to change the instance name, add parameters, and specify the line and text color.

You can use conduits to connect blocks (including pins) in the Block Editor. Conduits contain signals for the connected objects (see Figure 3–12). You can determine the connections between various blocks in the **Conduit Properties** dialog box by right-clicking a conduit and clicking **Properties**.

Figure 3–12. Blocks and Pins Connected with Conduits

Making Assignments

The Quartus II software stores all project and design assignments in a **.qsf** file, which is a collection of assignments stored as Tcl commands and organized by the compilation stage and assignment type. The **.qsf** file stores all assignments, regardless of how they are made, from the Floorplan Editor, the Pin Planner, the Assignment Editor, with Tcl, or any other method.

Assignment Editor

The Assignment Editor is an intuitive spreadsheet interface designed to allow you to make, change, and manage a large number of assignments easily. With the Assignment Editor, you can list all available pin numbers and design pin names for efficiently creating pin assignments. You also can filter all assignments based on assignment categories and node names for viewing and creating assignments.

The Assignment Editor is composed of the **Category** bar, **Node Filter** bar, **Information** bar, **Edit** bar, and spreadsheet.

To make an assignment, follow these steps:

1. On the Assignments menu, click **Assignment Editor**. The Assignment Editor window appears.
2. Select an assignment category in the **Category** bar.
3. Select a node name using the Node Finder or type a node name filter into the **Node Filter** bar. (This step is optional; it excludes all assignments unrelated to the node name.)
4. Type the required values into the spreadsheet.
5. On the File menu, click **Save**.

If you are unsure about the purpose of a cell in the spreadsheet, select the cell and read the description displayed in the **Information** bar.

You can use the **Edit** bar to change the contents of multiple selected cells simultaneously. Select cells in the spreadsheet and type the value in the **Edit** box.

Other advantages of the Assignment Editor include clipboard support in the spreadsheet and automatic font coloring to identify the status of assignments.

For more information, refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook.*

Timing Assignments

You can use the timing wizard to help you set your timing requirements. On the Assignments menu, click **Timing Wizard** to create global clock and timing settings. The settings include f_{MAX}, setup times, hold times, clock to output delay times, and individual absolute or derived clocks.

You also can set timing settings manually by performing the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Timing Requirements & Options**. The **Timing Requirements & Options** page appears.
3. Set your timing settings.

You can make more complex timing assignments with the Quartus II software than allowed by the MAX+PLUS II software, including multicycle and point-to-point assignments using wildcards and time groups.

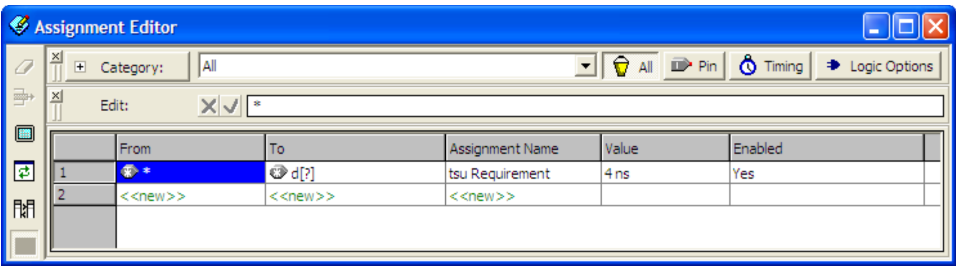
A time group is a collection of design nodes grouped together and represented as a single unit for the purpose of making timing assignments to the collection.

Multicycle timing assignments allow you to identify register-to-register paths in the design where you expect a delayed latch edge. This assignment enables accurate timing analysis of your design.

Point-to-point timing assignments allow you to specify the required delay between two pins, two registers, or a pin and a register. This assignment helps you optimize and verify your design timing requirements.

Wildcard characters "?" and " * " allow you to apply an assignment to a large number of nodes with just a few assignments. For example, Figure 3–13 shows a 4 ns t_{SU} requirement assignment to all paths from any node to the "d" bus in the Assignment Editor.

Figure 3–13. Single t_{SU} Timing Assignment Applied to All Nodes of a Bus



For more information, refer to the *Quartus II Classic Timing Analyzer* or the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook.*

Synthesis

The Quartus II advanced integrated synthesis software fully supports the hardware description languages, Verilog HDL, VHDL, and AHDL, schematic entry, and also provides options to control the synthesis process. With this synthesis support, the Quartus II software provides a complete, easy-to-use, stand-alone solution for today's designs.

You can specify synthesis options in the **Analysis & Synthesis Settings** page of the **Settings** dialog box. Similar to MAX+PLUS II synthesis options, you select one of these optimization techniques: **Speed**, **Area**, or **Balanced**.

To achieve higher design performance, you can turn on synthesis netlist optimizations that are available when targeting certain devices. You can unmap a netlist created by an EDA tool and remap the components in the netlist back to Altera primitives by turning on **Perform WYSIWYG primitive resynthesis**. Additionally, you can move registers across combinational logic to balance timing without changing design functionality by turning on **Perform gate-level register retiming**. Both of these options are accessible from the **Synthesis Netlist Optimizations** page under **Analysis & Synthesis Settings** in the **Settings** dialog box on the Assignments menu.

For more information, refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook.*

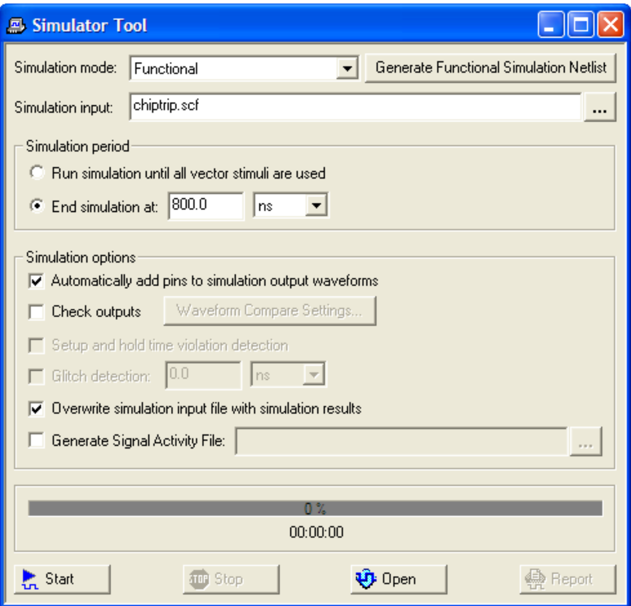
Functional Simulation

Similar to the MAX+PLUS II Simulator, the Quartus II Simulator Tool performs both functional and timing simulations.

To open the Simulator Tool, on MAX+PLUS II menu, click **Simulator**, or on the Tools menu, click **Simulator Tool**. Before you perform a functional simulation, an internal functional simulation netlist is required. Click **Generate Functional Simulation Netlist** in the **Simulator Tool** dialog box (Figure 3–14), or on the Processing menu, click **Generate Functional Simulation Netlist**.

Generating a functional simulation netlist creates a separate database that improves the performance of the simulation significantly.

Figure 3–14. Simulator Tool Dialog Box



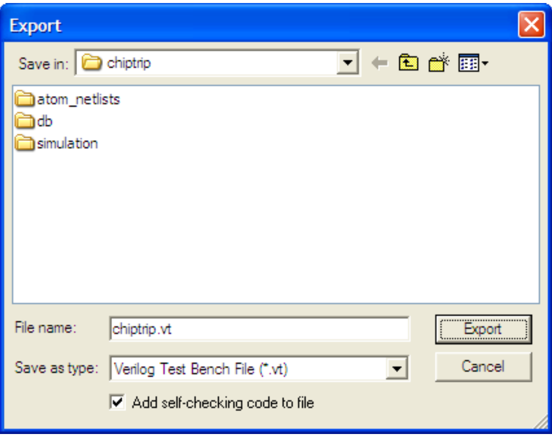
You can view and modify the simulator options on the **Simulator Settings** page of the **Settings** dialog box or in the **Simulator Tool** dialog box. You can set the simulation period and turn **Check outputs** on or off. You can choose to display the simulation outputs in the simulation report or in the Vector Waveform File. To display the simulation results in the simulation input vector waveform file, which is the MAX+PLUS II behavior, turn on **Overwrite simulation input file with simulation results**.

When using either the MAX+PLUS II or Quartus II software, you may have to compile additional behavioral models to perform a simulation with an EDA simulation tool. In the Quartus II software, behavioral models for library of parameterized modules (LPM) functions and Altera-specific megafunctions are available in the **altera_mf** and **220model** library files, respectively. The **220model** and **altera_mf** files can be found in the \<*Quartus II Installation*>**eda\sim_lib directory**.

The Quartus II schematic design files (Block Design File, or **.bdf**) are not compatible with EDA simulation tools. To perform a register transfer level (RTL) functional simulation of a Block Design File using an EDA tool, convert your schematic designs to a VHDL or Verilog HDL design file. Open the schematic design file and on the File menu, point to **Create/Update** and then click **Create HDL Design File for Current File** to create an HDL design file that corresponds to your Block Design File.

You can export a **.vwf** file or Simulator Channel File (**.scf**) as a Verilog HDL or VHDL testbench file for simulation with an EDA tool. Open your Vector Waveform File or **.scf** file and on the File menu, click **Export**. See Figure 3–15. Select **Verilog** or **VHDL Test Bench File (*.vt)** from the **Save as type** list. Turn on **Add self-checking code to file** to add additional self-checking code to the testbench.

Figure 3–15. Export Dialog Box



Place and Route

The Quartus II PowerFit is an incremental fitter that performs place-and-route to fit your design into the targeted device. You can control the Fitter behavior with options in the **Fitter Settings** page of the **Settings** dialog box on the Assignments menu.

High-density device families supported in the Quartus II software, such as the Stratix series, sometimes require significant fitter effort to achieve an optimal fit. The Quartus II software offers several options to reduce the time required to fit a design. You can control the effort the Quartus II Fitter expends to achieve your timing requirements with these options:

- **Optimize timing** performs timing-based placement using the timing requirements you specify for the design. You can use this option by itself or with one or more of the options below.
- **Optimize hold timing** optimizes the hold times within a device to meet timing requirements and assignments you specify. You can select this option only if the Optimize timing option is also chosen.
- **Optimize fast-corner timing** instructs the Fitter, when optimizing your design, to consider fast-corner delays, in addition to slow-corner delays, from the fast-corner timing model (fastest manufactured device, operating in low-temperature and high-voltage conditions). You can select this option only if the **Optimize timing** option is also chosen.

If minimizing compilation time is more important than achieving specific timing results, you can turn these options off.

Another way to decrease the processing time and effort the Fitter expends to fit your design is to select either **Standard Fit** or **Fast Fit** in the **Fitter Effort** box of the **Fitter Settings** page in the **Settings** dialog box on the Assignments menu. The option you select affects the Fitter behavior and your design as described below.

- Select **Standard Fit** for the Fitter to use the highest effort and preserve the performance from previous compilations.
- Select **Fast Fit** for up to 50% faster compilation times, although this may reduce design performance.

You can also select **Auto Fit** to decrease compilation time by directing the Fitter to reduce Fitter effort after meeting your timing requirements. The **Auto Fit** option is available for select devices.

For more information, refer to the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*.

To further reduce compilation times, turn on **Limit to one fitting attempt** in the **Fitter Settings** page in the **Settings** dialog box on the Assignments menu.

If your design is very close to meeting your timing requirements, you can control the seed number used in the fitting algorithm by changing the value in the **Seed** box of the **Fitter Settings** page of the **Settings** dialog box on the Assignments menu. The default seed value is 1. You can specify any non-negative integer value. Changing the value of the seed only repositions the starting location of the Fitter, but does not affect compilation time or the Fitter effort level. However, if your design is difficult to fit optimally or takes a long time to fit, sometimes you can improve results or processing time by changing the seed value.

Timing Analysis

Version 6.1 and later of the Quartus II software supports two native timing analysis tools: the TimeQuest Timing Analyzer and the Classic Timing Analyzer. Both timing analysis tools provide more complex clocking schemes than is possible with the MAX+PLUS II Timing Analyzer. The TimeQuest Timing Analyzer uses the industry-standard Synopsys Design Constraint (SDC) methodology for constraining designs and reporting results. In general, the TimeQuest Timing Analyzer provides more control in constraining a design as compared to the Classic Timing Analyzer. However, the Classic Timing Analyzer incorporates a basic graphical user interface and the timing analysis flow is similar to the flow in the MAX+PLUS II software. As such, the section that follows provides a more detailed look at timing analysis using the Classic Timing Analyzer.

For more information about choosing between the TimeQuest Timing Analyzer or the Classic Timing Analyzer, refer to the Timing Analysis Section in the *Introduction to the Quartus II Software* manual.

Launch the Classic Timing Analyzer tool on the MAX+PLUS II menu by clicking **Classic Timing Analyzer** or by selecting **Classic Timing Analyzer Tool** on the **Processing** menu. See Figure 3–16. To start the analysis, click **Start** in the Timing Analyzer Tool, or on the Processing menu, point to **Start** and clicking **Start Timing Analyzer**.

Figure 3–16. Registered Performance Tab of the Timing Analyzer Tool

The Quartus II Classic Timing Analyzer analyzes all clock domains in your design, including paths that cross clock domains. You can ignore paths that cross clock domains by using the following options in the **Timing Requirements & Options** page in the **Settings** dialog box on the Assignments menu:

- Create a **Cut Timing Path** assignment
- Turn on **Cut paths between unrelated clock domains**

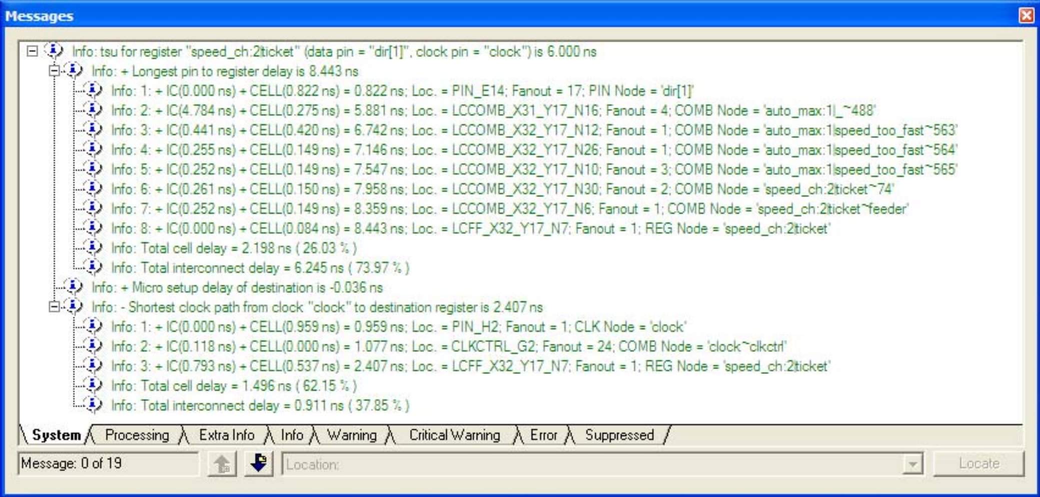
To view the results from the Classic Timing Analyzer Tool, click the **Report** button located at the bottom of the **Classic Timing Analyzer** dialog box, or to get specific information, click on any of the following tabs at the top of the Classic Timing Analyzer window:

- **Registered Performance**
- **tpd**
- **tsu**
- **tco**
- **th**
- **Custom Delays**

The Quartus II Classic Timing Analyzer reports both f_{MAX} and slack. Slack is the margin by which the timing requirement was met or not met. A positive slack value, displayed in black, indicates the margin by which a requirement was met. A negative slack value, displayed in red, indicates the margin by which a requirement was not met.

To analyze a particular path in more detail, select a path in the Classic Timing Analyzer Tool and click **List Paths**. This displays a detailed description of the path in the **System** tab of the Messages window (Figure 3–17).

Figure 3–17. Messages Window Displaying Detailed Timing Information



For more information, refer to the *Quartus II Classic Timing Analyzer* or the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook.*

Timing Closure Floorplan

The Quartus II Timing Closure Floorplan is similar to the MAX+PLUS II Floorplan Editor but has many improvements to help you more effectively view and debug your design. With its ability to display logic cell usage, routing congestion, critical paths, and LogicLock™ regions, the Timing Closure Floorplan also makes the task of improving your design performance much easier.

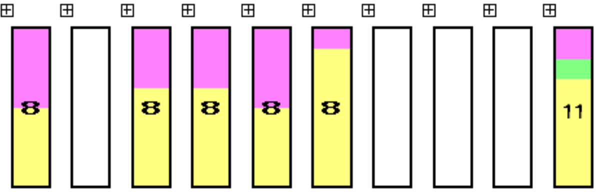
To view the Timing Closure Floorplan, on the MAX+PLUS II menu, click **Floorplan Editor** or **Timing Closure Floorplan**.

The Timing Closure Floorplan Editor provides Interior Cell views equivalent to the MAX+PLUS II logic array block (LAB) views. In addition to these views, available from the View menu, you also can select from the Interior MegaLABs (where applicable), Interior LABs, and Field views.

The Pin Planner is equivalent to the MAX+PLUS II Device view. The Pin Planner can be launched from the View menu or on the Assignments menu by clicking **Pin Planner**.

The Interior LABs view hides cell details for logic cells, Adaptive Logic Modules (ALM), and macrocells, and shows LAB information (see Figure 3–18). You can display the number of cells used in each LAB on the View menu by clicking **Show Usage Numbers**.

Figure 3–18. Interior LAB View of the Timing Closure Floorplan



The Field view is a color-coded, high-level view of your device resources that hides both cell and LAB details. In the Field view, you can see critical paths and routing congestion in your design.

The View Critical Paths feature shows a percentage of all critical paths in your floorplan. You can enable this feature on the View menu by clicking **Show Critical Paths**. You can control the number of critical paths shown by modifying the settings in the **Critical Paths Settings** dialog box on the View menu.

The View Congestion feature displays routing congestion by coloring and shading logic resources. Darker shading shows greater resource utilization. This feature assists in identifying locations where there is a lack of routing resources.

To show lower level details in any view, right-click on a resource and click **Show Details**.

For more information, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook.*

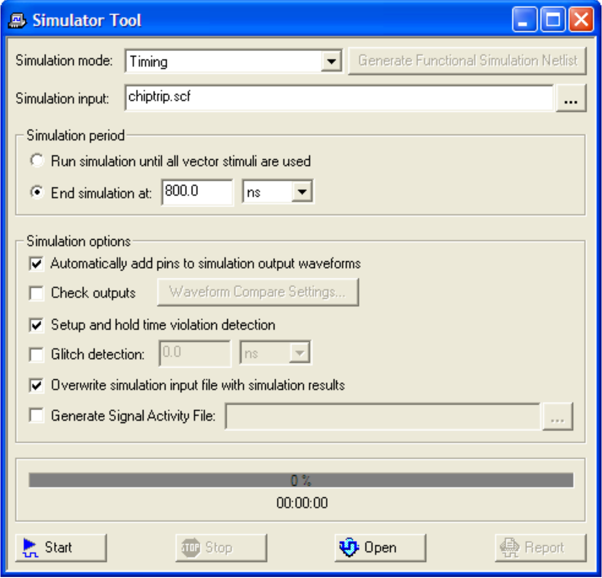
Timing Simulation

Timing simulation is an important part of the verification process. The Quartus II software supports native timing simulation and exports simulation netlists to third-party software for design verification.

Quartus II Simulator Tool

The Quartus II Simulator tool is an easy-to-use integrated solution that uses the compiler database to simulate the logical and timing performance of your design (Figure 3–19). When performing timing simulation, the simulator uses place-and-route timing information.

Figure 3–19. Quartus II Simulator Tool



You can use Vector Table Output Files (**.tbl**), Vector Waveform Files, Vector Files (**.vec**), or an existing **.scf** file as the vector stimuli for your simulation.

The simulation options available are similar to the options available in the MAX+PLUS II Simulator. You can control the length of the simulation and the type of checks performed by the Simulator. When the MAX+PLUS II look and feel is selected, the **Overwrite simulation input file with simulation results** option is on by default. If you turn it off, the simulation results are written to the report file. To view the report file, click **Report** in the Simulator Tool window.

EDA Timing Simulation

The Quartus II software also supports timing simulation with other EDA simulation software. Performing timing simulation with other EDA simulation software requires a Quartus II generated timing netlist file in the form of a Verilog Output File (**.vo**) or VHDL Output File (**.vho**), a Standard Delay Format Output File (**.sdo**), and a device-specific atom file (or files), shown in Table 3–3.

Table 3–3. Altera Timing Simulation Library Files

Verilog	VHDL
*<device_family>*_**atoms.v**	*<device_family>*_**atoms_87.vhd**
	*<device_family>*_**atoms.vhd**
	*<device_family>*_**components.vhd**

Specify your EDA simulation tool by performing the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears.
3. In the **Tool name list**, select your EDA Tool.

You can generate a timing netlist for the selected EDA simulator tool by running a full compile or on the Processing menu, by pointing to **Start** and clicking **Start EDA Netlist Writer**. The generated netlist and SDF file are placed into the ****<*project directory*>**\simulation**<*EDA simulator tool*> directory. The device-specific atom files are located in the ****<*Quartus II Install*>**\eda\sim_lib** directory.

Power Estimation

To develop an appropriate power budget and to design the power supplies, voltage regulators, heat sink, and cooling system, you need an accurate estimate of the power that your design consumes. You can estimate power by using the PowerPlay Early Power Estimation spreadsheet available on the Altera website at www.altera.com, or with the PowerPlay Power Analyzer in the Quartus II software.

You can perform early power estimation with the PowerPlay Early Power Estimation spreadsheet by entering device resource and performance information. The Quartus II PowerPlay Analyzer tool performs vector-based power analysis by reading either a Signal Activity File (**.saf**), generated from a Quartus II simulation, or a Verilog Value Change Dump File (**.vcd**) generated from a third-party simulation.

For more information about how to use the PowerPlay Power Analyzer tool, refer to the *PowerPlay Power Analysis* chapter in volume 3 of the *Quartus II Handbook.*

Programming

The Quartus II Programmer has the same functionality as the MAX+PLUS II Programmer, including programming, verifying, examining, and blank checking operations. Additionally, the Quartus II Programmer now supports the erase capability for CPLDs. To improve usability, the Quartus II Programmer displays all programming-related information in one window (Figure 3–20).

Click **Add File** or **Add Device** in the Programmer window to add a file or device, respectively.

Figure 3–20. Programmer Window

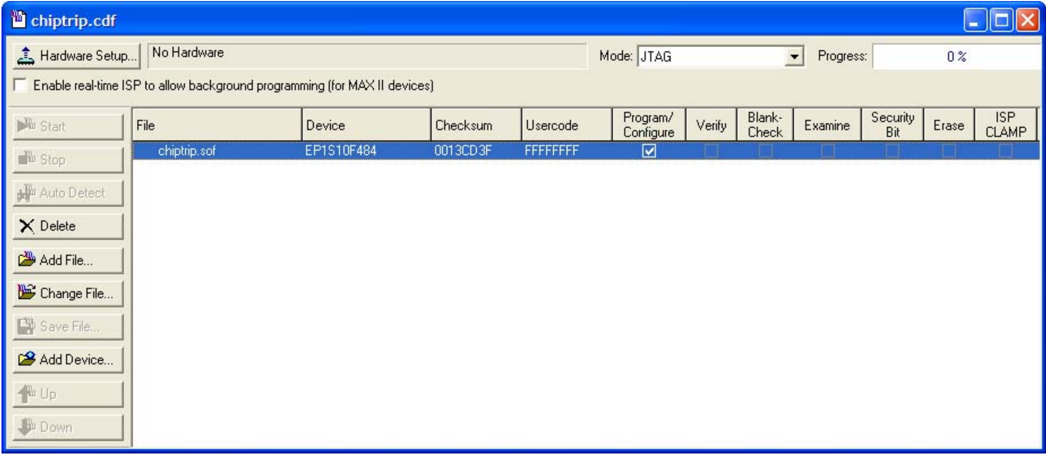


Figure 3–20 shows that the Programmer window now supports Erase capability.

You can save the programmer settings as a Chain Description File (**.cdf**). The **.cdf** file is an ASCII text file that stores device name, device order, and programming file name information.

Conclusion

The Quartus II software is the most comprehensive design environment available for programmable logic designs. Features such as the MAX+PLUS II look and feel help you make the transition from Altera's MAX+PLUS II design software and become more productive with the Quartus II software. The Quartus II software has all the capabilities and features of the MAX+PLUS II software and many more to speed up your design cycle.

Quartus II Command Reference for MAX+PLUS II Users

Table 3–4 lists the commands in the MAX+PLUS II software and gives their equivalent commands in the Quartus II software.

NA means either Not Applicable or Not Available. If a command is not listed, the command is the same in both tools.

4. Quartus II Support for HardCopy Series Devices

QII51004-9.0.0

Introduction

This chapter describes Quartus® II support for HardCopy® Series devices, including legacy HardCopy Stratix® series devices. This chapter is divided into the following sections:

- "HardCopy Series Device Support"
- "Legacy HardCopy Device Support" on page 4–34

HardCopy Series Device Support

Altera® HardCopy ASICs are the lowest risk, lowest total cost ASICs. The HardCopy system development methodology offers fast time-to-market, low risk, and using the Quartus II software, you can design with one set of RTL code and one IP set for both FPGA and ASIC implementations. This flow enables you to conduct true hardware/software co-design and completely prepare your system for production prior to ASIC design hand-off. Altera provides a turn-key process to convert your design to a HardCopy ASIC for production.

In this chapter, the term FPGA refers to a Stratix® II, Stratix III, or Stratix IV device which is the prototype device for a HardCopy II, HardCopy III, or HardCopy IV device, respectively.

For legacy HardCopy Stratix devices, refer to "Legacy HardCopy Device Support" on page 4–34.

This chapter discusses the following topics:

- "HardCopy Development Flow" on page 4–3
- "HardCopy Device Resource Guide" on page 4–7
- "HardCopy Companion Device Selection" on page 4–10
- "HardCopy Recommended Settings in the Quartus II Software" on page 4–11
- "HardCopy Utilities Menu" on page 4–17
- "HardCopy Design Readiness Check" on page 4–23
- "Performing ECOs with Quartus II Engineering Change Management with the Chip Planner" on page 4–29
- "Formal Verification of FPGA and HardCopy Revisions" on page 4–32
- "Legacy HardCopy Device Support" on page 4–34

For more information about HardCopy series devices, refer to the respective HardCopy device handbook on the Altera website (www.altera.com).

HardCopy Series Design Benefits

Designing with HardCopy ASICs offers substantial benefits over other ASIC offerings:

- Seamless prototyping using an FPGA for at-speed system verification and system development reduces total project development time and cost
- Dependable conversion from an FPGA prototype to a HardCopy ASIC expands product planning options
- Unified design methodology for FPGA design and HardCopy design reduces the need for ASIC development software, two sets of intellectual property, and project risk
- System development methodology delivers lowest total cost

Quartus II Features for HardCopy Planning

With the Quartus II software, you can design a HardCopy ASIC using seamless FPGA prototyping. The Quartus II software provides the following expanded features for HardCopy series device planning:

- **HardCopy Companion Device Assignment**—Identifies compatible HardCopy series devices for use with the FPGA prototyping device currently selected.

  This feature constrains the pins of your FPGA prototype, making it compatible with your HardCopy device. It also constrains the correct resources available for the HardCopy device, ensuring the compatibility of your FPGA design. In addition, you are required to compile the design targeting the HardCopy device to ensure that the design fits, routes, and meets timing requirements.

  Beginning with Quartus II software version 8.0, you can select HardCopy III as the companion device, but you cannot compile the HardCopy III device. This ensures that the FPGA is compatible with the HardCopy III device in the areas of pins, I/O standards, logic, and other resources. Compilation for the HardCopy III family will be supported in a later release of the Quartus II software.

  Beginning with Quartus II software version 8.1, you can select HardCopy IV E as the companion device, but you cannot compile the HardCopy IV E device. This ensures that the FPGA is compatible with the HardCopy IV E device in the areas of pins, I/O standards, logic, and other resources. Compilation for the HardCopy IV E will be supported in a later release of the Quartus II software. Companion and Compilation for the HardCopy IV GX family will be supported in a later release of the Quartus II software.

- **HardCopy Utilities**—The HardCopy Utilities menu provides a variety of functions to create or overwrite HardCopy companion revisions, change revisions to use, and compare revisions for equivalency.
- **HardCopy Advisor**—The HardCopy Advisor helps you follow the necessary steps to successfully submit a HardCopy design to Altera's HardCopy Design Center.

  The HardCopy Advisor is similar to other advisors in the Quartus II software. The HardCopy Advisor provides guidelines you can follow during development, reporting completed and uncompleted tasks.

- **HardCopy Floorplan**—The Quartus II Chip Planner software can show a preliminary floorplan view of your HardCopy design's Fitter placement results.
- **HardCopy Device Preliminary Timing**—The Quartus II TimeQuest software performs a timing analysis of HardCopy devices based on preliminary timing models and Fitter placements. Final timing results for HardCopy devices are provided by Altera's HardCopy Design Center.
- **HardCopy Design Readiness Check**—The Quartus II software tool checks the project settings to ensure compliance with the HardCopy device settings, I/O, PLL, and RAM usage checks.
- **HardCopy Handoff Report**—The Quartus II software generates a handoff report containing information about the HardCopy design used by Altera's HardCopy Design Center in the design review process.
- **HardCopy Design Archiving**—The Quartus II software archives the HardCopy design project's files required to hand off the design to Altera's HardCopy Design Center.
- **Formal Verification**—Cadence Encounter Conformal software performs formal verification between the source RTL design files and post-compile gate level netlist from a HardCopy design.

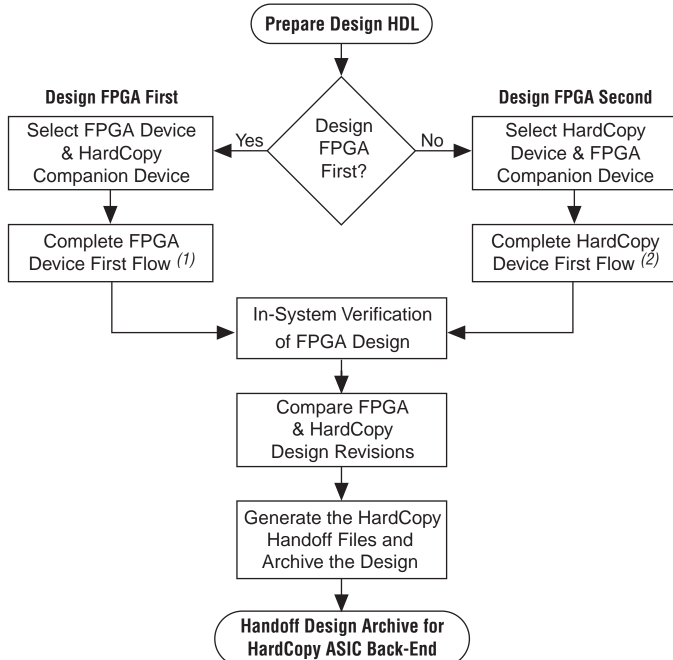
HardCopy Development Flow

In the Quartus II software, you design your FPGA and HardCopy companion device together in one Quartus II project using one of the following methods:

- Design the FPGA first for in-system verification and then create a HardCopy companion device second
- Design the HardCopy device first and then create the FPGA companion device second for in-system verification

Both of these flows are illustrated at a high level in Figure 4–1. The added features in the HardCopy Utilities menu help you complete your HardCopy design for submission to Altera's HardCopy Design Center for back-end implementation.

Figure 4–1. HardCopy Flow in Quartus II Software



Notes to Figure 4–1:

(1) Refer to Figure 4–2 on page 4–5 for an expanded description of this process.

(2) Refer to Figure 4–3 on page 4–7 for an expanded description of this process.

The FPGA first flow is the default flow and the rest of this chapter is based on this flow.

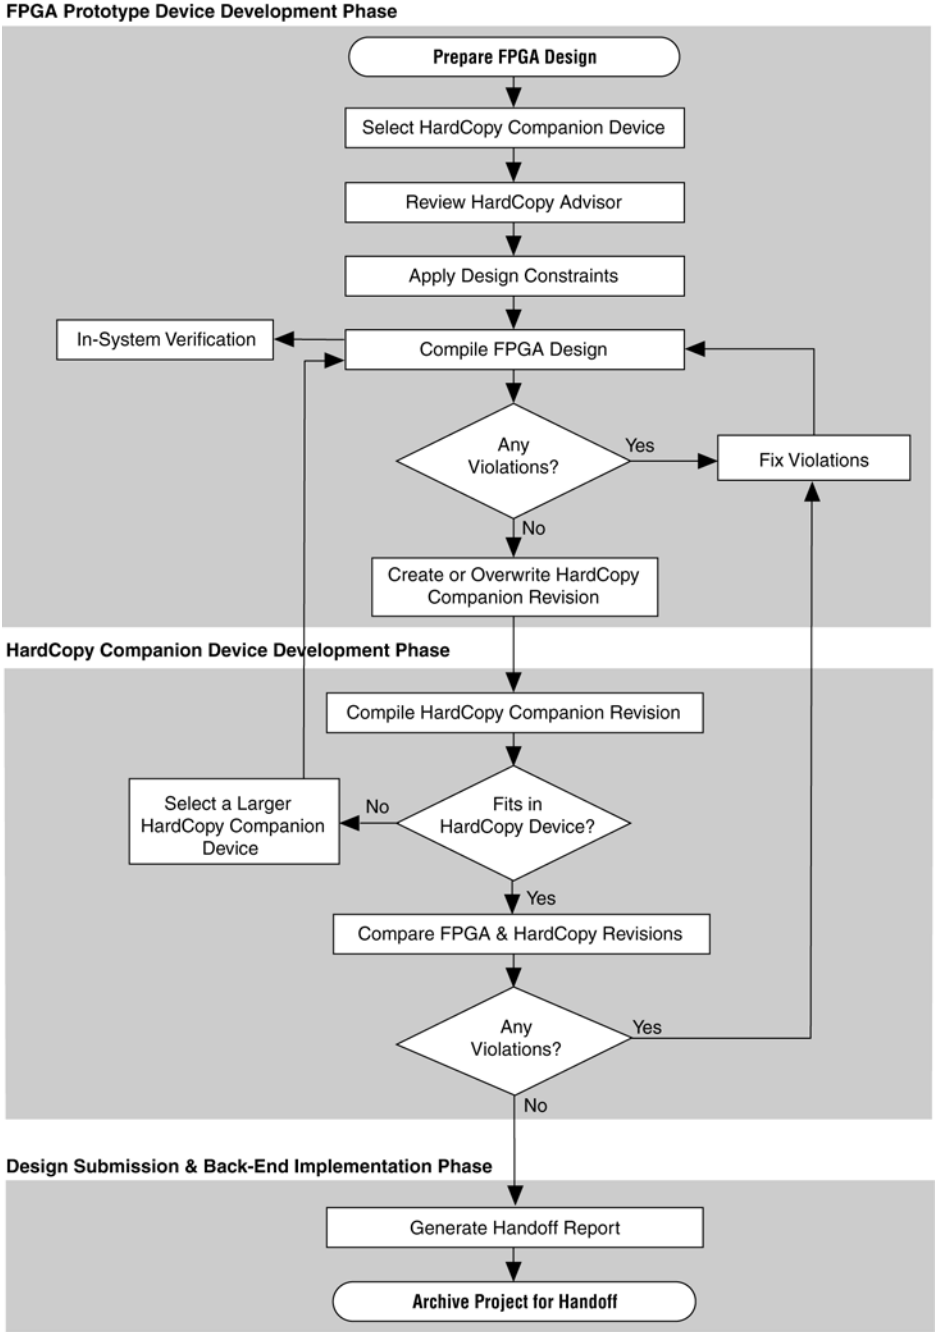
Designing the FPGA First

The HardCopy development flow, with the FPGA first flow begins with seamless FPGA prototyping, is identical to the traditional FPGA design flow, with a few additional tasks to be performed to convert the design to the HardCopy companion device within the same project. To design your HardCopy device when selecting the FPGA companion device first, complete the following tasks:

- Specify an FPGA device and a HardCopy companion device
- Compile the FPGA design
- Create and compile the HardCopy companion revision
- Compare the HardCopy companion revision compilation to the FPGA device compilation

Figure 4–2 provides an overview highlighting the development process for designing with an FPGA first and creating a HardCopy companion device second.

Figure 4–2. Designing FPGA Device First Flow



You must select a target FPGA device and a companion HardCopy device when compiling an FPGA design that you will migrate over to a HardCopy device.

During the early stages of the design, picking the right HardCopy device can be a problem. In such cases, the HardCopy Device Resource Guide should help. After you have selected an FPGA and a HardCopy Device, compile the FPGA and review the HardCopy Device Resource Guide to see if all resources are available in the targeted HardCopy device. If there are not enough resources available in the target HardCopy device, you must select a larger HardCopy device and restart the FPGA compilation.

Once the FPGA and the HardCopy devices have been finalized perform the following tasks:

- Review the HardCopy Advisor for required and recommended tasks to perform
- Enable Design Assistant to run during compilation
- Add timing and location assignments
- Compile your FPGA design
- Create your HardCopy companion revision
- Compile your design for the HardCopy companion device
- Compare the HardCopy companion device compilation with the FPGA revision
- Generate a HardCopy Handoff Report
- Generate a HardCopy Handoff Archive
- Arrange for submission of your HardCopy Handoff Archive to Altera's HardCopy Design Center for back-end implementation

For more information about the overall design flow using the Quartus II software, refer to the *Introduction to the Quartus II Software* manual.

Designing the HardCopy Device First

After you have selected an initial HardCopy ASIC device, you can design your HardCopy device first and create your FPGA prototype second in the Quartus II software. This approach is best when using the HardCopy ASIC to achieve higher performance than the FPGA prototype, because you can see your potential maximum performance in the HardCopy device immediately during development, and you can create a slower performing FPGA prototype of the design for in-system verification. This design process is similar to the HardCopy design flow where you build the FPGA first, but instead, you change the starting device family. The remaining tasks to complete your design for both the FPGA and HardCopy devices roughly follow the same process (Figure 4–3). The HardCopy Advisor adjusts its list of tasks based on which device family you start with, FPGA or HardCopy, to help you complete the process seamlessly.

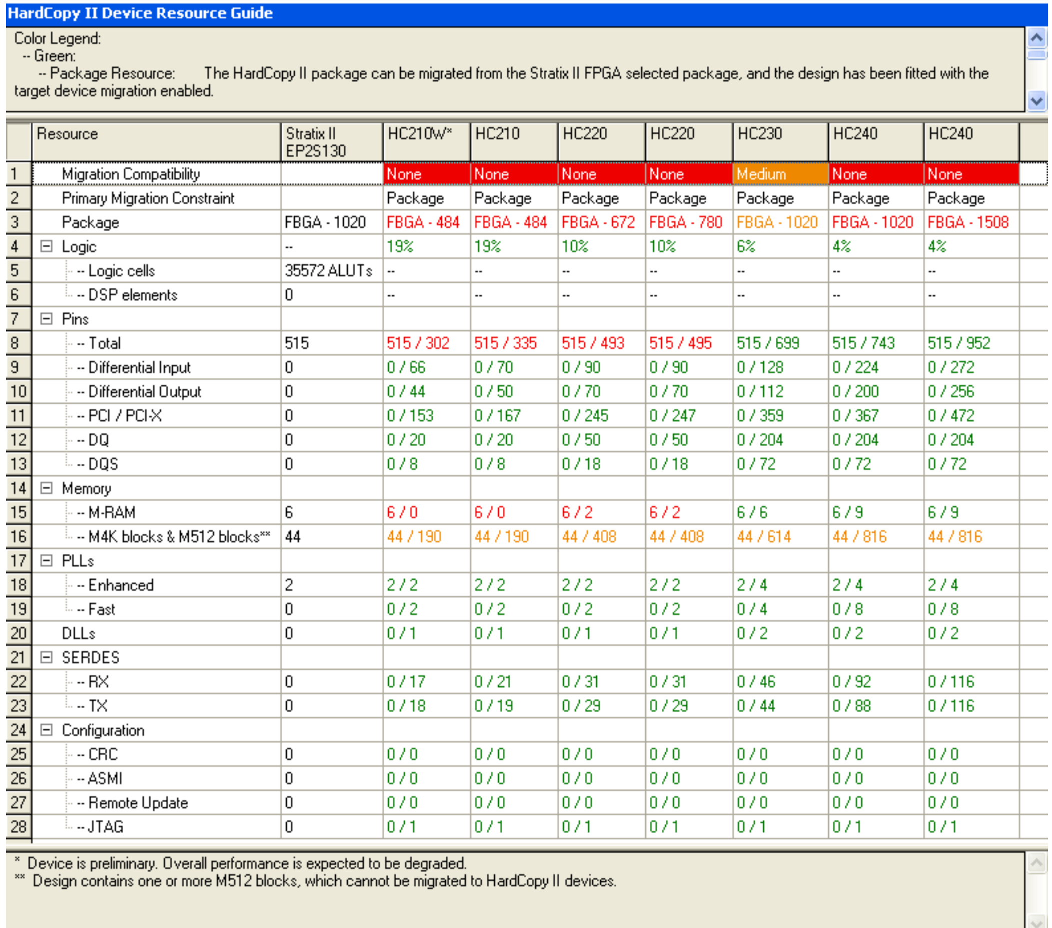
HardCopy Device Resource Guide

The HardCopy Device Resource Guide compares the resources required to successfully compile a design with the resources available in the various HardCopy devices. The report rates each HardCopy device and each device resource on how well it fits the design. The Quartus II software generates the HardCopy Device Resource Guide for all designs successfully compiled for FPGA devices. This guide is found in the Fitter folder of the Compilation Report. Figure 4–4 shows an example of the HardCopy Device Resource Guide. Refer to Table 4–1 for an explanation of the color codes in Figure 4–4.

Figure 4–4. HardCopy Device Resource Guide



HardCopy II Device Resource Guide

Color Legend:
-- Green:
-- Package Resource: The HardCopy II package can be migrated from the Stratix II FPGA selected package, and the design has been fitted with the target device migration enabled.

* Device is preliminary. Overall performance is expected to be degraded.
** Design contains one or more M512 blocks, which cannot be migrated to HardCopy II devices.

Use this report to determine which HardCopy device is a potential candidate for your design. The HardCopy device package must be compatible with the FPGA device package. A logic resource usage greater than 100% or a ratio greater than 1/1 in any category indicates that the design probably will not fit in that particular HardCopy device.

© March 2009 Altera Corporation

Table 4–1. HardCopy Device Resource Guide Color Legend

Color	Package Resource *(1)*	Device Resources
Green (High)	The design can map to the HardCopy package and the design has been fitted with target device migration enabled in the **HardCopy Companion Device** dialog box.	The resource quantity is within the range of the HardCopy device and the design can likely map if all other resources also fit. You are still required to compile the HardCopy revision to make sure the design is able to route and close timing.
Orange (Medium)	The design can map to the HardCopy package. However, the design has not been fitted with the target device migration enabled in the **HardCopy Companion Device** dialog box.	The resource quantity is within the range of the HardCopy device. However, the resource is at risk of exceeding the range for the HardCopy package. If your target HardCopy device falls in this category, compile your design targeting the HardCopy device as soon as possible to check if the design fits and is able to route and migrate all other resources. You might have to select a larger device.
Red (None)	The design cannot map to the HardCopy package.	The resource quantity exceeds the range of the HardCopy device. The design cannot migrate to this HardCopy device.

Note to Table 4–1:

(1) The package resource is constrained by the FPGA for which the design was compiled. Only vertical migration devices within the same package are able to migrate to HardCopy devices.

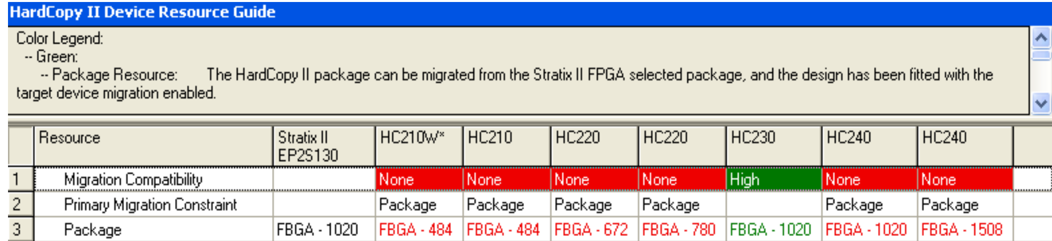
The HardCopy architecture consists of an array of fine-grained HCells, which are used to build logic equivalent to FPGA adaptive logic modules (ALMs) and digital signal processing (DSP) blocks. The DSP blocks in HardCopy devices match the functionality of the FPGA DSP blocks, though timing of these blocks is different than the FPGA DSP blocks because they are constructed of HCell Macros. The memory blocks in HardCopy devices are equivalent to the FPGA memory blocks. Preliminary timing reports of the HardCopy device are available in the Quartus II software. Final timing results of the HardCopy device are provided by Altera's HardCopy Design Center after the HardCopy back-end is complete.

For more information about the HardCopy device resources, refer to the respective HardCopy Series device handbook on the Altera website.

The report example in Figure 4–4 shows the resource comparisons for a design compiled for an EP2S130F1020 device. Based on the report, the HC230F1020 device in the 1,020-pin FineLine BGA package is an appropriate HardCopy device. If the HC230F1020 device is not specified as a migration target during the compilation, its package and migration compatibility is rated orange, or Medium. The migration compatibilities of the other HardCopy devices are rated red, or None, because the package types are incompatible with the FPGA device. The 1,020-pin FBGA HC240 device is rated red because it is only compatible with the EP2S180F1020 device.

Figure 4–5 shows the report after the (unchanged) design was recompiled with the HardCopy HC230F1020 device specified as a migration target. Now the HC230F1020 device package and migration compatibility is rated green, or High.

Figure 4–5. HardCopy Device Resource Guide with Target Migration Enabled



HardCopy II Device Resource Guide

Color Legend:
-- Green:
-- Package Resource: The HardCopy II package can be migrated from the Stratix II FPGA selected package, and the design has been fitted with the target device migration enabled.

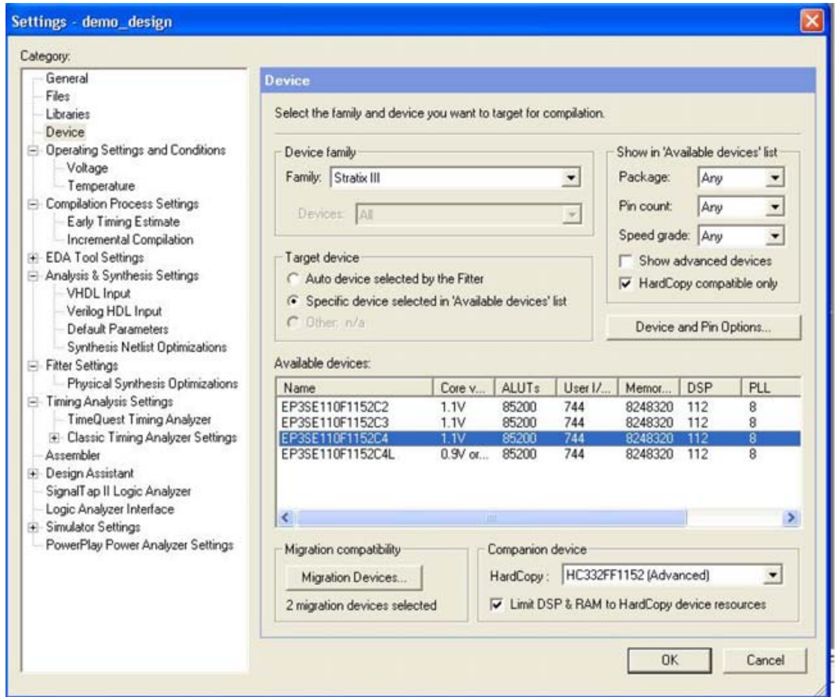
	Resource	Stratix II EP2S130	HC210W*	HC210	HC220	HC220	HC230	HC240	HC240
1	Migration Compatibility		None	None	None	None	High	None	None
2	Primary Migration Constraint		Package	Package	Package	Package		Package	Package
3	Package	FBGA - 1020	FBGA - 484	FBGA - 484	FBGA - 672	FBGA - 780	FBGA - 1020	FBGA - 1020	FBGA - 1508

HardCopy Companion Device Selection

In the Quartus II software, you can select a HardCopy companion device to ensure compatibility between the FPGA design and the HardCopy device's resources. To make your HardCopy companion device selection, on the Assignments menu, click **Device** (Figure 4–6) and select your companion device from the **Companion device** list.

Selecting a HardCopy companion device for your FPGA prototype constrains the memory blocks, DSP blocks, and pin assignments, so that your design fits into the HardCopy device resources. Pin assignments are constrained in the FPGA design revision, so that the HardCopy device selected is pin-compatible. The Quartus II software also constrains the FPGA design revision so that identical device resources are targeted in both the FPGA and the HardCopy ASIC.

Figure 4–6. Quartus II Settings Dialog Box



You can also specify your HardCopy companion device using the following tool command language (Tcl) command:

```
set_global_assignment -name\
DEVICE_TECHNOLOGY_MIGRATION_LIST <HardCopy Device Part Number>
```

For example, to select the HC230F1020 device as your HardCopy companion device for the EP2S130F1020C4 FPGA, the Tcl command is:

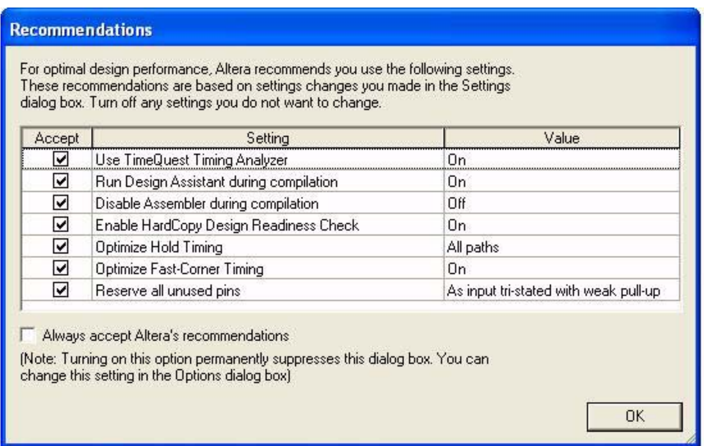
```
set_global_assignment -name\
DEVICE_TECHNOLOGY_MIGRATION_LIST HC230F1020C
```

HardCopy Recommended Settings in the Quartus II Software

The HardCopy development flow involves additional planning and preparation in the Quartus II software compared to a standard FPGA design. This is because you are developing your design to be implemented in two devices: a prototype of your design/system in an FPGA and a companion revision in a HardCopy device for production. Additional settings and constraints are required to make the FPGA design compatible with the HardCopy device, and in some cases, you must remove certain settings in the design. This section explains the additional settings and constraints necessary for your design to be successful in both FPGA and HardCopy ASIC devices.

Figure 4–7 shows the **Recommendations** dialog box with the recommended settings.

Figure 4–7. Quartus II Recommended Settings

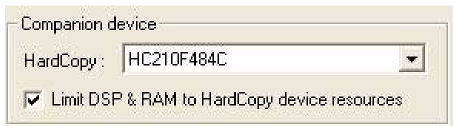


Limit DSP and RAM to HardCopy Device Resources

On the Assignments menu, click **Device**. For example, if the prototype device is a Stratix II FPGA, in the **Family** list, select **Stratix II**. Under **Companion device**, **Limit DSP & RAM to HardCopy device resources** is turned on by default (Figure 4–8). This setting maintains compatibility between the FPGA and HardCopy devices by ensuring your design does not use resources in the FPGA device that are not available in the selected HardCopy device or vice versa.

If you require additional memory blocks or DSP blocks for debugging purposes using the SignalTap® II Embedded Logic Analyzer, you can temporarily turn this setting off to compile and verify your design in your test environment. However, your final FPGA and HardCopy designs submitted to Altera for the HardCopy back-end must be compiled with this setting turned on.

Figure 4–8. Limit DSP & RAM to HardCopy Device Resources Check Box



Enable Design Assistant to Run During Compile

You must use the Quartus II Design Assistant to check all HardCopy designs for design rule violations before submitting the designs to Altera's HardCopy Design Center. Additionally, you must fix all critical and high-level errors.

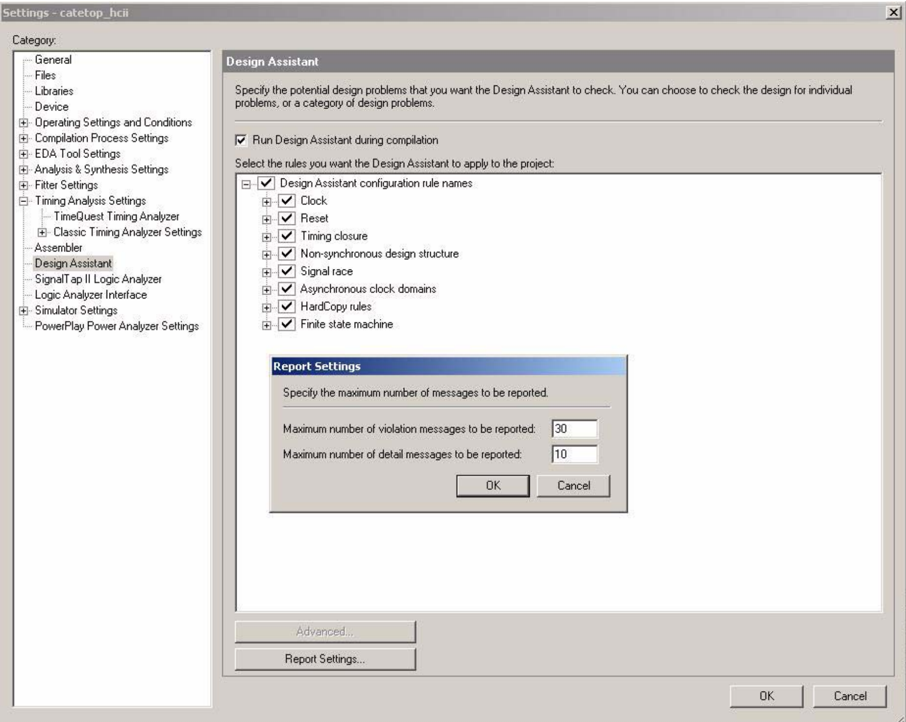
Altera recommends turning on the Design Assistant to run automatically during each compilation so that you can see the violations you must fix or waive after reviewing each violation.

For more information about the Design Assistant and its rules, refer to the respective HardCopy Series device handbook on the Altera website.

To enable the Design Assistant to run during compilation, on the Assignments menu, click **Settings**. In the **Category** list, select **Design Assistant** and turn on **Run Design Assistant during compilation** (Figure 4–9) or enter the following Tcl command in the Tcl Console:

```
set_global_assignment -name ENABLE_DRC_SETTINGS ON ↵
```

Figure 4–9. Enabling Design Assistant



Timing Settings

Beginning with Quartus II software version 7.1, the TimeQuest Timing Analyzer is the required timing analysis tool for all designs. The Classic Timing Analyzer is no longer supported and Altera's HardCopy Design Center does not accept any designs that use the Classic Timing Analyzer for timing closure.

If you are using the Classic Timing Analyzer, Altera strongly recommends that you switch to the TimeQuest Timing Analyzer.

For more information about switching to the TimeQuest Timing Analyzer, refer to the *Switching to the Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

When you specify the TimeQuest Timing Analyzer as the timing analysis tool, the TimeQuest Timing Analyzer guides the Fitter and analyzes timing results after compilation.

TimeQuest Timing Analyzer

The TimeQuest Timing Analyzer is a powerful ASIC-style timing analysis tool that validates timing in your design by using an industry-standard constraint, analysis, and reporting methodology. You can use the TimeQuest Timing Analyzer's GUI or command-line interface to constrain, analyze, and report results for all timing paths in your design.

Before running the TimeQuest Timing Analyzer, you must specify initial timing constraints that describe the clock characteristics, timing exceptions, and signal transition arrival and required times. You can specify timing constraints in the Synopsys Design Constraints (**.sdc**) file format using the GUI or command-line interface. The Quartus II Fitter optimizes the placement of logic to meet your constraints.

During timing analysis, the TimeQuest Timing Analyzer analyzes the timing paths in the design, calculates the propagation delay along each path, checks for timing constraint violations, and reports timing results as slack in the **Report** pane and in the **Console** pane. If the TimeQuest Timing Analyzer reports any timing violations, you can customize the reporting to view precise timing information about specific paths, and then constrain those paths to correct the violations. When your design is free of timing violations, you can be confident that the logic will operate as intended in the target device.

The TimeQuest Timing Analyzer is a complete static timing analysis tool that you use as a sign-off tool for Altera FPGAs and HardCopy ASICs.

Setting Up the TimeQuest Timing Analyzer

To use the TimeQuest Timing Analyzer for timing analysis, on the Assignments menu, click **Timing Analysis Settings**, and on the **Timing Analysis Settings** page, select **Use TimeQuest Timing Analyzer during compilation**.

Use the following Tcl command to use the TimeQuest Timing Analyzer as your timing analysis engine:

```
set_global_assignment -name USE_TIMEQUEST_TIMING_ANALYZER ON
```

You can launch the TimeQuest Timing Analyzer in one of the following modes:

- Directly from the Quartus II software
- Stand-alone mode
- Command-line mode

To perform a thorough Static Timing Analysis, you must specify all the timing requirements. The most important timing requirements are clocks and generated clocks, input and output delays, false paths and multi-cycle paths, and minimum and maximum delays.

In the TimeQuest Timing Analyzer, clock latency, and recovery and removal analysis are enabled by default.

For more information about the TimeQuest Timing Analyzer, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Constraints for Clock Effect Characteristics

The `create_clock`, `create_generated_clock` commands create ideal clocks and do not account for board effects. In order to account for clock effect characteristics, you can use the following commands:

- `set_clock_latency`
- `set_clock_uncertainty`

For more information about how to use these commands, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Beginning in Quartus II software version 7.1, you can use the command `derive_clock_uncertainty` to automatically derive the clock uncertainties in your **.sdc** file. This command is useful when you are unsure what the clock uncertainties might be. The calculated clock uncertainty values are based on I/O buffer, static phase errors (SPE) and jitter in the PLLs, clock networks, and core noise.

The `derive_clock_uncertainty` command applies inter-clock, intra-clock, and I/O interface uncertainties. This command automatically calculates and applies setup and hold clock uncertainties for each clock-to-clock transfer found in your design.

To determine I/O interface uncertainty, you must create a virtual clock, then assign delays to the input/output ports by using the `set_input_delay` and `set_output_delay` commands for that virtual clock.

These uncertainties are applied in addition to those you specified using the `set_clock_uncertainty` command. However, if a clock uncertainty assignment for a source and destination pair was already defined, the new one is ignored. In this case, you can use either the `-overwrite` command to overwrite the previous clock uncertainty command, or manually remove them by using the `remove_clock_uncertainty` command.

The syntax for the `derive_clock_uncertainty` command is as follows:

```
derive_clock_uncertainty [-h | -help] [-long_help] \
[-overwrite]
```

where the arguments are listed in Table 4–2:

Table 4–2. Arguments for derive_clock_uncertainty

Option	Description
`-h | -help`	Short help
`-long_help`	Long help with examples and possible return values
`-overwrite`	Overwrites previously performed clock uncertainty assignments

When the `derive_clock_uncertainty` constraint is used, a **PLLJ_PLLSPE_INFO.txt** file is automatically generated in the project directory. This file lists the names of the PLLs, as well as their jitter and SPE values in the design. This text file can be used by the HCII_DTW_CU_Calculator.

For more information about the `derive_clock_uncertainty` command, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Altera strongly recommends that you use the `derive_clock_uncertainty` command in the HardCopy revision. Altera's HardCopy Design Center does not accept designs that do not have clock uncertainty constraint by either using the `derive_clock_uncertainty` command or the HardCopy II Clock Uncertainty Calculator, and then using the `set_clock_uncertainty` command.

For more information about how to use the HardCopy II Clock Uncertainty Calculator, refer to the *HardCopy II Clock Uncertainty Calculator User Guide*.

Quartus II Software Features Supported for HardCopy Designs

The Quartus II software supports optimization features for HardCopy prototype development, including:

- Physical Synthesis Optimization
- LogicLock™ Regions
- PowerPlay Power Analyzer
- Incremental Compilation (Synthesis and Fitter)

Physical Synthesis Optimization

To enable **Physical Synthesis Optimizations** for the FPGA revision of the design, on the Assignments menu, click **Settings**. In the **Settings** dialog box, in the **Category** list, expand **Fitter Settings**. These optimizations are passed into the HardCopy companion revision for placement and timing closure. When designing with a HardCopy device first, physical synthesis optimizations can be enabled for the HardCopy device, and these post-fit optimizations are passed to the FPGA revision.

LogicLock Regions

The use of LogicLock regions in the FPGA is supported for designs targeted to HardCopy devices. However, LogicLock regions are not passed into the HardCopy companion revision. You can use LogicLock regions in the HardCopy design, but you must create new LogicLock regions in the HardCopy companion revision. In addition, LogicLock regions in HardCopy devices cannot have their properties set to **Auto Size**. However, floating LogicLock regions are supported. HardCopy LogicLock regions must be manually sized and placed in the floorplan. When LogicLock regions are created in a HardCopy device, they start with width and height dimensions set to (**1**,**1**), and the origin coordinates for placement are at **X1_Y1** in the lower left corner of the floorplan. You must adjust the size and location of the LogicLock regions you created in the HardCopy device before compiling the design.

For information about using LogicLock regions, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

PowerPlay Power Analyzer

You can perform power estimation and analysis of your HardCopy and FPGA devices using the PowerPlay Early Power Estimator. Use the PowerPlay Power Analyzer for more accurate estimation of your device’s power consumption.

For more information about using the PowerPlay Power Analyzer, refer to the *Quartus II PowerPlay Power Analysis* chapter in volume 3 of the *Quartus II Handbook*.

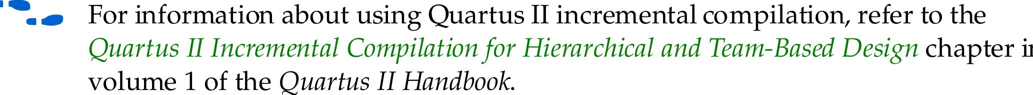
Incremental Compilation

Quartus II incremental compilation using the top-down flow in the FPGA is supported in both the FPGA First design flow and the HardCopy First design flow.

To take advantage of Quartus II Incremental Compilation, organize your design into logical and physical partitions for synthesis and fitting (or place-and-route). Incremental compilation preserves the compilation results and performance of unchanged partitions in your design. This feature dramatically reduces your design iteration time by focusing new compilations only on changed design partitions. New compilation results are then merged with the previous compilation results from unchanged design partitions. You can also target optimization techniques, such as physical synthesis, to specific partitions while leaving other partitions untouched.

In addition, be aware of the following guidelines:

- User partitions and synthesis results are passed to a companion device.
- LogicLock regions are suggested for user partitions, but are not migrated automatically.
- The compilation after migration to a companion device requires a full compilation (all partitions are compiled).
- The entire design must be migrated between the FPGA and HardCopy companion devices. The Quartus II software does not support migration of partitions between companion devices.
- Bottom-up Quartus II incremental compilation is not supported for designs targeting HardCopy devices.
- Physical Synthesis can be run on individual partitions within the originating device only. The resulting optimizations are preserved in the migration to the companion device.



For information about using Quartus II incremental compilation, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

HardCopy Utilities Menu

The HardCopy Utilities menu contains the main functions you use to develop your HardCopy design and FPGA prototype companion revision. To access this menu, on the Project menu, click **HardCopy Utilities**. From the HardCopy Utilities menu, you can perform the following tasks:

- Create or update HardCopy companion revisions
- Specify the current HardCopy companion revision
- Compare the companion revisions for functional equivalence
- Generate a HardCopy Handoff Report for design reviews
- Archive HardCopy Handoff Files for submission to Altera's HardCopy Design Center
- Enable the HardCopy Design Readiness Check tool if you disabled it (the tool is enabled by default)
- Track your design progress using the HardCopy Advisor

Each of the features within **HardCopy Utilities** is summarized in Table 4–3. The process for using each of these features is explained in the following sections.

Table 4–3. HardCopy Utilities Menu Options

Menu	Description	Applicable Design Revision	Restrictions
Create/Overwrite HardCopy Companion Revision	Create a new companion revision or update an existing companion revision for your FPGA and HardCopy design.	FPGA prototype design and HardCopy Companion Revision	■ Must disable Auto Device selection ■ Must set an FPGA device and a HardCopy companion device
Set Current HardCopy Companion Revision	Specify which companion revision to associate with current design revision.	FPGA prototype design and HardCopy Companion Revision	Companion Revision must already exist
Compare HardCopy Companion Revisions	Compares the FPGA design revision with the HardCopy companion design revision and generates a report.	FPGA prototype design and HardCopy Companion Revision	Compilation of both revisions must be complete
Generate HardCopy Handoff Report	Generate a report containing important design information files and messages generated by the Quartus II compile.	FPGA prototype design and HardCopy Companion Revision	■ Compilation of both revisions must be complete ■ Compare HardCopy Companion Revisions must have been executed
Archive HardCopy Handoff Files	Generate a Quartus II Archive File (**.qar**) specifically for submitting the design to Altera's HardCopy Design Center.	HardCopy Companion Revision	■ Compilation of both revisions must be completed ■ Compare HardCopy Companion Revisions must have been executed ■ Generate HardCopy Handoff Report must have been executed
HardCopy Advisor	Open an Advisor, similar to the Resource Optimization Advisor, helping you through the steps of creating a HardCopy project.	FPGA prototype design and HardCopy Companion Revision	None
HardCopy Design Readiness Check	Generates a reports with the design's settings, I/O check, PLL, and RAM usage checks.	FPGA prototype design and HardCopy Companion Revision.	None

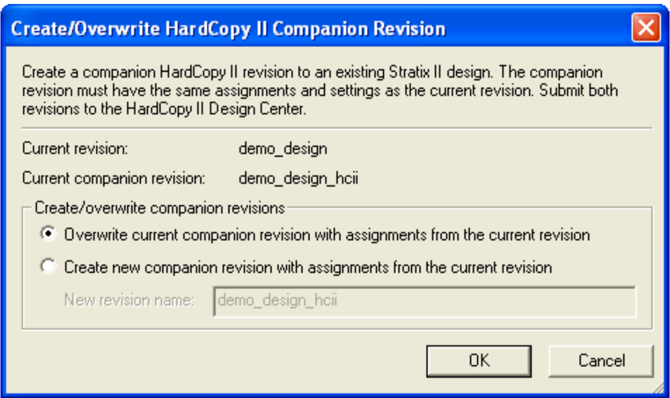
Companion Revisions

You can create multiple revisions of both the FPGA and the HardCopy device. For example, if your initial FPGA revision is called *top* and the corresponding HardCopy II revision is *top_hcii*, you could create another FPGA revision, *top_fpga*, and the corresponding HardCopy II revision would be *top_fpga_hcii*. The Quartus II software creates specific HardCopy design revisions of the project in conjunction to the regular project revisions. These parallel design revisions for HardCopy devices are called companion revisions.

Although you can create multiple project revisions, Altera recommends that you maintain only one FPGA revision once you have created the HardCopy companion revision.

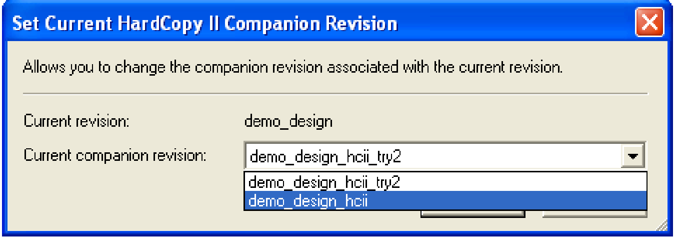
When you have successfully compiled your FPGA prototype, you can create a HardCopy companion revision of your design and proceed with compiling the HardCopy companion revision. To create a companion revision, on the Project menu, point to **HardCopy Utilities** and click **Create/Overwrite HardCopy Companion Revision**. Use the dialog box to create a new companion revision or overwrite an existing companion revision (Figure 4–10).

Figure 4–10. Create or Overwrite HardCopy Companion Revision



You can associate only one FPGA revision to one HardCopy companion revision. If you created more than one revision or more than one companion revision, set the current companion for the revision you are working on. On the Project menu, point to **HardCopy Utilities** and click **Set Current HardCopy Companion Revision** (Figure 4–11).

Figure 4–11. Set Current HardCopy Companion Revision

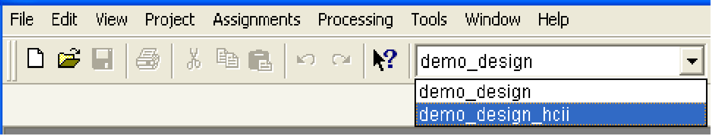


Compiling the HardCopy Companion Revision

The Quartus II software allows you to compile your HardCopy design with preliminary timing information. The timing constraints for the HardCopy companion revision can be the same as the FPGA design used to create the revision. The Quartus II software contains preliminary timing models for HardCopy devices and you can gauge how much performance improvement you can achieve in the HardCopy device compared to the FPGA. Altera verifies that the HardCopy Companion Device timing requirements are met in Altera's HardCopy Design Center.

After you create your HardCopy companion revision from your compiled FPGA design, select the companion revision in the Quartus II software design revision pull-down list (Figure 4–12) or from the **Revisions** list. Compile the HardCopy companion revision. After the Quartus II software compiles your design, you can perform a comparison check of the HardCopy companion revision to the FPGA prototype revision.

Figure 4–12. Changing Current Revision



Comparing HardCopy and FPGA Companion Revisions

Altera uses the companion revisions in a single Quartus II project to maintain compatibility between the FPGA and HardCopy ASIC. This methodology allows you to design with one set of RTL code to be used in both the FPGA and HardCopy ASIC, guaranteeing functional equivalency.

When making changes to companion revisions, use the **Compare HardCopy Companion Revisions** command to ensure that your design matches your HardCopy design functionality and compilation settings. To compare companion revisions, on the Project menu, point to **HardCopy Utilitie**s and click **Compare HardCopy Companion Revisions**.

You must perform this comparison after both the FPGA and HardCopy designs are compiled to hand off the design to Altera's HardCopy Design Center.

The Comparison Revision Summary is found in the Compilation Report and identifies where assignments were changed between revisions or if there is a change in the logic resource count due to different compilation settings.

Generate a HardCopy Handoff Report

To submit a design to Altera's HardCopy Design Center, you must generate a HardCopy Handoff Report providing important information about the design that you want Altera's HardCopy Design Center to review. To generate the HardCopy Handoff Report, you must:

- Successfully compile both FPGA and HardCopy revisions of your design
- Successfully run the **Compare HardCopy Companion Revisions** command

After you generate the HardCopy Handoff Report, you can archive the design using the **Archive HardCopy Handoff Files** command described in "Archive HardCopy Handoff Files" on page 4–21.

Archive HardCopy Handoff Files

The last step in the HardCopy design methodology is to archive the HardCopy project for submission to Altera's HardCopy Design Center for the HardCopy back-end. The **Archive HardCopy Handoff** command creates a different **.qar** file than the standard Quartus II project archive utility generates. This archive contains only the necessary data from the Quartus II project required to implement the design in Altera's HardCopy Design Center.

To use the **Archive HardCopy Handoff Files command**, you must complete the following:

- Compile both the FPGA and HardCopy revisions of your design
- Run the **Compare HardCopy Companion Revisions** command
- Generate the HardCopy Handoff Report

To select this option, on the Project menu, point to **HardCopy Utilities** and click **Archive HardCopy Handoff Files**.

HardCopy Advisor

The HardCopy Advisor provides the list of tasks you should follow to develop your FPGA prototype and your HardCopy design. To open the HardCopy Advisor, on the Project menu, point to **HardCopy Utilities** and click **HardCopy Advisor**. The following tasks highlight the checkpoints that the HardCopy Advisor reviews. These tasks include the major checkpoints in the design process, but they do not include show every step in the process for completing your FPGA and HardCopy designs:

1. Select an FPGA device.
2. Select a HardCopy device.
3. Turn on the Design Assistant.
4. Set up timing constraints.
5. Check for incompatible assignments.
6. Compile and check the FPGA design.
7. Create or overwrite the companion revision.
8. Compile and check the HardCopy companion results.
9. Compare companion revisions.
10. Generate a Handoff Report.
11. Archive Handoff Files and send to Altera.

The HardCopy Advisor shows the necessary steps that pertain to your currently selected device. The Advisor shows a slightly different view for a design with FPGA selected as compared to a design with HardCopy selected.

In the Quartus II software, you can start designing with the HardCopy device selected first, and build an FPGA companion revision second. When you use this approach, the HardCopy Advisor task list adjusts automatically to guide you from HardCopy development through FPGA prototyping, then completes the comparison archiving and handoff to Altera.

When your design uses the FPGA as your starting point, Altera recommends following the Advisor guidelines for your FPGA until you complete the prototype revision.

When the FPGA design is complete, create and switch to your HardCopy companion revision and follow the Advisor steps shown in that revision until you are finished with the HardCopy revision and are ready to submit the design to Altera for the HardCopy back-end.

Each category in the HardCopy Advisor list has an explanation of the recommended settings and constraints, as well as quick links to the features in the Quartus II software that are required for each section. The HardCopy Advisor displays:

- A green check box when you have successfully completed one of the steps
- A yellow caution sign for steps that must be completed before submitting your design to Altera for HardCopy development
- An information callout for items you must verify

Selecting an item within the HardCopy flow menu provides a description of the task and recommended action. The view in the HardCopy Advisor can vary depending on the device you select.

Figure 4–13 shows the HardCopy Advisor with the FPGA device selected.

Figure 4–13. HardCopy Advisor with FPGA Selected

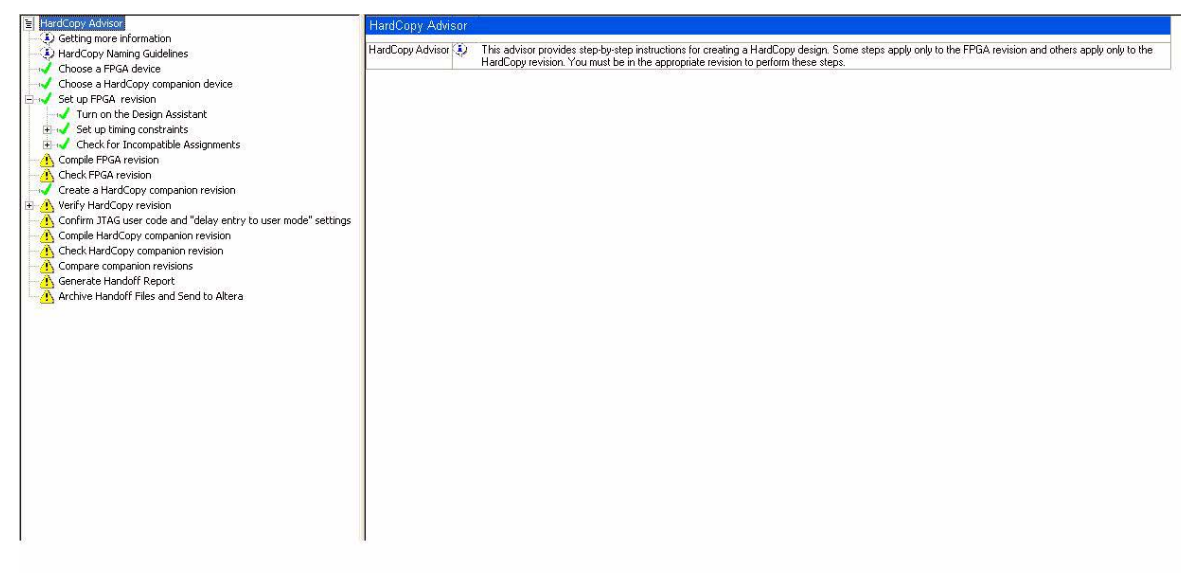


Figure 4–14 shows the HardCopy Advisor with the HardCopy device selected.

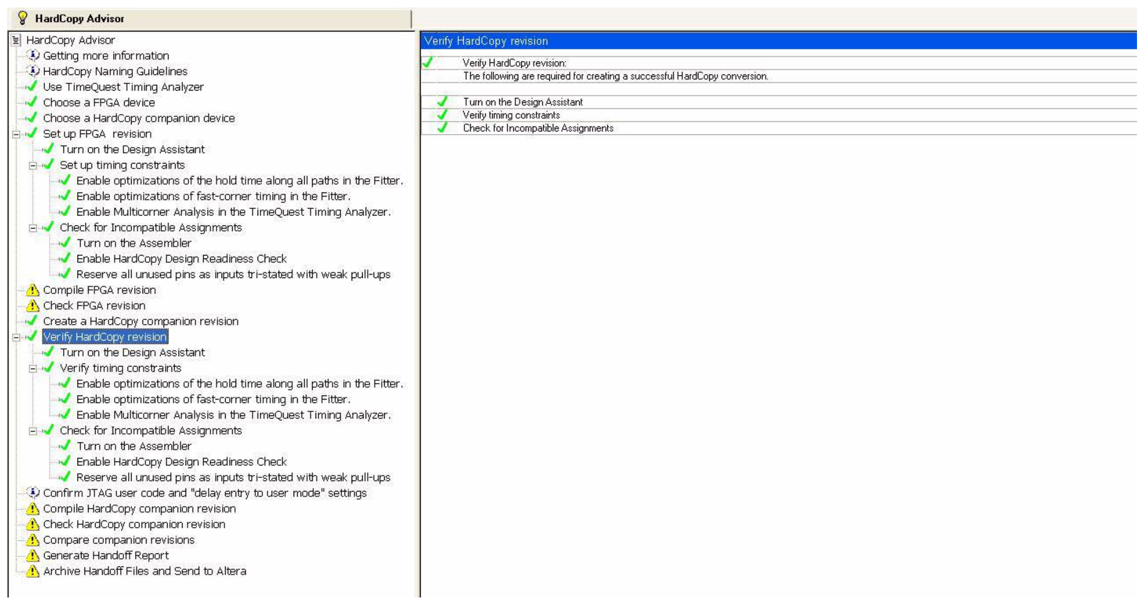
Figure 4–14. HardCopy Advisor with HardCopy Device Selected



HardCopy Design Readiness Check

Beginning in the Quartus II software version 7.2, the HardCopy Design Readiness Check (HCDRC) is available as one of the processing steps in the default compilation of either the FPGA or the HardCopy flow. This feature checks issues that must be addressed prior to handing off the HardCopy design to Altera's HardCopy Design Center for the HardCopy back-end process. This is different from the user-driven approach in HardCopy Advisor, in which you must manually open the Advisor to check for any violations.

The implemented checking in the HCDRC for the Quartus II software version 7.2 is only I/O-related. Beginning in the Quartus II software version 8.0, the checks have been extended to include other logic checks such as PLL, RAM, and Setting checks (**Global Setting**, **Instance Setting**, and **Operating Setting**).

Execution of HardCopy Design Readiness Check

The tool can be turned on through the **.qsf** file, as follows:

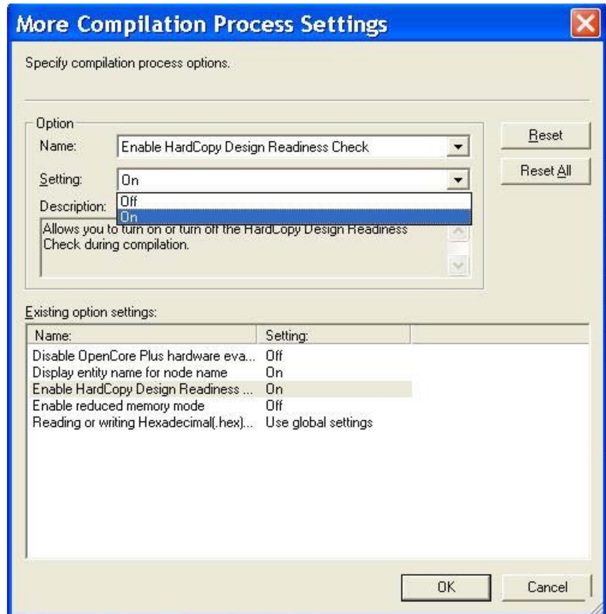
```
set_global_assignment -name \
FLOW_HARDCOPY_DESIGN_READINESS_CHECK ON
```

```
set_global_assignment -name \
FLOW_HARDCOPY_DESIGN_READINESS_CHECK OFF
```

The tool can also be turned on through the GUI, as shown in Figure 4–15.

☞ The tool is On by default.

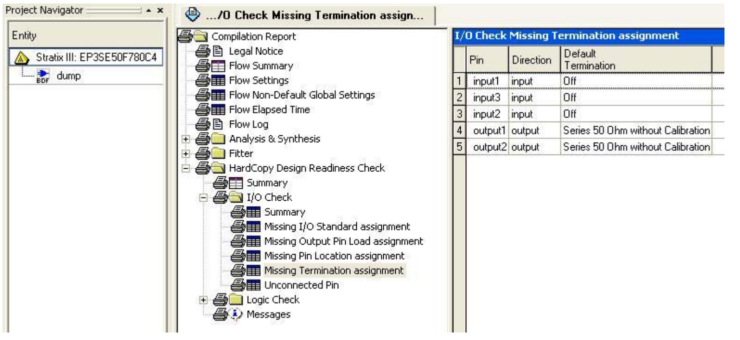
Figure 4–15. HardCopy Design Readiness Check through the GUI



Stratix III Support

Beginning in the Quartus II software version 8.0, the HCDRC enables support for Stratix III devices. This includes automated execution of HCDRC in the Stratix III design flow. However, users must select a HardCopy III companion first for HCDRC to run during the compilation. Refer to Figure 4–16.

Figure 4–16. Stratix III Support in HardCopy Design Readiness Check



All checks are the same as for other families. If the check is specific to Stratix III devices only, HCDRC dynamically runs the check exclusive to the Stratix III revision.

Setting Check

Beginning in Quartus II version 8.0, HCDRC provides the Setting Check report section. The report panels in this category are the setting checks from the HandOff Report. Setting Check consists of the following three sections.

Summary

The Summary section displays the number of settings that do not follow the recommendations. One of the following messages is displayed:

`<number> global setting(s) do not meet recommendation. Please review the recommendation and do appropriate correction as it may affect the result of the migration to HardCopy.`

or

`<number> instance setting(s) do not meet recommendation. Please review the recommendation and do appropriate correction as it may affect the result of the migration to HardCopy.`

Global Setting

The settings check in this section only displays recommendations for global settings. Global settings that currently have a different value than the recommended value are highlighted in red.

Instance Setting

This section is the same as **Global Setting**, but only checks for instances assignments.

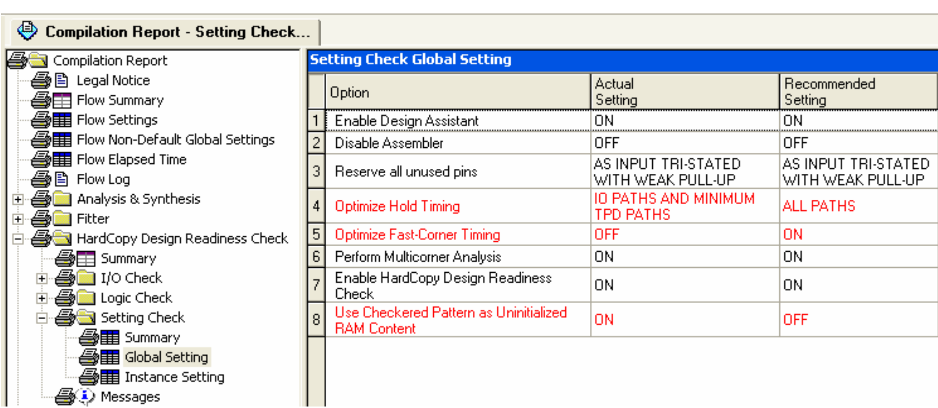
Operating Setting

In this section, checks related to the recommended operating settings for the FPGA and the HardCopy device are reported.

The Operating Setting check is primarily applicable to Stratix III devices used as prototype FPGAs because HardCopy III devices only support 0.9-V core voltage, whereas the Stratix III devices support both 1.1 V and 0.9 V.

Figure 4–17 shows the **Setting Check** category for HCDRC in the Quartus II software version 8.0.

Figure 4–17. Setting Check



Setting Check also includes checking for illegal assignments in the HardCopy design flow. The illegal assignments checks are shown in Example 4–1.

Example 4–1. Illegal Assignment Checks

```
USE_CHECKERED_PATTERN_AS_UNINITIALIZED_RAM_CONTENT ON (1)
SIGNAL_PROBE_ENABLE ON|OFF
SIGNAL_PROBE_SOURCE ON|OFF (2)
```

Notes to Example 4–1:

(1) Refer to the section "RAM Usage Check" on page 4–28.
(2) SignalProbe is not supported in HardCopy ASICs.

I/O Check

The HCDRC I/O Check ensures that you have assigned location assignments for the pins, I/O Standard, current strength assignment, output pin load assignment, termination assignments, and also checks for any unconnected pins. The tool issues a Warning if you have not specified the assignment for the I/O check.

For example, for missing I/O Standard assignments, the HCDRC issues the following warning:

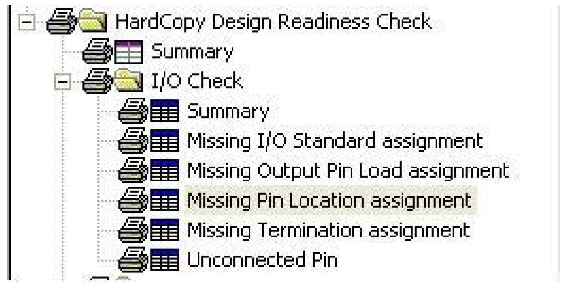
```
5 pin(s) have no explicit I/O Standard assignments provided in
the setting file and default values are being used. Please add a
specific I/O Standard assignment for these pins.
```

Input Pin Placement for Global and Regional Clock

Due to the difference in the interconnect delays between the FPGA and HardCopy, the use of non-primary clock inputs as clock inputs in a design can cause timing closure to be a problem when migrating the FPGA to HardCopy. The Input Pin Placement for Global and Regional Clock check informs you of the problem before finalizing the pin location, so that any clock inputs can be moved to the primary clock input.

This check lists all the pins that drive the global or regional clock but are not placed in a dedicated clock pad. All pins are required to have manual location assignments. This is highlighted prior to this check. See Figure 4–18.

Figure 4–18. I/O Check in the HardCopy Design Readiness Check



The following message appears in the message panel during compilation and also appears in the I/O Check Summary:

```
<number> pin(s) drives global or regional clock, but is not
placed in a dedicated clock pin position. Clock insertion delay
will be different between FPGA and HardCopy companion revisions
because of differences in local routing interconnect delays.
```

PLL Usage Check

There is a new dedicated checking category for PLLs in the HCDRC. The report folder that appears in the UI report is PLL Usage Check. This is for requirements and violations checks relating to PLL usage.

PLL Real-Time Reconfigurable Check

This check highlights the PLLs that do not have PLL reconfiguration. PLL reconfiguration allows fine tuning of the PLLs in the design after manufacturing.

The following message appears in the message panel during compilation and also appears in the Logic Check Summary:

```
<number> PLL(s) don't have real time reconfiguration. It is
highly recommended that each PLL to have PLL reconfiguration
for designs migrating to HardCopy.
```

There is a table listing the PLL elements that do not have PLL reconfiguration.

PLL Clock Outputs Driving Multiple Clock Network Types Check

This check is derived from the Design Assistant rule check for HardCopy (H102). It lists all PLL instances in the current design that have clock outputs driving multiple clock network types. The following message is displayed if the tool detects violations of this type:

```
Found <number> PLL(s) with clock outputs that drives multiple
clock network types.
```

PLL with No Compensation Mode Check

This check list all PLLs that are in "No compensation" operating mode. This setting is not recommended for a design migrating to a HardCopy device. This is due to the differences in the clock networks and the clock delays between FPGA and HardCopy devices.

The following warning message appears during compilation when a PLL is in a "No compensation mode":

```
<number> PLL(s) is operating in a "No compensation" mode.
```

PLL with Normal or Source Synchronous Mode Feeding Output Pin Check

When a PLL is directly feeding an output pin, it must be set to **Zero Delay Buffer** operating mode. However, if a PLL mode is set either in normal compensation mode or source synchronous mode, a warning message is printed during compilation.

During the runtime of HC Ready, the following warning message appears:

```
<number> PLL(s) is in normal or source synchronous mode that is
not fully compensated because it feeds an output pin -- only
PLLs in zero delay buffer mode can fully compensate output pins.
```

RAM Usage Check

HardCopy Series devices do not support initialized RAM blocks upon power-up. However, you can use the ALTMEM_INIT megafunction to initialize the RAMs in your design.

The ALTMEM_INIT megafunction initializes the RAM of a HardCopy Series device with the content of a ROM.

For more information about the ALTMEM_INIT megafunction, refer to the *RAM Initializer (ALTMEM_INIT) Megafunction User Guide*.

In HardCopy Series devices, the RAMs power up uninitialized. In the RAM Usage Check, the HCDRC tool checks to see if there are any RAMs that are initialized using a Memory Initialization File (**.mif**). Any RAM that has a **.mif** file is listed in a table with the following compilation warning message:

```
<number> RAM(s) have Memory Initialization File (MIF). HardCopy
devices do not allow initialized RAM. Please ensure that no RAM
is initialized by a MIF file.
```

Initialized Memory Dependency Testing

Beginning in Quartus II 7.2, there is an option added to the Assembler for the FPGA revision that allows you to write out an FPGA programming file with an initialized checkerboard pattern for memory contents of M4K memories. This option should not be part of your regular Stratix II revision used to migrate to the HardCopy II revision, as it creates irreconcilable revision differences between the Stratix II and HardCopy II designs (the HardCopy hand-off cannot physically have any initialized memory content. Only use this option on a parallel copy of your compiled Stratix II design that you wish to test on your board.

The recommended usage of this feature is as follows:

1. Compile your completed Stratix II design revision to use for prototype testing. This is the revision you should eventually create your HardCopy II companion revision from. On the Project menu, point to **HardCopy II Utilities** and click **Create/Overwrite HardCopy II Companion Revision**.
2. Complete the HardCopy II companion revision creation, and then compile, compare, and hand-off archive generation as usual for your design.
3. After completing the HardCopy II hand-off archive generation, switch back to your Stratix II revision, and on the Quartus II Project menu, select **Revisions** and **Create** to create a copy of your Stratix II revision.
4. In the **Create Revision** dialog box, create a new revision copy of your Stratix II design revision, selecting both the **Copy database** and **Set as current revision** check box options. This copies your Stratix II revision and sets the new revision as the current open revision in the Quartus II software.
5. On the Assignments menu, point to **Settings**, click **Assembler**, and enable **Use checkered pattern as uninitialized RAM content**, or edit the revision **.qsf** file and add the following line:

   ```
   set_global_assignment -name
   USE_CHECKERED_PATTERN_AS_UNINITIALIZED_RAM_CONTENT ON
   ```

6. Run the Assembler in the Stratix II revision to generate a new programming file for your FPGA.
7. Test the new programming file in your prototype environment to determine if your design has a dependency for initial FPGA RAM contents being initialized with zeros after power-up and configuration.

Because it is only a simple checkerboard pattern used for testing, the checkerboard patterns written into the RAMs for the new programming file are not guaranteed to detect all cases of zero-initialized RAM content dependency, but this is one way to look for it. Some designs might only be looking to detect one bit as zero (for example, the LSB of a memory word) so this is not foolproof. If a full RAM word line is expected as zeros at startup, this checkerboard pattern test exposes it.

Performing ECOs with Quartus II Engineering Change Management with the Chip Planner

As designs grow larger and larger in density, analyzing designs for performance, routing congestion, logic placement, and executing Engineering Change Orders (ECOs) becomes critical. In addition to design analysis, you can use various bottom-up and top-down flows to implement and manage the design. This becomes difficult to manage, because ECOs are often implemented as last minute changes to your design.

With the Altera Chip Planner tool, you can shorten the design cycle time significantly. When changes are made to your design as ECOs, you do not have to perform a full compilation in the Quartus II software. Instead, you make changes directly to the post place-and-route netlist, generate a new programming file, test the revised design by performing a gate-level simulation and timing analysis, and proceed to verify the fix on the system. When the fix has been verified on the FPGA, switch to the HardCopy revision, apply the same ECOs, run the timing analyzer and assembler, perform a revision compare, and then run the HardCopy Netlist Writer for design submission.

There are three scenarios from a migration point of view:

- There are changes which can map one-to-one (that is, the same change can be implemented on each architecture—FPGA and HardCopy).
- There are changes that must be implemented differently on the two architectures to achieve the same result.
- There are some changes that cannot be implemented on both architectures.

The following sections outline the methods for migrating each of these types of changes.

Migrating One-to-One Changes

One-to-one changes are implemented using identical commands in both architectures. In general, such changes include those that affect only I/O cells or PLL cells. Some examples of one-to-one changes are changes such as creating, deleting, or moving pins, changing pin or PLL properties, or changing pin connectivity (provided the source and destination of the connectivity changes are I/Os or PLLs). These can be implemented identically on both architectures.

If such changes are exported to Tcl, a direct reapplication of the generated Tcl script (with a minor text edit) on the companion revision should implement the appropriate changes as follows:

- Export the changes from the Change Manager to Tcl.
- Open the generated Tcl script, change the line `project_open <project> -revision <revision>` to refer to the appropriate companion revision.
- Apply the Tcl script to the companion revision.

The following is a partial list of examples of this type:

- I/O creation, deletion, and moves
- I/O property changes (for example, I/O standards, delay chain settings, and so forth)
- PLL property changes
- Connectivity changes between non-LCELL_COMB atoms (for example, PLL to I/O, DSP to I/O, and so forth)

Migrating Changes that Must be Implemented Differently

Some changes must be implemented differently on the two architectures. Changes affecting the logic of the design can fall into this category. Examples are LUTMASK changes, `LC_COMB/HSADDER` creation and deletion, and connectivity changes not covered in the previous section.

Another example of this would be to have different PLL settings for the FPGA and the HardCopy revisions.

For more information about how to use different PLL settings for the FPGA and HardCopy Devices, refer to *AN 432: Using Different PLL Settings Between Stratix II and HardCopy II Devices*.

Table 4–4 summarizes suggested implementation for various changes.

Table 4–4. Implementation Suggestions for Various Changes (Part 1 of 2)

Change Type	Suggested Implementation
LUTMASK changes	Because a single FPGA atom can require multiple HardCopy II atoms to implement, it might be necessary to change multiple HardCopy II atoms to implement the change, including adding or modifying connectivity
Make/Delete LC_COMB	If you are using a FPGA `LC_COMB` in extended mode (7-LUT) or are using a SHARE chain, you must create multiple atoms to implement the same logic functions in HardCopy. Additionally, the placement of the `LC_COMB` cell has no meaning in the companion revision as the underlying resources are different.

Table 4–4. Implementation Suggestions for Various Changes (Part 2 of 2)

Change Type	Suggested Implementation
Make/Delete LC_FF	The basic creation and deletion is the same on both architectures. However, as with `LC_COMB` creation and deletion, the location of an `LC_FF` in a HardCopy revision has no meaning in the FPGA revision, and vice versa.
Editing Logic Connectivity	Because a `LCELL_COMB` atom might have to be broken up into several HardCopy `LCELL_COMB` atoms, the source or destination ports for connectivity changes might have to be analyzed to properly implement the change in the companion revision.

Changes that Cannot be Migrated

A small set of changes cannot be implemented in the other architecture because they do not make sense in the other architecture. The best example of this occurs when moving logic in a design; because the logic fabric is different between the two architectures, locations in the FPGA make no sense in HardCopy, and vice versa.

Overall Migration Flow

This section outlines the migration flow and the suggested procedure for implementing changes in both revisions to ensure a successful Revision Compare such that the design can be submitted to Altera's HardCopy Design Center.

Preparing the Revisions

The general procedure for migrating changes between devices is the same, whether going from the FPGA to HardCopy or vice versa. The major steps are as follows:

1. Compile the design on the initial device.
2. Migrate the design from the initial device to the target device in the companion revision.
3. Compile the companion revision.
4. Perform a Revision Compare operation. The two revisions should pass the Revision Compare.

If testing identifies problems requiring ECO changes, equivalent changes can be applied to both FPGA and HardCopy revisions, as described in the following section.

Applying ECO Changes

The general flow for applying equivalent changes in companion revisions is as follows:

1. Make changes in one revision using the Chip Planner tools (Chip Planner, Resource Property Editor, and Change Manager), then verify and export these changes. The procedure for doing this is as follows:
   a. Make changes using the Chip Planner tool.
   b. Perform a netlist check using the **Check and Save All Netlist Changes** command.

c. Verify correctness using timing analysis, simulation, and prototyping (FPGA only). If more changes are required, repeat steps a and b.

d. Export change records from the Change Manager to Tcl scripts, or **.csv** or **.txt** file formats.

This exported file is used to assist in making the equivalent changes in the companion revision.

2. Open the companion revision in the Quartus II software.
3. Using the exported file, manually reapply the changes using the Chip Planner tool.

   As stated previously, some changes can be reapplied directly to the companion revision (either manually or by applying the Tcl commands), while others require some modifications.

4. Run the **Compare HardCopy Revision** command. The revisions should match.
5. Verify the correctness of all changes (you might have to run timing analysis).
6. Run the **HardCopy Assembler** command and the **HardCopy Netlist Writer** command for design submission along with handoff files.

The Tcl command for running the HardCopy Assembler is as follows:

```
execute_module -tool asm -args "--read_settings_files=off --
write_settings_files=off"
```

The Tcl command for the HardCopy Netlist Writer is as follows:

```
execute_module -tool cdb \
       -args "--generate_hardcopy_files"\
```

For more information about using Chip Planner, refer to the *Quartus II Engineering Change Management with Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

Formal Verification of FPGA and HardCopy Revisions

Third-party formal verification software, Cadence Encounter Conformal verification software, is used for FPGA and HardCopy families, as well as several other Altera device families.

The formal verification flow for HardCopy ASIC designs is a two-step process. First, you run formal verification on the FPGA netlist to ensure that the FPGA netlist matches the RTL. Second, within the Quartus II software, use the Revision Compare tool to ensure that the HardCopy implementation matches the FPGA.

While this flow is enabled, performing formal verification is not necessary due to the one-to-one mapping of logic between the Stratix series FPGA prototype and the HardCopy series ASIC.

To use the Conformal software with the Quartus II software project for your FPGA design revision, you must enable the EDA Netlist Writer. You must turn on the EDA Netlist Writer so it can generate the necessary netlist and command files required to run the Conformal software. To automatically run the EDA Netlist Writer during the compile of your FPGA revision, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, under **EDA Tool Settings**, select **Formal Verification**, and then in the **Tool name** list, select **Conformal LEC**.
3. Compile your FPGA and HardCopy design revisions.

The Quartus II EDA Netlist Writer produces the netlist for the FPGA when it is run on that revision. You can compare your FPGA post-compilation netlist to your RTL source code using the scripts generated by the EDA Netlist Writer.

After both the FPGA and HardCopy revisions have been compiled, the Revision Compare tool can be run to ensure that the HardCopy implementation matches the FPGA.

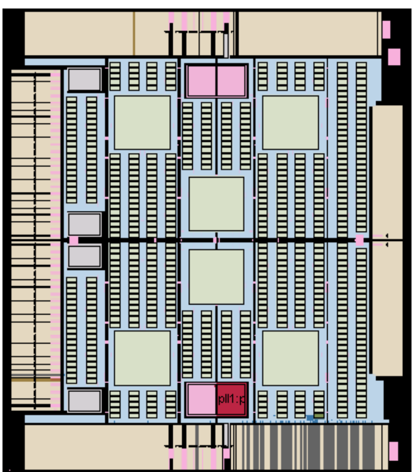
For more information about using the Cadence Encounter Conformal verification software, refer to the *Cadence Encounter Conformal Support* chapter in volume 3 of the *Quartus II Handbook*.

HardCopy Floorplan View

The Quartus II software displays the floorplan and placement of your HardCopy companion revision. This floorplan shows the preliminary placement and connectivity of all I/O pins, PLLs, memory blocks, HCell macros, and DSP HCell macros. Congestion mapping of routing connections can be viewed using the **Layers Setting** dialog box (in the View menu) settings. This is useful in analyzing densely packed areas of your floorplan that can reduce the peak performance of your design. Altera's HardCopy Design Center verifies final HCell macro timing and placement to guarantee timing closure is achieved.

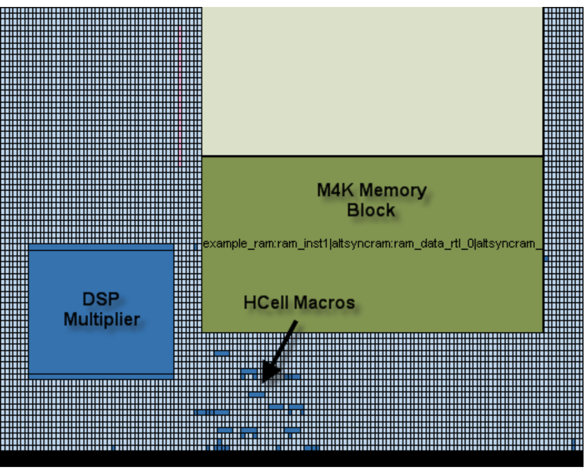
Figure 4–19 shows an example of the HC230F1020 device floorplan.

Figure 4–19. HC230F1020 Device Floorplan



In this small example design, the logic is placed near the bottom edge. You can see the placement of a DSP block constructed of HCell Macros, various logic HCell Macros, and an M4K memory block. A labeled close-up view of this region is shown in Figure 4–20.

Figure 4–20. Close-Up View of Floorplan



Altera's HardCopy Design Center performs final placement and timing closure on your HardCopy design based on the timing constraints provided in the FPGA design.

For more information about Altera's HardCopy Design Center process, refer to the respective HardCopy Series device handbook on the Altera website.

Legacy HardCopy Device Support

Altera HardCopy devices provide a comprehensive alternative to ASICs. HardCopy ASICs offer a complete solution from prototype to high-volume production, and maintain the powerful features and high-performance architecture of their equivalent FPGAs with the programmability removed. You can use the Quartus II design software to design HardCopy devices in a manner similar to the traditional ASIC design flow, and you can prototype with Altera's high density Stratix FPGAs before seamlessly migrating to the corresponding HardCopy device for high-volume production.

HardCopy ASICs provide the following key benefits:

- Improves performance, on the average, by 40% over the corresponding -6 speed grade FPGA device
- Lowers power consumption, on the average, by 40% over the corresponding FPGA
- Preserves the FPGA architecture and features and minimizes risk
- Guarantees first-silicon success through a fast and predictable turnkey backend process

Altera's Quartus II software has built-in support for HardCopy Stratix devices. The HardCopy design flow in Quartus II software offers the following advantages:

- Unified design flow from prototype to production
- Performance estimation of the HardCopy Stratix device allows you to design systems for maximum throughput
- Easy-to-use and inexpensive design tools from a single vendor
- An integrated design methodology that enables system-on-a-chip designs

The next sections discuss the following topics:

- How to design HardCopy Stratix and HardCopy APEX ASICs using the Quartus II software
- An explanation of what the HARDCOPY_FPGA_PROTOTYPE devices are and how to target designs to these devices
- Performance and power estimation of HardCopy Stratix devices
- How to generate the HardCopy design database for submitting HardCopy Stratix designs to Altera's HardCopy Design Center

Features

Beginning in Quartus II software version 4.2, the Quartus II software contains several powerful features that facilitate design of HardCopy Stratix devices:

- **HARDCOPY_FPGA_PROTOTYPE Devices**

  These are virtual Stratix FPGA devices with features identical to HardCopy Stratix devices. You must use these FPGA devices to prototype your designs and verify the functionality in silicon.

- **HardCopy Timing Optimization Wizard**

  Using this feature, you can target your design to HardCopy Stratix devices, providing an estimate of the design's performance in a HardCopy Stratix device.

- **HardCopy Stratix Floorplans and Timing Models**

  The Quartus II software supports post-migration HardCopy Stratix device floorplans and timing models and facilitates design optimization for design performance.

- **Placement Constraints**

  Location and LogicLock constraints are supported at the HardCopy Stratix floorplan level to improve overall performance.

- **Improved Timing Estimation**

  Beginning with version 4.2, the Quartus II software determines routing and associated buffer insertion for HardCopy Stratix designs, and provides the Timing Analyzer with more accurate information about the delays than was possible in previous versions of the Quartus II software. The **.qar** file automatically receives buffer insertion information, which greatly enhances the timing closure process in the back-end migration of your HardCopy Stratix device.

- **Design Assistant**

  This feature checks your design for compliance with all HardCopy device design rules and quickly establishes a seamless migration path.

- **HardCopy Files Wizard**

  This wizard allows you to deliver the design database and all the deliverables required for migration to Altera. This feature is used for HardCopy Stratix devices.

The HardCopy Stratix PowerPlay Early Power Estimator is available on the Altera website at www.altera.com.

HARDCOPY_FPGA_PROTOTYPE, HardCopy Stratix, and Stratix Devices

You must use the HARDCOPY_FPGA_PROTOTYPE virtual devices available in the Quartus II software to target your designs to the actual resources and package options available in the equivalent post-migration HardCopy Stratix device. The programming file generated for the HARDCOPY_FPGA_PROTOTYPE can be used in the corresponding Stratix FPGA device.

The purpose of the HARDCOPY_FPGA_PROTOTYPE is to guarantee seamless migration to HardCopy by making sure that your design only uses resources in the FPGA that can be used in the HardCopy device after migration. You can use the equivalent Stratix FPGAs to verify the design's functionality in-system, then generate the design database necessary to migrate to a HardCopy device. This process ensures the seamless migration of the design from a prototyping device to a production device in high volume. It also minimizes risk, assures samples in about eight weeks, and guarantees first-silicon success.

HARDCOPY_FPGA_PROTOTYPE devices are only available for HardCopy Stratix devices.

Table 4–5 compares HARDCOPY_FPGA_PROTOTYPE devices, Stratix devices, and HardCopy Stratix devices.

Table 4–5. Qualitative Comparison of HARDCOPY_FPGA_PROTOTYPE to Stratix and HardCopy Stratix Devices

Stratix Device	HARDCOPY_FPGA_PROTOTYPE Device	HardCopy Stratix Device
FPGA	Virtual FPGA	ASIC
FPGA	Architecture identical to Stratix FPGA	Architecture identical to Stratix FPGA
FPGA	Resources identical to HardCopy Stratix device	M-RAM resources different than Stratix FPGA in some devices
Ordered by Altera part number	Cannot be ordered; use the Altera Stratix FPGA part number	Ordered by Altera part number

Table 4–6 lists the resources available in each of the HardCopy Stratix devices.

Table 4–6. HardCopy Stratix Device Physical Resources

Device	LEs	ASIC Equivalent Gates (K) *(1)*	M512 Blocks	M4K Blocks	M-RAM Blocks	DSP Blocks	PLLs	Maximum User I/O Pins
HC1S25F672	25,660	250	224	138	2	10	6	473
HC1S30F780	32,470	325	295	171	2 *(2)*	12	6	597
HC1S40F780	41,250	410	384	183	2 *(2)*	14	6	615
HC1S60F1020	57,120	570	574	292	6	18	12	773
HC1S80F1020	79,040	800	767	364	6 *(2)*	22	12	773

Notes to Table 4–6:

(1) Combinational and registered logic do not include DSP blocks, on-chip RAM, or PLLs.

(2) The M-RAM resources for these HardCopy devices differ from the corresponding Stratix FPGA.

For a given device, the number of available M-RAM blocks in HardCopy Stratix devices is identical with the corresponding HARDCOPY_FPGA_PROTOTYPE devices, but can be different from the corresponding Stratix devices. Maintaining the identical resources between HARDCOPY_FPGA_PROTOTYPE and HardCopy Stratix devices facilitates seamless migration from the FPGA to the ASIC device.

For more information about HardCopy Stratix devices, refer to the *HardCopy Stratix Device Family Data Sheet* on the Altera website (www.altera.com).

The three devices, Stratix FPGA, HARDCOPY_FPGA_PROTOTYPE, and HardCopy device, are distinct devices in the Quartus II software. The HARDCOPY_FPGA_PROTOTYPE programming files are used in the Stratix FPGA for your design. The three devices are tied together with the same netlist, thus a single SRAM Object File (**.sof**) can be used to achieve the various goals at each stage. The same **.sof** file is generated in the HARDCOPY_FPGA_PROTOTYPE design, and is used to program the Stratix FPGA device, the same way that it is used to generate the HardCopy Stratix device, guaranteeing a seamless migration.

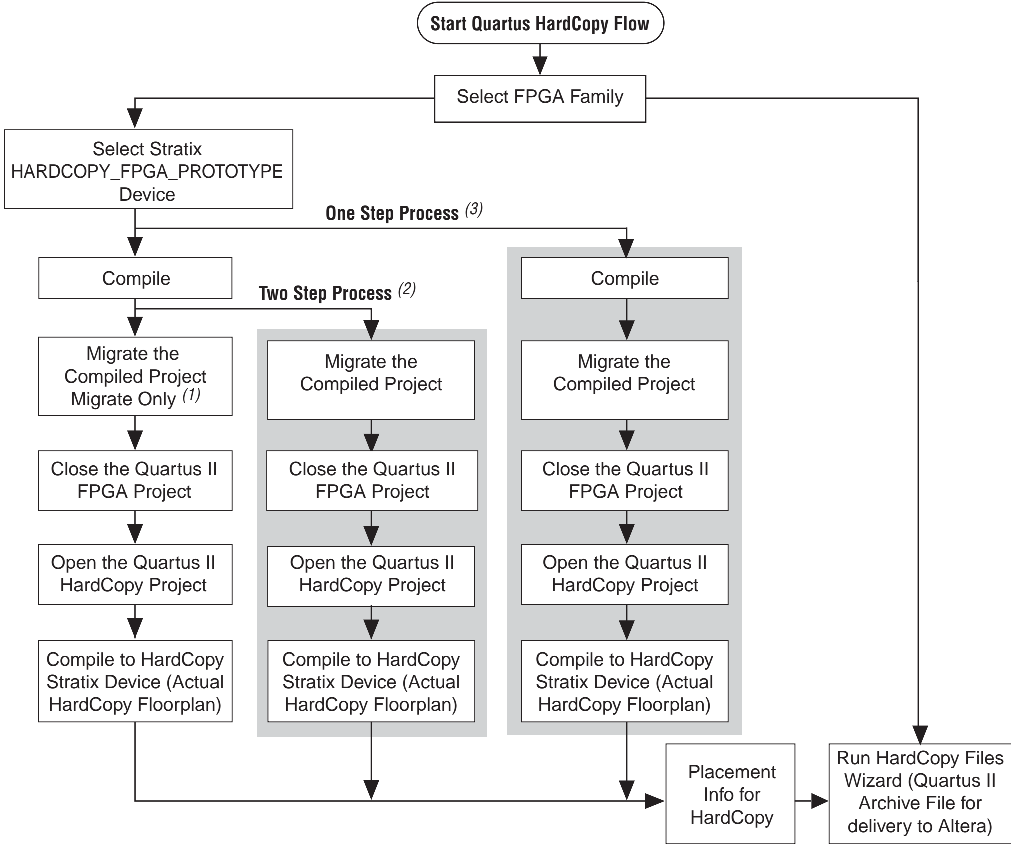
For more information about the **.sof** file and programming Stratix FPGA devices, refer to the *Programming and Configuration* chapter of the *Introduction to the Quartus II Software* manual.

HardCopy Design Flow

Figure 4–21 shows a HardCopy Stratix design flow diagram. The design steps are explained in detail in the following sections of this chapter. The HardCopy Stratix design flow utilizes the HardCopy Timing Optimization Wizard to automate the migration process into a one-step process. The remainder of this section explains the tasks performed by this automated process.

For a detailed description of the HardCopy Timing Optimization Wizard and HardCopy Files Wizard, refer to "HardCopy Timing Optimization Wizard" on page 4–40 and "Generating the HardCopy Design Database" on page 4–49.

Figure 4–21. HardCopy Stratix Design Flow Diagram



Notes to Figure 4–21:

(1) Migrate-Only Process: The displayed flow is completed manually.

(2) Two-Step Process: Migration and Compilation are done automatically (shaded area).

(3) One-Step Process: Full HardCopy Compilation. The entire process is completed automatically (shaded area).

The Design Flow Steps of the One-Step Process

The following sections describe each step of the full HardCopy compilation (the One Step Process), as shown in Figure 4–21.

Compile the Design for an FPGA

This step compiles the design for a HARDCOPY_FPGA_PROTOTYPE device and gives you the resource utilization and performance of the FPGA.

Migrate the Compiled Project

This step generates the Quartus II Project File (**.qpf**) and the other files required for HardCopy implementation. The Quartus II software also assigns the appropriate HardCopy Stratix device for the design migration.

Close the Quartus FPGA Project

Because you must compile the project for a HardCopy Stratix device, you must close the existing project which you have targeted your design to a HARDCOPY_FPGA_PROTOTYPE device.

Open the Quartus HardCopy Project

Open the Quartus II project that you created in the "Migrate the Compiled Project" step. The selected device is one of the devices from the HardCopy Stratix family that was assigned during that step.

Compile for HardCopy Stratix Device

Compile the design for a HardCopy Stratix device. After successful compilation, the Timing Analysis section of the Compilation Report shows the performance of the design implemented in the HardCopy device.

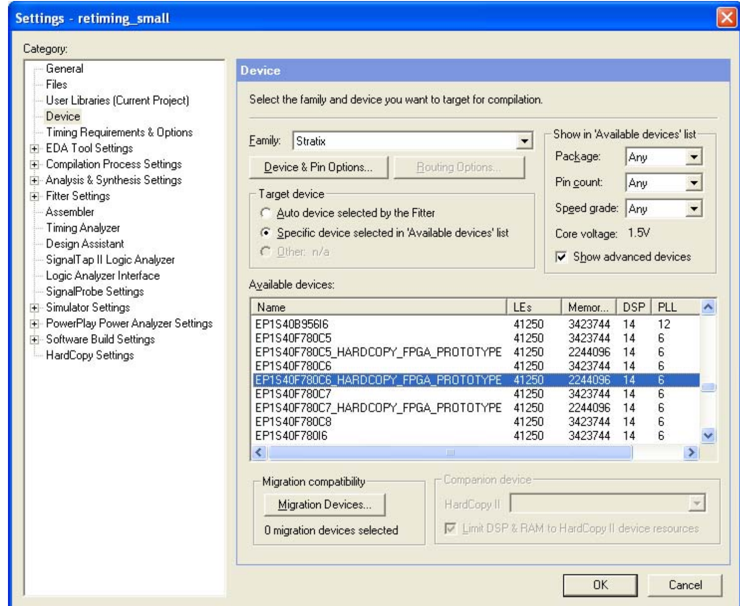
How to Design HardCopy Stratix Devices

This section describes the design process for a HardCopy Stratix device using the HARDCOPY_FPGA_PROTOTYPE as your initial selected device. To use the HardCopy Timing Optimization Wizard, you must first design with the HARDCOPY_FPGA_PROTOTYPE for the design to migrate to a HardCopy Stratix device.

To target a design to a HardCopy Stratix device in the Quartus II software, follow these steps:

1. If you have not yet done so, create a new project or open an existing project.
2. On the Assignments menu, click **Settings**. In the **Category** list, select **Device**.
3. On the **Device** page, in the **Family** list, select **Stratix**. Select the desired HARDCOPY_FPGA_PROTOTYPE device in the **Available Devices list** (Figure 4–22).

Figure 4–22. Selecting a HARDCOPY_FPGA_PROTOTYPE Device



By choosing the HARDCOPY_FPGA_PROTOTYPE device, all the design information, available resources, package option, and pin assignments are constrained to guarantee a seamless migration of your project to the HardCopy Stratix device. The netlist resulting from the HARDCOPY_FPGA_PROTOTYPE device compilation contains information about the electrical connectivity, resources used, I/O placements, and the unused resources in the FPGA device.

1. On the Assignments menu, click **Settings**. In the **Category** list, select **HardCopy Settings** and specify the input transition timing to be modeled for both clock and data input pins. These transition times are used in static timing analysis during back-end timing closure of the HardCopy device.
2. Add constraints to your HARDCOPY_FPGA_PROTOTYPE device, and on the Processing menu, click **Start Compilation** to compile the design.

HardCopy Timing Optimization Wizard

After you have successfully compiled your design in the HARDCOPY_FPGA_PROTOTYPE, you must migrate the design to the HardCopy Stratix device to get a performance estimation of the HardCopy Stratix device. This migration is required before submitting the design to Altera for the HardCopy Stratix device implementation. To perform the required migration, on the Project menu, point to **HardCopy Utilities** and click **HardCopy Timing Optimization Wizard**.

At this point, you are presented with the following three choices to target the designs to HardCopy Stratix devices (Figure 4–23):

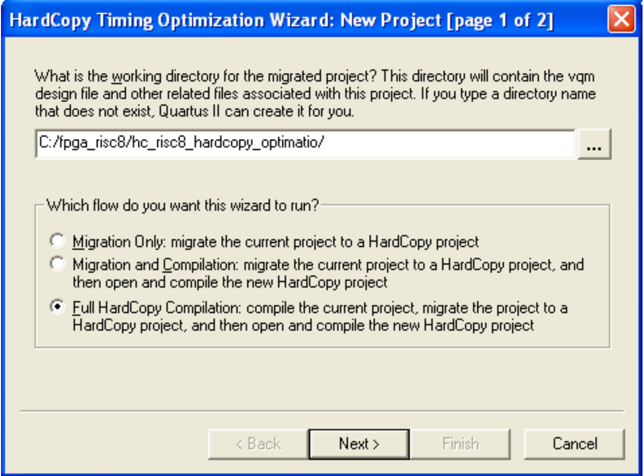
- **Migration Only**: You can select this option after compiling the HARDCOPY_FPGA_PROTOTYPE project to migrate the project to a HardCopy Stratix project.

You can now perform the following tasks manually to target the design to a HardCopy Stratix device. Refer to "Performance Estimation" on page 4–43 for additional information about how to perform these tasks.

- Close the existing project
- Open the migrated HardCopy Stratix project
- Compile the HardCopy Stratix project for a HardCopy Stratix device

- **Migration and Compilation**: You can select this option after compiling the project. This option results in the following actions:
  - Migrating the project to a HardCopy Stratix project
  - Opening the migrated HardCopy Stratix project and compiling the project for a HardCopy Stratix device
- **Full HardCopy Compilation**: Selecting this option results in the following actions:
  - Compiling the existing HARDCOPY_FPGA_PROTOTYPE project
  - Migrating the project to a HardCopy Stratix project
  - Opening the migrated HardCopy Stratix project and compiling it for a HardCopy Stratix device

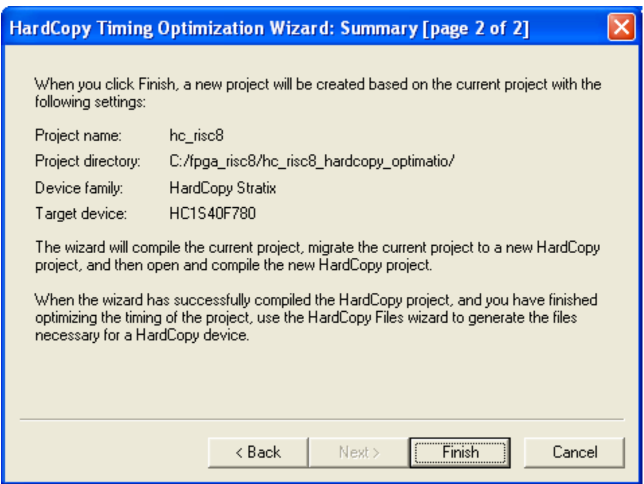
Figure 4–23. HardCopy Timing Optimization Wizard Options



The main benefit of the HardCopy Timing Wizard's three options is flexibility of the conversion process automation. The first time you migrate your HARDCOPY_FPGA_PROTOTYPE project to a HardCopy Stratix device, you might want to use **Migration Only**, and then work on the HardCopy Stratix project in the Quartus II software. As your prototype FPGA project and HardCopy Stratix project constraints stabilize and you have fewer changes, the **Full HardCopy Compilation** is ideal for one-click compiling of your HARDCOPY_FPGA_PROTOTYPE and HardCopy Stratix projects.

After selecting the wizard you want to run, the **HardCopy Timing Optimization Wizard: Summary** page shows you details about the settings you made in the wizard, as shown in Figure 4–24.

Figure 4–24. HardCopy Timing Optimization Wizard Summary Page



When either of the second two options in Figure 4–23 are selected (**Migration and Compilation** or **Full HardCopy Compilation**), designs are targeted to HardCopy Stratix devices and optimized using the HardCopy Stratix placement and timing analysis to estimate performance. For details about the performance optimization and estimation steps, refer to "Performance Estimation" on page 4–43. If the performance requirement is not met, you can modify your RTL source, optimize the FPGA design, and estimate timing until you reach timing closure.

Tcl Support for HardCopy Migration

To complement the GUI features for HardCopy migration, the Quartus II software provides the following command-line executables (which provide the Tcl shell to run the `--flow` Tcl command) to migrate the HARDCOPY_FPGA_PROTOTYPE project to HardCopy Stratix devices:

```
quartus_sh --flow migrate_to_hardcopy <project_name> [-c <revision>] ↵
```

This command migrates the project compiled for the HARDCOPY_FPGA_PROTOTYPE device to a HardCopy Stratix device:

```
quartus_sh --flow hardcopy_full_compile <project_name> [-c <revision>] ↵
```

This command performs the following tasks:

- Compiles the existing project for a HARDCOPY_FPGA_PROTOTYPE device.
- Migrates the project to a HardCopy Stratix project.
- Opens the migrated HardCopy Stratix project and compiles it for a HardCopy Stratix device.

Design Optimization and Performance Estimation

The HardCopy Timing Optimization Wizard creates the HardCopy Stratix project in the Quartus II software, where you can perform design optimization and performance estimation of your HardCopy Stratix device.

 © March 2009 Altera Corporation

Design Optimization

Beginning with version 4.2, the Quartus II software supports HardCopy Stratix design optimization by providing floorplans for placement optimization and HardCopy Stratix timing models. These features allow you to refine placement of logic array blocks (LABs) and optimize the HardCopy design further than the FPGA performance. Customized routing and buffer insertion done in the Quartus II software are then used to estimate the design's performance in the migrated device. The HardCopy device floorplan, routing, and timing estimates in the Quartus II software reflect the actual placement of the design in the HardCopy Stratix device, and can be used to see the available resources, and the location of the resources in the actual device.

Performance Estimation

Figure 4–25 illustrates the design flow for estimating performance and optimizing your design. You can target your designs to HARDCOPY_FPGA_PROTOTYPE devices, migrate the design to the HardCopy Stratix device, and get placement optimization and timing estimation of your HardCopy Stratix device.

In the event that the required performance is not met, you can:

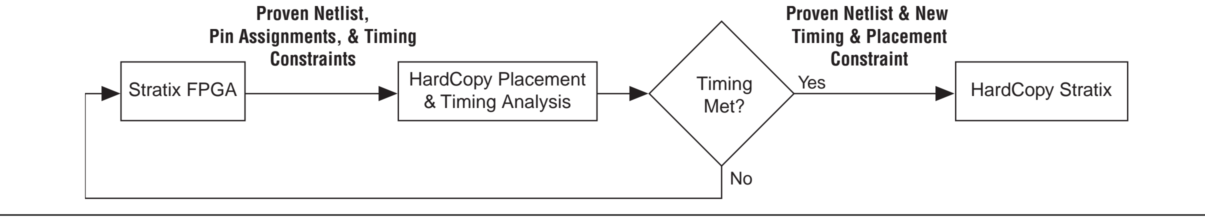
- Work to improve LAB placement in the HardCopy Stratix project.

or

- Go back to the HARDCOPY_FPGA_PROTOTYPE project and optimize that design, modify your RTL source code, repeat the migration to the HardCopy Stratix device, and perform the optimization and timing estimation steps.

On average, HardCopy Stratix devices are 40% faster than the equivalent -6 speed grade Stratix FPGA device. These performance numbers are highly design dependent, and you must obtain final performance numbers from Altera.

Figure 4–25. Obtaining a HardCopy Performance Estimation



To perform Timing Analysis for a HardCopy Stratix device, follow these steps:

1. Open an existing project compiled for a HARDCOPY_FPGA_PROTOYPE device.
2. On the Project menu, point to **HardCopy Utilities** and click **HardCopy Timing Optimization Wizard**.
3. Select a destination directory for the migrated project and complete the HardCopy Timing Optimization Wizard process.

On completion of the HardCopy Timing Optimization Wizard, the destination directory created contains the Quartus II project file, and all files required for HardCopy Stratix implementation. At this stage, the design is copied from the HARDCOPY_FPGA_PROTOTYPE project directory to a new directory to perform the timing analysis. This two-project directory structure enables you to move back and forth between the HARDCOPY_FPGA_PROTOTYPE design database and the HardCopy Stratix design database. The Quartus II software creates the <*project name*>**_hardcopy_optimization** directory.

You do not have to select the HardCopy Stratix device while performing performance estimation. When you run the HardCopy Timing Optimization Wizard, the Quartus II software selects the HardCopy Stratix device corresponding to the specified HARDCOPY_FPGA_PROTOTYPE FPGA. Thus, the information necessary for the HardCopy Stratix device is available from the earlier HARDCOPY_FPGA_PROTOTYPE device selection.

All constraints related to the design are also transferred to the new project directory. You can modify these constraints, if necessary, in your optimized design environment to achieve the necessary timing closure. However, if the design is optimized at the HARDCOPY_FPGA_PROTOTYPE device level by modifying the RTL code or the device constraints, you must migrate the project with the HardCopy Timing Optimization Wizard.

If an existing project directory is selected when the HardCopy Timing Optimization Wizard is run, the existing information is overwritten with the new compile results.

The project directory is the directory that you chose for the migrated project. A snapshot of the files inside the <*project name*>**_hardcopy_optimization** directory is shown in Table 4–7.

1. Open the migrated Quartus II project created in step 3, "Select a destination directory for the migrated project and complete the HardCopy Timing Optimization Wizard process."
2. Perform a full compilation.

After successful compilation, the Timing Analysis section of the Compilation Report shows the performance of the design.

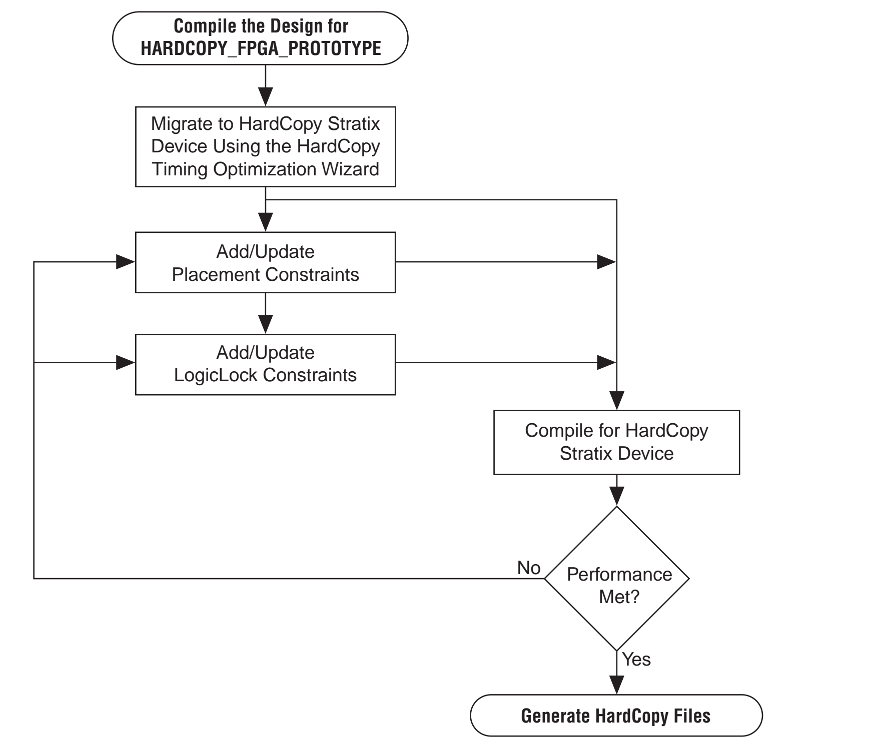
Buffer Insertion

Beginning with version 4.2, the Quartus II software provides improved HardCopy Stratix device timing closure and estimation, to more accurately reflect the results expected after back-end migration. The Quartus II software performs the necessary buffer insertion in your HardCopy Stratix device during the Fitter process, and stores the location of these buffers and necessary routing information in the **.qaf** file. This buffer insertion improves the estimation of the Quartus II Timing Analyzer for the HardCopy Stratix device.

Placement Constraints

Beginning with version 4.2, the Quartus II software supports placement constraints and LogicLock regions for HardCopy Stratix devices. Figure 4–26 shows an iterative process to modify the placement constraints until the best placement for the HardCopy Stratix device is achieved.

Figure 4–26. Placement Constraints Flow for HardCopy Stratix Devices



Location Constraints

This section provides information about HardCopy Stratix logic location constraints.

LAB Assignments

Logic placement in HardCopy Stratix is limited to LAB placement and optimization of the interconnecting signals between them. In a Stratix FPGA, individual logic elements (LEs) are placed by the Quartus II Fitter into LABs. The HardCopy Stratix migration process requires that LAB contents cannot change after the Timing Optimization Wizard task is done. Therefore, you can only make LAB-level placement optimization and location assignments after migrating the HARDCOPY_FPGA_PROTOTYPE project to the HardCopy Stratix device.

The Quartus II software supports these LAB location constraints for HardCopy Stratix devices. The entire contents of a LAB is moved to an empty LAB when using LAB location assignments. If you want to move the logic contents of LAB A to LAB B, the entire contents of LAB A are moved to an empty LAB B. For example, the logic contents of LAB_X33_Y65 can be moved to an empty LAB at LAB_X43_Y56 but individual logic cell LC_X33_Y65_N1 cannot be moved by itself in the HardCopy Stratix Timing Closure Floorplan.

LogicLock Assignments

The LogicLock feature of the Quartus II software provides a block-based design approach. Using this technique you can partition your design and create each block of logic independently, optimize placement and area, and integrate all blocks into the top level design.

To learn more about this methodology, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

LogicLock constraints are supported when you migrate the project from a HARDCOPY_FPGA_PROTOTYPE project to a HardCopy Stratix project. If the LogicLock region was specified as “Size=Fixed“ and “Location=Locked“ in the HARDCOPY_FPGA_PROTOTYPE project, it is converted to have “Size=Auto“ and “Location=Floating“ as shown in the following LogicLock examples. This modification is necessary because the floorplan of a HardCopy Stratix device is different from that of the Stratix device, and the assigned coordinates in the HARDCOPY_FPGA_PROTOTYPE do not match the HardCopy Stratix floorplan. If this modification did not occur, LogicLock assignments would lead to incorrect placement in the Quartus II Fitter. Making the regions auto-size and floating maintains your LogicLock assignments, allowing you to easily adjust the LogicLock regions as required and lock their locations again after HardCopy Stratix placement.

Example 4–2 and Example 4–3 show two examples of LogicLock assignments.

Example 4–2. LogicLock Region Definition in the HARDCOPY_FPGA_PROTOTYPE Quartus II Settings File

```
set_global_assignment -name LL_HEIGHT 15 -entity risc8 -section_id test
set_global_assignment -name LL_WIDTH 15 -entity risc8 -section_id test
set_global_assignment -name LL_STATE LOCKED -entity risc8 -section_id test
set_global_assignment -name LL_AUTO_SIZE OFF -entity risc8 -section_id test
```

Example 4–3. LogicLock Region Definition in the Migrated HardCopy Stratix Quartus II Settings File

```
set_global_assignment -name LL_HEIGHT 15 -entity risc8 -section_id test
set_global_assignment -name LL_WIDTH 15 -entity risc8 -section_id test
set_global_assignment -name LL_STATE FLOATING -entity risc8 -section_id test
set_global_assignment -name LL_AUTO_SIZE ON -entity risc8 -section_id test
```

Checking Designs for HardCopy Design Guidelines

When you develop a design with HardCopy migration in mind, you must follow Altera-recommended design practices to ensure a straightforward migration process or the design will not be able to be implemented in a HardCopy device. Prior to starting migration of the design to a HardCopy device, you must review the design and identify and address all the design issues. Any design issues that have not been addressed can jeopardize silicon success.

Altera-Recommended HDL Coding Guidelines

Designing for Altera PLD, FPGA, and HardCopy ASIC devices requires that certain specific design guidelines and HDL coding style recommendations be followed.

For more information about design recommendations and HDL coding styles, refer to the *Design Guidelines* section in volume 1 of the *Quartus II Handbook*.

Design Assistant

The Quartus II software includes the Design Assistant feature to check your design against the HardCopy design guidelines. Some of the design rule checks performed by the Design Assistant include the following rules:

- Design should not contain combinational loops
- Design should not contain delay chains
- Design should not contain latches

To use the Design Assistant, you must run Analysis and Synthesis on the design in the Quartus II software. Altera recommends that you run the Design Assistant to check for compliance with the HardCopy design guidelines early in the design process and after every compilation.

Design Assistant Settings

You must select the design rules on the **Design Assistant** page prior to running the design. On the Assignments menu, click **Settings**. In the **Settings** dialog box, in the **Category** list, select **Design Assistant** and turn on **Run Design Assistant during compilation**. Altera recommends enabling this feature to run the Design Assistant automatically during compilation of your design.

Running Design Assistant

To run Design Assistant independently of other Quartus II features, on the Processing menu, point to **Start** and click **Start Design Assistant**.

The Design Assistant automatically runs in the background of the Quartus II software when the HardCopy Timing Optimization Wizard is launched, and does not display the Design Assistant results immediately to the display. The design is checked before the Quartus II software migrates the design and creates a new project directory for performing timing analysis.

Also, the Design Assistant runs automatically whenever you generate the HardCopy design database with the HardCopy Files Wizard. The Design Assistant report generated is used by Altera's HardCopy Design Center to review your design.

Reports and Summary

The results of running the Design Assistant on your design are available in the Design Assistant Results section of the Compilation Report. The Design Assistant also generates the summary report in the <*project name*>**hardcopy** subdirectory of the project directory. This report file is titled <*project name*>**_violations.datasheet**. Reports include the settings, run summary, results summary, and details of the results and messages. The Design Assistant report indicates the rule name, severity of the violation, and the circuit path where any violation occurred.

To learn about the design rules and standard design practices to comply with HardCopy design rules, refer to the Quartus II Help and the *Design Guidelines for HardCopy Series Devices* chapter in the *HardCopy Stratix Device Handbook* on the Altera website.

Generating the HardCopy Design Database

You can use the HardCopy Files Wizard to generate the complete set of deliverables required for migrating the design to a HardCopy device in a single click. The HardCopy Files Wizard asks questions related to the design and archives your design, settings, results, and database files for delivery to Altera. Your responses to the design details are stored in <*project name*>**_hardcopy_optimization**<*project name*>**.hps.txt**.

You can generate the archive of the HardCopy design database only after compiling the design to a HardCopy Stratix device. The **.qaf** file is generated at the same directory level as the targeted project, either before or after optimization.

The Design Assistant automatically runs when the HardCopy Files Wizard is started.

Table 4–8 shows the archive directory structure and files collected by the HardCopy Files Wizard.

Table 4–8. HardCopy Stratix Design Files Collected by the HardCopy Files Wizard

    - *<project name>***_rba_pt_hcpy_v.tcl**
    - *<project name>***_target.datasheet**
    - *<project name>***_violations.datasheet**
  - **hardcopy_fpga_prototype**
    - fpga_*<project name>***.asm.rpt**
    - fpga_*<project name>***.cmp.rcf**
    - fpga_*<project name>***.cmp.xml**
    - fpga_*<project name>***.db_info**
    - fpga_*<project name>***.fit.rpt**
    - fpga_*<project name>***.map.atm**
    - fpga_*<project name>***.map.rpt**
    - fpga_*<project name>***.pin**
    - fpga_*<project name>***.qsf**
    - fpga_*<project name>***.tan.rpt**
    - fpga_*<project name>***_cksum.datasheet**
    - fpga_*<project name>***_cpld.datasheet**
    - fpga_*<project name>***_hcpy.vo**
    - fpga_*<project name>***_hcpy_v.sdo**
    - fpga_*<project name>***_pt_hcpy_v.tcl**
    - fpga_*<project name>***_rba_pt_hcpy_v.tcl**
    - fpga_*<project name>***_target.datasheet**
    - fpga_*<project name>***_violations.datasheet**
  - **db_export**
    - *<project name>***.db_info**
    - *<project name>***.map.atm**
    - *<project name>***.map.hdbx**

After creating the migration database with the HardCopy Timing Optimization Wizard, you must compile the design before generating the project archive. You will receive an error if you create the archive before compiling the design.

Static Timing Analysis

In addition to performing timing analysis, the Quartus II software also provides all of the requisite netlists and Tcl scripts to perform static timing analysis (STA) using the Synopsys STA tool, PrimeTime. The following files, necessary for timing analysis with the PrimeTime tool, are generated by the HardCopy Files Wizard:

- <*project name*>**_hcpy.vo**—Verilog HDL output format
- <*project name*>**_hpcy_v.sdo**—Standard Delay Format Output File
- <*project name*>**_pt_hcpy_v.tcl**—Tcl script

These files are available in the <*project name*>**\hardcopy** directory. PrimeTime libraries for the HardCopy Stratix and Stratix devices are included with the Quartus II software.

Use the HardCopy Stratix libraries for PrimeTime to perform STA during timing analysis of designs targeted to HARDCOPY_FPGA_PROTOTYPE device.

For more information about static timing analysis, refer to the *Quartus II Classic Timing Analyzer* and the *Synopsys PrimeTime Support* chapters in volume 3 of the *Quartus II Handbook*.

Early Power Estimation

You can use PowerPlay Early Power Estimation to estimate the amount of power your HardCopy Stratix or HardCopy APEX device will consume. This tool is available on the Altera website. Using the Early Power Estimator requires some knowledge of your design resources and specifications, including:

- Target device and package
- Clock networks used in the design
- Resource usage for LEs, DSP blocks, PLL, and RAM blocks
- High speed differential interfaces (HSDI), general I/O power consumption requirements, and pin counts
- Environmental and thermal conditions

HardCopy Stratix Early Power Estimation

The PowerPlay Early Power Estimator provides an initial estimate of I_{CC} for any HardCopy Stratix device based on typical conditions. This calculation saves significant time and effort in gaining a quick understanding of the power requirements for the device. No stimulus vectors are necessary for power estimation, which is established by the clock frequency and toggle rate in each clock domain.

This calculation should only be used as an estimation of power, not as a specification. The actual I_{CC} should be verified during operation because this estimate is sensitive to the actual logic in the device and the environmental operating conditions.

For more information about simulation-based power estimation, refer to the *Power Estimation and Analysis* section in volume 3 of the *Quartus II Handbook*.

On average, HardCopy Stratix devices are expected to consume 40% less power than the equivalent FPGA.

Tcl Support for HardCopy Stratix

The Quartus II software also supports the HardCopy Stratix design flow at the command prompt using Tcl scripts.

For details about Quartus II support for Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Conclusion

The methodology for designing HardCopy devices using the Quartus II software is the same as that for designing the Stratix FPGA equivalent. You can use the familiar Quartus II software tools and design flow, target designs to HardCopy devices, optimize designs for higher performance and lower power consumption than the Stratix FPGAs, and deliver the design database for migration to a HardCopy device. Submit the files to Altera's HardCopy Design Center to complete the back-end migration.

Document Revision History

Table 4–9 shows the revision history for this chapter.

Table 4–9. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Updated "RAM Usage Check" on page 4–28 ■ Updated "Referenced Documents"	Updated for Quartus II software version 9.0
November 2008 v8.1.0	■ Added HardCopy IV E support information ■ Added notes for Initialized Memory Dependency testing ■ Changed page size to 8.5" × 11"	Updated for Quartus II software version 8.1
May 2008 v8.0.0	■ Added new section "HardCopy Design Readiness Check". ■ Updated the tables and figures for HardCopy Series devices.	Updated for Quartus II software version 8.0

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

Section II. Design Guidelines

When designing large and complex FPGAs, your design and coding styles can impact your quality of results significantly. Designs following synchronous design practices behave in a predictable and reliable manner, even when re-targeted to different device families or speed grades. Using recommended HDL coding styles ensures that synthesis tools can infer the optimal device hardware to implement your design. Following best practices when creating your design hierarchy and logic provides the most flexibility when partitioning the design for incremental compilation, and leads to the best results. If you create floorplan location assignments to control the placement of different design blocks (useful in team-based designs so each designer can target a different area of the device floorplan), following best practices is important to maintaining good design performance.

This section presents design and coding style recommendations for your Altera® design, and includes the following chapters:

- Chapter 5, Design Recommendations for Altera Devices and the Quartus II Design Assistant

  This chapter describes synchronous design practices, and provides guidelines for combinational logic structures and clocking schemes. It also explains how to check design “rules” using the Quartus® II Design Assistant. Finally, it discusses targeting your design to use the clock and register-control features in the device architecture.

  Use this chapter at the start of your design process to guide the design.

- Chapter 6, Recommended HDL Coding Styles

  This chapter discusses Altera megafunctions and provides specific Verilog HDL and VHDL coding examples for inferring Altera dedicated logic such as memory and DSP blocks. It also provides device-specific coding recommendations for registers and certain logic functions such as tri-state signals, multiplexers, and cyclic redundancy check (CRC) functions, and includes references to other Altera documentation for low-level logic design.

  Use this chapter when you code specific design blocks to ensure you create HDL code that infers the optimal Altera device architecture.

- Chapter 8, Best Practices for Incremental Compilation Partitions and Floorplan Assignments

  This chapter provides a set of guidelines to help you set up and partition your design to take advantage of the compilation time savings, performance preservation, and hierarchical design features offered by Quartus II incremental compilation, and to help you create a design floorplan (using LogicLock™ regions) to support the flow when required.

Use this chapter when setting up your design hierarchy and determining the interfaces between logic blocks in your design, as well as if/when you create a design floorplan. You can also use this chapter to make changes to a design that was not originally set up to take advantage of incremental compilation, because it provides tips on changing a design to work better with an incremental design flow.

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

5. Design Recommendations for Altera Devices and the Quartus II Design Assistant

QII51006-9.0.0

Introduction

Current FPGA applications have reached the complexity and performance requirements of ASICs. In the development of such complex system designs, good design practices have an enormous impact on your device's timing performance, logic utilization, and system reliability. Well-coded designs behave in a predictable and reliable manner even when re-targeted to different families or speed grades. Good design practices also aid in successful design migration between FPGA and HardCopy® or ASIC implementations for prototyping and production.

For optimal performance, reliability, and faster time-to-market when designing with Altera® devices, adhere to the following guidelines:

- Understand the impact of synchronous design practices
- Follow recommended design techniques including hierarchical design partitioning
- Take advantage of the architectural features in the targeted device

This chapter presents design recommendations in these areas and describes the Quartus® II Design Assistant that can help you check your design for violations of design recommendations.

This chapter contains the following sections:

- "Synchronous FPGA Design Practices" on page 5–2
- "Design Guidelines" on page 5–4
- "Checking Design Violations Using the Design Assistant" on page 5–13
- "Targeting Clock and Register-Control Architectural Features" on page 5–41
- "Targeting Embedded RAM Architectural Features" on page 5–43

For specific HDL coding examples and recommendations, including coding guidelines for targeting dedicated device hardware, such as memory and digital signal processing (DSP) blocks, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

For information about migrating designs to HardCopy devices, refer to the *Design Guidelines for HardCopy Series Devices* chapter in volume 1 of the *HardCopy Series Handbook*.

For guidelines on partitioning a hierarchical design for incremental compilation, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Synchronous FPGA Design Practices

The first step in good design methodology is to understand the implications of your design practices and techniques. This section outlines some of the benefits of optimal synchronous design practices and the hazards involved in other techniques. Good synchronous design practices can help you meet your design goals consistently. Problems with other design techniques can include reliance on propagation delays in a device, incomplete timing analysis, and possible glitches.

In a synchronous design, a clock signal triggers all events. As long as all the registers' timing requirements are met, a synchronous design behaves in a predictable and reliable manner for all process, voltage, and temperature (PVT) conditions. You can easily target synchronous designs to different device families or speed grades. In addition, synchronous design practices help ensure successful migration if you plan to migrate your design to a high-volume solution such as an Altera HardCopy device or if you are prototyping an ASIC.

Fundamentals of Synchronous Design

In a synchronous design, everything is related to the clock signal. On every active edge of the clock (usually the rising edge), the data inputs of registers are sampled and transferred to outputs. Following an active clock edge, the outputs of combinational logic feeding the data inputs of registers change values. This change triggers a period of instability due to propagation delays through the logic as the signals go through a number of transitions and finally settle to new values. Changes happening on data inputs of registers do not affect the values of their outputs until the next active clock edge.

Because the internal circuitry of registers isolates data outputs from inputs, instability in the combinational logic does not affect the operation of the design as long as the following timing requirements are met:

- Before an active clock edge, the data input has been stable for at least the setup time of the register
- After an active clock edge, the data input remains stable for at least the hold time of the register

When you specify all of your clock frequencies and other timing requirements, the Quartus II Classic Timing Analyzer reports actual hardware requirements for the setup times (t_{SU}) and hold times (t_H) for every pin of your design. By meeting these external pin requirements and following synchronous design techniques, you ensure that you satisfy the setup and hold times for all registers within the Altera device.

To meet setup and hold time requirements on all input pins, any inputs to combinational logic that feeds a register should have a synchronous relationship with the clock of the register. If signals are asynchronous, you can register the signals at the input of the Altera device to help prevent a violation of the required setup and hold times.

When the setup or hold time of a register is violated, the output can be set to an intermediate voltage level between the high and low levels, called a metastable state. In this unstable state, small perturbations such as noise in power rails can cause the register to assume either the high or low voltage level, resulting in an unpredictable valid state. Various undesirable effects can occur, including increased propagation delays and incorrect output states. In some cases, the output can even oscillate between the two valid states for a relatively long period of time.

For details about timing requirements and analysis in the Quartus II software, refer to the *Quartus II Classic Timing Analyzer* or the *Quartus II TimeQuest Timing Analyzer* chapters in volume 3 of the *Quartus II Handbook*.

Hazards of Asynchronous Design

In the past, designers have often used asynchronous techniques such as ripple counters or pulse generators in programmable logic device (PLD) designs, enabling them to take “short cuts” to save device resources. Asynchronous design techniques have inherent problems such as relying on propagation delays in a device, which can result in incomplete timing constraints and possible glitches and spikes. Because current FPGAs provide many high-performance logic gates, registers, and memory, resource and performance trade-offs have changed. Now it is more important to focus on design practices that help you meet design goals consistently than to save device resources using problematic asynchronous techniques.

Some asynchronous design structures rely on the relative propagation delays of signals to function correctly. In these cases, race conditions can arise where the order of signal changes can affect the output of the logic. PLD designs can have varying timing delays, depending on how the design is placed and routed in the device with each compilation. Therefore, it is almost impossible to determine the timing delay associated with a particular block of logic ahead of time. As devices become faster because of device process improvements, the delays in an asynchronous design may decrease, resulting in a design that does not function as expected. Specific examples are provided in “Design Guidelines” on page 5–4. Relying on a particular delay also makes asynchronous designs very difficult to migrate to different architectures, devices, or speed grades.

The timing of asynchronous design structures is often difficult or impossible to model with timing assignments and constraints. If you do not have complete or accurate timing constraints, the timing-driven algorithms used by your synthesis and place-and-route tools may not be able to perform the best optimizations and the reported results may not be complete.

Some asynchronous design structures can generate harmful glitches, which are pulses that are very short compared with clock periods. Most glitches are generated by combinational logic. When the inputs of combinational logic change, the outputs exhibit a number of glitches before they settle to their new values. These glitches can propagate through the combinational logic, leading to incorrect values on the outputs in asynchronous designs. In a synchronous design, glitches on the data inputs of registers are normal events that have no negative consequences because the data is not processed until the clock edge.

Design Guidelines

When designing with HDL code, it is important to understand how a synthesis tool interprets different HDL design techniques and what results to expect. Your design techniques can affect logic utilization and timing performance, as well as the design's reliability. This section describes some basic design techniques that ensure optimal synthesis results for designs targeted to Altera devices while avoiding several common causes of unreliability and instability. Design your combinational logic carefully to avoid potential problems and pay attention to your clocking schemes so you can maintain synchronous functionality and avoid timing problems.

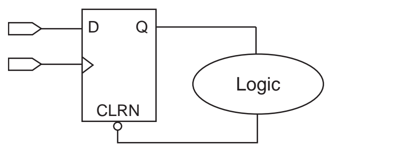
Combinational Logic Structures

Combinational logic structures consist of logic functions that depend only on the current state of the inputs. In Altera FPGAs, these functions are implemented in the look-up tables (LUTs) of the device's architecture, using either logic elements (LEs) or adaptive logic modules (ALMs). For some cases in which combinational logic feeds registers, the register control signals can also be used to implement part of the logic function to save LUT resources. By following the recommendations in this section, you can improve the reliability of your combinational design.

Combinational Loops

Combinational loops are among the most common causes of instability and unreliability in digital designs. They should be avoided whenever possible. In a synchronous design, feedback loops should include registers. Combinational loops generally violate synchronous design principles by establishing a direct feedback loop that contains no registers. For example, a combinational loop occurs when the left-hand side of an arithmetic expression also appears on the right-hand side in HDL code. A combinational loop also occurs when you feed back the output of a register to an asynchronous pin of the same register through combinational logic, as shown in Figure 5–1.

Figure 5–1. Combinational Loop through Asynchronous Control Pin



Use recovery and removal analysis to perform timing analysis on asynchronous ports such as `clear` or `reset` in the Quartus II software.

- If you are using the Classic Timing Analyzer, on the Assignments menu, click **Settings**. In the **Settings** dialog box, under **Timing Analysis Settings**, select **Classic Timing Analyzer Settings**. On the **Classic Timing Analyzer Settings** page, click **More Settings** and turn on the **Enable Recovery/Removal Analysis** option.
- If you are using the TimeQuest Timing Analyzer, refer to the "Recovery and Removal" section in the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook* for details about how the TimeQuest Timing Analyzer performs recovery and removal analysis.

 © March 2009 Altera Corporation

Combinational loops are inherently high-risk design structures for the following reasons:

- Combinational loop behavior generally depends on relative propagation delays through the logic involved in the loop. As discussed, propagation delays can change, which means the behavior of the loop is unpredictable.
- Combinational loops can cause endless computation loops in many design tools. Most tools break open combinational loops to process the design. The various tools used in the design flow may open a given loop in a different manner, processing it in a way that is inconsistent with the original design intent.

Latches

A latch is a small circuit with combinational feedback that holds a value until a new value is assigned. Latches can be implemented directly with primitives, using `LPM_LATCH`, or inferred from HDL code. It is common for mistakes in HDL code to cause unintended latch inference. Quartus II Synthesis issues a warning message if this occurs.

Unlike other technologies, a latch in an FPGA architecture is not significantly smaller than a register. The architecture is not optimized for latch implementation and latches generally have slower timing performance compared to equivalent registered circuitry.

Latches have a transparent mode in which data flows continuously from input to output. A positive latch is in transparent mode when the enable signal is high (low for negative latch). In transparent mode, glitches on the input can pass through the output because of the direct path created. This presents significant complexity for timing analysis. Typical latch schemes use multiple enable phases to prevent long transparent paths from occurring. However, timing analysis is generally not able to identify these safe applications.

The Quartus II software setting **Analyze latches as Synchronous Elements** allows you to treat latches as having nontransparent start and end points. Bear in mind that even an instantaneous transition through transparent mode can lead to glitch propagation. The Quartus II software does not perform cycle-borrowing analysis, such as that performed by third-party timing analysis tools (such as the Synopsys PrimeTime software).

Due to various timing complexities, latches have limited support in formal verification tools. Therefore, it is very important that you do not use latches when using formal verification.

Altera recommends you avoid using latches to ensure that you can completely analyze the timing performance and reliability of your design.

Delay Chains

Delay chains occur when two or more consecutive nodes with a single fan-in and a single fan-out are used to cause delay. Inverters are often chained together to add delay. Delay chains are sometimes used to resolve race conditions created by other asynchronous design practices.

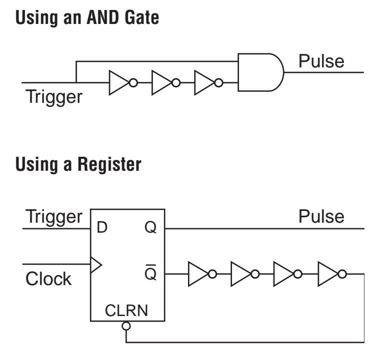
Delays in PLD designs can change with each place-and-route cycle. Effects such as rise and fall time differences and on-chip variation mean that delay chains, especially those placed on clock paths, can cause significant problems in your design. Refer to "Hazards of Asynchronous Design" on page 5–3 for examples of the kinds of problems that delay chains can cause. Avoid using delay chains to prevent these kind of problems.

In some ASIC designs, delays are used for buffering signals as they are routed around the device. This functionality is not required in FPGA devices because the routing structure provides buffers throughout the device.

Pulse Generators and Multivibrators

Delay chains are sometimes used to generate either one pulse (pulse generators) or a series of pulses (multivibrators). There are two common methods for pulse generation, as shown in Figure 5–2. These techniques are purely asynchronous and need to be avoided.

Figure 5–2. Asynchronous Pulse Generators



In "Using an AND Gate" (Figure 5–2), a trigger signal feeds both inputs of a 2-input AND gate, but the design inverts or adds a delay chain to one of the inputs. The width of the pulse depends on the relative delays of the path that feeds the gate directly and the one that goes through the delay. This is the same mechanism responsible for the generation of glitches in combinational logic following a change of input values. This technique artificially increases the width of the glitch by using a delay chain.

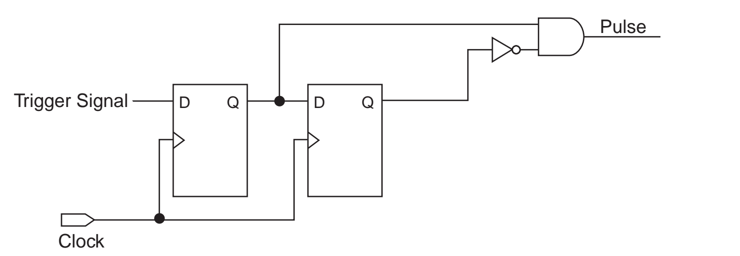
In "Using a Register" (Figure 5–2), a register's output drives the same register's asynchronous reset signal through a delay chain. The register resets itself asynchronously after a certain delay.

The width of pulses generated in this way are difficult for synthesis and place-and-route software to determine, set, or verify. The actual pulse width can only be determined after placement and routing, when routing and propagation delays are known. You cannot reliably determine the width of the pulse when creating HDL code and it cannot be set by EDA tools. The pulse may not be wide enough for the application under all PVT conditions. Also, the pulse width changes if you change to a different device. In addition, static timing analysis cannot be used to verify the pulse width, so verification is very difficult.

Multivibrators use a glitch generator to create pulses, together with a combinational loop that turns the circuit into an oscillator. This creates additional problems because of the number of pulses involved. In addition, when the structures generate multiple pulses, they also create a new artificial clock in the design that has to be analyzed by the design tools.

When you must use a pulse generator, use synchronous techniques, as shown in Figure 5–3.

Figure 5–3. Recommended Pulse-Generation Technique



In this design, the pulse width is always equal to the clock period. This pulse generator is predictable, can be verified with timing analysis, and is easily moved to other architectures, devices, or speed grades.

Clocking Schemes

Like combinational logic, clocking schemes have a large effect on your design's performance and reliability. Avoid using internally generated clocks wherever possible because they can cause functional and timing problems in the design. Clocks generated with combinational logic can introduce glitches that create functional problems and the delay inherent in combinational logic can lead to timing problems.

Specify all clock relationships in the Quartus II software to allow for the best timing-driven optimizations during fitting and to allow correct timing analysis. Use clock setting assignments on any derived or internal clocks to specify their relationship to the base clock.

Altera recommends using global device-wide, low-skew dedicated routing for all internally-generated clocks, instead of routing clocks on regular routing lines. For a detailed explanation, refer to "Clock Network Resources" on page 5–42.

Avoid data transfers between different clocks wherever possible. If you require a data transfer between different clocks, use FIFO circuitry. You can use the clock uncertainty features in the Quartus II software to compensate for the variable delays between clock domains. Consider setting a Clock Setup Uncertainty and Clock Hold Uncertainty value of 10% to 15% of the clock delay.

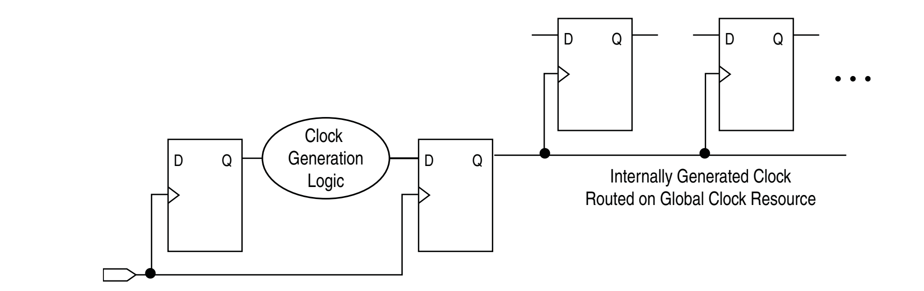
The following sections provide some specific examples and recommendations for avoiding these problems.

Internally Generated Clocks

If you use the output from combinational logic as a clock signal or as an asynchronous reset signal, expect to see glitches in your design. In a synchronous design, glitches on data inputs of registers are normal events that have no consequences. However, a glitch or a spike on the clock input (or an asynchronous input) to a register can have significant consequences. Narrow glitches can violate the register's minimum pulse width requirements. Setup and hold times may also be violated if the data input of the register is changing when a glitch reaches the clock input. Even if the design does not violate timing requirements, the register output can change value unexpectedly and cause functional hazards elsewhere in the design.

Because of these problems, Altera recommends that you always register the output of combinational logic before you use it as a clock signal (Figure 5–4).

Figure 5–4. Recommended Clock-Generation Technique



Registering the output of combinational logic ensures that the glitches generated by the combinational logic are blocked at the data input of the register.

Divided Clocks

Designs often require clocks created by dividing a master clock. Most Altera FPGAs provide dedicated phase-locked loop (PLL) circuitry for clock division. Using dedicated PLL circuitry can help you to avoid many of the problems that can be introduced by asynchronous clock division logic.

When you must use logic to divide a master clock, always use synchronous counters or state machines. In addition, create your design so that registers always directly generate divided clock signals, as described in "Internally Generated Clocks" on page 5–8, and route the clock on global clock resources. To avoid glitches, do not decode the outputs of a counter or a state machine to generate clock signals.

Ripple Counters

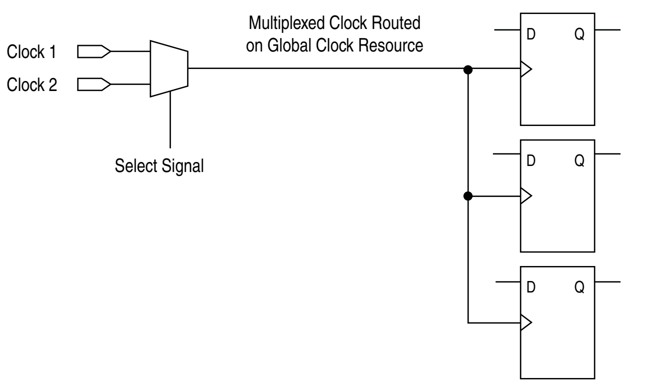
To simplify verification, Altera recommends avoiding ripple counters in your design. In the past, FPGA designers implemented ripple counters to divide clocks by a power of two because the counters are easy to design and may use fewer gates than their synchronous counterparts. Ripple counters use cascaded registers, in which the output pin of each register feeds the clock pin of the register in the next stage. This cascading can cause problems because the counter creates a ripple clock at each stage. These ripple clocks have to be handled properly during timing analysis, which can be difficult and may require you to make complicated timing assignments in your synthesis and place-and-route tools.

Ripple clock structures are often used to make ripple counters out of the smallest amount of logic possible. However, in all Altera devices supported by the Quartus II software, using a ripple clock structure to reduce the amount of logic used for a counter is unnecessary because the device allows you to construct a counter using one logic element per counter bit. Altera recommends that you avoid using ripple counters under any circumstances.

Multiplexed Clocks

Use clock multiplexing to operate the same logic function with different clock sources. In these designs, multiplexing selects a clock source, as in Figure 5–5. For example, telecommunications applications that deal with multiple frequency standards often use multiplexed clocks.

Figure 5–5. Multiplexing Logic and Clock Sources



Adding multiplexing logic to the clock signal can create the problems addressed in the previous sections, but requirements for multiplexed clocks vary widely, depending on the application. Clock multiplexing is acceptable when the clock signal uses global clock routing resources and if the following criteria are met:

- The clock multiplexing logic does not change after initial configuration
- The design uses multiplexing logic to select a clock for testing purposes
- Registers are always reset when the clock switches
- A temporarily incorrect response following clock switching has no negative consequences

If the design switches clocks in real time with no reset signal, and your design cannot tolerate a temporarily incorrect response, you must use a synchronous design so that there are no timing violations on the registers, no glitches on clock signals, and no race conditions or other logical problems. By default, the Quartus II software optimizes and analyzes all possible paths through the multiplexer and between both internal clocks that may come from the multiplexer. This may lead to more restrictive analysis than required if the multiplexer is always selecting one particular clock. If you do not require the more complete analysis, you can assign the output of the multiplexer as a base clock in the Quartus II software, so that all register-register paths are analyzed using that clock.

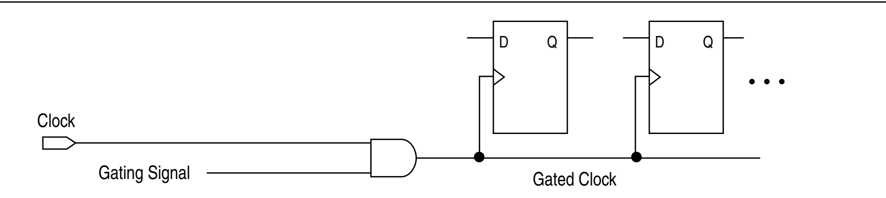
Altera recommends using dedicated hardware to perform clock multiplexing when it is available, instead of using multiplexing logic. For example, you can use the Clock Switchover feature or Clock Control Block available in certain Altera devices. These dedicated hardware blocks ensure that you use global low-skew routing lines and avoid any possible hold time problems on the device due to logic delay on the clock line.

Refer to the appropriate device data sheet or handbook for device-specific information about clocking structures.

Gated Clocks

Gated clocks turn a clock signal on and off using an enable signal that controls some sort of gating circuitry, as shown in Figure 5–6. When a clock is turned off, the corresponding clock domain is shut down and becomes functionally inactive.

Figure 5–6. Gated Clock



You can use gated clocks to reduce power consumption in some device architectures by effectively shutting down portions of a digital circuit when they are not in use. When a clock is gated, both the clock network and the registers driven by it stop toggling, thereby eliminating their contributions to power consumption. However, gated clocks are not part of a synchronous scheme and therefore can significantly increase the effort required for design implementation and verification. Gated clocks contribute to clock skew and make device migration difficult. These clocks are also sensitive to glitches, which can cause design failure.

Altera recommends that you use dedicated hardware to perform clock gating rather than using an AND or OR gate. For example, you can use the clock control block in newer Altera devices to shut down an entire clock network. Dedicated hardware blocks ensure that you use global routing with low skew and avoid any possible hold time problems on the device due to logic delay on the clock line.

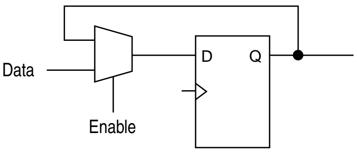
Refer to the appropriate device data sheet or handbook for device-specific information about clocking structures.

From a functional point of view, you can shut down a clock domain in a purely synchronous manner using a synchronous clock enable signal. However, when using a synchronous clock enable scheme, the clock network continues toggling. This practice does not reduce power consumption as much as gating the clock at the source does. In most cases, use a synchronous scheme such as those described in "Synchronous Clock Enables". For improved power reduction when gating clocks with logic, refer to "Recommended Clock-Gating Methods" on page 5–11.

Synchronous Clock Enables

To turn off a clock domain in a synchronous manner, use a synchronous clock enable signal. FPGAs efficiently support clock enable signals because there is a dedicated clock enable signal available on all device registers. This scheme does not reduce power consumption as much as gating the clock at the source because the clock network keeps toggling, but it performs the same function as a gated clock by disabling a set of registers. Insert a multiplexer in front of the data input of every register to either load new data or copy the output of the register (Figure 5–7).

Figure 5–7. Synchronous Clock Enable

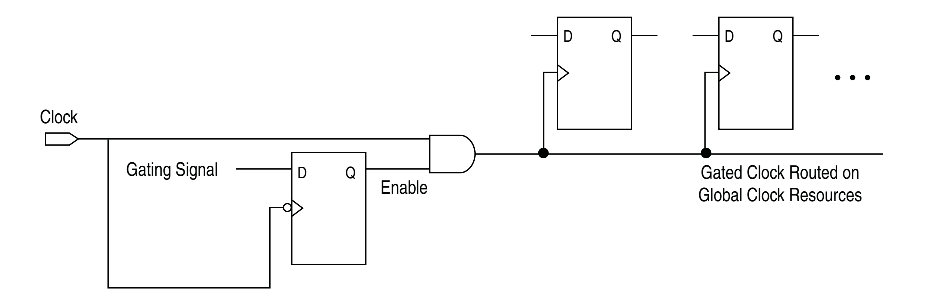


Recommended Clock-Gating Methods

Use gated clocks only when your target application requires power reduction and when gated clocks are able to provide the required reduction in your device architecture. If you must use clocks gated by logic, implement these clocks using the robust clock-gating technique shown in Figure 5–8 and ensure that the gated clock signal uses dedicated global clock routing.

You can gate a clock signal at the source of the clock network, at each register, or somewhere in between. Because the clock network contributes to switching power consumption, gate the clock at the source whenever possible, so you can shut down the entire clock network instead of gating it further along the clock network at the registers.

Figure 5–8. Recommended Clock-Gating Technique



In the technique shown in Figure 5–8, a register generates the enable signal to ensure that the signal is free of glitches and spikes. The register that generates the enable signal is triggered on the inactive edge of the clock to be gated (use the falling edge when gating a clock that is active on the rising edge, as shown in Figure 5–8). Using this technique, only one input of the gate that turns the clock on and off changes at a time. This prevents any glitches or spikes on the output. Use an AND gate to gate a clock that is active on the rising edge. For a clock that is active on the falling edge, use an OR gate to gate the clock and register the enable command with a positive edge-triggered register.

When using this technique, pay attention to the duty cycle of the clock and the delay through the logic that generates the enable signal because the enable command must be generated in one-half the clock cycle. This situation might cause problems if the logic that generates the enable command is particularly complex, or if the duty cycle of the clock is severely unbalanced. However, careful management of the duty cycle and logic delay may be an acceptable solution when compared with problems created by other methods of gating clocks.

Ensure that you apply a clock setting to the gated clock in the Quartus II software. As shown in Figure 5–8 on page 5–11, apply a clock setting to the output of the AND gate. Otherwise, the timing analyzer may analyze the circuit using the clock path through the register as the longest clock path and the path that skips the register as the shortest clock path, resulting in artificial clock skew.

In certain cases, converting the gated clocks to clock enables may help to reduce glitch and clock skew, and eventually produce a more accurate timing analysis. You can set the Quartus II software to automatically convert gated clocks to clock enables by turning on the **Auto Gated Clock Conversion** option. The conversion applies to two types of gated clocking schemes: single-gated clock and cascaded-gated clock. This option is only available for devices that are supported by the TimeQuest Timing Analyzer, except for Stratix® and Cyclone® devices.

For information about the settings and limitations of this option, refer to the "Auto Gated Clock Conversion" section of the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*.

Design Techniques to Save Power

The total FPGA power consumption is comprised of I/O power, core static power, and core dynamic power. Knowledge of the relationship between these components is fundamental in calculating the overall total power consumption. You can use various optimization techniques and tools to minimize power consumption when applied during FPGA design implementation. The Quartus II software offers power-driven compilation features to fully optimize device power consumption. Power-driven compilation focuses on reducing your design's total power consumption using power-driven synthesis and power-driven place-and-route.

For information about power-driven compilation flow and low-power design guidelines, refer to the *Power Optimization* chapter in volume 2 of the *Quartus II Handbook*.

For information about power optimization techniques available for Stratix III devices, refer to *AN 437: Power Optimization in Stratix III FPGAs*. For information about power optimization techniques available for Stratix IV devices, refer to *AN 514: Power Optimization in Stratix IV FPGAs*.

In addition, you can use the Quartus II PowerPlay Power Analyzer to aid you during the design process by delivering fast and accurate estimations of power consumption. For information about the PowerPlay Power Analyzer, refer to the *PowerPlay Power Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Checking Design Violations Using the Design Assistant

To improve the reliability, timing performance, and logic utilization of your design, practicing good design methodology and understanding how to avoid design rule violations are important. The Quartus II software provides a tool that automatically checks for design rule violations and reports their location.

The Design Assistant is a design rule checking tool that allows you to check for design issues early in the design flow. The Design Assistant checks your design for adherence to Altera-recommended design guidelines. You can specify which rules you want the Design Assistant to apply to your design. This is useful if you know that your design violates particular rules that are not critical, so you can allow these rule violations. The Design Assistant generates design violation reports with clear details about each violation, based on the settings you specified.

The first parts in this section provide an introduction to the Quartus II design flow with Design Assistant, message severity levels, and an explanation about how to set up the Design Assistant. The last parts of the section describe the design rules and the reports generated by the Design Assistant.

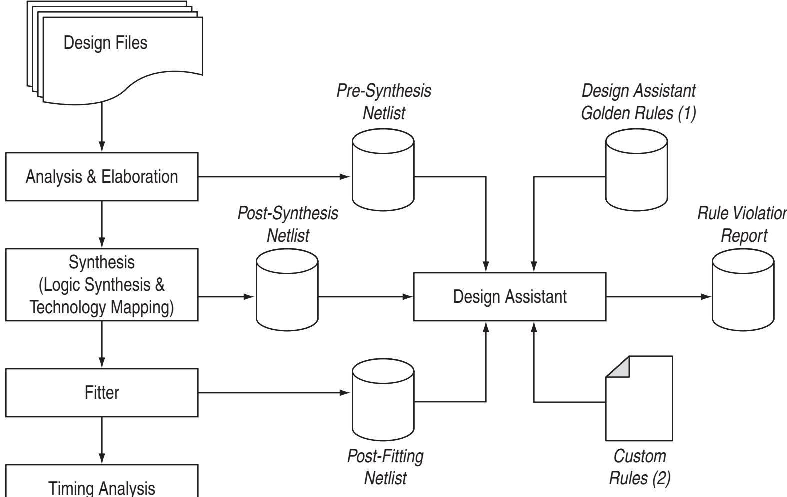
Quartus II Design Flow with the Design Assistant

You can run the Design Assistant after Analysis and Elaboration, Analysis and Synthesis, fitting, or a full compilation. To run the Design Assistant, on the Processing menu, point to **Start**, and click **Start Design Assistant**.

To set the Design Assistant to run automatically during compilation, on the Assignments menu, click **Settings**. In the **Category** list, select **Design Assistant**. Turn on **Run Design Assistant during compilation**. This enables the Design Assistant to perform a post-fitting netlist analysis of your design. The default is to apply all of the rules to your project. But if there are some rules that are unimportant to your design, you can turn off the rules that you do not want the Design Assistant to use. Refer to “The Design Assistant Settings Page” on page 5–15.

Figure 5–9 shows the Quartus II software design flow with the Design Assistant.

Figure 5–9. Quartus II Design Flow with the Design Assistant



Notes to Figure 5–9:

(1) Database of the default rules for the Design Assistant.

(2) A file that contains the **.xml** codes of the custom rules for the Design Assistant. For more details about how to create this file, refer to "Custom Rules" on page 5–35.

The Design Assistant analyzes your design netlist at different stages of the compilation flow and may yield different warnings or errors, even though the netlists are functionally the same. Your pre-synthesis, post-synthesis, and post-fitting netlists may be different due to optimizations performed by the Quartus II software. For example, a warning message in a pre-synthesis netlist may be removed after the netlist has been synthesized into a post-synthesis or post-fitting netlist.

- When you run the Design Assistant after running a full compilation or fitting, the Design Assistant performs a post-fitting analysis on the design.
- When you start the Design Assistant after performing Analysis and Synthesis, the Design Assistant performs post-synthesis analysis on the design.
- When you start the Design Assistant after performing Analysis and Elaboration, the Design Assistant performs a pre-synthesis analysis on the design. You can also perform pre-synthesis analysis with the Design Assistant using the command-line. You can use the `-rtl` option with the `quartus_drc` executable, as shown in the following example:

  quartus_drc <*project_name*> --rtl=on ↵

The Design Assistant generates warning messages when your design violates design rules and generates information messages to provide information regarding the rules. The Design Assistant supports all Altera devices supported by the Quartus II software.

The Design Assistant Settings Page

To apply design rules in the Design Assistant, follow these steps:

1. On the Assignments menu, click **Settings**.
2. In the **Settings** dialog box, in the **Category** list, select **Design Assistant**.
3. In the **Design Assistant** page, turn on the rules that you want the Design Assistant to apply during analysis. By default, all of the rules except the finite state machine rules are turned on.

To specify the file path to the custom rule file of the user-defined rules, refer to "Specifying the Path to the Custom Rules File" on page 5–37.

In the **Timing Closure** category, if **Nodes with more than specified number of fan-outs** or **Top nodes with highest fan-out** are turned on, you can use the **High Fan-Out Net Settings** dialog box to specify the number of fan-out a node must have to be reported by the Design Assistant. To open the **High Fan-Out Net Settings** dialog box, in the **Design Assistant** page, in the **Timing Closure** category, select **Nodes with more than specified number of fan-outs** or **Top nodes with highest fan-out**. Click **High Fan-Out Net Settings**.

In the **Clock** category, if you turn on **Clock signal should be a global signal**, you can use the **Global Clock Threshold Settings** dialog box to specify the number of nodes with the highest fan-out that you want the Design Assistant to report. To open the **Global Clock Threshold Settings** dialog box, on the **Design Assistant** page, in the **Clock** category, select **Clock signal should be a global signal**. Click **Global Clock Threshold Settings**.

To specify the maximum number of messages reported by the Design Assistant, on the **Design Assistant** page, click **Report Settings** and enter the maximum number of violation messages and detail messages to be reported.

Message Severity Levels

The Design Assistant classifies messages and rules using the four severity levels described in Table 5–1. Following Altera guidelines is very important for designs that are migrated to the HardCopy series of devices; therefore, the table highlights the impact of a rule violation on a HardCopy migration. Designs that adhere to Altera-recommended design guidelines do not produce any messages with critical-, high-, or medium-level severity.

Table 5–1. Design Assistant Message Severity Levels

Severity Level	Explanation
Critical	A violation of the rule critically affects the reliability of the design. Altera may not be able to implement the design successfully without closely reviewing the violations with the designer for HardCopy device conversions.
High	A violation of the rule affects the reliability of the design. Altera must review the violation before implementing the design for HardCopy device conversions.
Medium	The rule violation may result in implementation complexity that may have an impact for HardCopy device conversions.
Information Only	The rule provides information regarding the design.

Design Assistant Rules

This section describes the Design Assistant rules and details some of the reasons that Altera recommends following certain guidelines. Many of the Design Assistant rules enforce the design guidelines described in previous sections of this chapter.

Every rule is represented by a rule ID and has its own severity level. The rule ID is normally used in Tcl commands for rule suppression. The letter in each rule ID corresponds to the group of rules based on the following scheme:

- **A**—Asynchronous design structure rules
- **C**—Clock rules
- **R**—Reset rules
- **S**—Signal race rules
- **T**—Timing closure rules
- **D**—Asynchronous clock domain rules
- **H**—HardCopy rules
- **M**—Finite state machine rules

For example, the rule "Design Should Not Contain Combinational Loops" is the first rule in the asynchronous design structure rules; therefore, it is represented by rule ID A101.

Finite state machine rules are applicable only to register transfer level (RTL) check.

Summary of Rules and IDs

Table 5–2 lists the rules, their rule IDs, and their severity level.

Table 5–2. Summary of Rules and IDs (Part 1 of 2)

Rule ID	Rule Name	Severity Level
A101	Design Should Not Contain Combinational Loops	Critical
A102	Register Output Should Not Drive Its Own Control Signal Directly or through Combinational Logic	Critical
A103	Design Should Not Contain Delay Chains	High
A104	Design Should Not Contain Ripple Clock Structures	Medium
A105	Pulses Should Not Be Implemented Asynchronously	Critical
A106	Multiple Pulses Should Not Be Generated in the Design	Critical
A107	Design Should Not Contain SR Latches	High
A108	Design Should Not Contain Latches	High
A109	Combinational Logic Should Not Directly Drive Write Enable Signal of Asynchronous RAM	Medium
A110	Design Should Not Contain Asynchronous Memory	Medium
C101	Gated Clocks Should Be Implemented According to Altera Standard Scheme	Critical
C102	Logic Cell Should Not Be Used to Generate Inverted Clock	High
C103	Gated Clock Is Not Feeding At Least A Pre-Defined Number Of Clock Ports to Effectively Save Power: <n>	Medium
C104	Clock Signal Source Should Drive Only Input Clock Ports	Medium

Table 5–2. Summary of Rules and IDs (Part 2 of 2)

Rule ID	Rule Name	Severity Level
C105	Clock Signal Should Be a Global Signal	High
C106	Clock Signal Source Should Not Drive Registers that Are Triggered by Different Clock Edges	Medium
R101	Combinational Logic Used as a Reset Signal Should Be Synchronized	High
R102	External Reset Should Be Synchronized Using Two Cascaded Registers	Medium
R103	External Reset Should Be Synchronized Correctly	High
R104	Reset Signal Generated in One Clock Domain and Used in Other Asynchronous Clock Domains Should Be Synchronized Correctly	High
R105	Reset Signal Generated in One Clock Domain and Used in Other Asynchronous Clock Domains Should Be Synchronized	Medium
S101	Output Enable and Input of the Same Tri-State Nodes Should Not Be Driven by the Same Signal Source	High
S102	Synchronous Port and Asynchronous Port of the Same Register Should Not Be Driven by the Same Signal Source	High
S103	More Than One Asynchronous Signal Source of the Same Register Should Not Be Driven by the Same Source	High
S104	Clock Port and Any Other Signal Port of the Same Register Should Not Be Driven by the Same Signal Source	High
T101	Nodes with More Than Specified Number of Fan-outs: <n>	Information Only
T102	Top Nodes with Highest Fan-out: <n>	Information Only
D101	Data Bits Are Not Synchronized When Transferred between Asynchronous Clock Domains	High
D102	Multiple Data Bits Transferred Across Asynchronous Clock Domains Are Synchronized, But Not All Bits May Be Aligned in the Receiving Clock Domain	Medium
D103	Data Bits Are Not Correctly Synchronized When Transferred Between Asynchronous Clock Domains	High

H102	A PLL Drives Multiple Clock Network Types	Medium
M101	Data Bits Are Not Synchronized When Transferred to the State Machine of Asynchronous Clock Domains	High
M102	No Reset Signal Defined to Initialize the State Machine	Medium
M103	State Machine Should Not Contain Unreachable State	Medium
M104	State Machine Should Not Contain a Deadlock State	Medium
M105	State Machine Should Not Contain a Dead Transition	Medium

Design Should Not Contain Combinational Loops

Severity Level: Critical
Rule ID: A101

A combinational loop is created by establishing a direct feedback loop on combinational logic that is not synchronized by a register. A combinational loop also occurs when the output of a register is fed back to an asynchronous pin of the same register through combinational logic. Combinational loops are among the most common causes of instability and reliability in your designs and should be avoided whenever possible. Refer to "Combinational Loops" on page 5–4 for examples of the kinds of problems that combinational loops can cause.

Register Output Should Not Drive Its Own Control Signal Directly or through Combinational Logic

Severity Level: Critical
Rule ID: A102

A combinational loop occurs when you feed back the output of a register to an asynchronous pin of the same register (for example, the register's preset or asynchronous load signal), or the register drives combinational logic that drives one of the control signals on the same register. Combinational loops are among the most common causes of instability and reliability in your designs and should be avoided whenever possible. Refer to "Combinational Loops" on page 5–4 for examples of the kinds of problems that combinational loops can cause.

Design Should Not Contain Delay Chains

Severity Level: High
Rule ID: A103

Delay chains are created when one or more consecutive nodes with a single fan-in and a single fan-out are used to cause delay. Delay chains are sometimes used to create intentional delay to resolve race conditions. Delay chains may cause significant problems because they affect the rise and fall time differences in your design.

This rule applies only for delay chains implemented in logic cells and is limited to the clock and reset path of your design. This rule does not apply to delay chains in the data path. Altera recommends that you do not instantiate a cell that does not benefit the design and is used only to delay the signal. Refer to "Delay Chains" on page 5–5 for examples of the kinds of problems that delay chains can cause.

Design Should Not Contain Ripple Clock Structures

Severity Level: Medium
Rule ID: A104

Designs should not contain ripple clock structures. These structures use two or more cascaded registers in which the output of each register feeds the clock pin of the register in the next stage. Cascading structures cause large skew in the output signal because each stage of the structure causes a new clock domain to be defined. The additional clock domains from each stage of the ripple clock are difficult for static timing analysis tools to analyze. Refer to "Ripple Counters" on page 5–8 for examples of the kinds of problems that ripple clock structures can cause.

Pulses Should Not Be Implemented Asynchronously

Severity Level: Critical
Rule ID: A105

There are two common methods for pulse generation:

- Increasing the width of a glitch using a 2-input AND, NAND, OR, or NOR gate, where the source for the two gate inputs are the same, but one of the gate inputs is inverted
- Using a register where the register output drives the register's own asynchronous reset signal through a delay chain (refer to "Delay Chains" on page 5–5 for more details).

These techniques are purely asynchronous and therefore need to be avoided. Refer to "Pulse Generators and Multivibrators" on page 5–6 for recommended pulse generation guidelines.

Multiple Pulses Should Not Be Generated in the Design

Severity Level: Critical
Rule ID: A106

A common asynchronous multiple-pulse-generation technique consists of a combinational logic gate in which the inverted output feeds back to one of the inputs of the same gate. This feedback path causes a combinational loop that forces the output to change state and therefore, oscillate. Sometimes multiple pulse generators or multivibrator circuits are built out of a series of cascaded inverters in a structure called a "ring oscillator." Oscillation creates a new artificial clock in your design that is difficult for the Quartus II software to determine, set, or verify.

Structures that generate multiple pulses cause more problems than pulse generators because of the number of pulses involved. In addition, multiple pulse generators increase the frequency of the design. Refer to "Pulse Generators and Multivibrators" on page 5–6 for recommended pulse generation guidelines.

Design Should Not Contain SR Latches

Severity Level: High
Rule ID: A107

A latch is a combinational loop that holds the value of a signal until a new value is assigned. Combinational loops are hazardous to your design and are the most common causes of instability and unreliability. Refer to "Combinational Loops" on page 5–4 for examples of the kinds of problems that combinational loops can cause.

Rule A107 triggers only when your design contains SR latches. An SR latch can cause glitches and ambiguous timing, which complicates the timing analysis of your design. Refer to "Latches" on page 5–5 for details about latches and for more examples of the kinds of problems that latches can cause.

Design Should Not Contain Latches

Severity Level: High
Rule ID: A108

The Design Assistant generates warnings when it identifies one or more structures as latches.

Refer to "Latches" on page 5–5 for details about latches and for examples of the kinds of problems that latches can cause.

The difference between A107 ("Design Should Not Contain SR Latches") and A108 is that A107 triggers only when an SR latch is detected. A108 triggers when an unidentified latch exists in your design.

Combinational Logic Should Not Directly Drive Write Enable Signal of Asynchronous RAM

Severity Level: Medium
Rule ID: A109

Altera FPGA devices contain flexible embedded memory structures that can be configured into many different modes. One possible mode is asynchronous RAM. The definition of an asynchronous RAM circuit is one in which the write-enable signal driving into the RAM causes data to be written into it without a clock being required.

Do not use combinational logic to directly drive the write-enable signal of an asynchronous RAM. Any glitches that exist on the write-enable signal can cause the asynchronous RAM to be corrupted. Also, the data and write address ports of the RAM needs to be stable before the write pulse is asserted and must remain stable until the write pulse is de-asserted. Because of the limitations to using memory structures in this asynchronous mode, synchronous memories are always preferred. In addition, synchronous memories provide higher design performance.

As a guideline, a register should be used between combinational logic and asynchronous RAM or the asynchronous RAM should be replaced with synchronous memory. Refer to “Hazards of Asynchronous Design” on page 5–3 for examples of the kinds of problems asynchronous techniques can cause.

This rule applies only to device families that support asynchronous RAM.

Design Should Not Contain Asynchronous Memory

Severity Level: Medium
Rule ID: A110

Avoid using asynchronous memory (for example, asynchronous RAM) in your design because asynchronous memory can become corrupted by glitches created in the combinational logic that drives the write-enable signal of the memory. Asynchronous memory requires that the data and write address ports of the memory be stable before the write pulse is asserted and must remain stable until the write pulse is de-asserted. In addition, asynchronous memory has lower performance than synchronous memory.

As a guideline, a register should be used between combinational logic and asynchronous RAM or the asynchronous RAM should be replaced with synchronous memory. Immediately registering both input and output of the RAM improves performance and timing closure. Refer to “Hazards of Asynchronous Design” on page 5–3 for examples of the kinds of problems asynchronous techniques can cause.

This rule applies only to device families that support asynchronous RAM.

 © March 2009 Altera Corporation

Gated Clocks Should Be Implemented According to Altera Standard Scheme

Severity Level: Critical
Rule ID: C101

Clock gating is sometimes used to turn parts of a circuit on and off to reduce the total power consumption of a device. Clock gating is implemented using an enable signal that controls some sort of gating circuitry. The gated clock signal prevents any of the logic driven by it from switching so the logic does not consume any power. For example, when a clock is turned off, the corresponding clock domain is shut down and becomes functionally inactive. However, the disadvantage of using this type of circuit is that it can lead to unexpected glitches on the resultant gated clock signal if certain rules are not followed.

Refer to "Gated Clocks" on page 5–10 for examples of the kinds of problems gated clocks can cause. Refer to "Recommended Clock-Gating Methods" on page 5–11 for a recommended clock gating technique. However, when following the recommended clock gating techniques, your design must have a minimum number of fan-outs to meet rule C103, "Gated Clock Is Not Feeding At Least A Pre-Defined Number Of Clock Ports to Effectively Save Power: <n>."

Logic Cell Should Not Be Used to Generate Inverted Clock

Severity Level: High
Rule ID: C102

Your design may require both positive and negative edges of a clock to operate. However, do not implement an inverter to drive the clock input of a register in your design with a logic cell. Implementing the inverter with a logic cell can lead to clock insertion delay and skew, which is hazardous to your design and can cause problems with the timing closure of the design.

In addition, using a logic cell to implement an inverter is unnecessary. Use the programmable clock inversion featured in the register to generate the inverted clock signal. Refer to "Clocking Schemes" on page 5–7 for details about different types of clocking methods.

Gated Clock Is Not Feeding At Least A Pre-Defined Number Of Clock Ports to Effectively Save Power: <n>

Severity Level: Medium
Rule ID: C103

Your design can contain an input clock pin that fans out to more than one gated clock. However, to effectively reduce power consumption, Altera recommends that the gated clock feed at least a pre-defined number of clock ports (*n* ports). The default value for *n* is 30. You can set the number of clock ports (*n*) by performing the following steps:

1. Click **Settings** on the Assignments menu.
2. In the **Category** list, select **Design Assistant**.
3. On the **Design Assistant** page, expand the **Clock** category and turn on **Gated clock is not feeding at least a pre-defined number of clock port to effectively save power: <n>**.

4. Click on the **Gated Clock Settings** button, and in the **Gated Clock Settings** dialog box, set the number of clock ports a gated clock should feed.

Refer to "Clocking Schemes" on page 5–7, and "Recommended Clock-Gating Methods" on page 5–11 for proper clock-gating techniques.

Clock Signal Source Should Drive Only Input Clock Ports

Severity Level: Medium
Rule ID: C104

Clock signal sources in a design should drive only input clock ports of registers. Rule C104 triggers when a design contains a clock signal source of a register that connects to the port rather than the clock port of another register. Note that if the clock signal source and ports are of the same register, rule S104 "Clock Port and Any Other Signal Port of the Same Register Should Not Be Driven by the Same Signal Source" is triggered instead. Such a design is considered asynchronous and should be avoided. Asynchronous design structures can be hazardous to your design because some of them rely on the relative propagation delays of signals to function correctly, which can result in incomplete timing constraints and possible glitches and spikes.

Refer to "Hazards of Asynchronous Design" on page 5–3 for examples of the kinds of problems that asynchronous design structures can cause. Also refer to "Clocking Schemes" on page 5–7 for proper clocking techniques.

This rule does not apply in the following conditions:

- When the clock signal source drives combinational logic that is used as a clock signal and the combinational logic is implemented according to the Altera standard scheme
- When the clock signal source drives only a clock multiplexer that selects one clock source from a number of different clock sources

  This type of multiplexer adds complexity to the timing analysis of a design. Avoid using the multiplexer in the design.

- Using a clock multiplexer causes the "Gated Clocks Should Be Implemented According to Altera Standard Scheme" rule (C101) to be applied; refer to "Multiplexed Clocks" on page 5–9 for recommended clock multiplexing techniques

Clock Signal Should Be a Global Signal

Severity Level: High
Rule ID: C105

Ensure that all clock signals in your design use the global clock networks that exist in the target FPGA. Mapping clock signals to use non-dedicated clock networks can negatively affect the performance of your design. A non-global signal can be slower and have larger skew than a global signal because the clock must be distributed using regular FPGA routing resources.

To specify the number of minimum fan-outs that you want the Design Assistant to report, on the **Design Assistant** page, in the **Clock** category, select **Clock signal should be a global signal**. Click **Global Clock Threshold Settings** and enter the number in the dialog box.

If a design contains more clock signals than are available in the target device, consider reducing the number of clock signals in the design, such that only dedicated clock resources are used for clock distribution. However, if the design must use more clock signals than you can specify as global signals, implement the clock signals with the lowest fan-out using regular routing resources. Also, implement the fastest clock signals as global signals. Refer to “Clock Network Resources” on page 5–42 for detailed information about clock resources.

Clock Signal Source Should Not Drive Registers that Are Triggered by Different Clock Edges

Severity Level: Medium
Rule ID: C106

This rule triggers an error message if your design contains a clock signal source that drives the clock inputs of both positive and negative edge-sensitive registers. This error also triggers if your design contains an inverted clock signal that drives the clock inputs of either positive or negative edge-sensitive registers.

These two scenarios can cause an increase in timing requirement complexity and difficulties in design optimization. Also, synchronous resetting may not be possible because registers are not clocked on the same edge in the design. Refer to “Clocking Schemes” on page 5–7 for some specific examples and recommended clocking methods.

Combinational Logic Used as a Reset Signal Should Be Synchronized

Severity Level: High
Rule ID: R101

All combinational logic used to drive reset signals in your design needs to be synchronized. This means that a register is required between the combinational logic that drives the reset signal and input reset pin. Unsynchronized combinational logic can cause glitches and spikes that lead to unintentional reset signals. Synchronizing the combinational logic that drives the reset signal delays the resulting reset signal by an extra clock cycle and avoids unintentional reset. You must consider the extra clock cycle delay when using this method in your design.

Rule R101 does not trigger if the combinational logic used is either a 2-input AND or NOR that feeds active low reset port, or either a 2-input OR or NAND that feeds active high reset port.

External Reset Should Be Synchronized Using Two Cascaded Registers

Severity Level: Medium
Rule ID: R102

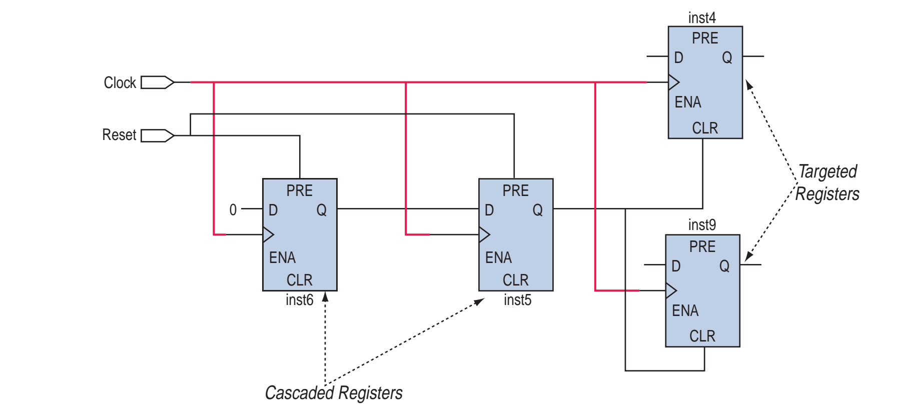
The only way to put your design into a reset state in the absence of a clock signal is to use an asynchronous reset or external reset. However, an asynchronous reset can affect the recovery time of a register, cause design stability problems, and unintentionally reset the state machines in your design to incorrect states.

As a guideline, you can synchronize an external reset signal by using a double-buffer circuit, which consists of two cascaded registers triggered on the same clock edge and on the same clock domain as the targeted registers.

This rule does not apply in the following two conditions:

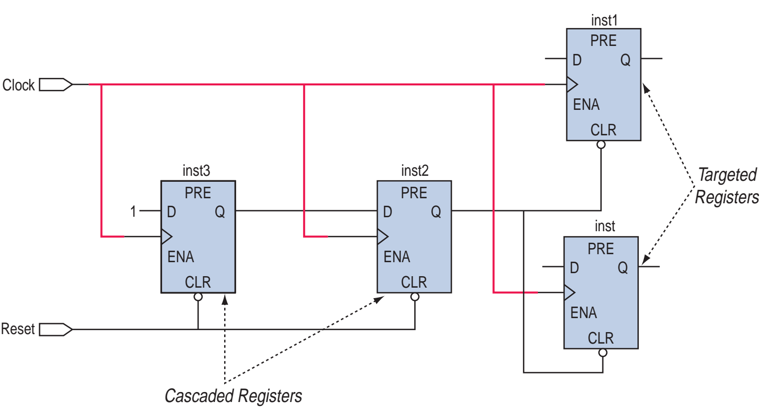
- When the targeted registers use active-high reset ports and the external reset signal drives the PRE ports on the cascaded registers with the input port of the first cascaded registers is fed to GND. Refer to Figure 5–10.

Figure 5–10. Active-High Reset Ports



- When the targeted registers use active-low reset ports and the external reset signal drives the CLR ports on the cascaded registers with the input port of the first cascaded registers is fed to V_{CC}. Refer to Figure 5–11.

Figure 5–11. Active-Low Reset Ports



External Reset Should Be Synchronized Correctly

Severity Level: High
Rule ID: R103

The only way to put your design into a reset state in the absence of a clock signal is to use an asynchronous reset or external reset. However, asynchronous reset can affect the recovery time of a register, cause design stability problems, and unintentionally reset the state machines in your design to incorrect states.

As a guideline, you can synchronize an external reset signal by using two cascaded registers. The registers need to be triggered on the same clock edge and should be in the same clock domain as the targeted registers.

This rule applies when an asynchronous reset or external reset signal is synchronized but fails to follow the recommended guidelines, as described in rule R102 ("External Reset Should Be Synchronized Using Two Cascaded Registers"). This violation happens when the external reset is synchronized with only one register or the cascaded synchronization registers are triggered on different clock edges.

R102 triggers when you don't use two cascaded registers to synchronize the external reset. R103 triggers when the external reset is synchronized but fails to follow the recommended guidelines.

Reset Signal Generated in One Clock Domain and Used in Other Asynchronous Clock Domains Should Be Synchronized Correctly

Severity Level: High
Rule ID: R104

If your design uses an internally generated reset signal generated in one clock domain and used in one or more other asynchronous clock domains, the reset signal needs to be synchronized. An unsynchronized reset signal can cause metastability issues. To synchronize reset signals across clock domains, use the following guidelines:

- The reset signal needs to be synchronized with two or more cascading registers in the receiving asynchronous clock domain.
- The cascading registers needs to be triggered on the same clock edge.
- There must be no logic between the output of the transmitting clock domain and the cascaded registers in the receiving asynchronous clock domain. The synchronization registers may sample unintended data due to the glitches caused by the logic.

This rule applies when the internal reset signal is synchronized but fails to follow the recommended guidelines. This happens when the external reset is only synchronized with one register, when the cascaded synchronization registers are triggered on different clock edges, or when there is logic between the output of the transmitting clock domain and the cascaded registers in the receiving asynchronous clock domain. Synchronizing the reset signal delays the signal by an extra clock cycle. Consider this delay when using the reset signal in a design.

Reset Signal Generated in One Clock Domain and Used in Other Asynchronous Clock Domains Should Be Synchronized

Severity Level: Medium
Rule ID: R105

If your design uses an internally generated reset signal that is generated in one clock domain and used in one or more other asynchronous clock domain, the reset signal needs to be synchronized. An unsynchronized reset signal can cause metastability issues. To synchronize reset signals across clock domains, follow the guidelines described in Rule R104 ("Reset Signal Generated in One Clock Domain and Used in Other Asynchronous Clock Domains Should Be Synchronized Correctly").

This rule applies when the internally generated reset signal is not being synchronized.

Output Enable and Input of the Same Tri-State Nodes Should Not Be Driven by the Same Signal Source

Severity Level: High
Rule ID: S101

This rule applies when your design contains a tri-state node in which the input and output enable are driven by the same signal source. Signal race occurs between the input and output enable signals of the tri-state when they are propagated simultaneously. Race conditions lead to incorrect design function and unpredictable results. To avoid violation of this rule, the input and output enable of the tri-state should be driven by separate signal sources.

Synchronous Port and Asynchronous Port of the Same Register Should Not Be Driven by the Same Signal Source

Severity Level: High
Rule ID: S102

A purely synchronous design is free of signal race conditions as long as the clock signal is properly distributed and the timing requirements of the registers are met. However, race conditions can occur typically when the synchronous and asynchronous input pins of the register are driven by the same signal source. Race conditions can cause incorrect design function and unpredictable results. Rule S102 triggers when the synchronous and asynchronous pins of a register are driven by the same signal source. Rule S102 does not trigger if the signal source is from a negative-edge sensitive register of the same clock and if the source register is directly feeding the reset port, provided there is no combinational logic in-between the signal and register.

More Than One Asynchronous Signal Source of the Same Register Should Not Be Driven by the Same Source

Severity Level: High
Rule ID: S103

To avoid race conditions in your design, Altera recommends that you avoid using the same signal source to drive more than one port on a register. The following ports are affected: `ALOAD`, `ADATA`, `Preset`, and `Clear`.

Clock Port and Any Other Signal Port of the Same Register Should Not Be Driven by the Same Signal Source

Severity Level: High
Rule ID: S104

Any clock signal source in your design needs to drive only input clock ports of registers. Rule S104 triggers only when your design contains clock signal sources that connect to ports other than the clock ports of the same register. Rule S104 is a subset of C104, "Clock Signal Source Should Drive Only Input Clock Ports" on page 5–22. Such a design is considered asynchronous and should be avoided.

Refer to "Hazards of Asynchronous Design" for examples of the kinds of problems that asynchronous design structures can cause. Refer to "Clocking Schemes" for proper clocking techniques.

 © March 2009 Altera Corporation

Nodes with More Than Specified Number of Fan-outs: <n>

Severity Level: Information Only
Rule ID: T101

This rule reports nodes that have more than a specified number of fan-outs, which can create timing challenges for your design.

To specify the number of fan-outs, follow these steps:

1. On the Assignments menu, click **Settings**.
2. In the **Category** list, select **Design Assistant**.
3. On the **Design Assistant** page, expand the **Timing closure** category by clicking the ⊞ icon next to **Timing closure**.
4. Turn on **Nodes with more than specified number of fan-outs**.
5. Click **High Fan-Out Net Settings**. In the **High Fan-Out Net Settings** dialog box, enter the number of fan-outs a node must have to be reported by the Design Assistant.

Top Nodes with Highest Fan-out: <n>

Severity Level: Information Only
Rule ID: T102

This rule reports the specified number of nodes with the highest fan-out, which can create timing challenges for your design.

To specify the number of fan-outs, follow these steps:

1. On the Assignments menu, click **Settings**.
2. In the **Category** list, select **Design Assistant**.
3. On the **Design Assistant** page, click the ⊞ icon next to **Timing closure** to expand the folder.
4. Select **Nodes with more than specified number of fan-outs**.
5. Click **High Fan-Out Net Settings**.
6. In the **High Fan-Out Net Settings** dialog box, enter the number of nodes with the highest fan-out to be reported by the Design Assistant.

Data Bits Are Not Synchronized When Transferred between Asynchronous Clock Domains

Severity Level: High
Rule ID: D101

The data bits transferred between asynchronous clock domains in a design need to be synchronized to avoid metastability problems.

If the data bits belong to single-bit data, each data bit needs to be synchronized with two cascading registers in the receiving asynchronous clock domain, in which the cascaded registers are triggered on the same clock edge. Do not put any logic between the output of the transmitting clock domain and the cascaded registers in the receiving asynchronous clock domain.

If the data bits belong to multiple-bit data, use a handshake protocol to guarantee that all bits of the data bus are stable when the receiving clock domain samples the data. If you use a handshake protocol, only the data bits that act as `REQ` (request) and `ACK` (acknowledge) signals must be synchronized. The data bits that belong to multiple-bit data do not need to be synchronized. Ignore the violation on the data bits that use a handshake protocol.

Multiple Data Bits Transferred Across Asynchronous Clock Domains Are Synchronized, But Not All Bits May Be Aligned in the Receiving Clock Domain

Severity Level: Medium
Rule ID: D102

This rule applies when data bits from a multiple-bit data that are transferred between asynchronous clock domains are synchronized. However, not all data bits may be aligned in the receiving clock domain. Propagation delays may cause skew when the data reaches the receiving clock domain.

If the data bits belong to multiple-bit data and you use a handshake protocol, only the data bits that act as `REQ`, `ACK`, or both signals for the transfer need to be synchronized with two or more cascading registers in the receiving asynchronous clock domain.

If all of the data bits belong to single-bit data, the synchronization of the data bits does not cause problems in the design.

Data Bits Are Not Correctly Synchronized When Transferred Between Asynchronous Clock Domains

Severity Level: High
Rule ID: D103

The data bits that are transferred between asynchronous clock domains in a design need to be synchronized to avoid metastability problems.

If the data bits belong to single-bit data, each data bit needs to be synchronized with two cascading registers in the receiving asynchronous clock domain. In this case, the cascaded registers are triggered on the same clock edge. Do not put any logic between the output of the transmitting clock domain and the cascaded registers in the receiving asynchronous clock domain.

This rule only applies when the data bits across asynchronous clock domains are synchronized but fail to follow the guidelines.

Only One VREF Pin Should Be Assigned to HardCopy Test Pin in an I/O Bank

Severity Level: Medium
Rule ID: H101

If your design targets a HardCopy APEX™ 20K device, do not assign more than one VREF pin to a HardCopy test pin in an I/O bank in that targeted device. The assignment of more than one VREF pin to a HardCopy test pin can cause contention of the VREF bus.

You can find the list of HardCopy test pins that are in each of a HardCopy APEX 20K device’s I/O banks in the Messages window, the Design Assistant Messages report, and the Design Assistant HardCopy Test Pins report. Use this information to ensure that only one VREF pin is assigned to a HardCopy test pin.

However, the Fitter may have assigned the VREF pins to the HardCopy test pins during compilation. To prevent the Fitter from making these assignments during the next compilation, create and assign VREF pins manually instead of allowing the Fitter to do so automatically.

This rule applies only to designs that target HardCopy APEX 20K devices.

A PLL Drives Multiple Clock Network Types

Severity Level: Medium
Rule ID: H102

A PLL can compensate only one of the clock network types; therefore, the other non-compensated clock network types have a non-zero delay. However, the non-zero delay for the non-compensated clock network types can change between a Stratix device and its corresponding HardCopy Stratix device, or a Stratix II device and its corresponding HardCopy II device.

Therefore, if a Stratix FPGA design relies on the relative offset between the compensated clock network type and the non-compensated clock network types driven by a PLL, an error can occur in the corresponding HardCopy Stratix design because the relative offset in the HardCopy Stratix design may differ from the relative offset in the original Stratix FPGA design.

This rule reports only nodes in a design where a PLL drives multiple clock network types.

Data Bits Are Not Synchronized When Transferred to the State Machine of Asynchronous Clock Domains

Severity Level: High
Rule ID: M101

Data bits that are transferred between asynchronous clock domains in your design need to be synchronized to avoid metastability problems. Rule M101 is a state-machine-specific rule that triggers when input signals of a state machine across asynchronous clock domains are not synchronized or improperly synchronized. Rule M101 applies to state machines only, while the “Data Bits Are Not Synchronized When Transferred between Asynchronous Clock Domains” rule (D101) and the “Data Bits Are Not Correctly Synchronized When Transferred Between Asynchronous Clock Domains” rule (D103) apply only to data synchronization between registers.

No Reset Signal Defined to Initialize the State Machine

Severity Level: Medium
Rule ID: M102

A finite state machine (FSM) needs to have a reset signal that initializes the state machine to its initial state. A finite state machine without a proper initialization state is susceptible to functional problems and can introduce extra difficulty in analysis, verification, and maintenance.

State Machine Should Not Contain Unreachable State

Severity Level: Medium
Rule ID: M103

An unreachable state is a state that can never be reached from the initial state. Having an unreachable state in your design causes logic redundancy and affects your design functionality. Rule M103 triggers when the initial state cannot traverse to a state through any of the reachable states and transitions.

State Machine Should Not Contain a Deadlock State

Severity Level: Medium
Rule ID: M104

A deadlock state is a state that does not have any transitions to another state except to loop to itself. When the state machine enters a deadlock state, it stays in that state until the state machine is reset. Your design may have a single state, or a few states forming a deadlock structure. Having a deadlock state in your design leads to design functionality problems, and theoretically may consume more power.

You can change the maximum number of states to be detected as a deadlock structure by clicking **Settings** on the Assignments menu, and in the **Settings** dialog box, in the **Category** list, select **Design Assistant**. In the **Design Assistant** page, click **Finite State Machine Deadlock Settings**. In the **Finite State Machine Deadlock Settings** dialog box, specify the maximum number of states to be reported as a deadlock structure. The default setting is `2`.

State Machine Should Not Contain a Dead Transition

Severity Level: Medium
Rule ID: M105

A dead transition is a redundant transition that never occurs regardless of the event sequence input to the state machine. A dead transition indicates logic redundancy in your design, although it may not affect your design functionality. Rule M105 triggers when the condition required to trigger a transition is not possible.

Enabling and Disabling Design Assistant Rules

You can selectively enable or disable Design Assistant rules on individual nodes by making an assignment in the Assignment Editor or by using the `altera_attribute` synthesis attribute in Verilog HDL or VHDL, or using a Tcl command.

For a list of the types of nodes that allow Design Assistant rule suppression, refer to *Node Types Eligible for Rule Suppression* in the Quartus II Help.

Assignments made with Assignment Editor, the Quartus Settings File (**.qsf**), and Tcl scripts and commands, take precedence over assignments made with the `altera_attribute` synthesis attribute. Assignments made to nodes, entities, or instances, take precedence over global assignments.

Using the Assignment Editor

You can enable or disable a Design Assistant rule on selected nodes in your design by using the Assignments Editor. You must first compile your design if you have not already done so.

 © March 2009 Altera Corporation

To enable or disable a Design Assistant rule, follow these steps:

1. On the Assignments menu, click **Assignment Editor**.
2. In the spreadsheet, for the desired node, entity, or instance, double-click the cell in the **Assignment Name** column and select **Enable Design Assistant Rule** or **Disable Design Assistant Rule** in the pull-down menu.
3. Double-click the **Value** cell and type in the Rule ID.

   or

   Click **Browse** to open the **Design Assistant Rules** dialog box. In the **Design Assistant Rules** dialog box, select the rule you want to enable or disable for that particular node.

You can enable or disable multiple rules by typing more than one Rule ID in the cell and separating each Rule ID with a comma.

Using Verilog HDL

You can use the `altera_attributes` synthesis attribute in your Verilog HDL code to enable or disable a Design Assistant rule on the selected nodes in your design.

To enable the rule on the selected node, the syntax is shown in the following example:

```
<entity class> <object> /* synthesis altera_attribute="enable_da_rule=<ruleID>" */
```

You can enable more than one rule on a selected node as shown in the following example:

```
<entity class> <object> /* synthesis altera_attribute="enable_da_rule=\"<ruleID>,
<ruleID>, <ruleID>\""*/
```

To disable the rule on the selected node, the syntax is shown in the following example:

```
<entity class> <object> /* synthesis altera_attribute="disable_da_rule=<ruleID>" */
```

You can disable more than one rule on a selected node as shown in the following example:

```
<entity class> <object> /* synthesis altera_attribute="disable_da_rule=\"<ruleID>,
<ruleID>, <ruleID>\""*/
```

When enabling or disabling multiple rules in Verilog HDL, you must separate the Rule ID strings with commas and spaces only and they must be enclosed within the `\"` and `\"` characters.

Using VHDL

You can use the `altera_attributes` synthesis attribute in your VHDL code to enable or disable a Design Assistant rule on the selected nodes in your design.

To enable the rule on the selected node, use the following syntax:

```
attribute altera_attribute : string;attribute altera_attribute of <object>: <entity
class> is "enable_da_rule=<ruleID>"
```

You can enable more than one rule on a selected node as shown in the following example:

```
attribute altera_attribute : string;attribute altera_attribute of <object>: <entity
class> is "enable_da_rule=""<ruleID>, <ruleID>, <ruleID>"""
```

To disable the rule on the selected node, use the following syntax:

```
attribute altera_attribute : string;attribute altera_attribute of <object>: <entity
class> is "disable_da_rule=<ruleID>"
```

You can disable more than one rule on a selected node as shown in the following example:

```
attribute altera_attribute : string;attribute altera_attribute of <object>: <entity
class> is "disable_da_rule=""<ruleID>, <ruleID>, <ruleID>"""
```

When enabling or disabling multiple rules in VHDL, you must separate the Rule ID strings with commas and spaces only and they must be enclosed with double quotation mark (" ") characters.

Using TCL Commands

To enable a Design Assistant rule on the selected node in your design using Tcl in a script or at a Tcl prompt, use the following Tcl command:

```
set_instance_assignment -name enable_da_rule "<rule ID>" -to <design element> ↵
```

To enable more than one rule on a selected node, use the following Tcl command:

```
set_instance_assignment -name enable_da_rule "<rule ID>, <rule ID>"
-to <design element> ↵
```

To disable a Design Assistant rule on a selected node in your design using Tcl in a script, or at a command or Tcl prompt, use the following Tcl command:

```
set_instance_assignment -name disable_da_rule "<rule ID>" -to <design element> ↵
```

To disable more than one rule on a selected node, use the following Tcl command:

```
set_instance_assignment -name disable_da_rule "<rule ID>, <rule ID>"
-to <design element> ↵
```

Viewing Design Assistant Results

If your design violates a design rule, the Design Assistant generates warning messages and information messages about the violated design rule. The Design Assistant displays these messages in the Messages window, in the Design Assistant Messages report, and in the Design Assistant report files. You can find the Design Assistant report files called *<project_name>*.**drc.rpt** in the *<project_name>* subdirectory of the project directory.

The Design Assistant generates the following reports based on the settings specified in the Design Assistant page:

- Summary Report
- Settings Report
- Detailed Results Report
- Messages Report
- HardCopy Test Pins Report
- Rule Suppression Assignments Report

- Ignored Design Assistant Assignments Report
- Custom Rules Report

Summary Report

The Design Assistant Summary report contains a summary of the Design Assistant process on a particular project. The Design Assistant Summary report provides the following information:

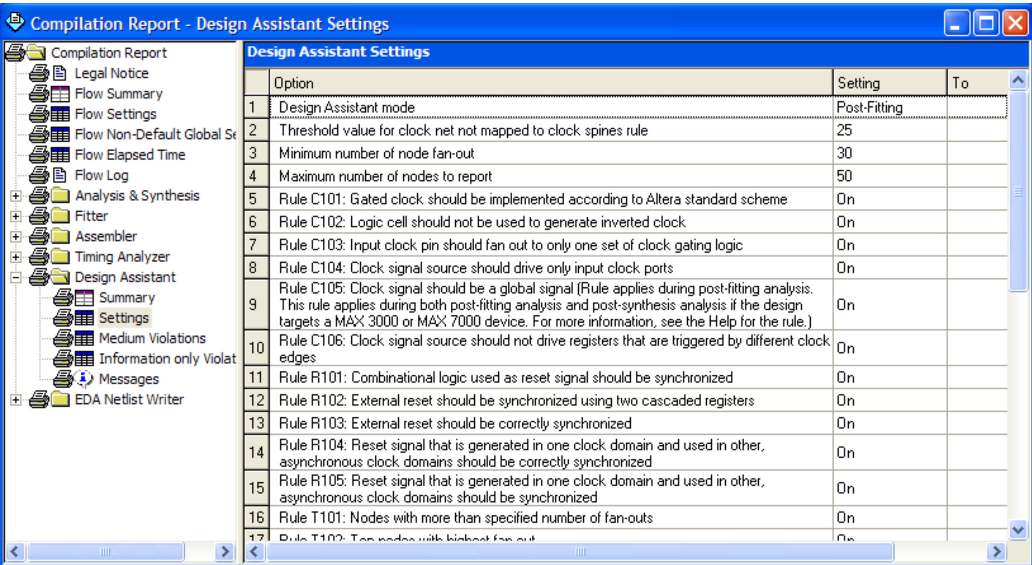
- **Design Assistant Status—**the status, end date, and end time of the Design Assistant operation
- **Revision Name—**the revision name specified in the **Revisions** dialog box
- **Top-level Entity Name—**the top-level entity of your design
- **Family—**the device family name specified in the **Device** page of the **Settings** dialog box
- **Total Critical Violations**, **Total High Violations**, **Total Medium Violations**, and **Total Information Only Violations—**the total violations of the rules organized by level, some of which might affect the reliability of the design

Review the violations closely before converting your design for HardCopy devices to achieve a successful conversion.

Settings Report

The Design Assistant Settings report contains a list of enabled Design Assistant rules and options that you specified in the **Design Assistant Settings** page, as shown in Figure 5–12.

Figure 5–12. The Design Assistant Settings Report

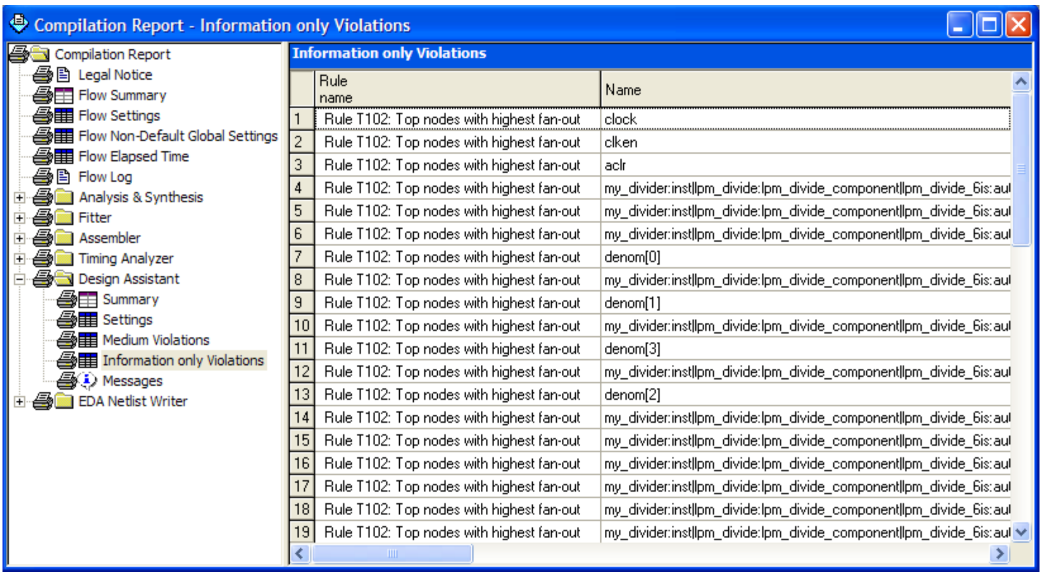


Detailed Results Report

The Detailed Results report contains detailed information of every rule violation including the rule name, node name, and fan-out. This report appears only if you specify settings in the **Design Assistant Settings** page. For more information about how to specify the settings, refer to “The Design Assistant Settings Page” on page 5–15.

Separate Detailed Results reports are generated for critical, high, medium, and information only results. Figure 5–13 shows the **Information Only Violations** report.

Figure 5–13. The Design Detailed Results Report, Information Only



Messages Report

The Messages report contains current information, warning, and error messages generated during the Design Assistant process. You can right-click a message in the Messages report and click **Help** to display the Quartus II software Help with details about the selected message, or click **Locate** to trace or cross-probe the selected node and locate the source of the violation.

HardCopy Test Pins Report

The HardCopy Test Pins report appears only if you turn on **Run Design Assistant during compilation** in the **Design Assistant** page and if your design violates the “Only One VREF Pin Should Be Assigned to HardCopy Test Pin in an I/O Bank” rule (H101). The report lists all the HardCopy design rule violations and all of the test pins in the HardCopy device.

Rule Suppression Assignments Report

The Rule Suppression Assignments report contains detailed information about which Design Assistant rules are enabled or disabled, as explained in the “Enabling and Disabling Design Assistant Rules” on page 5–30. The report shows the following information:

- **Assignment**—shows the name of the assignment

- **Value**—identifies the rule
- **To**—shows the name of the node where the rule is being applied

Ignored Design Assistant Assignments Report

The Ignored Design Assistant Assignments report lists detailed information about the invalid and conflicting rule assignments reported by the Design Assistant. This report is generated only if you specify an invalid rule ID in the rule suppression or a conflicting rule assignment. The following information appears in the report:

- **Assignment**—shows the name of the assignment
- **Value**—identifies the rule
- **To**—shows the name of the node where the rule is being applied
- **Comment**—shows why the assignment is being ignored

Custom Rules Report

The Design Assistant Custom Rules report contains the names of the custom rules used in the design checking, the path to the custom rules files from which the custom rules are read, and the list of ignored custom rules.

Custom Rules

In addition to the existing design rules that the Design Assistant offers, you can also create your own rules and specify your own reporting format in a text file (with any file extension) using the XML format. You then specify the path to that file in the Design Assistant settings page and run the Design Assistant for violations checking.

The file that contains the default rules for the Design Assistant is located at <*Quartus II install path*>**\quartus\libraries\design-assistant\da_golden_rule.xml**.

For details about how to set the file path to your custom rules, refer to "Specifying the Path to the Custom Rules File" on page 5–37.

This section explains the basics of writing a custom rule, the Design Assistant settings, and provides coding examples on how to check for clock relationship and node relationship in a design.

XML File Format for Custom Rules

All XML commands in custom rules file must be written within the `<ROOT>` and `</ROOT>` tags. Every user-defined rule consists of three main sections:

- Rule Attribute
- Rule Definition
- Reporting

The Rule Definition and Reporting sections must be defined inside the Rule Attribute section. Example 5–1 shows all three sections in a pre-defined custom rule file.

XML commands and attributes are case sensitive. However, attribute values are *not* case sensitive.

Example 5–1. Predefined XML File Format for a Custom Rule

```
<ROOT>
<!-Start creating a rule here -->

<!--Define rule attribute for a rule here -->
<DA_RULE ID=<rule id> NAME=<rule name> SEVERITY=<rule severity> DEFAULT_RUN=<default run> >

<RULE_DEFINITION>
      <!--Define rule definition here -->
   </RULE_DEFINITION>

   <REPORTING>
      <!--Define report settings here -->
   </REPORTING>

</DA_RULE>

</ROOT>
```

The Rule Attribute section contains the name, ID, severity level, and enable value of a rule. The order of these attributes is not important. This section is enclosed within `<DA_RULE>` and `</DA_RULE>` tags. Table 5–3 describes the attributes of the Rule Attribute section.

Table 5–3. Attributes for the Rule Attribute Section

Attribute	Description
ID	The value for this attribute is string type and must be unique. This attribute is required. For the list of IDs of the default rules, refer to Table 5–2 on page 5–16.
NAME	The value for this attribute is string type. This attribute is optional.
SEVERITY	This attribute presents the severity level of the rule. The value is string type and can be `CRITICAL`, `HIGH`, `MEDIUM`, or `INFORMATION`. This attribute is required. For details about rule severity level, refer to "Message Severity Levels" on page 5–15.
DEFAULT_RUN	The value is string type and can only be `YES`, or `NO`. If the value is `YES`, the rule is included in the design rule check, and vice versa. By default, the value is `YES`. This attribute is optional.

All string-type values must be enclosed within double quotes.

Command lines that begin with a single XML tag must end with the "`/>`" sign before another command begins.

The Rule Definition section is where you declare the node properties and rule triggering conditions, enclosed by `<RULE_DEFINITION>` and `</RULE_DEFINITION>` tags.

There are four subsections within the Rule Definition section that you can use to declare the properties and conditions:

- `<DECLARE>`—Global nodes that are used in the file are declared in this subsection. Every node name must be unique.

A node declared outside of the `<DECLARE>` subsection is considered a local node. You can perform local node declaration at any place in the `<BASIC>`, `<REQUIRED>`, and `<FORBID>` subsections, and can be performed using the node declaration command directly without being enclosed within the `<DECLARE>` tag.

- `<BASIC>`—This subsection contains the condition that acts like a trigger point which the Design Assistant continuously checks for a match. If the condition is fulfilled, the Design Assistant checks the remaining conditions in the `<REQUIRED>` and `<FORBID>` subsections.
- `<REQUIRED>`—This subsection contains the acceptable conditions that your design must meet. If the condition is not fulfilled, the Design Assistant reports a rule violation.
- `<FORBID>`—This subsection contains the undesirable condition for a design. If the condition is fulfilled, the Design Assistant highlights a rule violation. This subsection may be optional, depending on your rule situation.

The Reporting section is where you describe the settings for rule violation reporting, enclosed by `<REPORTING>` and `</REPORTING>` tags. This section is optional. If there is no Reporting section defined, the violated rule is not reported. If the Reporting section is defined, the Design Assistant reports the name of the violated rule and the nodes that violated the rule according to the reporting format that you defined.

Specifying the Path to the Custom Rules File

To specify the path to the custom rule file, follow these steps:

1. To specify the path, on the Assignments menu, click **Settings**.
2. In the Category list, click **Design Assistant** and select **Custom Rules Settings**.
3. In the **Custom Rules Settings** dialog box, in the **Project custom rules file name** field, specify the path to your custom rules file.
4. Click **OK**.

Your rules are now included in the list of default Design Assistant rules.

The default file extension for a Design Assistant custom rules file is **.dacr**, but the file can have any file name or extension.

To specify the rules that you want the Design Assistant to check for violations, refer to “The Design Assistant Settings Page” on page 5–15.

Custom Rules Coding Examples

The following examples of custom rules show how to check node relationships and clock relationships in a design.

Checking SR Latch Structures In a Design

Example 5–2 shows the XML codes for checking SR latch structures in a design.

Example 5–2. Detecting SR Latches in a Design

```
<DA_RULE ID="EX01" SEVERITY="CRITICAL" NAME="Checking Design for SR Latch"
DEFAULT_RUN="YES">
<RULE_DEFINITION>
   <FORBID>
   <OR>
      <NODE NAME="NODE_1" TYPE="SRLATCH" />
      <HAS_NODE NODE_LIST="NODE_1" />
      <NODE NAME="NODE_1" TOTAL_FANIN="EQ2" />
      <NODE NAME="NODE_2" TOTAL_FANIN="EQ2" />
      <AND>
         <NODE_RELATIONSHIP FROM_NAME="NODE_1" FROM_TYPE="NAND" TO_NAME="NODE_2"
TO_TYPE="NAND" />
         <NODE_RELATIONSHIP FROM_NAME="NODE_2" FROM_TYPE="NAND" TO_NAME="NODE_1"
TO_TYPE="NAND" />
      </AND>
      <AND>
         <NODE_RELATIONSHIP FROM_NAME="NODE_1" FROM_TYPE="NOR" TO_NAME="NODE_2"
TO_TYPE="NOR" />
         <NODE_RELATIONSHIP FROM_NAME="NODE_2" FROM_TYPE="NOR" TO_NAME="NODE_1"
TO_TYPE="NOR" />
      </AND>
      </OR>
   </FORBID>
</RULE_DEFINITION>

<REPORTING_ROOT>
   <MESSAGE NAME="Rule %ARG1%: Found %ARG2% node(s) related to this rule.">
      <MESSAGE_ARGUMENT NAME="ARG1" TYPE="ATTRIBUTE" VALUE="ID" />
      <MESSAGE_ARGUMENT NAME="ARG2" TYPE="TOTAL_NODE" VALUE="NODE_1" />
   </MESSAGE>
</REPORTING_ROOT>
</DA_RULE>
```

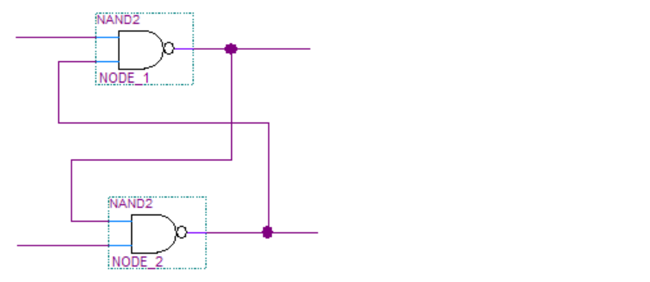
In Example 5–2, the possible SR latch structures are specified in the rule definition section. Codes defined in the `<AND></AND>` block are tied together, meaning that each statement in the block must be true for the block to be fulfilled (AND gate similarity). In the `<OR></OR>` block, as long as one statement in the block is true, the block is fulfilled (OR gate similarity). If no `<AND></AND>` or `<OR></OR>` block is specified, the default is `<AND></AND>`.

The `<FORBID></FORBID>` section contains the undesirable condition for the design, which in this case is the SR latch structures. If the condition is fulfilled, the Design Assistant highlights a rule violation.

The following examples are the undesired conditions from Example 5–2 with their equivalent block diagrams (Figure 5–14 and Figure 5–15):

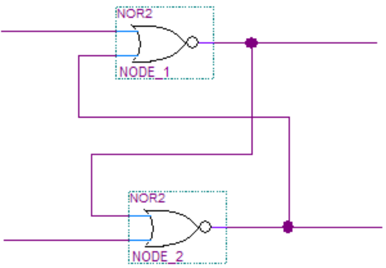
```
<AND>
  <NODE_RELATIONSHIP FROM_NAME="NODE_1" FROM_TYPE="NAND" TO_NAME="NODE_2"
TO_TYPE="NAND" />
  <NODE_RELATIONSHIP FROM_NAME="NODE_2" FROM_TYPE="NAND" TO_NAME="NODE_1"
TO_TYPE="NAND" />
</AND>
```

Figure 5–14. Undesired Condition 1



```
<AND>
 <NODE_RELATIONSHIP FROM_NAME="NODE_1" FROM_TYPE="NOR" TO_NAME="NODE_2" TO_TYPE="NOR" />
 <NODE_RELATIONSHIP FROM_NAME="NODE_2" FROM_TYPE="NOR" TO_NAME="NODE_1" TO_TYPE="NOR" />
</AND>
```

Figure 5–15. Undesired Condition 2



Relating Nodes to a Clock Domain

Example 5–3 shows how to use the CLOCK_RELATIONSHIP attribute to relate nodes to clock domains. This example checks for correct synchronization in data transfer between asynchronous clock domains. Synchronization is done using cascaded registers, also called synchronizers, at the receiving clock domain. The code in Example 5–3 checks for the synchronizer configuration based on the following guidelines:

- The cascading registers need to be triggered on the same clock edge
- Do not put any logic between the register output of the transmitting clock domain and the cascaded registers in the receiving asynchronous clock domain

Example 5–3. Detecting Incorrect Synchronizer Configuration

```
<DA_RULE ID="EX02" SEVERITY="HIGH" NAME="Data Transfer Not Synch Correctly"
DEFAULT_RUN="YES">

<RULE_DEFINITION>
<DECLARE>
   <NODE NAME="NODE_1" TYPE="REG" />
   <NODE NAME="NODE_2" TYPE="REG" />
   <NODE NAME="NODE_3" TYPE="REG" />
</DECLARE>
<FORBID>
   <NODE_RELATIONSHIP FROM_NAME="NODE_1" TO_NAME="NODE_2" TO_PORT="D_PORT"
CLOCK_RELATIONSHIP="ASYN" />
   <NODE_RELATIONSHIP FROM_NAME="NODE_2" TO_NAME="NODE_3" TO_PORT="D_PORT"
CLOCK_RELATIONSHIP="!ASYN" />
   <OR>
      <NODE_RELATIONSHIP FROM_NAME="NODE_1" TO_NAME="NODE_2" TO_PORT="D_PORT"
REQUIRED_THROUGH="YES" THROUGH_TYPE="COMB" CLOCK_RELATIONSHIP="ASYN" />
      <CLOCK_RELATIONSHIP NAME="SEQ_EDGE|ASYN" NODE_LIST="NODE_2, NODE_3" />
   </OR>
</FORBID>
</RULE_DEFINITION>

<REPORTING_ROOT>
<MESSAGE NAME="Rule %ARG1%: Found %ARG2% node(s) related to this rule.">
   <MESSAGE_ARGUMENT NAME="ARG1" TYPE="ATTRIBUTE" VALUE="ID" />
   <MESSAGE_ARGUMENT NAME="ARG2" TYPE="TOTAL_NODE" VALUE="NODE_1" />
   <MESSAGE NAME="Source node(s): %ARG3%, Destination node(s): %ARG4%">
      <MESSAGE_ARGUMENT NAME="ARG3" TYPE="NODE" VALUE="NODE_1" />
      <MESSAGE_ARGUMENT NAME="ARG4" TYPE="NODE" VALUE="NODE_2" />
   </MESSAGE>
</MESSAGE>
</REPORTING_ROOT>
</DA_RULE>
```

The codes differentiate the clock domains. ASYN means asynchronous, and !ASYN means non-asynchronous. This notation is useful for describing nodes that are in different clock domains. The following lines from Example 5–3 state that NODE_2 and NODE_3 are in the same clock domain, but NODE_1 is not.

```
<NODE_RELATIONSHIP FROM_NAME="NODE_1" TO_NAME="NODE_2" TO_PORT="D_PORT"
CLOCK_RELATIONSHIP="ASYN" />

<NODE_RELATIONSHIP FROM_NAME="NODE_2" TO_NAME="NODE_3" TO_PORT="D_PORT"
CLOCK_RELATIONSHIP="!ASYN" />
```

The next line of code states that NODE_2 and NODE_3 have a clock relationship of either sequential edge or asynchronous.

```
 <CLOCK_RELATIONSHIP NAME="SEQ_EDGE|ASYN" NODE_LIST="NODE_2, NODE_3" />
```

The <FORBID></FORBID> section contains the undesirable condition for the design, which in this case is the undesired configuration of the synchronizer. If the condition is fulfilled, the Design Assistant highlights a rule violation.

The following examples are the undesired conditions from Example 5–3 with their equivalent block diagrams (Figure 5–16 and Figure 5–17):

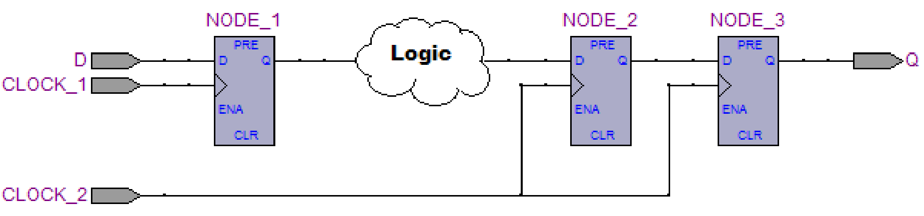
Example 5–4.

```
<NODE_RELATIONSHIP FROM_NAME="NODE_1" TO_NAME="NODE_2" TO_PORT="D_PORT"
CLOCK_RELATIONSHIP="ASYN" />

<NODE_RELATIONSHIP FROM_NAME="NODE_2" TO_NAME="NODE_3" TO_PORT="D_PORT"
CLOCK_RELATIONSHIP="!ASYN" />

<NODE_RELATIONSHIP FROM_NAME="NODE_1" TO_NAME="NODE_2" TO_PORT="D_PORT"
REQUIRED_THROUGH="YES" THROUGH_TYPE="COMB" CLOCK_RELATIONSHIP="ASYN" />
```

Figure 5–16. Undesired Condition 3



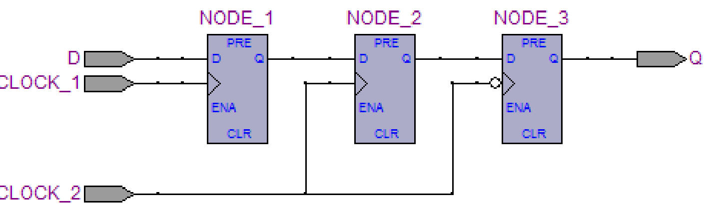
Example 5–5.

```
<NODE_RELATIONSHIP FROM_NAME="NODE_1" TO_NAME="NODE_2" TO_PORT="D_PORT"
CLOCK_RELATIONSHIP="ASYN" />

<NODE_RELATIONSHIP FROM_NAME="NODE_2" TO_NAME="NODE_3" TO_PORT="D_PORT"
CLOCK_RELATIONSHIP="!ASYN" />

<CLOCK_RELATIONSHIP NAME="SEQ_EDGE|ASYN" NODE_LIST="NODE_2, NODE_3" />
```

Figure 5–17. Undesired Condition 4



Targeting Clock and Register-Control Architectural Features

In addition to following general design guidelines, it is important to code your design with the device architecture in mind. FPGAs provide device-wide clocks and register control signals that can improve performance.

Clock Network Resources

Altera FPGAs provide device-wide global clock routing resources and dedicated inputs. Use the FPGA's low-skew, high fan-out dedicated routing where available. By assigning a clock input to one of these dedicated clock pins or using a Quartus II logic option to assign global routing, you can take advantage of the dedicated routing available for clock signals.

In ASIC design, balancing clock delay as it is distributed across the device is important. Because Altera FPGAs provides device-wide global clock routing resources and dedicated inputs, there is no need to manually balance delays on the clock network.

Altera recommends limiting the number of clocks in your design to the number of dedicated global clock resources available in your FPGA. Clocks feeding multiple locations that do not use global routing may exhibit clock skew across the device that could lead to timing problems. In addition, when you use combinational logic to generate an internal clock, it adds delays on the clock line. In some cases, delay on a clock line can result in a clock skew greater than the data path length between two registers. If the clock skew is greater than the data delay, the timing parameters of the register (such as hold time requirements) are violated and the design will not function correctly.

Current FPGAs offer increasing numbers of global clocks to address large designs with many clock domains. Many large FPGA devices provide dedicated global clock networks, regional clock networks, and dedicated fast regional clock networks. These clocks are typically organized into a hierarchical clock structure that allows many clocks in each device region with low skew and delay. There are typically a number of dedicated clock pins to drive either the global or regional clock networks and both PLL outputs and internal clocks can drive various clock networks.

To reduce clock skew within a given clock domain and ensure that hold times are met within that clock domain, assign each clock signal to one of the global high fan-out, low-skew clock networks in the FPGA device. The Quartus II software automatically uses global routing for high fan-out control signals, PLL outputs, and signals feeding the global clock pins on the device. You can make explicit Global Signal logic option settings by turning on the **Global Signal** option settings. On the Assignments menu, click **Assignment Editor**. Use this option when it is necessary to force the software to use the global routing for particular signals.

To take full advantage of these routing resources, the sources of clock signals in a design (input clock pins or internally-generated clocks) need to drive only the clock input ports of registers. In older Altera device families (such as FLEX® 10K and ACEX® 1K), if a clock signal feeds the data ports of a register, the signal may not be able to use dedicated routing, which can lead to decreased performance and clock skew problems. In general, allowing clock signals to drive the data ports of registers is not considered synchronous design and can complicate timing analysis. Altera does not recommend this practice.

Reset Resources

ASIC designs may use local resets to avoid long routing delays on the signal. Take advantage of the device-wide asynchronous reset pin available on most FPGAs to eliminate these problems. This reset signal provides low-skew routing across the device.

 © March 2009 Altera Corporation

Register Control Signals

Avoid using an asynchronous load signal if the design target device architecture does not include registers with dedicated circuitry for asynchronous loads. Also, avoid using both asynchronous clear and preset if the architecture provides only one of those control signals. Stratix III devices, for example, directly support an asynchronous clear function, but not a preset or load function. When the target device does not directly support the signals, the synthesis or place-and-route software must use combinational logic to implement the same functionality. In addition, if you use signals in a priority other than the inherent priority in the device architecture, combinational logic may be required to implement the desired control signals. Combinational logic is less efficient and can cause glitches and other problems; it is best to avoid these implementations.

For Verilog HDL and VHDL examples of registers with various control signals, and information about the inherent priority order of register control signals in Altera device architecture, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

Targeting Embedded RAM Architectural Features

Altera's dedicated memory architecture offers many advanced features that you can target easily using the MegaWizard™ Plug-In Manager or using the recommended HDL coding styles that infer the appropriate RAM megafunction (ALTSYNCRAM or ALTDPRAM). Altera recommends using synchronous memory blocks for your design, so the blocks can be mapped directly into the device dedicated memory blocks. You can choose to use single-port, dual-port, or three-port RAM with a single- or dual-clocking method. Asynchronous memory logic is not inferred as a memory block or placed in the dedicated memory block, but is implemented in regular logic cells.

Altera memory blocks have differing read-during-write behaviors, depending on the targeted device family, memory mode, and block type. Read-during-write behavior refers to read and write from the same memory address in the same clock cycle; for example, you read from the same address to which you write in the same clock cycle.

It is important to check how you specify the memory in your HDL code when you use read-during-write behavior. The HDL code describes that the read returns either the old data at the memory location, or the new data being written to the memory location. The old data refers to the data stored in the memory location. The new data refers to the data that is being written to the memory location.

In some cases, when the device architecture cannot implement the memory behavior described in your HDL code, the memory block is not mapped to the dedicated RAM blocks, or the memory block is implemented using extra logic in addition to the dedicated RAM block. Altera recommends that you implement the read-during-write behavior using single-port RAM in Arria® GX devices and the Stratix and Cyclone series of devices to avoid this extra logic implementation.

For Verilog HDL and VHDL examples and guidelines for inferring RAM functions that match the dedicated memory architecture in Altera devices, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

In many synthesis tools, you can specify that the read-during-write behavior is not important to your design; if, for example, you never read and write from the same address in the same clock cycle. For Quartus II integrated synthesis, add the synthesis attribute `ramstyle="no_rw_check"` to allow the software to choose the read-during-write behavior of a RAM, rather than using the read-during-write behavior specified in your HDL code. Using this type of attribute prevents the synthesis tool from using extra logic to implement the memory block and, in some cases, can allow memory inference when it would otherwise be impossible.

For details about using the `ramstyle` attribute, refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*. For information about the synthesis attributes in other synthesis tools, refer to your synthesis tool documentation, or to the appropriate chapter in the *Synthesis* section in volume 1 of the *Quartus II Handbook*.

Conclusion

Following the design practices described in this chapter can help you to consistently meet your design goals. Asynchronous design techniques may result in incomplete timing analysis, may cause glitches on data signals, and may rely on propagation delays in a device leading to race conditions and unpredictable results. Taking advantage of the architectural features in your FPGA device can also improve the quality of your results.

Document Revision History

Table 5–4 shows the revision history for this chapter.

Table 5–4. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	No change to content.	Updated for the Quartus II software version 9.0 release.
November 2008 v8.1.0	■ Changed to 8-1/2 x 11 page size. ■ Added new section "Custom Rules Coding Examples" on page 5–37 ■ Added paragraph to "Recommended Clock-Gating Methods" on page 5–11. ■ Added new section: "Design Techniques to Save Power" on page 5–12.	Updated for the Quartus II software version 8.1 release.
May 2008 v8.0.0	■ Updated Figure 5–9 on page 5–13; added custom rules file to the flow ■ Added notes to Figure 5–9 on page 5–13 ■ Added new section: "Custom Rules Report" on page 5–34 ■ Added new section: "Custom Rules" on page 5–34 ■ Added new section: "Targeting Embedded RAM Architectural Features" on page 5–38 ■ Minor editorial updates throughout the chapter ■ Added hyperlinks to referenced documents throughout the chapter	Updated for the Quartus II software version 8.0 release.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

6. Recommended HDL Coding Styles

QII51007-9.0.0

Introduction

HDL coding styles can have a significant effect on the quality of results that you achieve for programmable logic designs. Synthesis tools optimize HDL code for both logic utilization and performance. However, sometimes the best optimizations require human understanding of the design, and synthesis tools have no information about the purpose or intent of the design. You are often in the best position to improve your quality of results.

This chapter addresses HDL coding style recommendations to ensure optimal synthesis results when targeting Altera® devices, including the following sections:

- "Quartus II Language Templates" on page 6–1
- "Using Altera Megafunctions" on page 6–2
- "Instantiating Altera Megafunctions in HDL Code" on page 6–3
- "Inferring Multiplier and DSP Functions from HDL Code" on page 6–6
- "Inferring Memory Functions from HDL Code" on page 6–12
- "Coding Guidelines for Registers and Latches" on page 6–36
- "General Coding Guidelines" on page 6–46
- "Designing with Low-Level Primitives" on page 6–71

For additional guidelines about structuring your design, refer to the *Design Recommendations for Altera Devices and the Quartus II Design Assistant* chapter in volume 1 of the *Quartus II Handbook*. For additional hand-crafted techniques, you can use to optimize design blocks for the adaptive logic modules (ALMs) in many Altera devices, including a collection of circuit building blocks and related discussions, refer to the *Advanced Synthesis Cookbook: A Design Guide for Stratix II, Stratix III, and Stratix IV Devices*.

Altera's website also provides design examples for other types of functions and to target specific applications. Refer to the Design Examples page and the Reference Designs page.

For style recommendations, options, or HDL attributes specific to your synthesis tool (including Quartus® II integrated synthesis and other EDA tools), refer to the tool vendor's documentation or the appropriate chapter in the *Synthesis* section in volume 1 of the *Quartus II Handbook*.

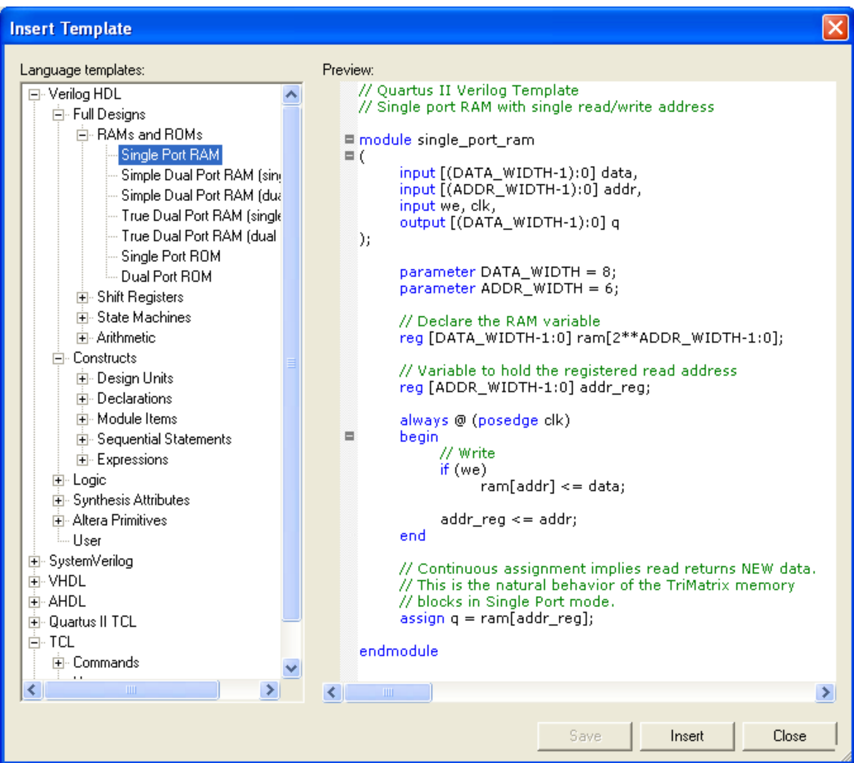
Quartus II Language Templates

The Quartus II software provides Verilog HDL, VHDL, AHDL, Tcl script, and megafunction language templates that can help you with your design.

Many of the Verilog HDL and VHDL examples in this document correspond with examples in the templates. You can easily insert examples from this document into your HDL source code using the **Insert Template** dialog box in the Quartus II user interface, shown in Figure 6–1.

To open the **Insert Template** dialog box when you have a file open in the Quartus II Text Editor, on the Edit menu, click **Insert Template**. Alternatively, you can right-click in the Text Editor window and choose **Insert Template**.

Figure 6–1. Insert Template Dialog Box



Using Altera Megafunctions

Altera provides parameterizable megafunctions that are optimized for Altera device architectures. Using megafunctions instead of coding your own logic saves valuable design time. Additionally, the Altera-provided megafunctions may offer more efficient logic synthesis and device implementation. You can scale the megafunction's size and set various options by setting parameters. Megafunctions include the library of parameterized modules (LPM) and Altera device-specific megafunctions.

To use megafunctions in your HDL code, you can instantiate them as described in "Instantiating Altera Megafunctions in HDL Code" on page 6–3.

© March 2009 Altera Corporation

Sometimes it is preferable to make your code independent of device family or vendor. In this case, you might not want to instantiate megafunctions directly. For some types of logic functions, such as memories and DSP functions, you can infer a megafunction instead of instantiating it. Synthesis tools, including Quartus II integrated synthesis, recognize certain types of HDL code and automatically infer the appropriate megafunction. The synthesis tool uses the Altera megafunction code when compiling your design—even when you do not specifically instantiate the megafunction. Synthesis tools infer megafunctions to take advantage of logic that is optimized for Altera devices or to target dedicated architectural blocks.

In cases where you prefer to use generic HDL code instead of instantiating a megafunction, follow the guidelines and coding examples in "Inferring Multiplier and DSP Functions from HDL Code" on page 6–6 and "Inferring Memory Functions from HDL Code" on page 6–12 to ensure your HDL code infers the appropriate Altera megafunction.

You must use megafunctions to access some Altera device-specific architecture features. You can infer or instantiate megafunctions to target some features such as memory and DSP blocks. You must instantiate megafunctions to target certain device and high-speed features such as LVDS drivers, phase-locked loops (PLLs), transceivers, and double-data rate input/output (DDIO) circuitry.

For some designs, generic HDL code can provide better results than instantiating a megafunction. Refer to the following general guidelines and examples that describe when to use standard HDL code and when to use megafunctions:

- For simple addition or subtraction functions, use the + or − symbol instead of an LPM function. Instantiating an LPM function for simple arithmetic operations can result in a less efficient result because the function is hard coded and the synthesis algorithms cannot take advantage of basic logic optimizations.
- For simple multiplexers and decoders, use array notation (such as `out = data[sel]`) instead of an LPM function. Array notation works very well and has simple syntax. You can use the `lpm_mux` function to take advantage of architectural features such as cascade chains in APEX™ series devices, but use the LPM function only if you understand the device architecture in detail and want to force a specific implementation.
- Avoid division operations where possible. Division is an inherently slow operation. Many designers use multiplication creatively to produce division results.

Instantiating Altera Megafunctions in HDL Code

The following sections describe how to use megafunctions by instantiating them in your HDL code with the following methods:

- "Instantiating Megafunctions Using the MegaWizard Plug-In Manager"—You can use the MegaWizard™ Plug-In Manager to parameterize the function and create a wrapper file.
- "Creating a Netlist File for Other Synthesis Tools"—You can optionally create a netlist file instead of a wrapper file.

- "Instantiating Megafunctions Using the Port and Parameter Definition"—You can instantiate the function directly in your HDL code.

Instantiating Megafunctions Using the MegaWizard Plug-In Manager

Use the MegaWizard Plug-In Manager as described in this section to create megafunctions in the Quartus II GUI that you can instantiate in your HDL code. The MegaWizard Plug-In Manager provides a GUI to customize and parameterize megafunctions, and ensures that you set all megafunction parameters properly. When you finish setting parameters, you can specify which files you want generated. Depending on which language you choose, the MegaWizard Plug-In Manager instantiates the megafunction with the correct parameters and generates a megafunction variation file (wrapper file) in Verilog HDL (**.v**), VHDL (**.vhd**), or AHDL (**.tdf**), along with other supporting files.

The MegaWizard Plug-In Manager provides options to create the following files:

- A sample instantiation template for the language of the variation file (**_inst.v** | **vhd** | **tdf**).
- Component Declaration File (**.cmp**) that can be used in VHDL Design Files
- ADHL Include File (**.inc**) that can be used in Text Design Files (**.tdf**)
- Quartus II Block Symbol File (**.bsf**) for schematic designs
- Verilog HDL module declaration file that can be used when instantiating the megafunction as a black box in a third-party synthesis tool (**_bb.v**).
- If you enable the option to generate a synthesis area and timing estimation netlist, the MegaWizard Plug-In Manager generates an additional synthesis netlist file (**_syn.v**). Refer to "Creating a Netlist File for Other Synthesis Tools" on page 6–5 for details.

Table 6–1 lists and describes the files generated by the MegaWizard Plug-In Manager.

Table 6–1. MegaWizard Plug-In Manager Generated Files (Part 1 of 2)

File	Description
*<output file>***.v** (1)	Verilog HDL Variation Wrapper File—Megafunction wrapper file for instantiation in a Verilog HDL design.
*<output file>***.vhd** (1)	VHDL Variation Wrapper File—Megafunction wrapper file for instantiation in a VHDL design.
*<output file>***.tdf** (1)	AHDL Variation Wrapper File—Megafunction wrapper file for instantiation in an AHDL design.
*<output file>***.inc**	ADHL Include File—Used in AHDL designs.
*<output file>***.cmp**	Component Declaration File—Used in VHDL designs.
*<output file>***.bsf**	Block Symbol File—Used in Quartus II Block Design Files (**.bdf**).
*<output file>***_inst.v**	Verilog HDL Instantiation Template—Sample Verilog HDL instantiation of the module in the megafunction wrapper file.
*<output file>***_inst.vhd**	VHDL Instantiation Template—Sample VHDL instantiation of the entity in the megafunction wrapper file.
*<output file>***_inst.tdf**	Text Design File Instantiation Template—Sample AHDL instantiation of the subdesign in the megafunction wrapper file.

Table 6–1. MegaWizard Plug-In Manager Generated Files (Part 2 of 2)

File	Description
*<output file>*_**bb.v**	Black box Verilog HDL Module Declaration—Hollow-body module declaration that can be used in Verilog HDL designs to specify port directions when creating black boxes in third-party synthesis tools.
*<output file>*_**syn.v** (2)	Synthesis area and timing estimation netlist—Megafunction netlist may be used by third-party synthesis tools to improve area and timing estimations.

Notes to Table 6–1:

(1) The MegaWizard Plug-In Manager generates either the **.v**, **.vhd**, or **.edf** ile, depending on the language you select for the output file on the megafunction-selection page of the wizard.

(2) The MegaWizard Plug-In Manager generates this file only if you turn on the **Generate netlist** option under **Timing and resource estimation** on the **EDA** page of the wizard.

Creating a Netlist File for Other Synthesis Tools

When you use certain megafunctions with third-party EDA synthesis tools (that is, tools other than Quartus II integrated synthesis), you can optionally create a netlist for area and timing estimation instead of a wrapper file.

The netlist file is a representation of the customized logic used in the Quartus II software. The file provides the connectivity of architectural elements in the megafunction but may not represent true functionality. This information enables certain third-party synthesis tools to better report area and timing estimates. In addition, synthesis tools can use the timing information to focus timing-driven optimizations and improve the quality of results.

To generate the netlist, turn on **Generate a synthesis area and timing estimation netlist** on the EDA page of the MegaWizard Plug-In Manager. The netlist file is called <*output file*>**_syn.v**. If you use this netlist for synthesis, you must include the megafunction wrapper file <*output file*>**.v** | **vhd** in your Quartus II project for placement and routing.

Your synthesis tool may call the Quartus II software in the background to generate this netlist, so you might not be required to perform the extra step of turning on this option.

For information about support for area and timing estimation netlists in your synthesis tool, refer to the tool vendor's documentation or the appropriate chapter in the *Synthesis* section in volume 1 of the *Quartus II Handbook*.

Instantiating Megafunctions Using the Port and Parameter Definition

You can instantiate the megafunction directly in your Verilog HDL, VHDL, or AHDL code by calling the megafunction and setting its parameters as you would any other module, component, or subdesign.

Refer to the specific megafunction in the Quartus II Help for a list of the megafunction ports and parameters. The Quartus II Help also provides a sample VHDL component declaration and AHDL function prototype for each megafunction.

Altera strongly recommends that you use the MegaWizard Plug-In Manager for complex megafunctions such as PLLs, transceivers, and LVDS drivers. For details about using the MegaWizard Plug-In Manager, refer to "Instantiating Megafunctions Using the MegaWizard Plug-In Manager" on page 6–4.

Inferring Multiplier and DSP Functions from HDL Code

The following sections describe how to infer multiplier and DSP functions from generic HDL code, and, if applicable, how to target the dedicated DSP block architecture in Altera devices:

- "Multipliers—Inferring the LPM_MULT Megafunction from HDL Code"
- "Multiply-Accumulators and Multiply-Adders—Inferring ALTMULT_ACCUM and ALTMULT_ADD Megafunctions from HDL Code" on page 6–8

For synthesis tool features and options, refer to your synthesis tool documentation or the appropriate chapter in the *Synthesis* section in volume 1 of the *Quartus II Handbook.*

For more design examples involving advanced multiply functions and complex DSP functions, refer to the DSP Design Examples page on Altera's website.

Multipliers—Inferring the LPM_MULT Megafunction from HDL Code

To infer multiplier functions, synthesis tools look for multipliers and convert them to LPM_MULT or ALTMULT_ADD megafunctions, or may map them directly to device atoms. For devices with DSP blocks, the software can implement the function in a DSP block instead of logic, depending on device utilization. The Quartus II Fitter can also place input and output registers in DSP blocks (that is, perform register packing) to improve performance and area utilization.

For additional information about the DSP block and the supported functions, refer to the appropriate Altera device family handbook and Altera's DSP Solutions Center website.

Example 6–1 and Example 6–2 show Verilog HDL code examples, and Example 6–3 and Example 6–4 show VHDL code examples, for unsigned and signed multipliers that synthesis tools can infer as an LPM_MULT or ALTMULT_ADD megafunction. Each example fits into one DSP block 9-bit element. In addition, when register packing occurs, no extra logic cells for registers are required.

The `signed` declaration in Verilog HDL is a feature of the Verilog 2001 Standard.

Example 6–1. Verilog HDL Unsigned Multiplier

```
module unsigned_mult (out, a, b);
   output [15:0] out;
   input  [7:0] a;
   input  [7:0] b;
   assign out = a * b;
endmodule
```

© March 2009 Altera Corporation

Example 6–2. Verilog HDL Signed Multiplier with Input and Output Registers (Pipelining = 2)

```
module signed_mult (out, clk, a, b);
   output [15:0] out;
   input clk;
   input signed [7:0] a;
   input signed [7:0] b;

   reg signed [7:0] a_reg;
   reg signed [7:0] b_reg;
   reg signed [15:0] out;
   wire signed [15:0] mult_out;

   assign mult_out = a_reg * b_reg;

   always @ (posedge clk)
   begin
      a_reg <= a;
      b_reg <= b;
      out <= mult_out;
   end
endmodule
```

Example 6–3. VHDL Unsigned Multiplier with Input and Output Registers (Pipelining = 2)

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
USE ieee.numeric_std.all;

ENTITY unsigned_mult IS
   PORT (
      a: IN UNSIGNED (7 DOWNTO 0);
      b: IN UNSIGNED (7 DOWNTO 0);
      clk: IN STD_LOGIC;
      aclr: IN STD_LOGIC;
      result: OUT UNSIGNED (15 DOWNTO 0)
   );
END unsigned_mult;

ARCHITECTURE rtl OF unsigned_mult IS
   SIGNAL a_reg, b_reg: UNSIGNED (7 DOWNTO 0);
BEGIN
   PROCESS (clk, aclr)
   BEGIN
      IF (aclr ='1') THEN
         a_reg <= (OTHERS => '0');
         b_reg <= (OTHERS => '0');
         result <= (OTHERS => '0');
      ELSIF (clk'event AND clk = '1') THEN
         a_reg <= a;
         b_reg <= b;
         result <= a_reg * b_reg;
      END IF;
   END PROCESS;
END rtl;
```

Example 6–4. VHDL Signed Multiplier

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
USE ieee.numeric_std.all;

ENTITY signed_mult IS
   PORT (
      a: IN SIGNED (7 DOWNTO 0);
      b: IN SIGNED (7 DOWNTO 0);
      result: OUT SIGNED (15 DOWNTO 0)
   );
END signed_mult;

BEGIN
   result <= a * b;
END rtl;
```

Multiply-Accumulators and Multiply-Adders—Inferring ALTMULT_ACCUM and ALTMULT_ADD Megafunctions from HDL Code

Synthesis tools detect multiply-accumulators or multiply-adders and convert them to ALTMULT_ACCUM or ALTMULT_ADD megafunctions, respectively, or may map them directly to device atoms. The Quartus II software then places these functions in DSP blocks during placement and routing.

Synthesis tools infer multiply-accumulator and multiply-adder functions only if the Altera device family has dedicated DSP blocks that support these functions.

A simple multiply-accumulator consists of a multiplier feeding an addition operator. The addition operator feeds a set of registers that then feeds the second input to the addition operator. A simple multiply-adder consists of two to four multipliers feeding one or two levels of addition, subtraction, or addition/subtraction operators. Addition is always the second-level operator, if it is used. In addition to the multiply-accumulator and multiply-adder, the Quartus II Fitter also places input and output registers into the DSP blocks to pack registers and improve performance and area utilization.

Some device families offer additional advanced multiply-add and accumulate functions, such as complex multiplication, input shift register, or larger multiplications.

For details about advanced DSP block features, refer to the appropriate device handbook. For more design examples involving DSP functions and inferring advanced features in the multiply-add and multiply-accumulate circuitry, refer to the DSP Design Examples page on Altera’s website.

The Verilog HDL and VHDL code samples shown in Example 6–5 through Example 6–8 infer multiply-accumulators and multiply-adders with input, output, and pipeline registers as well as an optional asynchronous clear signal. Using the three sets of registers provides the best performance through the function, with a latency of 3. You can remove the registers in your design to reduce the latency.

© March 2009 Altera Corporation

Example 6–5. Verilog HDL Unsigned Multiply-Accumulator

```
module unsig_altmult_accum (dataout, dataa, datab, clk, aclr, clken);
   input [7:0] dataa;
   input [7:0] datab;
   input clk;
   input aclr;
   input clken;
   output [31:0] dataout;

   reg [31:0] dataout;
   reg [7:0] dataa_reg;
   reg [7:0] datab_reg;
   reg [15:0] multa_reg;
   wire [15:0] multa;
   wire [31:0] adder_out;
   assign multa = dataa_reg * datab_reg;
   assign adder_out = multa_reg + dataout;

   always @ (posedge clk or posedge aclr)
   begin
      if (aclr)
      begin
         dataa_reg <= 8'b0;
         datab_reg <= 8'b0;
         multa_reg <= 16'b0;
         dataout <= 32'b0;
      end
      else if (clken)
      begin
         dataa_reg <= dataa;
         datab_reg <= datab;
         multa_reg <= multa;
         dataout <= adder_out;
      end
   end
endmodule
```

Example 6–6. Verilog HDL Signed Multiply-Adder

```
module sig_altmult_add (dataa, datab, datac, datad, clock, aclr,
result);
   input signed [15:0] dataa, datab, datac, datad;
   input clock, aclr;
   output reg signed [32:0] result;

   reg signed [15:0] dataa_reg, datab_reg, datac_reg, datad_reg;
   reg signed [31:0] mult0_result, mult1_result;

   always @ (posedge clock or posedge aclr) begin
       if (aclr) begin
           dataa_reg <= 16'b0;
           datab_reg <= 16'b0;
           datac_reg <= 16'b0;
           datad_reg <= 16'b0;
           mult0_result <= 32'b0;
           mult0_result <= 32'b0;
           result <= 33'b0;
        end
        else begin
           dataa_reg <= dataa;
           datab_reg <= datab;
           datac_reg <= datac;
           datad_reg <= datad;
           mult0_result <= dataa_reg * datab_reg;
           mult1_result <= datac_reg * datad_reg;
           result <= mult0_result + mult1_result;
       end
   end
endmodule
```

Example 6–7. VHDL Signed Multiply-Accumulator

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
USE ieee.numeric_std.all;

ENTITY sig_altmult_accum IS
   PORT (
      a: IN SIGNED(7 DOWNTO 0);
      b: IN SIGNED (7 DOWNTO 0);
      clk: IN STD_LOGIC;
      aclr: IN STD_LOGIC;
      accum_out: OUT SIGNED (15 DOWNTO 0)
   ) ;
END sig_altmult_accum;

ARCHITECTURE rtl OF sig_altmult_accum IS
   SIGNAL a_reg, b_reg: SIGNED (7 DOWNTO 0);
   SIGNAL pdt_reg: SIGNED (15 DOWNTO 0);
   SIGNAL adder_out: SIGNED (15 DOWNTO 0);
BEGIN
   PROCESS (clk, aclr)
   BEGIN
      IF (aclr = '1') then
          a_reg <= (others => '0');
          b_reg <= (others => '0');
          pdt_reg <= (others => '0');
          adder_out <= (others => '0');
      ELSIF (clk'event and clk = '1') THEN
          a_reg <= (a);
          b_reg <= (b);
          pdt_reg <= a_reg * b_reg;
          adder_out <= adder_out + pdt_reg;
      END IF;
   END process;
   accum_out <= adder_out;
END rtl;
```

Example 6–8. VHDL Unsigned Multiply-Adder

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
USE ieee.numeric_std.all;

ENTITY unsignedmult_add IS
   PORT (
      a: IN UNSIGNED (7 DOWNTO 0);
      b: IN UNSIGNED (7 DOWNTO 0);
      c: IN UNSIGNED (7 DOWNTO 0);
      d: IN UNSIGNED (7 DOWNTO 0);
      clk: IN STD_LOGIC;
      aclr: IN STD_LOGIC;
      result: OUT UNSIGNED (15 DOWNTO 0)
   );
END unsignedmult_add;

ARCHITECTURE rtl OF unsignedmult_add IS
   SIGNAL a_reg, b_reg, c_reg, d_reg: UNSIGNED (7 DOWNTO 0);
   SIGNAL pdt_reg, pdt2_reg: UNSIGNED (15 DOWNTO 0);
   SIGNAL result_reg: UNSIGNED (15 DOWNTO 0);
BEGIN
   PROCESS (clk, aclr)
   BEGIN
      IF (aclr = '1') THEN
         a_reg <= (OTHERS => '0');
         b_reg <= (OTHERS => '0');
         c_reg <= (OTHERS => '0');
         d_reg <= (OTHERS => '0');
         pdt_reg <= (OTHERS => '0');
         pdt2_reg <= (OTHERS => '0');

      ELSIF (clk'event AND clk = '1') THEN
         a_reg <= a;
         b_reg <= b;
         c_reg <= c;
         d_reg <= d;
         pdt_reg <= a_reg * b_reg;
         pdt2_reg <= c_reg * d_reg;
         result_reg <= pdt_reg + pdt2_reg;
      END IF;
      END PROCESS;
   result <= result_reg;
END rtl;
```

Inferring Memory Functions from HDL Code

The following sections describe how to infer memory functions from generic HDL code and, if applicable, to target the dedicated memory architecture in Altera devices:

- "RAM Functions—Inferring ALTSYNCRAM and ALTDPRAM Megafunctions from HDL Code" on page 6–13
- "ROM Functions—Inferring ALTSYNCRAM and LPM_ROM Megafunctions from HDL Code" on page 6–29
- "Shift Registers—Inferring the ALTSHIFT_TAPS Megafunction from HDL Code" on page 6–32

For synthesis tool features and options, refer to your synthesis tool documentation or the appropriate chapter in the *Synthesis* section in volume 1 of the *Quartus II Handbook*.

Altera's dedicated memory architecture offers a number of advanced features that can be easily targeted using the MegaWizard Plug-In Manager, as described in "Instantiating Altera Megafunctions in HDL Code" on page 6–3. The coding recommendations in the following sections provide portable examples of generic HDL code that infer the appropriate megafunction. However, if you want to use some of the advanced memory features in Altera devices, consider using the megafunction directly so that you can control the ports and parameters more easily.

RAM Functions—Inferring ALTSYNCRAM and ALTDPRAM Megafunctions from HDL Code

To infer RAM functions, synthesis tools detect sets of registers and logic that can be replaced with the ALTSYNCRAM or ALTDPRAM megafunctions for device families that have dedicated RAM blocks, or may map them directly to device memory atoms. Tools typically consider all signals and variables that have a two-dimensional array type and then create a RAM block, if applicable, based on the way the signals, variables, or both are assigned, referenced, or both in the HDL source description. This section provides examples demonstrating the coding styles that are inferred to create a memory block.

Standard synthesis tools recognize single-port and simple dual-port (one read port and one write port) RAM blocks. Some tools (such as the Quartus II software) also recognize true dual-port RAM blocks that map to the memory blocks in certain Altera devices. Tools usually do not infer small RAM blocks because small RAM blocks typically can be implemented more efficiently using the registers in regular logic.

If you are using Quartus II integrated synthesis, you can direct the software to infer ROM blocks for all sizes with the **Allow Any RAM Size for Recognition** option under **More Settings** on the **Analysis & Synthesis Settings** page of the **Settings** dialog box.

If your design contains a RAM block that your synthesis tool does not recognize and infer, the design might require a large amount of system memory that can potentially cause compilation problems.

Some synthesis tools provide options to control the implementation of inferred RAM blocks for Altera devices with TriMatrix memory blocks. For example, Quartus II integrated synthesis provides the `ramstyle` synthesis attribute to specify the type of memory block or to specify the use of regular logic instead of a dedicated memory block. Quartus II integrated synthesis does not map inferred memory into Stratix® III MLABs unless the HDL code specifies the appropriate `ramstyle` attribute, although the Fitter may map some memories to MLABs.

For details about using the `ramstyle` attribute, refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*. For information about synthesis attributes in other synthesis tools, refer to the appropriate chapter in the *Synthesis* section in volume 1 of the *Quartus II Handbook*.

When you use a formal verification flow, Altera recommends that you create RAM blocks in separate entities or modules that contain only the RAM logic. In certain formal verification flows, for example, when using Quartus II integrated synthesis, the entity or module containing the inferred RAM is put into a black box automatically because formal verification tools do not support RAM blocks. The Quartus II software issues a warning message when this occurs. If the entity or module contains any additional logic outside the RAM block, this logic also must be treated as a black box for formal verification and therefore cannot be verified.

The following subsections present several guidelines for inferring RAM functions that match the dedicated memory architecture in Altera devices, and then provide recommended HDL code for different types of memory logic.

Use Synchronous Memory Blocks

Altera recommends using synchronous memory blocks for Altera designs. The TriMatrix memory blocks in Altera's newest devices are synchronous, so RAM designs that are targeted towards architectures that contain these dedicated memory blocks must be synchronous to be mapped directly into the device architecture. For these devices, asynchronous memory logic is implemented in regular logic cells.

Synchronous memories are supported in all Altera device families. A memory block is considered synchronous if it uses one of the following read behaviors:

- Memory read occurs in a Verilog always block with a clock signal or a VHDL clocked process.
- Memory read occurs outside a clocked block, but there is a synchronous read address (that is, the address used in the read statement is registered). This type of logic is not always inferred as a memory block, depending on the target device architecture.

The synchronous memory structures in Altera devices differ from the structures in other vendors' devices. Match your design to the target device architecture to achieve the best results.

Later subsections provide coding recommendations for various memory types. All of these examples are synchronous to ensure that they can be directly mapped into the dedicated memory architecture available in Altera FPGAs.

For additional information about the dedicated memory blocks in your specific device, refer to the appropriate Altera device family data sheet on the Altera website at www.altera.com.

Avoid Unsupported Reset and Control Conditions

To ensure that your HDL code can be implemented in the target device architecture, avoid unsupported reset conditions or other control logic that does not exist in the device architecture.

The RAM contents of Altera memory blocks cannot be cleared with a reset signal during device operation. If your HDL code describes a RAM with a reset signal for the RAM contents, the logic is implemented in regular logic cells instead of a memory block. As a general rule, avoid putting RAM read or write operations in an always block or process block with a reset signal. If you want to specify memory contents, initialize the memory as described in "Specifying Initial Memory Contents at Power-Up" on page 6–27 or write the data to the RAM during device operation.

Example 6–9 shows an example of undesirable code where there is a reset signal that clears part of the RAM contents. Avoid this coding style because it is not supported in Altera memories.

Example 6–9. Verilog RAM with Reset Signal that Clears RAM Contents: Not Supported in Device Architecture

```
module clear_ram
(
    input clock,
    input reset,
    input we,
    input [7:0] data_in,
    input [4:0] address,
    output reg [7:0] data_out
);

    reg [7:0] mem [0:31];
    integer i;

    always @ (posedge clock or posedge reset)
    begin
        if (reset == 1'b1)
            mem[address] <= 0;
        else if (we == 1'b1)
            mem[address] <= data_in;

        data_out <= mem[address];
    end
endmodule
```

Example 6–10 shows an example of undesirable code where the reset signal affects the RAM, although the effect may not be intended. Avoid this coding style because it is not supported in Altera memories.

Example 6–10. Verilog RAM with Reset Signal that Affects RAM: Not Supported in Device Architecture

```
module bad_reset
(
    input clock,
    input reset,
    input we,
    input [7:0] data_in,
    input [4:0] address,
    output reg [7:0] data_out,
    input d,
    output reg q
);

    reg [7:0] mem [0:31];
    integer i;

    always @ (posedge clock or posedge reset)
    begin
        if (reset == 1'b1)
            q <= 0;
        else
        begin
            if (we == 1'b1)
                mem[address] <= data_in;

            data_out <= mem[address];
            q <= d;
        end
    end
endmodule
```

In addition to reset signals, other control logic can prevent memory logic from being inferred as a memory block. For example, you cannot use a clock enable on the read address registers in Stratix devices, because doing so affects the output latch of the RAM, and therefore the synthesized result in the device RAM architecture would not match the HDL description. In Stratix II, Cyclone® II, Arria® GX, and other newer devices, however, you can use the address stall feature as a read address clock enable, so there is no such limitation. Check the documentation on your device architecture to ensure that your code matches the hardware available in the device.

Check Read-During-Write Behavior

It is important to check the read-during-write behavior of the memory block described in your HDL design as compared to the behavior in your target device architecture. Your HDL source code specifies the memory behavior when you read and write from the same memory address in the same clock cycle. The code specifies that the read returns either the old data at the address, or the new data being written to the address. This is referred to as the read-during-write behavior of the memory block. Altera memory blocks have different read-during-write behavior depending on the target device family, memory mode, and block type.

Synthesis tools map an HDL design into the target device architecture, with the goal of maintaining the functionality described in your source code. Therefore, if your source code specifies unsupported read-during-write behavior for the device RAM blocks, the software must implement the logic outside the RAM hardware in regular logic cells.

One common problem occurs when there is a continuous read in the HDL code, as shown in the following samples. You should avoid using these coding styles:

```
//Verilog HDL concurrent signal assignment
assign q = ram[raddr_reg];

-- VHDL concurrent signal assignment
q <= ram(raddr_reg);
```

When a write operation occurs, this type of HDL implies that the read should immediately reflect the new data at the address, independent of the read clock. However, that is not the behavior of TriMatrix memory blocks. In the device architecture, the new data is not available until the next edge of the read clock. Therefore, if the synthesis tool mapped the logic directly to a TriMatrix memory block, the device functionality and gate-level simulation results would not match the HDL description or function simulation results. If the write clock and read clock are the same, the synthesis tool can infer memory blocks and add extra bypass logic so that the device behavior does match the HDL behavior. If the write and read clocks are different, the synthesis tool cannot reliably add bypass logic, so the logic is implemented in regular logic cells instead of dedicated RAM blocks. The examples in the following sections discuss some of these differences for read-during-write conditions.

In addition, the MLAB feature in Stratix III logic array blocks (LABs) does not easily support old data or new data behavior for a read during write in the dedicated device architecture. Implementing the extra logic to support this behavior significantly reduces timing performance through the memory.

For best performance in MLAB memories, your design should not depend on the read data during a write operation.

In many synthesis tools, you can specify that the read-during-write behavior is not important to your design; for example, if you never read from the same address to which you write in the same clock cycle. For Quartus II integrated synthesis, add the synthesis attribute `ramstyle="no_rw_check"` to allow the software to choose the read-during-write behavior of a RAM, rather than use the behavior specified by your HDL code. Using this type of attribute prevents the synthesis tool from using extra logic to implement the memory block, and in some cases, can allow memory inference when it would otherwise be impossible.

For more information about attribute syntax, the `no_rw_check` attribute value, or specific options for your synthesis tool, refer to your synthesis tool documentation or the appropriate chapter in the *Synthesis* section in volume 1 of the *Quartus II Handbook*.

The following subsections provide coding recommendations for various memory types. Each example describes the read-during-write behavior and addresses the support for the memory type in Altera devices.

Single-Clock Synchronous RAM with Old Data Read-During-Write Behavior

The code examples in this section show Verilog HDL and VHDL code that infers simple dual-port, single-clock synchronous RAM. Single-port RAM blocks use a similar coding style.

The read-during-write behavior in these examples is to read the old data at the memory address. Refer to "Check Read-During-Write Behavior" on page 6–16 for details. Altera recommends that you use this coding style for most RAM blocks as long as your design does not require that a simultaneous read and write to the same RAM location read the new value that is currently being written to that RAM location. For best performance in MLAB memories, use the appropriate attribute so that your design does not depend on the read data during a write operation.

If you require that the read-during-write results in new data, refer to "Single-Clock Synchronous RAM with New Data Read-During-Write Behavior" on page 6–19.

The simple dual-port RAM code samples shown in Example 6–11 and Example 6–12 map directly into Altera TriMatrix memory.

Single-port versions of memory blocks (that is, using the same read address and write address signals) can allow better RAM utilization than dual-port memory blocks, depending on the device family.

Example 6–11. Verilog HDL Single-Clock Simple Dual-Port Synchronous RAM with Old Data Read-During-Write Behavior

```
module single_clk_ram(
    output reg [7:0] q,
    input [7:0] d,
    input [6:0] write_address, read_address,
    input we, clk
);
    reg [7:0] mem [127:0];

    always @ (posedge clk) begin
        if (we)
            mem[write_address] <= d;
        q <= mem[read_address]; // q doesn't get d in this clock cycle
    end
endmodule
```

Example 6–12. VHDL Single-Clock Simple Dual-Port Synchronous RAM with Old Data Read-During-Write Behavior

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;

ENTITY single_clock_ram IS
    PORT (
        clock: IN STD_LOGIC;
        data: IN STD_LOGIC_VECTOR (2 DOWNTO 0);
        write_address: IN INTEGER RANGE 0 to 31;
        read_address: IN INTEGER RANGE 0 to 31;
        we: IN STD_LOGIC;
        q: OUT STD_LOGIC_VECTOR (2 DOWNTO 0)
    );
END single_clock_ram;

ARCHITECTURE rtl OF single_clock_ram IS
    TYPE MEM IS ARRAY(0 TO 31) OF STD_LOGIC_VECTOR(2 DOWNTO 0);
    SIGNAL ram_block: MEM;
BEGIN
    PROCESS (clock)
    BEGIN
        IF (clock'event AND clock = '1') THEN
            IF (we = '1') THEN
                ram_block(write_address) <= data;
            END IF;
            q <= ram_block(read_address);
            -- VHDL semantics imply that q doesn't get data
            -- in this clock cycle
        END IF;
    END PROCESS;
END rtl;
```

Single-Clock Synchronous RAM with New Data Read-During-Write Behavior

The examples in this section describe RAM blocks in which a simultaneous read and write to the same location reads the new value that is currently being written to that RAM location.

To implement this behavior in the target device, synthesis software adds bypass logic around the RAM block. This bypass logic increases the area utilization of the design and decreases the performance if the RAM block is part of the design's critical path. Refer to "Check Read-During-Write Behavior" on page 6–16 for details. If this behavior is not required for your design, use the examples from "Single-Clock Synchronous RAM with Old Data Read-During-Write Behavior" on page 6–17.

The simple dual-port RAM shown in Example 6–13 and Example 6–14 require the software to create bypass logic around the RAM block.

Single-port versions of the Verilog memory block (that is, using the same read address and write address signals) do not require any logic cells to create bypass logic in the Arria GX, Stratix, and Cyclone series of devices, because the device memory supports new data read-during-write behavior when in single-port mode (same clock, same read, and write address).

Example 6–13. Verilog HDL Single-Clock Simple Dual-Port Synchronous RAM with New Data Read-During-Write Behavior

```
module single_clock_wr_ram(
    output reg [7:0] q,
    input [7:0] d,
    input [6:0] write_address, read_address,
    input we, clk
);
    reg [7:0] mem [127:0];

    always @ (posedge clk) begin
        if (we)
            mem[write_address] = d;
        q = mem[read_address]; // q does get d in this clock cycle if
we is high
    end
endmodule
```

Example 6–13 is similar to Example 6–11, but Example 6–13 uses a blocking assignment for the write so that the data is assigned immediately.

An alternative way to create a single-clock RAM is to use an assign statement to read the address of mem to create the output q, as shown in the following coding style. By itself, the code describes new data read-during-write behavior. However, if the RAM output feeds a register in another hierarchy, then a read-during-write would result in the old data. Synthesis tools may not infer a RAM block if the tool cannot determine which behavior is described, such as when the memory feeds a hard hierarchical partition boundary. For this reason, avoid using this alternate type of coding style:

```
reg [7:0] mem [127:0];
reg [6:0] read_address_reg;

always @ (posedge clk) begin
    if (we)
        mem[write_address] <= d;

    read_address_reg <= read_address;
end

assign q = mem[read_address_reg];
```

The VHDL sample in Example 6–14 uses a concurrent signal assignment to read from the RAM. By itself, this example describes new data read-during-write behavior. However, if the RAM output feeds a register in another hierarchy, a read-during-write results in the old data. Synthesis tools may not infer a RAM block if the tool cannot determine which behavior is described, such as when the memory feeds a hard hierarchical partition boundary.

Example 6–14. VHDL Single-Clock Simple Dual-Port Synchronous RAM with New Data Read-During-Write Behavior

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;

ENTITY single_clock_rw_ram IS
    PORT (
        clock: IN STD_LOGIC;
        data: IN STD_LOGIC_VECTOR (2 DOWNTO 0);
        write_address: IN INTEGER RANGE 0 to 31;
        read_address: IN INTEGER RANGE 0 to 31;
        we: IN STD_LOGIC;
        q: OUT STD_LOGIC_VECTOR (2 DOWNTO 0)
    );
END single_clock_rw_ram;

ARCHITECTURE rtl OF single_clock_rw_ram IS
    TYPE MEM IS ARRAY(0 TO 31) OF STD_LOGIC_VECTOR(2 DOWNTO 0);
    SIGNAL ram_block: MEM;
    SIGNAL read_address_reg: INTEGER RANGE 0 to 31;
BEGIN
    PROCESS (clock)
    BEGIN
        IF (clock'event AND clock = '1') THEN
            IF (we = '1') THEN
                ram_block(write_address) <= data;
            END IF;
            read_address_reg <= read_address;
        END IF;
    END PROCESS;
    q <= ram_block(read_address_reg);
END rtl;
```

Example 6–14 does not infer a RAM block for the APEX series of devices, ACEX®, or the FLEX® series of devices by default because the read-during-write behavior depends on surrounding logic. For Quartus II integrated synthesis, if you do not require the read-through-write capability, add the synthesis attribute `ramstyle="no_rw_check"` to allow the software to choose the read-during-write behavior of a RAM, rather than use the behavior specified by your HDL code.

Simple Dual-Port, Dual-Clock Synchronous RAM

In dual clock designs, synthesis tools cannot accurately infer the read-during-write behavior because it depends on the timing of the two clocks within the target device. Therefore, the read-during-write behavior of the synthesized design is undefined and may differ from your original HDL code. Refer to "Check Read-During-Write Behavior" on page 6–16 for details.

When Quartus II integrated synthesis infers this type of RAM, it issues a warning because of the undefined read-during-write behavior. If this functionality is acceptable in your design, you can avoid the warning by adding the synthesis attribute `ramstyle="no_rw_check"` to allow the software to choose the read-during-write behavior of a RAM.

The code samples shown in Example 6–15 and Example 6–16 show Verilog HDL and VHDL code that infers dual-clock synchronous RAM. The exact behavior depends on the relationship between the clocks.

Example 6–15. Verilog HDL Simple Dual-Port, Dual-Clock Synchronous RAM

```
module dual_clock_ram(
   output reg [7:0] q,
   input [7:0] d,
   input [6:0] write_address, read_address,
   input we, clk1, clk2
);
   reg [6:0] read_address_reg;
   reg [7:0] mem [127:0];

   always @ (posedge clk1)
   begin
      if (we)
         mem[write_address] <= d;
   end

   always @ (posedge clk2) begin
      q <= mem[read_address_reg];
      read_address_reg <= read_address;
   end
endmodule
```

Example 6–16. VHDL Simple Dual-Port, Dual-Clock Synchronous RAM

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
ENTITY dual_clock_ram IS
   PORT (
      clock1, clock2: IN STD_LOGIC;
      data: IN STD_LOGIC_VECTOR (3 DOWNTO 0);
      write_address: IN INTEGER RANGE 0 to 31;
      read_address: IN INTEGER RANGE 0 to 31;
      we: IN STD_LOGIC;
      q: OUT STD_LOGIC_VECTOR (3 DOWNTO 0)
   );
END dual_clock_ram;
ARCHITECTURE rtl OF dual_clock_ram IS
   TYPE MEM IS ARRAY(0 TO 31) OF STD_LOGIC_VECTOR(3 DOWNTO 0);
   SIGNAL ram_block: MEM;
   SIGNAL read_address_reg : INTEGER RANGE 0 to 31;
BEGIN
   PROCESS (clock1)
   BEGIN
      IF (clock1'event AND clock1 = '1') THEN
         IF (we = '1') THEN
            ram_block(write_address) <= data;
         END IF;
      END IF;
   END PROCESS;
   PROCESS (clock2)
   BEGIN
      IF (clock2'event AND clock2 = '1') THEN
         q <= ram_block(read_address_reg);
         read_address_reg <= read_address;
      END IF;
   END PROCESS;
END rtl;
```

True Dual-Port Synchronous RAM

The code examples in this section show Verilog HDL and VHDL code that infers true dual-port synchronous RAM. Different synthesis tools may differ in their support for these types of memories. This section describes the inference rules for Quartus II integrated synthesis. This type of RAM inference is supported only for the Arria GX, Stratix, and Cyclone series of devices.

Altera TriMatrix memory blocks have two independent address ports, allowing for operations on two unique addresses simultaneously. A read operation and a write operation can share the same port if they share the same address. The Quartus II software infers true dual-port RAMs in Verilog HDL and VHDL with any combination of independent read or write operations in the same clock cycle, with at most two unique port addresses, performing two reads and one write, two writes and one read, or two writes and two reads in one clock cycle with one or two unique addresses.

In the TriMatrix RAM block architecture, there is no priority between the two ports. Therefore, if you write to the same location on both ports at the same time, the result is indeterminate in the device architecture. You must ensure your HDL code does not imply priority for writes to the memory block, if you want the design to be implemented in a dedicated hardware memory block. For example, if both ports are defined in the same process block, the code is synthesized and simulated sequentially so there would be a priority between the two ports. If your code does imply a priority, the logic cannot be implemented in the device RAM blocks and is implemented in regular logic cells.

You must also consider the read-during-write behavior of the RAM block, to ensure that it can be mapped directly to the device RAM architecture. Refer to "Check Read-During-Write Behavior" on page 6–16 for details.

When a read and write operation occur on the same port for the same address, the read operation may behave as follows:

- **Read new data**—This mode matches the behavior of TriMatrix memory blocks.
- **Read old data**—This mode is supported only by Stratix IV, Arria II GX, Stratix III, and Cyclone III TriMatrix memory blocks. This behavior is not possible in TriMatrix memory blocks of other families.

When a read and write operation occur on different ports for the same address (also known as mixed port), the read operation may behave as follows:

- **Read new data**—Quartus II integrated synthesis supports this mode by creating bypass logic around the TriMatrix memory block.
- **Read old data**—This behavior is supported by TriMatrix memory blocks.

The Verilog HDL single-clock code sample shown in Example 6–17 maps directly into Altera TriMatrix memory. When a read and write operation occur on the same port for the same address, the new data being written to the memory is read. When a read and write operation occur on different ports for the same address, the old data in the memory is read. Simultaneous writes to the same location on both ports results in indeterminate behavior.

A dual-clock version of this design describes the same behavior, but the memory in the target device will have undefined mixed port read-during-write behavior because it depends on the relationship between the clocks.

Example 6–17. Verilog HDL True Dual-Port RAM with Single Clock

```
module true_dual_port_ram_single_clock
(
    input [(DATA_WIDTH-1):0] data_a, data_b,
    input [(ADDR_WIDTH-1):0] addr_a, addr_b,
    input we_a, we_b, clk,
    output reg [(DATA_WIDTH-1):0] q_a, q_b
);

    parameter DATA_WIDTH = 8;
    parameter ADDR_WIDTH = 6;

    // Declare the RAM variable
    reg [DATA_WIDTH-1:0] ram[2**ADDR_WIDTH-1:0];

    always @ (posedge clk)
    begin // Port A
        if (we_a)
        begin
            ram[addr_a] <= data_a;
            q_a <= data_a;
        end
        else
            q_a <= ram[addr_a];
    always @ (posedge clk)
    begin // Port b
        if (we_b)
        begin
            ram[addr_b] <= data_b;
            q_b <= data_b;
        end
        else
            q_b <= ram[addr_b];
    end

endmodule
```

If you use the following Verilog HDL read statements instead of the `if-else` statements in Example 6–17, the HDL code specifies that the read results in old data when a read and write operation occur at the same time for the same address on the same port or mixed ports. (This behavior is supported only in the TriMatrix memories of Stratix IV, Arria II GX, Stratix III and Cyclone III devices, and is not inferred as memory for other device families):

```
    always @ (posedge clk)
    begin // Port A
      if (we_a)
        ram[addr_a] <= data_a;

      q_a <= ram[addr_a];
    end

    always @ (posedge clk)
    begin // Port B
      if (we_b)
        ram[addr_b] <= data_b;

      q_b <= ram[addr_b];
    end
```

The VHDL single-clock code sample shown in Example 6–18 maps directly into Altera TriMatrix memory. When a read and write operation occurs on the same port for the same address, the new data being written to the memory is read. When a read and write operation occurs on different ports for the same address, the old data in the memory is read. Because simultaneous writes to the same location on both ports results in indeterminate behavior, Altera recommends that you avoid this condition.

A dual-clock version of this design describes the same behavior, but the memory in the target device will have undefined mixed port read-during-write behavior because it depends on the relationship between the clocks.

Example 6–18. VHDL True Dual-Port RAM with Single Clock (Part 1 of 2)

```
library ieee;
use ieee.std_logic_1164.all;

entity true_dual_port_ram_single_clock is

    generic
    (
        DATA_WIDTH : natural := 8;
        ADDR_WIDTH : natural := 6
    );

    port
    (
        clk : in std_logic;
        addr_a: in natural range 0 to 2**ADDR_WIDTH - 1;
        addr_b: in natural range 0 to 2**ADDR_WIDTH - 1;
        data_a: in std_logic_vector((DATA_WIDTH-1) downto 0);
        data_b: in std_logic_vector((DATA_WIDTH-1) downto 0);
        we_a: in std_logic := '1';
        we_b: in std_logic := '1';
        q_a : out std_logic_vector((DATA_WIDTH -1) downto 0);
        q_b : out std_logic_vector((DATA_WIDTH -1) downto 0)
    );

end true_dual_port_ram_single_clock;

architecture rtl of true_dual_port_ram_single_clock is

    -- Build a 2-D array type for the RAM
    subtype word_t is std_logic_vector((DATA_WIDTH-1) downto 0);
    type memory_t is addr_a(raddr'high downto 0) of word_t;

    -- Declare the RAM signal.
    signal ram : memory_t;
```

Example 6-18. VHDL True Dual-Port RAM with Single Clock (Part 2of 2)

```
begin

    process(clk)
    begin
    if(rising_edge(clk)) then -- Port A
        if(we_a = '1') then
            ram(addr_a) <= data_a;

            -- Read-during-write on the same port returns NEW data
            q_a <= data_a;
        else
            -- Read-during-write on the mixed port returns OLD data
            q_a <= ram(addr_a);
        end if;
end if;

    end process;

    process(clk)
    begin
    if(rising_edge(clk)) then -- Port B
        if(we_b = '1') then
            ram(addr_b) <= data_b;

            -- Read-during-write on the same port returns NEW data
            q_b <= data_b;
        else
            -- Read-during-write on the mixed port returns OLD data
            q_b <= ram(addr_b);
        end if;
    end if;
    end process;

end rtl;
```

Specifying Initial Memory Contents at Power-Up

Your synthesis tool may offer various ways to specify the initial contents of an inferred memory.

Certain device memory types do not support initialized memory, such as the M-RAM blocks in Stratix and Stratix II devices.

There are slight power-up and initialization differences between dedicated RAM blocks and the Stratix III MLAB memory due to the continuous read of the MLAB. Altera dedicated RAM block outputs always power-up to zero and are set to the initial value on the first read. For example, if address `0` is pre-initialized to FF, the RAM block powers up with the output at `0`. A subsequent read after power up from address `0` outputs the pre-initialized value of FF. Therefore, if a RAM is powered up and an enable (read enable or clock enable) is held low, then the power-up output of `0` is maintained until the first valid read cycle. The Stratix III MLAB is implemented using registers that power-up to `0`, but are initialized to their initial value immediately at power-up or reset. Therefore, the initial value regardless of the enable status is seen. Quartus II integrated synthesis does not map inferred memory to MLABs unless the HDL code specifies the appropriate `ramstyle` attribute.

Quartus II integrated synthesis supports the `ram_init_file` synthesis attribute that allows you to specify a Memory Initialization File (**.mif**) for an inferred RAM block.

For information about the `ram_init_file` attribute, refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*. For information about synthesis attributes in other synthesis tools, refer to the tool vendor's documentation.

In Verilog HDL, you can use an initial block to initialize the contents of an inferred memory. Quartus II integrated synthesis automatically converts the initial block into a **.mif** for the inferred RAM. Example 6–19 shows Verilog HDL code that infers a simple dual-port RAM block and corresponding **.mif** file.

Example 6–19. Verilog HDL RAM with Initialized Contents

```
module ram_with_init(
   output reg [7:0] q,
   input [7:0] d,
   input [4:0] write_address, read_address,
   input we, clk
);
   reg [7:0] mem [0:31];
   integer i;

   initial begin
      for (i = 0; i < 32; i = i + 1)
         mem[i] = i[7:0];
   end

   always @ (posedge clk) begin
      if (we)
         mem[write_address] <= d;
      q <= mem[read_address];
   end
endmodule
```

Quartus II integrated synthesis and other synthesis tools also support the `$readmemb` and `$readmemh` commands so that RAM and ROM initialization work identically in synthesis and simulation. Example 6–20 shows an initial block that initializes an inferred RAM block using the `$readmemb` command.

Refer to the Verilog Language Reference Manual (LRM) 1364-2001 Section 17.2.8 for details about the format of the **ram.txt** file.

Example 6–20. Verilog HDL RAM Initialized with the readmemb Command

```
reg [7:0] ram[0:15];
initial
begin
$readmemb("ram.txt", ram);
end
```

In VHDL, you can initialize the contents of an inferred memory by specifying a default value for the corresponding signal. Quartus II integrated synthesis automatically converts the default value into a **.mif** file for the inferred RAM. Example 6–21 shows VHDL code that infers a simple dual-port RAM block and corresponding **.mif** file.

Example 6–21. VHDL RAM with Initialized Contents

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
use ieee.numeric_std.all;

ENTITY ram_with_init IS
    PORT(
            clock: IN STD_LOGIC;
            data: IN UNSIGNED (7 DOWNTO 0);
            write_address: IN integer RANGE 0 to 31;
            read_address: IN integer RANGE 0 to 31;
            we: IN std_logic;
            q: OUT UNSIGNED (7 DOWNTO 0));
END;

ARCHITECTURE rtl OF ram_with_init IS

    TYPE MEM IS ARRAY(31 DOWNTO 0) OF unsigned(7 DOWNTO 0);
    FUNCTION initialize_ram
        return MEM is
        variable result : MEM;
    BEGIN
        FOR i IN 31 DOWNTO 0 LOOP
            result(i) := to_unsigned(natural(i), natural'(8));
        END LOOP;
        RETURN result;
    END initialize_ram;

    SIGNAL ram_block : MEM := initialize_ram;
BEGIN
    PROCESS (clock)
    BEGIN
        IF (clock'event AND clock = '1') THEN
            IF (we = '1') THEN
            ram_block(write_address) <= data;
            END IF;
            q <= ram_block(read_address);
        END IF;
    END PROCESS;
END rtl;
```

ROM Functions—Inferring ALTSYNCRAM and LPM_ROM Megafunctions from HDL Code

To infer ROM functions, synthesis tools detect sets of registers and logic that can be replaced with the ALTSYNCRAM or LPM_ROM megafunctions, depending on the target device family, only for device families that have dedicated memory blocks.

ROMs are inferred when a `CASE` statement exists in which a value is set to a constant for every choice in the `case` statement. Because small ROMs typically achieve the best performance when they are implemented using the registers in regular logic, each ROM function must meet a minimum size requirement to be inferred and placed into memory.

If you use Quartus II integrated synthesis, you can direct the software to infer ROM blocks for all sizes with the **Allow Any ROM Size for Recognition** option under **More Settings** on the **Analysis & Synthesis Settings** page of the **Settings** dialog box.

Some synthesis tools provide options to control the implementation of inferred ROM blocks for Altera devices with TriMatrix memory blocks. For example, Quartus II integrated synthesis provides the `romstyle` synthesis attribute to specify the type of memory block or to specify the use of regular logic instead of a dedicated memory block.

For details about using the `romstyle` attribute, refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*. For information about synthesis attributes in other synthesis tools, refer to the appropriate chapter in the Synthesis section in volume 1 of the *Quartus II Handbook*.

When you are using a formal verification flow, Altera recommends that you create ROM blocks in separate entities or modules that contain only the ROM logic because you may need to treat the entity and module as a black box during formal verification.

Because formal verification tools do not support ROM megafunctions, Quartus II integrated synthesis does not infer ROM megafunctions when a formal verification tool is selected.

The Verilog HDL and VHDL code samples shown in Example 6–22 through Example 6–25 infer synchronous ROM blocks. Depending on the device family's dedicated RAM architecture, the ROM logic may have to be synchronous; consult the device family handbook for details.

For device architectures with synchronous RAM blocks, such as the Stratix series devices and newer device families, either the address or the output has to be registered for ROM code to be inferred. When output registers are used, the registers are implemented using the input registers of the RAM block, but the functionality of the ROM is not changed. If you register the address, the power-up state of the inferred ROM can be different from the HDL design. In this scenario, the synthesis software issues a warning. The Quartus II Help explains the condition under which the functionality changes when you use Quartus II integrated synthesis.

These ROM code samples map directly to the Altera TriMatrix memory architecture.

Example 6–22. Verilog HDL Synchronous ROM

```
module sync_rom (clock, address, data_out);
    input clock;
    input [7:0] address;
    output [5:0] data_out;

    reg [5:0] data_out;

    always @ (posedge clock)
    begin
        case (address)
            8'b00000000: data_out = 6'b101111;
            8'b00000001: data_out = 6'b110110;
            ...
            8'b11111110: data_out = 6'b000001;
            8'b11111111: data_out = 6'b101010;
        endcase
    end
endmodule
```

Example 6–23. VHDL Synchronous ROM

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;

ENTITY sync_rom IS
    PORT (
        clock: IN STD_LOGIC;
        address: IN STD_LOGIC_VECTOR(7 downto 0);
        data_out: OUT STD_LOGIC_VECTOR(5 downto 0)
    );
END sync_rom;

ARCHITECTURE rtl OF sync_rom IS
BEGIN
PROCESS (clock)
    BEGIN
    IF rising_edge (clock) THEN
        CASE address IS
            WHEN "00000000" => data_out <= "101111";
            WHEN "00000001" => data_out <= "110110";
            ...
            WHEN "11111110" => data_out <= "000001";
            WHEN "11111111" => data_out <= "101010";
            WHEN OTHERS => data_out <= "101111";
        END CASE;
    END IF;
    END PROCESS;
END rtl;
```

Example 6–24. Verilog HDL Dual-Port Synchronous ROM Using readmemb

```
module dual_port_rom (
    input [(addr_width-1):0] addr_a, addr_b,
    input clk,
    output reg [(data_width-1):0] q_a, q_b
);
    parameter data_width = 8;
    parameter addr_width = 8;

    reg [data_width-1:0] rom[2**addr_width-1:0];

    initial  // Read the memory contents in the file
dual_port_rom_init.txt.
    begin
        $readmemb("dual_port_rom_init.txt", rom);
    end

    always @ (posedge clk)
    begin
        q_a <= rom[addr_a];
        q_b <= rom[addr_b];
    end
endmodule
```

Example 6–25. VHDL Dual-Port Synchronous ROM Using Initialization Function

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.numeric_std.all;

entity dual_port_rom is
    generic (
        DATA_WIDTH : natural := 8;
        ADDR_WIDTH : natural := 8
    );
    port (
        clk    : in std_logic;
        addr_a: in natural range 0 to 2**ADDR_WIDTH - 1;
        addr_b: in natural range 0 to 2**ADDR_WIDTH - 1;
        q_a    : out std_logic_vector((DATA_WIDTH -1) downto 0);
        q_b    : out std_logic_vector((DATA_WIDTH -1) downto 0)
    );
end entity;

architecture rtl of dual_port_rom is
    -- Build a 2-D array type for the ROM
    subtype word_t is std_logic_vector((DATA_WIDTH-1) downto 0);
    type memory_t is array(addr_a'high downto 0) of word_t;

    function init_rom
        return memory_t is
        variable tmp : memory_t := (others => (others => '0'));
    begin
        for addr_pos in 0 to 2**ADDR_WIDTH - 1 loop
            -- Initialize each address with the address itself
            tmp(addr_pos) := std_logic_vector(to_unsigned(addr_pos,
DATA_WIDTH));
        end loop;
        return tmp;
    end init_rom;

    -- Declare the ROM signal and specify a default initialization value.
    signal rom : memory_t := init_rom;
begin
    process(clk)
    begin
    if (rising_edge(clk)) then
        q_a <= rom(addr_a);
        q_b <= rom(addr_b);
    end if;
    end process;
end rtl;
```

Shift Registers—Inferring the ALTSHIFT_TAPS Megafunction from HDL Code

To infer shift registers, synthesis tools detect a group of shift registers of the same length and convert them to an ALTSHIFT_TAPS megafunction. To be detected, all the shift registers must have the following characteristics:

- Use the same clock and clock enable
- Do not have any other secondary signals
- Have equally spaced taps that are at least three registers apart

When you use a formal verification flow, Altera recommends that you create shift register blocks in separate entities or modules containing only the shift register logic, because yoight have to treat the entity or module as a black box during formal verification.

Because formal verification tools do not support shift register megafunctions, Quartus II integrated synthesis does not infer the ALTSHIFT_TAPS megafunction when a formal verification tool is selected. You can select EDA tools for use with your Quartus II project on the **EDA Tool Settings** page of the **Settings** dialog box.

For more information about the ALTSHIFT_TAPS megafunction, refer to the *ALTSHIFT_TAPS Megafunction User Guide*.

Synthesis software recognizes shift registers only for device families that have dedicated RAM blocks and the software uses certain guidelines to determine the best implementation. The following guidelines are followed in Quartus II integrated synthesis and also are generally followed by other EDA tools:

- For FLEX 10K® and ACEX 1K devices, the software does not infer ALTSHIFT_TAPS megafunctions because FLEX 10K and ACEX 1K devices have a relatively small amount of dedicated memory.
- For APEX 20K and APEX II devices, the software infers the ALTSHIFT_TAPS megafunction only if the shift register has more than a total of 128 bits. Smaller shift registers typically do not benefit from implementation in dedicated memory.
- For the Arria GX, Stratix, and Cyclone series devices, the software determines whether to infer the ALTSHIFT_TAPS megafunction based on the width of the registered bus (W), the length between each tap (L), and the number of taps (N).
  - If the registered bus width is one ($W = 1$), the software infers ALTSHIFT_TAPS if the number of taps times the length between each tap is greater than or equal to 64 ($N \times L \geq 64$).
  - If the registered bus width is greater than one ($W > 1$), the software infers ALTSHIFT_TAPS if the registered bus width times the number of taps times the length between each tap is greater than or equal to 32 ($W \times N \times L \geq 32$).

If the length between each tap (L) is not a power of two, the software uses more logic to decode the read and write counters. This situation occurs because for different sizes of shift registers, external decode logic that uses logic elements (LEs) or Adaptive Logic Modules (ALMs) is required to implement the function. This decode logic eliminates the performance and utilization advantages of implementing shift registers in memory.

The registers that the software maps to the ALTSHIFT_TAPS megafunction and places in RAM are not available in a Verilog HDL or VHDL output file for simulation tools because their node names do not exist after synthesis.

Simple Shift Register

The code samples shown in Example 6–26 and Example 6–27 show a simple, single-bit wide, 64-bit long shift register. The synthesis software implements the register (`W` = 1 and `M = 64`) in an ALTSHIFT_TAPS megafunction for supported devices. If the length of the register is less than 64 bits, the software implements the shift register in logic.

Example 6–26. Verilog HDL Single-Bit Wide, 64-Bit Long Shift Register

```
module shift_1x64 (clk, shift, sr_in, sr_out);
    input clk, shift;
    input sr_in;
    output sr_out;

    reg [63:0] sr;

    always @ (posedge clk)
    begin
        if (shift == 1'b1)
        begin
            sr[63:1] <= sr[62:0];
            sr[0] <= sr_in;
        end
    end
    assign sr_out = sr[63];
endmodule
```

Example 6–27. VHDL Single-Bit Wide, 64-Bit Long Shift Register

```
LIBRARY IEEE;
USE IEEE.STD_LOGIC_1164.all;
ENTITY shift_1x64 IS
PORT (
clk: IN STD_LOGIC;
shift: IN STD_LOGIC;
sr_in: IN STD_LOGIC;
sr_out: OUT STD_LOGIC
);
END shift_1x64;

ARCHITECTURE arch OF shift_1x64 IS
TYPE sr_length IS ARRAY (63 DOWNTO 0) OF STD_LOGIC;
SIGNAL sr: sr_length;
BEGIN
PROCESS (clk)
BEGIN
IF (clk'EVENT and clk = '1') THEN
IF (shift = '1') THEN
sr(63 DOWNTO 1) <= sr(62 DOWNTO 0);
sr(0) <= sr_in;
END IF;
END IF;
END PROCESS;
sr_out <= sr(63);
END arch;
```

Shift Register with Evenly Spaced Taps

The code samples shown in Example 6–28 and Example 6–29 show a Verilog HDL and VHDL 8-bit wide, 64-bit long shift register (`W > 1` and `M = 64`) with evenly spaced taps at 15, 31, and 47. The synthesis software implements this function in a single ALTSHIFT_TAPS megafunction and maps it to RAM in supported devices.

Example 6–28. Verilog HDL 8-Bit Wide, 64-Bit Long Shift Register with Evenly Spaced Taps

```
module shift_8x64_taps (clk, shift, sr_in, sr_out, sr_tap_one,
sr_tap_two, sr_tap_three );
    input clk, shift;
    input [7:0] sr_in;
    output [7:0] sr_tap_one, sr_tap_two, sr_tap_three, sr_out;

    reg [7:0] sr [63:0];
    integer n;

    always @ (posedge clk)
    begin
        if (shift == 1'b1)
        begin
            for (n = 63; n>0; n = n-1)
            begin
                sr[n] <= sr[n-1];
            end
            sr[0] <= sr_in;
        end

    end
    assign sr_tap_one = sr[15];
    assign sr_tap_two = sr[31];
    assign sr_tap_three = sr[47];
    assign sr_out = sr[63];
endmodule
```

Example 6–29. VHDL 8-Bit Wide, 64-Bit Long Shift Register with Evenly Spaced Taps

```
LIBRARY IEEE;
USE IEEE.STD_LOGIC_1164.all;
ENTITY shift_8x64_taps IS
    PORT (
        clk: IN STD_LOGIC;
        shift: IN STD_LOGIC;
        sr_in: IN STD_LOGIC_VECTOR(7 DOWNTO 0);
        sr_tap_one: OUT STD_LOGIC_VECTOR(7 DOWNTO 0);
        sr_tap_two : OUT STD_LOGIC_VECTOR(7 DOWNTO 0);
        sr_tap_three: OUT STD_LOGIC_VECTOR(7 DOWNTO 0);
        sr_out: OUT STD_LOGIC_VECTOR(7 DOWNTO 0)
    );
    END shift_8x64_taps;

ARCHITECTURE arch OF shift_8x64_taps IS
    SUBTYPE sr_width IS STD_LOGIC_VECTOR(7 DOWNTO 0);
    TYPE sr_length IS ARRAY (63 DOWNTO 0) OF sr_width;
    SIGNAL sr: sr_length;
BEGIN
    PROCESS (clk)
    BEGIN
        IF (clk'EVENT and clk = '1') THEN
            IF (shift = '1') THEN
                sr(63 DOWNTO 1) <= sr(62 DOWNTO 0);
                sr(0) <= sr_in;
            END IF;
        END IF;
    END PROCESS;
    sr_tap_one <= sr(15);
    sr_tap_two <= sr(31);
    sr_tap_three <= sr(47);
    sr_out <= sr(63);
END arch;
```

Coding Guidelines for Registers and Latches

This section provides device-specific coding recommendations for Altera registers and latches. Understanding the architecture of the target Altera device helps ensure that your code produces the expected results and achieves the optimal quality of results.

This section provides guidelines in the following areas:

- "Register Power-Up Values in Altera Devices"
- "Secondary Register Control Signals Such as Clear and Clock Enable" on page 6–38
- "Latches" on page 6–42

Register Power-Up Values in Altera Devices

Registers in the device core always power up to a low (0) logic level on all Altera devices. However, there are ways to implement logic such that registers behave as if they were powering up to a high (1) logic level.

If you use a preset signal on a device that does not support presets in the register architecture, then your synthesis tool may convert the preset signal to a clear signal, which requires synthesis to perform an optimization referred to as NOT gate push-back. NOT gate push-back adds an inverter to the input and the output of the register so that the reset and power-up conditions will appear to be high but the device operates as expected. In this case, your synthesis tool may issue a message informing you about the power-up condition. The register itself powers up low, but the register output is inverted, so the signal that arrives at all destinations is high.

Due to these effects, if you specify a non-zero reset value, you may cause your synthesis tool to use the asynchronous clear (`aclr`) signals available on the registers to implement the high bits with NOT gate push-back. In that case, the registers look as though they power up to the specified reset value. You see this behavior, for example, if your design targets FLEX 10KE or ACEX devices.

When a load signal is available in the device, your synthesis tools can implement a reset of 1 or 0 value by using an asynchronous load of 1 or 0. When the synthesis tool uses an asynchronous load signal, it is not performing NOT gate push-back, so the registers power up to a `0` logic level.

For additional details, refer to the appropriate device family handbook or the appropriate handbook of the Altera website.

Designers typically use an explicit reset signal for the design, which forces all registers into their appropriate values after reset but not necessarily at power-up. You can create your design such that the asynchronous reset allows the board to operate in a safe condition and then you can bring up the design with the reset active. This is a good practice so you do not depend on the power-up conditions of the device.

You can make the your design more stable and avoid potential glitches by synchronizing external or combinational logic of the device architecture before you drive the asynchronous control ports of registers.

For additional information about good synchronous design practices, refer to the *Design Recommendations for Altera Devices and the Quartus II Design Assistant* chapter in volume 1 of the *Quartus II Handbook*.

If you want to force a particular power-up condition for your design, use the synthesis options available in your synthesis tool. With Quartus II integrated synthesis, you can apply the **Power-Up Level** logic option. You can also apply the option with an `altera_attribute` assignment in your source code. Using this option forces synthesis to perform NOT gate push-back because synthesis tools cannot actually change the power-up states of core registers.

You can apply the Quartus II integrated synthesis **Power-Up Level** logic option to a specific register or to a design entity, module or subdesign. If you do so, every register in that block receives the value. Registers power up to 0 by default; therefore you can use this assignment to force all registers to power up to 1 using NOT gate push-back.

Be aware that using NOT gate push-back as a global assignment could slightly degrade the quality of results due to the number of inverters that are required. In some situations, issues are caused by enable or secondary control logic inference. It may also be more difficult to migrate such a design to an ASIC or a HardCopy® device. You can simulate the power-up behavior in a functional simulation if you use initialization.

The **Power-Up Level** option and the `altera_attribute` assignment are described in the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*.

Some synthesis tools can also read the default or initial values for registered signals and implement this behavior in the device. For example, Quartus II integrated synthesis converts default values for registered signals into **Power-Up Level** settings. That way, the synthesized behavior matches the power-up state of the HDL code during a functional simulation.

For example, the code samples in Example 6–30 and Example 6–31 both infer a register for `q` and set its power-up level to high (while the reset value is `0`).

Example 6–30. Verilog Register with Reset and High Power-Up Value

```
reg q = 1'b1;

always @ (posedge clk or posedge aclr)
begin
if (aclr)
q <= 1'b0;
else
q <= d;
end
```

Example 6–31. VHDL Register with Reset and High Power-Up Level

```
SIGNAL q : STD_LOGIC := '1'; -- q has a default value of '1'

PROCESS (clk, reset)
BEGIN
IF (reset = '1') THEN
q <= '0';
ELSIF (rising_edge(clk)) THEN
q <= d;
END IF;
END PROCESS;
```

Secondary Register Control Signals Such as Clear and Clock Enable

FPGA device architectures contain registers, also known as “flipflops”. The registers in Altera FPGAs provide a number of secondary control signals (such as clear and enable signals) that you can use to implement control logic for each register without using extra logic cells. Device families vary in their support for secondary signals, so consult the device family data sheet to verify which signals are available in your target device.

To make the most efficient use of the signals in the device, your HDL code should match the device architecture as closely as possible. The control signals have a certain priority due to the nature of the architecture, so your HDL code should follow that priority where possible.

Your synthesis tool can emulate any control signals using regular logic, so getting functionally correct results is always possible. However, if your design requirements are flexible in terms of which control signals are used and in what priority, match your design to the target device architecture to achieve the most efficient results. If the priority of the signals in your design is not the same as that of the target architecture, then extra logic may be required to implement the control signals. This extra logic uses additional device resources and can cause additional delays for the control signals.

In addition, there are certain cases where using logic other than the dedicated control logic in the device architecture can have a larger impact. For example, the clock enable signal has priority over the synchronous reset or clear signal in the device architecture. The clock enable turns off the clock line in the LAB, and the clear signal is synchronous. So in the device architecture, the synchronous clear takes effect only when a clock edge occurs.

If you code a register with a synchronous clear signal that has priority over the clock enable signal, the software must emulate the clock enable functionality using data inputs to the registers. Because the signal does not use the clock enable port of a register, you cannot apply a Clock Enable Multicycle constraint. In this case, following the priority of signals available in the device is clearly the best choice for the priority of these control signals, and using a different priority causes unexpected results with an assignment to the clock enable signal.

The priority order for secondary control signals in Altera devices differs from the order for other vendors' devices. If your design requirements are flexible regarding priority, verify that the secondary control signals meet design performance requirements when migrating designs between FPGA vendors and try to match your target device architecture to achieve the best results.

The signal order is the same for all Altera device families, although as noted previously, not all device families provide every signal. The following priority order is observed:

1. Asynchronous Clear, `aclr`—highest priority
2. Preset, `pre`
3. Asynchronous Load, `aload`
4. Enable, `ena`
5. Synchronous Clear, `sclr`
6. Synchronous Load, `sload`
7. Data In, `data`—lowest priority

The following examples provide Verilog HDL and VHDL code that creates a register with the `aclr`, `aload`, and `ena` control signals.

The Verilog HDL example (Example 6–32) does not have adata on the sensitivity list, but the VHDL example (Example 6–33) does. This is a limitation of the Verilog HDL language—there is no way to describe an asynchronous load signal (in which q toggles if adata toggles while aload is high). All synthesis tools should infer an aload signal from this construct despite this limitation. When they perform such inference, you may see information or warning messages from the synthesis tool.

Example 6–32. Verilog HDL D-Type Flipflop (Register) with ena, aclr, and aload Control Signals

```
module dff_control(clk, aclr, aload, ena, data, adata, q);
    input clk, aclr, aload, ena, data, adata;
    output q;

    reg q;

    always @ (posedge clk or posedge aclr or posedge aload)
    begin
        if (aclr)
            q <= 1'b0;
        else if (aload)
            q <= adata;
        else if (ena)
            q <= data;
    end
endmodule
```

Example 6–33. VHDL D-Type Flipflop (Register) with ena, aclr, and aload Control Signals

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;

ENTITY dff_control IS
   PORT (
clk: IN STD_LOGIC;
aclr: IN STD_LOGIC;
aload: IN STD_LOGIC;
adata: IN STD_LOGIC;
ena: IN STD_LOGIC;
      data: IN STD_LOGIC;
q: OUT STD_LOGIC
    );
END dff_control;

ARCHITECTURE rtl OF dff_control IS
BEGIN
   PROCESS (clk, aclr, aload, adata)
   BEGIN
IF (aclr = '1') THEN
q <= '0';
ELSIF (aload = '1') THEN
q <= adata;
ELSE
           IF (clk = '1' AND clk'event) THEN
               IF (ena ='1') THEN
q <= data;
               END IF;
           END IF;
       END IF;
   END PROCESS;
END rtl;
```

The preset signal is not available in many device families; therefore, it is not included in the examples.

Creating many registers with different `sload` and `sclr` signals can make packing the registers into LABs difficult for the Quartus II Fitter because the `sclr` and `sload` signals are LAB-wide signals. In addition, using the LAB-wide `sload` signal prevents the Fitter from packing registers using the quick feedback path in the device architecture, which means that some registers cannot be packed with other logic.

Synthesis tools typically restrict use of `sload` and `sclr` signals to cases in which there are enough registers with common signals to allow good LAB packing. Using the look-up table (LUT) to implement the signals is always more flexible if it is available. Because different device families offer different numbers of control signals, inference of these signals is also device-specific. For example, Stratix II devices have more flexibility than Stratix devices with respect to secondary control signals, so synthesis tools might infer more `sload` and `sclr` signals for Stratix II devices.

If you use these additional control signals, use them in the priority order that matches the device architecture. To achieve the most efficient results, ensure the `sclr` signal has a higher priority than the `sload` signal in the same way that `aclr` has higher priority than `aload` in the previous examples. Remember that the register signals are not inferred unless the design meets the conditions described previously. However, if your HDL described the desired behavior, the software always implements logic with the correct functionality.

In Verilog HDL, the following code for `sload` and `sclr` could replace the `if (ena) q <= data;` statements in the Verilog HDL example shown in Example 6–32 (after adding the control signals to the module declaration).

Example 6–34. Verilog HDL sload and sclr Control Signals

```
if  (ena) begin
   if  (sclr)
     q <= 1'b0;
   else if  (sload)
     q <= sdata;
   else
     q <= data;
end
```

In VHDL, the following code for `sload` and `sclr` could replace the `IF (ena ='1') THEN q <= data; END IF;` statements in the VHDL example shown in Example 6–33 on page 6–40 (after adding the control signals to the entity declaration).

Example 6–35. VHDL sload and sclr Control Signals

```
IF (ena ='1') THEN
   IF (sclr = '1') THEN
     q <= '0';
   ELSIF (sload = '1') THEN
     q <= sdata;
   ELSE
     q <= data;
   END IF;
END IF;
```

Latches

A latch is a small combinational loop that holds the value of a signal until a new value is assigned.

Altera recommends that you design without the use of latches whenever possible.

For additional information about the issues involved in designing with latches and combinational loops, refer to the *Design Recommendations for Altera Devices and the Quartus II Design Assistant* chapter in volume 1 of the *Quartus II Handbook*.

Latches can be inferred from HDL code when you did not intend to use a latch, as described in "Unintentional Latch Generation". If you do intend to infer a latch, it is important to infer it correctly to guarantee correct device operation as detailed in "Inferring Latches Correctly" on page 6–43.

Unintentional Latch Generation

When you are designing combinational logic, certain coding styles can create an unintentional latch. For example, when `CASE` or `IF` statements do not cover all possible input conditions, latches may be required to hold the output if a new output value is not assigned. Check your synthesis tool messages for references to inferred latches. If your code unintentionally creates a latch, make code changes to remove the latch.

Latches have limited support in formal verification tools. Therefore, ensure that you do not infer latches unintentionally. For example, an incomplete `CASE` statement may create a latch when you are using formal verification in your design flow.

The `full_case` attribute can be used in Verilog HDL designs to treat unspecified cases as don't care values (`X`). However, using the `full_case` attribute can cause simulation mismatches because this attribute is a synthesis-only attribute, so simulation tools still treat the unspecified cases as latches.

Refer to the appropriate chapter in the *Synthesis* section in volume 1 of the *Quartus II Handbook* for more information about using attributes in your synthesis tool. The *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook* provides an example explaining possible simulation mismatches.

Omitting the final `else` or `when others` clause in an `if` or `case` statement can also generate a latch. Don't care (`X`) assignments on the default conditions are useful in preventing latch generation. For the best logic optimization, assign the default `case` or final `else` value to don't care (`X`) instead of a logic value.

The VHDL sample code shown in Example 6–36 prevents unintentional latches. Without the final `else` clause, this code creates unintentional latches to cover the remaining combinations of the `sel` inputs. When you are targeting a Stratix device with this code, omitting the final `else` condition can cause the synthesis software to use up to six LEs, instead of the three it uses with the `else` statement. Additionally, assigning the final `else` clause to `1` instead of `X` can result in slightly more LEs because the synthesis software cannot perform as much optimization when you specify a constant value compared to a don't care value.

Example 6–36. VHDL Code Preventing Unintentional Latch Creation

```
LIBRARY ieee;
USE IEEE.std_logic_1164.all;

ENTITY nolatch IS
    PORT (a,b,c: IN STD_LOGIC;
        sel: IN STD_LOGIC_VECTOR (4 DOWNTO 0);
        oput: OUT STD_LOGIC);
END nolatch;

ARCHITECTURE rtl OF nolatch IS
BEGIN
    PROCESS (a,b,c,sel) BEGIN
        if sel = "00000" THEN
            oput <= a;
        ELSIF sel = "00001" THEN
            oput <= b;
        ELSIF sel = "00010" THEN
            oput <= c;
        ELSE            --- Prevents latch inference
            oput <= ''X'; --/
        END if;
    END PROCESS;
END rtl;
```

Inferring Latches Correctly

Synthesis tools can infer a latch that does not exhibit the glitch and timing hazard problems typically associated with combinational loops.

Any use of latches generates warnings and is flagged if the design is migrated to a HardCopy ASIC. In addition, timing analysis does not completely model latch timing in some cases. Do not use latches unless you are very certain that your design requires it, and you fully understand the impact of using the latches.

When using Quartus II integrated synthesis, latches that are inferred by the software are reported in the **User-Specified and Inferred Latches** section of the Compilation Report. This report indicates whether the latch is considered safe and free of timing hazards.

If a latch or combinational loop in your design is not listed in the **User-Specified and Inferred Latches** section, it means that it was not inferred as a safe latch by the software and is not considered glitch-free.

All combinational loops listed in the **Analysis & Synthesis Logic Cells Representing Combinational Loops** table in the Compilation Report are at risk of timing hazards. These entries indicate possible problems with your design that you should investigate. However, it is possible to have a correct design that includes combinational loops. For example, it is possible that the combinational loop cannot be sensitized. This can occur in cases where there is an electrical path in the hardware, but either the designer knows that the circuit never encounters data that causes that path to be activated, or the surrounding logic is set up in a mutually exclusive manner that prevents that path from ever being sensitized, independent of the data input.

For macrocell-based devices such as MAX® 7000AE and MAX 3000A, all data (D-type) latches and set-reset (S-R) latches listed in the **Analysis & Synthesis User-Specified and Inferred Latches** table have an implementation free of timing hazards such as glitches. The implementation includes a cover term to ensure there is no glitching, and includes a single macrocell in the feedback loop.

For 4-input LUT-based devices such as Stratix devices, the Cyclone series, and MAX II devices, all latches in the **User-Specified and Inferred Latches** table with a single LUT in the feedback loop are free of timing hazards when a single input changes. Because of the hardware behavior of the LUT, the output does not glitch when a single input toggles between two values that are supposed to produce the same output value. For example, a D-type input toggling when the enable input is inactive, or a set input toggling when a reset input with higher priority is active. This hardware behavior of the LUT means that no cover term is required for a loop around a single LUT. The Quartus II software uses a single LUT in the feedback loop whenever possible. A latch that has data, enable, set, and reset inputs in addition to the output fed back to the input cannot be implemented in a single 4-input LUT. If the Quartus II software cannot implement the latch with a single-LUT loop because there are too many inputs, the **User-Specified and Inferred Latches** table indicates that the latch is not free of timing hazards.

For 6-input LUT-based devices, the software can implement all latch inputs with a single adaptive look-up table (ALUT) in the combinational loop. Therefore, all latches in the **User-Specified and Inferred Latches** table are free of timing hazards when a single input changes.

If a latch is listed as a safe latch, other Quartus II optimizations, such as physical synthesis netlist optimizations in the Fitter, maintain the hazard-free performance.

To ensure hazard-free behavior, only one control input may change at a time. Changing two inputs simultaneously, such as deasserting set and reset at the same time, or changing data and enable at the same time, can produce incorrect behavior in any latch.

Quartus II integrated synthesis infers latches from always blocks in Verilog HDL and process statements in VHDL, but not from continuous assignments in Verilog HDL or concurrent signal assignments in VHDL. These rules are the same as for register inference. The software infers registers or flipflops only from `always` blocks and `process` statements.

The Verilog HDL code sample shown in Example 6–37 infers a S-R latch correctly in the Quartus II software.

Example 6–37. Verilog HDL Set-Reset Latch

```
module simple_latch (
   input SetTerm,
   input ResetTerm,
   output reg LatchOut
   );

   always @ (SetTerm or ResetTerm) begin
      if (SetTerm)
         LatchOut = 1'b1
      else if (ResetTerm)
         LatchOut = 1'b0
   end
endmodule
```

The VHDL code sample shown in Example 6–38 infers a D-type latch correctly in the Quartus II software.

Example 6–38. VHDL Data Type Latch

```
LIBRARY IEEE;
USE IEEE.std_logic_1164.all;

ENTITY simple_latch IS
PORT (
enable, data     : IN STD_LOGIC;
q                : OUT STD_LOGIC
);
END simple_latch;

ARCHITECTURE rtl OF simple_latch IS
BEGIN

latch : PROCESS (enable, data)
BEGIN
IF (enable = '1') THEN
q <= data;
END IF;
END PROCESS latch;
END rtl;
```

The following example shows a Verilog HDL continuous assignment that does not infer a latch in the Quartus II software. (The behavior is similar to a latch, but it may not function correctly as a latch and its timing is not analyzed as a latch):

```
assign latch_out = (~en & latch_out) | (en & data);
```

Quartus II integrated synthesis also creates safe latches when possible for instantiations of the LPM_LATCH megafunction. You can use this megafunction to create a latch with any combination of data, enable, set, and reset inputs. The same limitations apply for creating safe latches as for inferring latches from HDL code.

Inferring the Altera LPM_LATCH function in another synthesis tool ensures that the implementation is also recognized as a latch in the Quartus II software. If a third-party synthesis tool implements a latch using the LPM_LATCH megafunction, then the Quartus II integrated synthesis lists the latch in the **User-Specified and Inferred Latches** table in the same way as it lists latches created in HDL source code. The coding style necessary to produce an LPM_LATCH implementation may depend on your synthesis tool. Some third-party synthesis tools list the number of LPM_LATCH functions that are inferred.

For LUT-based families, the Fitter uses global routing for control signals including signals that Analysis and Synthesis identifies as latch enables. In some cases the global insertion delay may decrease the timing performance. If necessary, you can turn off the **Quartus II Global Signal** logic option to manually prevent the use of global signals. Global latch enables are listed in the **Global & Other Fast Signals** table in the Compilation Report.

General Coding Guidelines

This section helps you understand how synthesis tools map various types of HDL code into the target Altera device. Following Altera recommended coding styles, and in some cases designing logic structures to match the appropriate device architecture, can provide significant improvements in the design's quality of results.

This section provides coding guidelines for the following logic structures:

- "Tri-State Signals". This section explains how to create tri-state signals for bidirectional I/O pins.
- "Clock Multiplexing" on page 6–47. This section provides recommendations for multiplexing clock signals.
- "Adder Trees" on page 6–51. This section explains the different coding styles that lead to optimal results for devices with 4-input look-up tables and 6-input ALUTs.
- "State Machines" on page 6–53. This section helps ensure the best results when you use state machines.
- "Multiplexers" on page 6–60. This section explains how multiplexers can be synthesized for 4-input LUT devices, addresses common problems, and provides guidelines to achieve optimal resource utilization.
- "Cyclic Redundancy Check Functions" on page 6–68. This section provides guidelines for getting good results when designing Cyclic Redundancy Check (CRC) functions.
- "Comparators" on page 6–69. This section explains different comparator implementations and provides suggestions for controlling the implementation.
- "Counters" on page 6–71. This section provides guidelines to ensure your counter design targets the device architecture optimally.

Tri-State Signals

When you target Altera devices, you should use tri-state signals only when they are attached to top-level bidirectional or output pins. Avoid lower level bidirectional pins, and avoid using the `Z` logic value unless it is driving an output or bidirectional pin.

Synthesis tools implement designs with internal tri-state signals correctly in Altera devices using multiplexer logic, but Altera does not recommend this coding practice.

In hierarchical block-based or incremental design flows, a hierarchical boundary cannot contain any bidirectional ports, unless the lower level bidirectional port is connected directly through the hierarchy to a top-level output pin without connecting to any other design logic. If you use boundary tri-states in a lower level block, synthesis software must push the tri-states through the hierarchy to the top-level to make use of the tri-state drivers on output pins of Altera devices. Because pushing tri-states requires optimizing through hierarchies, lower level tri-states are restricted with block-based design methodologies.

The code examples shown in Example 6–39 and Example 6–40 show Verilog HDL and VHDL code that creates tri-state bidirectional signals.

Example 6–39. Verilog HDL Tri-State Signal

```
module tristate (myinput, myenable, mybidir);
   input myinput, myenable;
   inout mybidir;
   assign mybidir = (myenable ? myinput : 1'bZ);
endmodule
```

Example 6–40. VHDL Tri-State Signal

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
USE ieee.std_logic_arith.all;

ENTITY tristate IS
PORT (
   mybidir : INOUT STD_LOGIC;
   myinput : IN STD_LOGIC;
   myenable : IN STD_LOGIC
    );
END tristate;

ARCHITECTURE rtl OF tristate IS
BEGIN
   mybidir <= 'Z' WHEN (myenable = '0') ELSE myinput;
END rtl;
```

Clock Multiplexing

Clock multiplexing is sometimes used to operate the same logic function with different clock sources. This type of logic can introduce glitches that create functional problems, and the delay inherent in the combinational logic can lead to timing problems. Clock multiplexers trigger warnings from a wide range of design rule check and timing analysis tools.

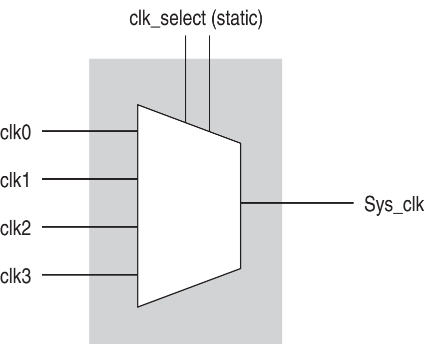
Altera recommends using dedicated hardware to perform clock multiplexing when it is available, instead of using multiplexing logic. For example, you can use the Clock Switchover feature or the Clock Control Block available in certain Altera devices. These dedicated hardware blocks avoid glitches, ensure that you use global low-skew routing lines, and avoid any possible hold time problems on the device due to logic delay on the clock line. Many Altera devices also support dynamic PLL reconfiguration, which is the safest and most robust method of changing clock rates during device operation.

Refer to the appropriate device data sheet or handbook for device-specific information about clocking structures. Also refer to the *ALTCLKCTRL Megafunction User Guide*, the *ALTPLL Megafunction User Guide*, and the *Phase-Locked Loops Reconfiguration (ALTPLL_RECONFIG) Megafunction User Guide*.

If you implement a clock multiplexer in logic cells because the design has too many clocks to use the clock control block, or if dynamic reconfiguration is too complex for your design, it is important to consider simultaneous toggling inputs and ensure glitch-free transitions.

Figure 6–2 shows a simple representation of a clock multiplexer (mux) in a device with 6-input LUTs.

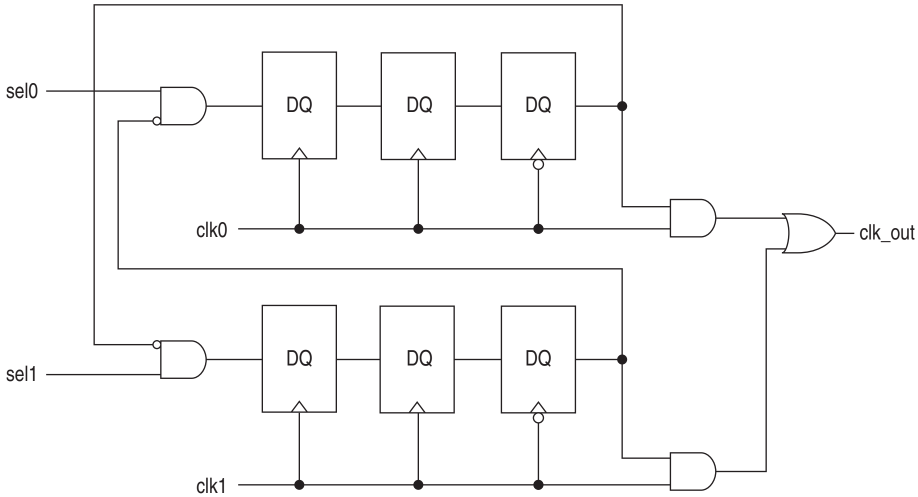
Figure 6–2. Simple Clock Multiplexer in a 6-Input LUT



The data sheet for your target device describes how LUT outputs may glitch during a simultaneous toggle of input signals, independent of the LUT function. Although in practice the 4:1 MUX function does not generate detectable glitches during simultaneous data input toggles, it is possible to construct cell implementations that do exhibit significant glitches, so this simple clock mux structure is not recommended. An additional problem with this implementation is that the output behaves erratically during a change in the `clk_select` signals. This behavior could create timing violations on all registers fed by the system clock and result in possible metastability.

A more sophisticated clock select structure can eliminate the simultaneous toggle and switching problems, as shown in Figure 6–3.

Figure 6–3. Glitch-Free Clock Multiplexer Structure



This structure can be generalized for any number of clock channels. Example 6–41 contains a parameterized version in Verilog HDL. The design enforces that no clock activates until all others have been inactive for at least a few cycles, and that activation occurs while the clock is low. The design applies a `synthesis_keep` directive to the AND gates on the right side of the figure, which ensures there are no simultaneous toggles on the input of the `clk_out` OR gate.

It is important to note that switching from clock `A` to clock `B` requires that clock `A` continue to operate for at least a few cycles. If the old clock stops immediately, the design sticks. The select signals are implemented as a “one-hot” control in this example, but you can use other encoding if you prefer. The input side logic is asynchronous and is not critical. This design can tolerate extreme glitching during the switch process.

Example 6–41. Verilog HDL Clock Multiplexing Design to Avoid Glitches

```
module clock_mux (clk,clk_select,clk_out);

parameter num_clocks = 4;

input [num_clocks-1:0] clk;
input [num_clocks-1:0] clk_select; // one hot
output clk_out;

genvar i;

reg [num_clocks-1:0] ena_r0;
reg [num_clocks-1:0] ena_r1;
reg [num_clocks-1:0] ena_r2;
wire [num_clocks-1:0] qualified_sel;

// A look-up-table (LUT) can glitch when multiple inputs
// change simultaneously. Use the keep attribute to
// insert a hard logic cell buffer and prevent
// the unrelated clocks from appearing on the same LUT.

wire [num_clocks-1:0] gated_clks /* synthesis keep */;

initial begin
ena_r0 = 0;
ena_r1 = 0;
ena_r2 = 0;
end

generate
for (i=0; i<num_clocks; i=i+1)
begin : lp0
wire [num_clocks-1:0] tmp_mask;
assign tmp_mask = {num_clocks{1'b1}} ^ (1 << i);

assign qualified_sel[i] = clk_select[i] &
          (~|(ena_r2 & tmp_mask));

always @(posedge clk[i]) begin
ena_r0[i] <= qualified_sel[i];
ena_r1[i] <= ena_r0[i];
end

always @(negedge clk[i]) begin
ena_r2[i] <= ena_r1[i];
end

assign gated_clks[i] = clk[i] & ena_r2[i];
end
endgenerate

// These will not exhibit simultaneous toggle by construction
assign clk_out = |gated_clks;

endmodule
```

Adder Trees

Structuring adder trees appropriately to match your targeted Altera device architecture can result in significant performance and density improvements. A good example of an application using a large adder tree is a finite impulse response (FIR) correlator. Using a pipelined binary or ternary adder tree appropriately can greatly improve the quality of your results.

This section explains why coding recommendations are different for Altera 4-input LUT devices and 6-input LUT devices.

Architectures with 4-Input LUTs in Logic Elements

Architectures such as Stratix devices and the Cyclone series, APEX series, and FLEX series of devices contain 4-input LUTs as the standard combinational structure in the LE.

If your design can tolerate pipelining, the fastest way to add three numbers `A`, `B`, and `C` in devices that use 4-input lookup tables is to add `A + B`, register the output, and then add the registered output to `C`. Adding `A + B` takes one level of logic (one bit is added in one LE), so this runs at full clock speed. This can be extended to as many numbers as desired.

Example 6–42 shows five numbers `A`, `B`, `C`, `D`, and `E` are added. Adding five numbers in devices that use 4-input lookup tables requires four adders and three levels of registers for a total of 64 LEs (for 16-bit numbers).

Example 6–42. Verilog HDL Pipelined Binary Tree

```
module binary_adder_tree (a, b, c, d, e, clk, out);
   parameter width = 16;
   input [width-1:0] a, b, c, d, e;
   input clk;
   output [width-1:0] out;

   wire [width-1:0] sum1, sum2, sum3, sum4;
   reg [width-1:0] sumreg1, sumreg2, sumreg3, sumreg4;
   // Registers

   always @ (posedge CLK)
      begin
         sumreg1 <= sum1;
         sumreg2 <= sum2;
         sumreg3 <= sum3;
         sumreg4 <= sum4;
      end

   // 2-bit additions
   assign sum1 = A + B;
   assign sum2 = C + D;
   assign sum3 = sumreg1 + sumreg2;
   assign sum4 = sumreg3 + E;
   assign out = sumreg4;
endmodule
```

Architectures with 6-Input LUTs in Adaptive Logic Modules

High-performance Altera device families use a 6-input LUT in their basic logic structure, so these devices benefit from a different coding style from the previous example presented for 4-input LUTs. Specifically, in these devices, ALMs can simultaneously add three bits. Therefore, the tree in Example 6–42 must be two levels deep and contain just two add-by-three inputs instead of four add-by-two inputs.

Although the code in the previous example compiles successfully for 6-input LUT devices, the code is inefficient and does not take advantage of the 6-input adaptive ALUT. By restructuring the tree as a ternary tree, the design becomes much more efficient, significantly improving density utilization. Therefore, when you are targeting with ALUTs and ALMs, large pipelined binary adder trees designed for 4-input LUT architectures should be rewritten to take advantage of the advanced device architecture.

Example 6–43 uses just 32 ALUTs in a Stratix II device—more than a 4:1 advantage over the number of LUTs in the prior example implemented in a Stratix device.

You cannot pack a LAB full when using this type of coding style because of the number of LAB inputs. However, in a typical design, the Quartus II Fitter can pack other logic into each LAB to take advantage of the unused ALMs.

Example 6–43. Verilog HDL Pipelined Ternary Tree

```
module ternary_adder_tree (a, b, c, d, e, clk, out);
   parameter width = 16;
   input [width-1:0] a, b, c, d, e;
   input clk;
   output [width-1:0] out;

   wire [width-1:0] sum1, sum2;
   reg [width-1:0] sumreg1, sumreg2;
   // registers

   always @ (posedge clk)
      begin
         sumreg1 <= sum1;
         sumreg2 <= sum2;
      end

   // 3-bit additions
   assign sum1 = a + b + c;
   assign sum2 = sumreg1 + d + e;
   assign out = sumreg2;
endmodule
```

These examples show pipelined adders, but partitioning your addition operations can help you achieve better results in nonpipelined adders as well. If your design is not pipelined, a ternary tree provides much better performance than a binary tree. For example, depending on your synthesis tool, the HDL code `sum = (A + B + C) + (D + E)` is more likely to create the optimal implementation of a 3-input adder for `A + B + C` followed by a 3-input adder for `sum1 + D + E` than the code without the parentheses. If you do not add the parentheses, the synthesis tool may partition the addition in a way that is not optimal for the architecture.

State Machines

Synthesis tools can recognize and encode Verilog HDL and VHDL state machines during synthesis. This section presents guidelines to ensure the best results when you use state machines. Ensuring that your synthesis tool recognizes a piece of code as a state machine allows the tool to recode the state variables to improve the quality of results, and allows the tool to use the known properties of state machines to optimize other parts of the design. When synthesis recognizes a state machine, it is often able to improve the design area and performance.

To achieve the best results on average, synthesis tools often use one-hot encoding for FPGA devices and minimal-bit encoding for CPLD devices, although the choice of implementation can vary for different state machines and different devices. Refer to your synthesis tool documentation for specific ways to control the manner in which state machines are encoded.

For information about state machine encoding in Quartus II integrated synthesis, refer to the *State Machine Processing* section in the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*.

To ensure proper recognition and inference of state machines and to improve the quality of results, Altera recommends that you observe the following guidelines, which apply to both Verilog HDL and VHDL:

- Assign default values to outputs derived from the state machine so that synthesis does not generate unwanted latches.
- Separate the state machine logic from all arithmetic functions and data paths, including assigning output values.
- If your design contains an operation that is used by more than one state, define the operation outside the state machine and cause the output logic of the state machine to use this value.
- Use a simple asynchronous or synchronous reset to ensure a defined power-up state. If your state machine design contains more elaborate reset logic, such as both an asynchronous reset and an asynchronous load, the Quartus II software generates regular logic rather than inferring a state machine.

If a state machine enters an illegal state due to a problem with the device, the design likely ceases to function correctly until the next reset of the state machine. Synthesis tools do not provide for this situation by default. The same issue applies to any other registers if there is some kind of fault in the system. A `default` or `when others` clause does not affect this operation, assuming that your design never deliberately enters this state. Synthesis tools remove any logic generated by a default state if it is not reachable by normal state machine operation.

Many synthesis tools (including Quartus II integrated synthesis) have an option to implement a safe state machine. The software inserts extra logic to detect an illegal state and force the state machine's transition to the reset state. It is commonly used when the state machine can enter an illegal state. The most common cause of this situation is a state machine that has control inputs that come from another clock domain, such as the control logic for a dual-clock FIFO.

This option protects only state machines. All other registers in the design are not protected this way.

For additional information about tool-specific options for implementing state machines, refer to the tool vendor's documentation or the appropriate chapter in the *Synthesis* section in volume 1 of the *Quartus II Handbook*.

The following two sections, "Verilog HDL State Machines" and "VHDL State Machines" on page 6–58, describe additional language-specific guidelines and coding examples.

Verilog HDL State Machines

To ensure proper recognition and inference of Verilog HDL state machines, observe the following additional Verilog HDL guidelines. Some of these guidelines may be specific to Quartus II integrated synthesis. Refer to your synthesis tool documentation for specific coding recommendations.

If the state machine is not recognized and inferred by the synthesis software (such as Quartus II integrated synthesis), the state machine is implemented as regular logic gates and registers and the state machine is not listed as a state machine in the **Analysis & Synthesis** section of the Quartus II Compilation Report. In this case, the software does not perform any of the optimizations that are specific to state machines.

- If you are using the SystemVerilog standard, use enumerated types to describe state machines (as shown in the "SystemVerilog State Machine Coding Example" on page 6–57).
- Represent the states in a state machine with the parameter data types in Verilog-1995 and -2001 and use the parameters to make state assignments (as shown below in the "Verilog-2001 State Machine Coding Example"). This implementation makes the state machine easier to read and reduces the risk of errors during coding.

  Altera recommends against the direct use of integer values for state variables such as `next_state <= 0`. However, using an integer does not prevent inference in the Quartus II software.

- No state machine is inferred in the Quartus II software if the state transition logic uses arithmetic similar to that shown in the following example:

```
case (state)
    0: begin
        if (ena) next_state <= state + 2;
        else next_state <= state + 1;
    end
    1: begin
    ...
endcase
```

- No state machine is inferred in the Quartus II software if the state variable is an output.
- No state machine is inferred in the Quartus II software for signed variables.

Verilog-2001 State Machine Coding Example

The following module `verilog_fsm` is an example of a typical Verilog HDL state machine implementation (Example 6–44).

This state machine has five states. The asynchronous reset sets the variable `state` to `state_0`. The sum of `in_1` and `in_2` is an output of the state machine in `state_1` and `state_2`. The difference (`in_1` – `in_2`) is also used in `state_1` and `state_2`. The temporary variables `tmp_out_0` and `tmp_out_1` store the sum and the difference of `in_1` and `in_2`. Using these temporary variables in the various states of the state machine ensures proper resource sharing between the mutually exclusive states.

Example 6–44. Verilog-2001 State Machine

```
module verilog_fsm (clk, reset, in_1, in_2, out);
   input clk, reset;
   input [3:0] in_1, in_2;
   output [4:0] out;
   parameter state_0 = 3'b000;
   parameter state_1 = 3'b001;
   parameter state_2 = 3'b010;
   parameter state_3 = 3'b011;
   parameter state_4 = 3'b100;

   reg [4:0] tmp_out_0, tmp_out_1, tmp_out_2;
   reg [2:0] state, next_state;

   always @ (posedge clk or posedge reset)
   begin
      if (reset)
         state <= state_0;
      else
         state <= next_state;
   end
   always @ (state or in_1 or in_2)
   begin
      tmp_out_0 = in_1 + in_2;
      tmp_out_1 = in_1 - in_2;
      case (state)
         state_0: begin
            tmp_out_2 <= in_1 + 5'b00001;
            next_state <= state_1;
         end
         state_1: begin
            if (in_1 < in_2) begin
               next_state <= state_2;
               tmp_out_2 <= tmp_out_0;
            end
            else begin
               next_state <= state_3;
               tmp_out_2 <= tmp_out_1;
            end
         end
         state_2: begin
            tmp_out_2 <= tmp_out_0 - 5'b00001;
            next_state <= state_3;
         end
         state_3: begin
            tmp_out_2 <= tmp_out_1 + 5'b00001;
            next_state <= state_0;
         end
         state_4:begin
            tmp_out_2 <= in_2 + 5'b00001;
            next_state <= state_0;
         end
         default:begin
            tmp_out_2 <= 5'b00000;
            next_state <= state_0;
         end
      endcase
   end
   assign out = tmp_out_2;
endmodule
```

An equivalent implementation of this state machine can be achieved by using `` `define `` instead of the `parameter` data type, as follows:

```
`define state_0 3'b000
`define state_1 3'b001
`define state_2 3'b010
`define state_3 3'b011
`define state_4 3'b100
```

In this case, the `state` and `next_state` assignments are assigned a `` `state_x `` instead of a `state_x`, as shown in the following example:

```
next_state <= `state_3;
```

Although the `` `define `` construct is supported, Altera strongly recommends the use of the `parameter` data type because doing so preserves the state names throughout synthesis.

SystemVerilog State Machine Coding Example

The module `enum_fsm` shown in Example 6–45 is an example of a SystemVerilog state machine implementation that uses enumerated types. Altera recommends using this coding style to describe state machines in SystemVerilog.

In Quartus II integrated synthesis, the enumerated type that defines the states for the state machine must be of an unsigned integer type as shown in Example 6–45. If you do not specify the enumerated type as `int unsigned`, a signed `int` type is used by default. In this case, the Quartus II integrated synthesis synthesizes the design, but does not infer or optimize the logic as a state machine.

Example 6–45. SystemVerilog State Machine Using Enumerated Types

```
module enum_fsm (input clk, reset, input int data[3:0], output int o);

enum int unsigned { S0 = 0, S1 = 2, S2 = 4, S3 = 8 } state, next_state;

always_comb begin : next_state_logic
      next_state = S0;
      case(state)
        S0: next_state = S1;
        S1: next_state = S2;
        S2: next_state = S3;
        S3: next_state = S3;
      endcase
end

always_comb begin
      case(state)
         S0: o = data[3];
         S1: o = data[2];
         S2: o = data[1];
         S3: o = data[0];
      endcase
end

always_ff@(posedge clk or negedge reset) begin
      if(~reset)
         state <= S0;
      else
         state <= next_state;
end
endmodule
```

VHDL State Machines

To ensure proper recognition and inference of VHDL state machines, represent the states in a state machine with enumerated types and use the corresponding types to make state assignments. This implementation makes the state machine easier to read and reduces the risk of errors during coding. If the state is not represented by an enumerated type, synthesis software (such as Quartus II integrated synthesis) does not recognize the state machine. Instead, the state machine is implemented as regular logic gates and registers and the state machine is not listed as a state machine in the **Analysis & Synthesis** section of the Quartus II Compilation Report. In this case, the software does not perform any of the optimizations that are specific to state machines.

VHDL State Machine Coding Example

The following entity, `vhd1_fsm`, is an example of a typical VHDL state machine implementation (Example 6–46).

This state machine has five states. The asynchronous reset sets the variable `state` to `state_0`. The sum of `in1` and `in2` is an output of the state machine in `state_1` and `state_2`. The difference (`in1` - `in2`) is also used in `state_1` and `state_2`. The temporary variables `tmp_out_0` and `tmp_out_1` store the sum and the difference of `in1` and `in2`. Using these temporary variables in the various states of the state machine ensures proper resource sharing between the mutually exclusive states.

Example 6–46. VHDL State Machine (Part 1 of 2)

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
USE ieee.numeric_std.all;

ENTITY vhdl_fsm IS
   PORT(
      clk: IN STD_LOGIC;
      reset: IN STD_LOGIC;
      in1: IN UNSIGNED(4 downto 0);
      in2: IN UNSIGNED(4 downto 0);
      out_1: OUT UNSIGNED(4 downto 0)
      );
END vhdl_fsm;

ARCHITECTURE rtl OF vhdl_fsm IS
   TYPE Tstate IS (state_0, state_1, state_2, state_3, state_4);
   SIGNAL state: Tstate;
   SIGNAL next_state: Tstate;

BEGIN
   PROCESS(clk, reset)
   BEGIN
      IF reset = '1' THEN
            state <=state_0;
      ELSIF rising_edge(clk) THEN
            state <= next_state;
      END IF;
   END PROCESS;

PROCESS (state, in1, in2)
      VARIABLE tmp_out_0: UNSIGNED (4 downto 0);
      VARIABLE tmp_out_1: UNSIGNED (4 downto 0);
```

Example 6-46. VHDL State Machine (Part 2 of 2))

```
   BEGIN
      tmp_out_0 := in1 + in2;
      tmp_out_1 := in1 - in2;
      CASE state IS
         WHEN state_0 =>
            out_1 <= in1;
            next_state <= state_1;
         WHEN state_1 =>
            IF (in1 < in2) then
               next_state <= state_2;
               out_1 <= tmp_out_0;
            ELSE
               next_state <= state_3;
               out_1 <= tmp_out_1;
            END IF;
         WHEN state_2 =>
            IF (in1 < "0100") then
               out_1 <= tmp_out_0;
            ELSE
               out_1 <= tmp_out_1;
            END IF;
               next_state <= state_3;

         WHEN state_3 =>
               out_1 <= "11111";
               next_state <= state_4;
         WHEN state_4 =>
               out_1 <= in2;
               next_state <= state_0;
         WHEN OTHERS =>
               out_1 <= "00000";
               next_state <= state_0;
      END CASE;
   END PROCESS;
END rtl;
```

Multiplexers

Multiplexers form a large portion of the logic utilization in many FPGA designs. By optimizing your multiplexer logic, you ensure the most efficient implementation in your Altera device. This section addresses common problems and provides design guidelines to achieve optimal resource utilization for multiplexer designs. The section also describes various types of multiplexers, and how they are implemented in the 4-input LUT found in many FPGA architectures, such as Altera's Stratix devices.

Stratix II and other high-performance devices have 6-input ALUTs and are not specifically addressed here. Although many of the principles and techniques for optimization are similar, device utilization differs in the 6-input LUT devices. For example, these devices can implement wider multiplexers in one ALM than can be implemented in the 4-input LUT of an LE.

Quartus II Software Option for Multiplexer Restructuring

Quartus II integrated synthesis provides the **Restructure Multiplexers** logic option that extracts and optimizes buses of multiplexers during synthesis. In certain situations, this option automatically performs some of the recoding functions described in this section without changing the HDL code in your design. This option is on by default, when the **Optimization technique** is set to **Balanced** (the default for most device families) or set to **Area**.

For details, refer to the *Restructure Multiplexers* subsection in the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*.

Even with this Quartus II-specific option turned on, it is beneficial to understand how your coding style can be interpreted by your synthesis tool, and avoid the situations that can cause problems in your design.

Multiplexer Types

This subsection addresses how multiplexers are created from various types of HDL code. `CASE` statements, `IF` statements, and state machines are all common sources of multiplexer logic in designs. These HDL structures create different types of multiplexers including binary multiplexers, selector multiplexers, and priority multiplexers. Understanding how multiplexers are created from HDL code and how they might be implemented during synthesis is the first step towards optimizing multiplexer structures for best results.

Binary Multiplexers

Binary multiplexers select inputs based on binary-encoded selection bits. Example 6–47 shows Verilog HDL code for two ways to describe a simple 4:1 binary multiplexer.

Example 6–47. Verilog HDL Binary-Encoded Multiplexers

```
case (sel)
   2'b00: z = a;
   2'b01: z = b;
   2'b10: z = c;
   2'b11: z = d;
endcase
```

A 4:1 binary multiplexer is efficiently implemented by using two 4-input LUTs. Larger binary multiplexers can be constructed that use the 4:1 multiplexer; constructing an N-input multiplexer (N:1 multiplexer) from a tree of 4:1 multiplexers can result in a structure using as few as 0.66*(N - 1) LUTs.

Selector Multiplexers

Selector multiplexers have a separate select line for each data input. The select lines for the multiplexer are one-hot encoded. Example 6–48 shows a simple Verilog HDL code example describing a one-hot selector multiplexer.

Example 6–48. Verilog HDL One-Hot-Encoded Case Statement

```
case (sel)
   4'b0001: z = a;
   4'b0010: z = b;
   4'b0100: z = c;
   4'b1000: z = d;
   default: z = 1'bx;
endcase
```

Selector multiplexers are commonly built as a tree of AND and OR gates. Using this scheme, two inputs can be selected using two select lines in a single 4-input LUT that uses two AND gates and an OR gate. The outputs of these LUTs can be combined with a wide OR gate. An N-input selector multiplexer of this structure requires at least 0.66*(N-0.5) LUTs, which is just slightly worse than the best binary multiplexer.

Priority Multiplexers

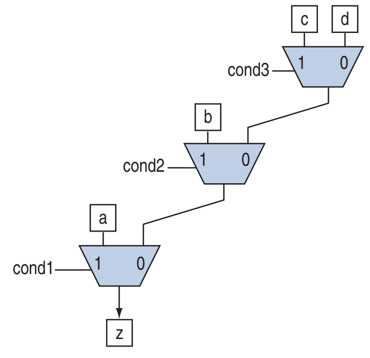
In priority multiplexers, the select logic implies a priority. The options to select the correct item must be checked in a specific order based on signal priority. These structures commonly are created from `IF`, `ELSE`, `WHEN`, `SELECT`, and `?:` statements in VHDL or Verilog HDL. The example VHDL code in Example 6–49 probably result in the schematic implementation illustrated in Figure 6–4.

Example 6–49. VHDL IF Statement Implying Priority

```
IF cond1 THEN z <= a;
ELSIF cond2 THEN z <= b;
ELSIF cond3 THEN z <= c;
ELSE z <= d;
END IF;
```

The multiplexers shown in Figure 6–4 form a chain, evaluating each condition or select bit, one at a time.

Figure 6–4. Priority Multiplexer Implementation of an IF Statement



An N-input priority multiplexer uses a LUT for every 2:1 multiplexer in the chain, requiring N-1 LUTs. This chain of multiplexers generally increases delay because the critical path through the logic traverses every multiplexer in the chain.

To improve the timing delay through the multiplexer, avoid priority multiplexers if priority is not required. If the order of the choices is not important to the design, use a `CASE` statement to implement a binary or selector multiplexer instead of a priority multiplexer. If delay through the structure is important in a multiplexed design requiring priority, consider recoding the design to reduce the number of logic levels to minimize delay, especially along your critical paths.

Default or Others Case Assignment

To fully specify the cases in a `CASE` statement, include a `default` (Verilog HDL) or `OTHERS` (VHDL) assignment. This assignment is especially important in one-hot encoding schemes where many combinations of the select lines are unused. Specifying a case for the unused select line combinations gives the synthesis tool information about how to synthesize these cases, and is required by the Verilog HDL and VHDL language specifications.

Some designs do not require that the outcome in the unused cases be considered, often because designers assume these cases will not occur. For these types of designs, you can choose any value for the `default` or `OTHERS` assignment. However, be aware that the assignment value you choose can have a large effect on the logic utilization required to implement the design due to the different ways synthesis tools treat different values for the assignment, and how the synthesis tools use different speed and area optimizations.

In general, to obtain best results, explicitly define invalid `CASE` selections with a separate `default` or `OTHERS` statement instead of combining the invalid cases with one of the defined cases.

If the value in the invalid cases is not important, specify those cases explicitly by assigning the `X` (don’t care) logic value instead of choosing another value. This assignment allows your synthesis tool to perform the best area optimizations.

You can experiment with different `default` or `OTHERS` assignments for your HDL design and your synthesis tool to test the effect they have on logic utilization in your design.

Implicit Defaults

The `IF` statements in Verilog HDL and VHDL can be a convenient way to specify conditions that do not easily lend themselves to a `CASE`-type approach. However, using `IF` statements can result in complicated multiplexer trees that are not easy for synthesis tools to optimize.

In particular, every `IF` statement has an implicit `ELSE` condition, even when it is not specified. These implicit defaults can cause additional complexity in a multiplexed design.

The code in Example 6–50 represents a multiplexer with four inputs (`a`, `b`, `c`, `d`) and one output (`z`). Altera does not recommend using this coding style.

Example 6–50. VHDL IF Statement with Implicit Defaults

```
IF cond1 THEN
   IF cond2 THEN
      z <= a;
   END IF;
ELSIF cond3 THEN
   IF cond4 THEN
      z <= b;
   ELSIF cond5 THEN
      z <= c;
   END IF;
ELSIF cond6 THEN
   z <= d;
END IF;
```

Although the code appears to implement a 4:1 multiplexer, each of the three separate IF statements in the code has an implicit ELSE condition that is not specified. Because the output values for the ELSE cases are not specified, the synthesis tool assumes the intent is to maintain the same output value for these cases and infers a combinational loop, such as a latch. Latches add to the design's logic utilization and can also make timing analysis difficult and lead to other problems.

The code sample shown in Example 6–51 shows code with the same functionality as the code shown in Example 6–50, but specifies the ELSE cases explicitly. (This is not a recommended coding style improvement, but it explicitly shows the default conditions from the previous example.)

Example 6–51. VHDL IF Statement with Default Conditions Explicitly Specified

```
IF cond1 THEN
   IF cond2 THEN
      z <= a;
   ELSE
      z <= z;
   END IF;
ELSIF cond3 THEN
   IF cond4 THEN
      z <= b;
   ELSIF cond5 THEN
      z <= c;
   ELSE
      z <= z;
   END IF;
ELSIF cond6 THEN
   z <= d;
ELSE
   z <= z;
END IF;
```

Figure 6–5 is a schematic representing the code in Example 6–51, which illustrates that the multiplexer logic is significantly more complicated than a basic 4:1 multiplexer, although there are only four inputs.

Figure 6–5. Multiplexer Implementation of an IF Statement with Implicit Defaults

There are several ways you can simplify the multiplexed logic and remove the unrequired defaults. The optimal method may be to recode the design so the logic takes the structure of a 4:1 `CASE` statement. Alternatively, if priority is important, you can restructure the code to deduce default cases and flatten the multiplexer. In this example, instead of `IF cond1 THEN IF cond2`, use `IF (cond1 AND cond2)`, which performs the same function. In addition, examine whether the defaults are don't care cases. In this example, you can promote the last `ELSIF cond6` statement to an `ELSE` statement if no other valid cases can occur.

Avoid unnecessary default conditions in your multiplexer logic to reduce the complexity and logic utilization required to implement your design.

Degenerate Multiplexers

A degenerate multiplexer is a multiplexer in which not all of the possible cases are used for unique data inputs. The cases that are not required tend to contribute to inefficiency in the logic utilization for these multiplexers. You can recode degenerate multiplexers so they take advantage of the efficient logic utilization possible with full binary multiplexers.

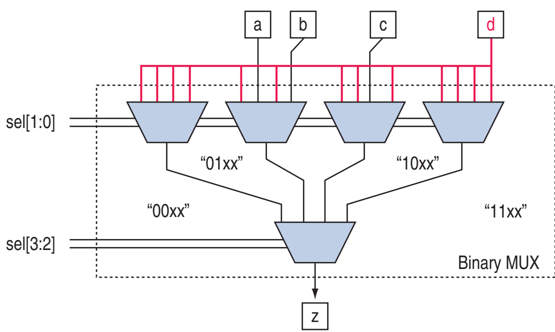
Example 6–52 shows a `VHDL CASE` statement describing a degenerate multiplexer.

Example 6–52. VHDL CASE Statement Describing a Degenerate Multiplexer

```
CASE sel[3:0] IS
   WHEN "0101" => z <= a;
   WHEN "0111" => z <= b;
   WHEN "1010" => z <= c;
   WHEN OTHERS => z <= d;
END CASE;
```

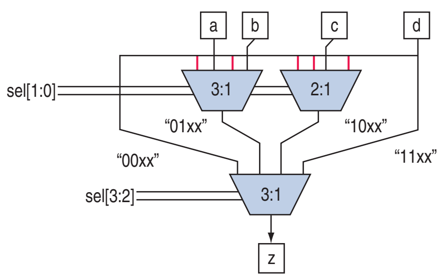
The number of select lines in a binary multiplexer normally dictates the size of a multiplexer required to implement the desired function. For example, the multiplexer structure represented in Figure 6–6 has four select lines capable of implementing a binary multiplexer with 16 inputs. However, the design does not use all 16 inputs, which makes this multiplexer a degenerate 16:1 multiplexer.

Figure 6–6. Binary Degenerate Multiplexer



In Figure 6–6, the first and fourth multiplexers in the top level can easily be eliminated because all four inputs to each multiplexer are the same value, and the number of inputs to the other multiplexers can be reduced, as shown in Figure 6–7.

Figure 6–7. Optimized Version of the Degenerate Binary Multiplexer



Implementing this version of the multiplexer still requires at least five 4-input LUTs, two for each of the remaining 3:1 multiplexers and one for the 2:1 multiplexer. This design selects an output from only four inputs, a 4:1 binary multiplexer can be implemented optimally in two LUTs, so this degenerate multiplexer tree reduces the efficiency of the logic.

You can improve logic utilization of this structure by recoding the select lines to implement a full 4:1 binary multiplexer. The code sample shown in Example 6–53 shows a recoder design that translates the original select lines into the `z_sel` signal with binary encoding.

Example 6–53. VHDL Recoder Design for Degenerate Binary Multiplexer

```
CASE sel[3:0] IS
   WHEN "0101" => z_sel <= "00";
   WHEN "0111" => z_sel <= "01";
   WHEN "1010" => z_sel <= "10";
   WHEN OTHERS => z_sel <= "11";
END CASE;
```

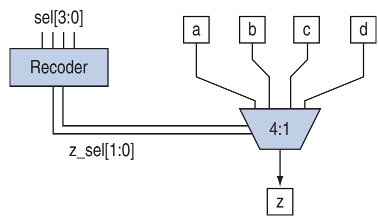
The code sample shown in Example 6–54 shows you how to implement the full binary multiplexer.

Example 6–54. VHDL 4:1 Binary Multiplexer Design

```
CASE z_sel[1:0] IS
   WHEN "00" => z <= a;
   WHEN "01" => z <= b;
   WHEN "10" => z <= c;
   WHEN "11" => z <= d;
END CASE;
```

Use the new `z_sel` control signal from the recoder design to control the 4:1 binary multiplexer that chooses between the four inputs `a`, `b`, `c`, and `d`, as illustrated in Figure 6–8. The complexity of the select lines is handled in the recoder design, and the data multiplexing is performed with simple binary select lines enabling the most efficient implementation.

Figure 6–8. Binary Multiplexer with Recorder



The design for the recoder can be implemented in two LUTs and the efficient 4:1 binary multiplexer uses two LUTs, for a total of four LUTs. The original degenerate multiplexer required five LUTs, so the recoded version uses 20% less logic than the original.

You can often improve the logic utilization of multiplexers by recoding the select lines into full binary cases. Although logic is required to perform the encoding, the overall logic utilization is often improved.

Buses of Multiplexers

The inputs to multiplexers are often data input buses in which the same multiplexer function is performed on a set of data input buses. In these cases, any inefficiency in the multiplexer is multiplied by the number of bits in the bus. The issues described in the previous sections become even more important for wide multiplexer buses.

For example, the recoding of select lines into full binary cases detailed in the previous section can often be used in multiplexed buses. Recoding the select lines may have to be completed only once for all the multiplexers in the bus. By sharing the recoder logic among all the bits in the bus, you can greatly improve the logic efficiency of a bus of multiplexers.

The degenerate multiplexer in the previous section requires five LUTs to implement. If the inputs and output are 32 bits wide, the function could require `32 ¥ 5` or 160 LUTs for the whole bus. The recoder design uses only two LUTs, and the select lines only have to be recoded once for the entire bus. The binary 4:1 multiplexer requires two LEs per bit of the bus. The total logic utilization for the recoded version could be 2 + (2 × 32) or 66 LUTs for the whole bus, compared to 160 LUTs for the original version. The logic savings become more important with wide multiplexer buses.

Using techniques to optimize degenerate multiplexers, removing implicit defaults are not required, and choosing the optimal `DEFAULT` or `OTHERS` case can play an important role when optimizing buses of multiplexers.

Cyclic Redundancy Check Functions

CRC computations are used heavily by communications protocols and storage devices to detect any corruption of the data. These functions are highly effective; there is a very low probability that corrupted data can pass a 32-bit CRC check.

CRC functions typically use wide XOR gates to compare the data. The way that synthesis tools flatten and factor these XOR gates to implement the logic in FPGA LUTs can greatly impact the area and performance results for the design. XOR gates have a cancellation property which creates an exceptionally large number of reasonable factoring combinations, so synthesis tools cannot always choose the best result by default.

The 6-input ALUT has a significant advantage over 4-input LUTs for these designs. When properly synthesized, CRC processing designs can run at high speeds in devices with 6-input ALUTs.

The following guidelines help you improve the quality of results for CRC designs in Altera devices.

If Performance is Important, Optimize for Speed

Synthesis tools flatten XOR gates to minimize area and depth of levels of logic. Synthesis tools such as Quartus II integrated synthesis target area optimization by default for these logic structures. Therefore, for more focus on depth reduction, set the synthesis optimization technique to speed.

Flattening for depth sometimes causes a significant increase in area.

Use Separate CRC Blocks Instead of Cascaded Stages

Some designers optimize their CRC designs to use cascaded stages, for example, four stages of 8 bits. In such designs, intermediate calculations are used as required (such as the calculations after 8, 24, or 32 bits) depending on the data width. This design is not optimal in FPGA devices. The XOR cancellations that can be performed in CRC designs mean that the function does not require all the intermediate calculations to determine the final result. Therefore, forcing the use of intermediate calculations increases the area required to implement the function, as well as increasing the logic depth because of the cascading. It is typically better to create full separate CRC blocks for each data width that you require in the design, then multiplex them together to choose the appropriate mode at a given time.

Use Separate CRC Blocks Instead of Allowing Blocks to Merge

Synthesis tools often attempt to optimize CRC designs by sharing resources and extracting duplicates in two different CRC blocks because of the factoring options in the XOR logic. As addressed previously, the CRC logic allows significant reductions but this works best when each CRC function is optimized separately. Check for duplicate extraction behavior if you have different CRC functions that are driven by common data signals or that feed the same destination signals.

If you are having problems with the quality of results and you see that two CRC functions are sharing logic, ensure that the blocks are synthesized independently using one of the following methods:

- Define each CRC block as a separate design partition in an incremental compilation design flow

 For details, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

- Synthesize each CRC block as a separate project in your third-party synthesis tool and then write a separate Verilog Quartus Mapping (**.vqm**) or EDIF netlist file for each

Take Advantage of Latency if Available

If your design can use more than one cycle to implement the CRC functionality, adding registers and retiming the design can help reduce area, improve performance, and reduce power utilization. If your synthesis tool offers a retiming feature (such as the Quartus II software **Perform gate-level register retiming** option), you can insert an extra bank of registers at the input and allow the retiming feature to move the registers for better results. You can also build the CRC unit half as wide and alternate between halves of the data in each clock cycle.

Save Power by Disabling CRC Blocks When Not in Use

CRC designs are heavy consumers of dynamic power because the logic toggles whenever there is a change in the design. To save power, use clock enables to disable the CRC function for every clock cycle that the logic is not required. Some designs don't check the CRC results for a few clock cycles while other logic is performed. It is valuable to disable the CRC function even for this short amount of time.

Use the Device Synchronous Load (sload) Signal to Initialize

The data in many CRC designs must be initialized to 1's before operation. If your target device supports the use of the `sload` signal, you should use it to set all the registers in your design to 1's before operation. To enable use of the `sload` signal, follow the coding guidelines presented in "Secondary Register Control Signals Such as Clear and Clock Enable" on page 6–38. You can check the register equations in the Timing Closure Floorplan or the Chip Planner to ensure that the signal was used as expected.

If you must force a register implementation using an `sload` signal, you can use low-level device primitives as described in the *Designing with Low-Level Primitives User Guide*.

Comparators

Synthesis software, including Quartus II integrated synthesis, uses device and context-specific implementation rules for comparators (<, >, or ==) and selects the best one for your design. This section provides some information about the different types of implementations available and provides suggestions on how you can code your design to encourage a specific implementation.

The == comparator is implemented in general logic cells. The < comparison can be implemented using the carry chain or general logic cells. In devices with 6-input ALUTs, the carry chain is capable of comparing up to three bits per cell. In devices with 4-input LUTs, the capacity is one bit of comparison per cell, similar to an add/subtract chain. The carry chain implementation tends to be faster than the general logic on standalone benchmark test cases, but can result in lower performance when it is part of a larger design due to the increased restriction on the Fitter. The area requirement is similar for most input patterns. The synthesis software selects an appropriate implementation based on the input pattern.

If you are using Quartus II integrated synthesis, you can guide the synthesis by using specific coding styles. To select a carry chain implementation explicitly, rephrase your comparison in terms of addition. As a simple example, the following coding style allows the synthesis tool to select the implementation, which is most likely using general logic cells in modern device families:

```
wire [6:0] a,b;
wire alb = a<b;
```

In the following coding style, the synthesis tool uses a carry chain (except for a few cases, such as when the chain is very short or the signals `a` and `b` minimize to the same signal):

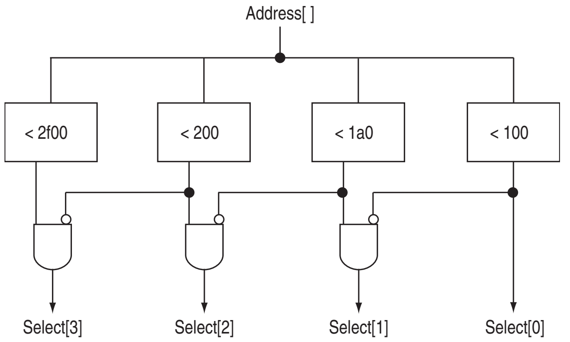
```
wire [6:0] a,b;
wire [7:0] tmp = a - b;
wire alb = tmp[7]
```

This second coding style uses the top bit of the `tmp` signal, which is 1 in twos complement logic if *a* is less than *b*, because the subtraction *a* – *b* results in a negative number.

If you have any information about the range of the input, you have "don't care" values that you can use to optimize the design. Because this information is not available to the synthesis tool, you can often reduce the device area required to implement the comparator with specific hand implementation of the logic.

You can also check whether a bus value is within a constant range with a small amount of logic area by using the logic structure shown in Figure 6–9. This type of logic occurs frequently in address decoders.

Figure 6–9. Example Logic Structure for Using Comparators to Check a Bus Value Range



Counters

Implementing counters in HDL code is easy; they are implemented with an adder followed by registers. Remember that the register control signals, such as enable (`ena`), synchronous clear (`sclr`), and synchronous load (`sload`), are available. For the best area utilization, ensure that the up/down control or controls are expressed in terms of one addition instead of two separate addition operators.

If you use the following coding style, your synthesis tool may implement two separate carry chains for addition (if it doesn't detect the issue and optimize the logic):

```
out <= count_up ? out + 1 : out - 1;
```

The following coding style requires only one adder along with some other logic:

```
out <= out + (count_up ? 1 : -1);
```

In this case, the coding style better matches the device hardware because there is only one carry chain adder, and the –1 constant logic is implemented in the LUT in front of the adder without adding extra area utilization.

Designing with Low-Level Primitives

Low-level HDL design is the practice of using low-level primitives and assignments to dictate a particular hardware implementation for a piece of logic. Low-level primitives are small architectural building blocks that assist you in creating your design. With the Quartus II software, you can use low-level HDL design techniques to force a specific hardware implementation that can help you achieve better resource utilization or faster timing results.

Using low-level primitives is an advanced technique to help with specific design challenges, and is optional in the Altera design flow. For many designs, synthesizing generic HDL source code and Altera megafunctions gives you the best results.

Low-level primitives allow you to use the following types of coding techniques:

- Instantiate the logic cell or `LCELL` primitive to prevent Quartus II integrated synthesis from performing optimizations across a logic cell
- Create carry and cascade chains using `CARRY`, `CARRY_SUM`, and `CASCADE` primitives
- Instantiate registers with specific control signals using `DFF` primitives
- Specify the creation of LUT functions by identifying the LUT boundaries
- Use I/O buffers to specify I/O standards, current strengths, and other I/O assignments
- Use I/O buffers to specify differential pin names in your HDL code, instead of using the automatically-generated negative pin name for each pair

For details about and examples of using these types of assignments, refer to the *Designing with Low-Level Primitives User Guide*.

Conclusion

Because coding style and megafunction implementation can have such a large effect on your design performance, it is important to match the coding style to the device architecture from the very beginning of the design process. To improve design performance and area utilization, take advantage of advanced device features, such as memory and DSP blocks, as well as the logic architecture of the targeted Altera device by following the coding recommendations presented in this chapter.

For additional optimization recommendations, refer to the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*.

Document Revision History

Table 6–2 shows the revision history for this chapter.

Table 6–2. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Corrected and updated several examples ■ Added support for Arria II GX devices ■ Other minor changes to chapter	Updated for the Quartus II 9.0 software release.
November 2008 v8.1.0	Changed to 8-1/2 x 11 page size. No change to content.	Updated for the Quartus II 8.1 software release.
May 2008 v8.0.0	Updates for the Quartus II software version 8.0 release, including: ■ Added information to “RAM Functions—Inferring ALTSYNCRAM and ALTDPRAM Megafunctions from HDL Code” on page 6–13 ■ Added information to “Avoid Unsupported Reset and Control Conditions” on page 6–14 ■ Added information to “Check Read-During-Write Behavior” on page 6–16 ■ Added two new examples to “ROM Functions—Inferring ALTSYNCRAM and LPM_ROM Megafunctions from HDL Code” on page 6–28: Example 6–24 and Example 6–25 ■ Added new section: “Clock Multiplexing” on page 6–46 ■ Added hyperlinks to references within the chapter ■ Minor editorial updates	Updates and enhancements to subject coverage for the Quartus II software version 8.0 release.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

7. Managing Metastability with the Quartus II Software

QII51018-9.0.0

Introduction

This chapter describes the industry-leading analysis, reporting, and optimization features that can help you manage metastability in Altera® devices. You can use the Quartus® II software to analyze the average mean time between failures (MTBF) due to metastability when a design synchronizes asynchronous signals, and optimize the design to improve the metastability MTBF. This chapter explains how to take advantage of these features in the Quartus II software, and provides guidelines to help you reduce the chance of metastability effects due to signal synchronization.

What is metastability? As is well known in digital design, all registers have defined signal timing requirements that allow the register to correctly capture data at the inputs and produce the output signal. To ensure reliable operation, the input to the register must be stable for a minimum time before the clock edge (register setup time or t_{SU}) and a minimum time after the clock edge (register hold time or t_H). The register output will then be available after a specified clock-to-output delay (t_{CO}). If the data violates a register's setup and/or hold time requirements, the output of the register may go into a metastable state. In this state, the register output hovers at a value between the high and low states, which means the output transition to a defined high or low state is delayed beyond the specified t_{CO}. Different destination registers might capture different values for the metastable signal, which can cause the system to fail.

In synchronous systems, the input signals must always meet the register timing requirements, so metastability does not occur. Metastability problems commonly occur when a signal is transferred between circuitry in unrelated or asynchronous clock domains, because the designer cannot guarantee that the signal will meet setup and hold time requirements in this case.

The MTBF due to metastability is an estimate of the average time between instances when metastability could cause a design failure. A high MTBF (such as hundreds or thousands of years between metastability failures) indicates a more robust design. You should determine an acceptable target MTBF given the context of your entire system and the fact that MTBF calculations are statistical estimates.

The metastability MTBF for a specific signal transfer, or all the transfers in a design, can be calculated using information about the design and the device characteristics. Improving the metastability MTBF for your design reduces the chance that signal transfers could cause metastability problems in your device.

For more information about metastability due to signal synchronization, its effects in FPGAs, and how MTBF is calculated, refer to the *Understanding Metastability in FPGAs* white paper. Your overall device MTBF is also affected by other FPGA failure mechanisms that you cannot control with your design. For information about Altera device reliability, refer to the *Reliability Report*.

The Quartus II software provides analysis, optimization, and reporting features to help manage metastability in Altera designs. These metastability features are supported only for designs constrained with the Quartus II TimeQuest Timing Analyzer, and for select device families. In Quartus II software version 9.0, typical MTBF values are generated for designs using Arria® II GX, Stratix® IV, Stratix III, and Cyclone® III devices. Additional worst-case MTBF values are reported for the fully characterized Stratix III devices.

This chapter contains the following topics:

- "Metastability Analysis in the Quartus II Software" on page 7–2, including the important first step "Identifying Synchronizers for Metastability Analysis"
- "Metastability and MTBF Reporting" on page 7–6
- "MTBF Optimization" on page 7–9
- "Reducing Metastability Effects" on page 7–11, including guidelines to ensure complete and accurate metastability analysis and some suggestions to follow if the Quartus II metastability reports calculate an unacceptable MTBF value

For details about device and version support for the metastability features in the Quartus II software, refer to Quartus II Help.

Metastability Analysis in the Quartus II Software

When a signal transfers between circuitry in unrelated or asynchronous clock domains, the first register in the new clock domain acts as a synchronization register. To minimize the failures due to metastability in asynchronous signal transfers, circuit designers typically use a sequence of registers (a synchronization register chain or synchronizer) in the destination clock domain to resynchronize the signal to the new clock domain and allow additional time for a potentially metastable signal to resolve to a known value. Designers commonly use two registers to synchronize a new signal, but Altera recommends using a standard of three registers for better metastability protection.

The TimeQuest Timing Analyzer can analyze and report the MTBF for each identified synchronizer that meets its timing requirements, and can generate an estimate of the overall design MTBF. The software uses this information to optimize the design MTBF, and you can use this information to determine whether you require longer synchronizer chains in your design.

The first step to enable metastability MTBF analysis and optimization in the Quartus II software is to identify which registers are part of a synchronization register chain.

This section contains the following subsections:

- "What is a Synchronization Register Chain?"
- "Identifying Synchronizers for Metastability Analysis" on page 7–4
- "How Timing Constraints Affect Synchronizer Chain Identification and Metastability Analysis" on page 7–6

For information about the reports generated by the TimeQuest Timing Analyzer, refer to "Metastability and MTBF Reporting" on page 7–6. For more information about optimizing the MTBF, refer to "MTBF Optimization" on page 7–9.

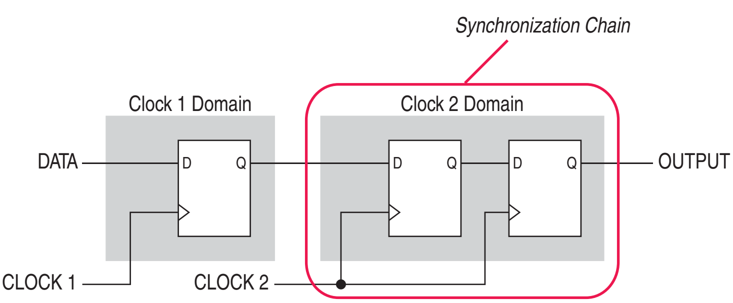
What is a Synchronization Register Chain?

A synchronization register chain, or synchronizer, is defined as a sequence of registers that meets the following requirements:

- The registers in the chain are all clocked by the same or phase-related clocks
- The first register in the chain is driven from an unrelated clock domain, or asynchronously
- Each register fans out to only one register, except the last register in the chain

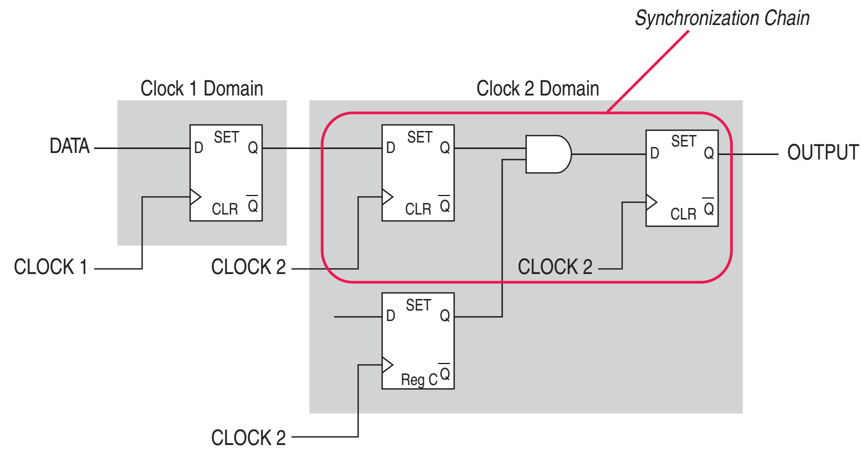
The length of the synchronization register chain is the number of registers in the synchronizing clock domain that meet the above requirements. Figure 7–1 shows a sample synchronization chain of length two, assuming the `OUTPUT` signal fans out to more than one register destination.

Figure 7–1. Sample Synchronization Register Chain



The path between synchronization registers can contain combinational logic, as long as all registers of the synchronization chain are in the same clock domain. Figure 7–2 shows an example of a synchronization register chain that includes logic between the registers.

Figure 7–2. Sample Synchronization Register Chain Containing Logic



The Quartus II software uses the design timing constraints to determine which connections are asynchronous signal transfers, as described in "How Timing Constraints Affect Synchronizer Chain Identification and Metastability Analysis" on page 7–6.

Synchronization registers allow time for a potentially metastable signal to resolve to a known value before the signal is used in the rest of the design. The timing slack available in the synchronizer register-to-register paths provides time for a metastable signal to settle, and is known as the available settling time. The available settling time for a synchronization chain is the sum of the output timing slacks for each register in the chain. Adding available settling time with additional synchronization registers improves the metastability MTBF.

Identifying Synchronizers for Metastability Analysis

The first step to enable metastability MTBF analysis and optimization in the Quartus II software is to identify which registers are part of a synchronization register chain with the **Synchronizer Identification** option.

You can apply synchronizer identification settings globally, to a design entity, or to specific registers of a synchronization chain. You can use the global options in "Using the Global Synchronizer Identification Setting" on page 7–4 to automatically list or analyze possible synchronizers. You should review this list of possible synchronizers, and identify the confirmed synchronization chains with specific registers assignments as described in "Refining Synchronizer Identification Using the Instance-Specific Assignment" on page 7–5.

Synchronization chains are already identified within most Altera intellectual property (IP) cores.

Using the Global Synchronizer Identification Setting

To set the global **Synchronizer Identification** option, on the Assignments menu, click **Settings**. Under **Timing Analysis Settings**, click on the **TimeQuest Timing Analyzer** page and select the appropriate **Synchronizer Identification** setting under **Metastability Analysis**: **Off**, **Auto**, or **Forced If Asynchronous**. To apply the global assignment with Tcl, use the following command:

```
set_global_assignment -name SYNCHRONIZER_IDENTIFICATION
<OFF|AUTO|"FORCED IF ASYNCHRONOUS">
```

Use the following guidelines to choose the global setting:

- The default global **Off** setting means that no synchronization registers are automatically analyzed.
- Use the global **Auto** setting to generate a list of likely synchronization chains in your design, based on the software's automatic synchronizer detection criteria.
  - With this setting, any chain synchronizing an asynchronous signal with more than one register is listed as a likely synchronizer if the chain does not contain logic.
  - MTBF is not reported or optimized for automatically detected register chains.

- You can use the global **Forced If Asynchronous** setting to report and optimize MTBF for all asynchronous signal transfers in the design.
  - This setting forces synchronization register identification and MTBF analysis if the software detects any asynchronous signal transfer, even if there is combinational logic or only one register in the synchronization register chain.
  - This setting is likely to identify some registers that were not designed as synchronizers, and thus might report an MTBF that is too conservative. For example, asynchronous reset signals to registers and SignalTap® II Embedded Logic Analyzer signals might generate metastability reports.
  - You can turn off synchronizer identification for specific registers using the instance-specific option, as described below.

Refining Synchronizer Identification Using the Instance-Specific Assignment

Altera recommends applying the **Synchronizer Identification** option **Forced If Asynchronous** to each register in a synchronization chain. Instance-specific assignments ensure that the software analyzes an accurate set of synchronizers to report an accurate MTBF. If you use the global **Auto Synchronizer Identification** setting to detect likely synchronizers, use specific assignments to identify the true synchronizers for MTBF analysis.

Use the Assignment Editor on the Assignments menu to set the **Synchronizer Identification** option on a register or design entity to **Auto**, **Forced If Asynchronous**, **Forced**, or **Off**. To apply the assignment with Tcl, use the following command:

```
set_instance_assignment -name SYNCHRONIZER IDENTIFICATION <AUTO|"FORCED
IF ASYNCHRONOUS"|FORCED|OFF> -to <register name>
```

Use the following guidelines to choose the register-specific settings:

- Enable MTBF analysis and optimization by identifying each synchronizer register with the **Forced If Asynchronous** setting
  - Use the register chains listed by the global **Auto Synchronizer Identification** option to help you identify these registers.
  - There may be additional synchronization chains in your design that are not detected by the **Auto** setting because they contain logic or only one register.
- If you have a specific register or register chain in your design that the software detects as synchronous but you want to be analyzed and optimized for metastability like an asynchronous signal, apply the **Forced** setting to the first synchronization register in the chain.
  - Use this setting as a manual "override" for a signal that the TimeQuest Timing Analyzer does not report as asynchronous, such as a virtual pin associated with a virtual clock.
  - This **Forced** setting is not available globally in the **Settings** dialog box because making this setting globally would incorrectly identify every design register as a synchronizer.

- If some register chains are misidentified as synchronizers when you apply a global or entity level **Forced If Asynchronous** setting, you can disable metastability analysis for specific registers. To do so, use the Assignment Editor to set **Synchronizer Identification** to **Off** for the first synchronization register in these register chains.

How Timing Constraints Affect Synchronizer Chain Identification and Metastability Analysis

The TimeQuest Timing Analyzer can analyze metastability MTBF only if a synchronization chain meets its timing requirements. The metastability failure rate depends on the timing slack available in the synchronizer's register-to-register connections, because that slack is the available settling time for a potential metastable signal. Therefore, it is important for your design to be correctly constrained with the real application frequency requirements to get an accurate MTBF report.

In addition, the **Auto** and **Forced If Asynchronous** synchronizer identification options use timing constraints to automatically detect the synchronizer chains in the design. These options check for signal transfers between circuitry in unrelated or asynchronous clock domains, so clock domains must be related correctly with timing constraints.

The TimeQuest Timing Analyzer views input ports as asynchronous signals unless they are associated correctly with a clock domain. If an input port fans out to registers that are not acting as synchronization registers, you should apply a `set_input_delay` constraint to the input port; otherwise, the input register is reported as a synchronization register. If you constrain a synchronous input port with a `set_max_delay` constraint for a setup (t_{SU}) requirement, this does not prevent synchronizer identification because the constraint does not associate the input port with a clock domain.

Instead, use the following syntax to specify an input setup requirement associated with a clock:

```
set_input_delay -max -clock <clock name> <latch – launch – tSU
requirement> <input port name>
```

Registers that are at the end of false paths are also considered synchronization registers because false paths are not timing-analyzed. Because there are no timing requirements for these paths, the signal may change at any point, which may violate the t_{SU} and t_H of the register. Therefore, these registers are identified as synchronization registers. If these registers are not used for synchronization, you can turn off synchronizer identification and analysis as described in the previous section.

Metastability and MTBF Reporting

The Quartus II software reports the metastability analysis results in the Compilation Report and TimeQuest Timing Analyzer reports as described in "Metastability Report". The MTBF calculation uses timing and structural information about the design, silicon characteristics, and operating conditions, along with the data toggle rate described in "Synchronizer Data Toggle Rate in MTBF Calculation" on page 7–9.

For more information about how metastability MTBF is calculated, refer to the *Understanding Metastability in FPGAs* white paper.

 © March 2009 Altera Corporation

If you change the **Synchronizer Identification** settings, you can generate new metastability reports by rerunning the TimeQuest Timing Analyzer. However, you should rerun the Fitter first so that the registers identified with the new setting can be optimized for metastability MTBF. For information about metastability optimization, refer to "MTBF Optimization" on page 7–9.

Metastability Report

The Metastability Report provides a summary of the metastability analysis results. In addition to the MTBF Summary and Synchronizer Summary reports, the TimeQuest Timing Analyzer tool reports additional statistics in a report for each synchronizer chain. This section provides more information about the reports.

To view the MTBF Summary and Synchronizer Summary reports, open the Metastability Report in the **TimeQuest Timing Analyzer** section of the Compilation Report. If the software performs multicorner timing analysis, expand the timing analysis results for one of the timing corners, and then select the Metastability Report for those operating conditions.

To view the additional synchronizer Statistics in the TimeQuest report, open the TimeQuest Timing Analyzer from the Tools menu, and double-click **Report Metastability** in the **Tasks** list (or use the `report_metastability` command). You can generate the reports with Tcl commands in addition to the TimeQuest Timing Analyzer user interface; refer to "Scripting Support" on page 7–13 for details.

If the design uses only the **Auto Synchronizer Identification** setting, the reports list likely synchronizers but do not report MTBF. To obtain an MTBF for each register chain, force identification of synchronization registers as described in "Identifying Synchronizers for Metastability Analysis" on page 7–4.

If the synchronizer chain does not meet its timing requirements, the reports list identified synchronizers but do not report MTBF. To obtain MTBF calculations, ensure that the design is properly constrained and that the synchronizer meets its timing requirements, as described in "How Timing Constraints Affect Synchronizer Chain Identification and Metastability Analysis" on page 7–6.

MTBF Summary Report

The MTBF Summary reports an estimate of the overall robustness of cross-clock domain and asynchronous transfers in the design. This estimate uses the MTBF results of all synchronization chains in the design to calculate an MTBF for the entire design.

The MTBF Summary Report reports the **Typical MTBF of Design** for supported devices and the **Worst-Case MTBF of Design** for supported fully-characterized devices. The typical MTBF result assumes typical conditions, defined as nominal silicon characteristics for the selected device speed grade, as well as nominal operating conditions. The worst case MTBF result uses the worst case silicon characteristics for the selected device speed grade.

When you analyze multiple timing corners in the TimeQuest Timing Analyzer, the MTBF calculation may vary because of changes in the operating conditions, and the timing slack or available metastability settling time. Altera recommends running multi-corner timing analysis to ensure that you analyze the worst MTBF results, because the worst timing corner for MTBF does not necessarily match the worst corner for timing performance. In the **Settings** dialog box, under **Timing Analysis Settings**, click the **TimeQuest Timing Analyzer** page, and turn on **Enable multicorner timing analysis during compilation**.

The MTBF Summary report also lists the **Number of Synchronizer Chains Found** and the length of the **Shortest Synchronizer Chain**, which can help you identify whether the report is based on accurate information. If the number of synchronizer chains found is different from what you expect, or if the length of the shortest synchronizer chain is less than you expect, you might have to add or change **Synchronizer Identification** settings for the design. The report also provides the **Worst Case Available Settling Time**, defined as the available settling time for the synchronizer with the worst MTBF.

You can use the reported **Fraction of Chains for which MTBFs Could Not be Calculated** to determine whether a high proportion of chains are missing in the metastability analysis. A fraction of 1, for example, means that MTBF could not be calculated for any chains in the design. MTBF is not calculated if you have not identified the chain with the appropriate Synchronizer Identification option, or if paths are not timing-analyzed and therefore have no valid slack for metastability analysis. You might have to correct your timing constraints to enable complete analysis of the applicable register chains.

Finally, the MTBF Summary report specifies how an increase of 100ps in available settling time increases the MTBF values. If your MTBF is not satisfactory, this metric can help you determine how much extra slack would be required in your synchronizer chain to allow you to reach the desired design MTBF.

Synchronizer Summary

The **Synchronizer Summary** lists the synchronization register chains detected in the design depending on the Synchronizer Identification setting. The **Source Node** is the register or input port that is the source of the asynchronous transfer. The **Synchronization Node** is the first register of the synchronization chain. The **Source Clock** is the clock domain of the source node, and the **Synchronization Clock** is the clock domain of the synchronizer chain.

This summary reports the calculated **Worst-Case MTBF**, if available, and the **Typical MTBF**, for each appropriately identified synchronization register chain that meets its timing requirement. To see more detail about each synchronizer, refer to the TimeQuest statistics report described in the following section.

Synchronizer Chain Statistics Report in the TimeQuest Timing Analyzer

The TimeQuest Timing Analyzer provides an additional report for each synchronizer chain. The **Chain Summary** tab matches the Synchronizer Summary information described in the previous section, while the **Statistics** tab adds more details. The Statistics list whether the **Method of Synchronizer Identification** was **User Specified** (with the **Forced if Asynchronous** or **Forced Synchronizer Identification** setting) or **Automatic** (with the **Auto** setting). The **Number of Synchronization Registers in Chain** is also reported. This report provides more details about the parameters that

affect the MTBF calculation: the **Available Settling Time** for the chain and the **Data Toggle Rate Used in MTBF Calculation** (for information about the toggle rate, see "Synchronizer Data Toggle Rate in MTBF Calculation" on page 7–9). There is also additional detail to help you identify where this chain is in your design: the **Source Clock** and **Asynchronous Source** node of the signal, the **Synchronization Clock** in the destination clock domain, and the node names of the **Synchronization Registers** in the chain.

Synchronizer Data Toggle Rate in MTBF Calculation

The MTBF calculations assume the data being synchronized is switching at a toggle rate of 12.5% of the source clock frequency. That is, the arriving data is assumed to switch once every eight source clock cycles. If multiple clocks apply, the highest frequency is used. If no source clocks can be determined, the data rate is taken as 12.5% of the synchronization clock frequency.

If you know the approximate rate at which the data changes, and would like to obtain a more accurate MTBF, use the **Synchronizer Toggle Rate** assignment in the Assignment Editor. Set the data toggle rate, in number of transitions per second, on the first register of a synchronization chain. The TimeQuest Timing Analyzer takes the specified rate into account when computing the MTBF of that particular register chain. You can also apply this assignment to an entity or the entire design. Because a **Synchronizer Toggle Rate** assignment of 0 indicates that the data signal never toggles, the affected synchronization chain will not be reported since it does not affect the reliability of the design. To apply the assignment with Tcl, use the following command:

```
set_instance_assignment -name SYNCHRONIZER_TOGGLE_RATE <toggle rate in
transitions/second> -to <register name>
```

There are two other assignments associated with toggle rates, which are not used for metastability MTBF calculations. The I/O Maximum Toggle Rate is only used for pins, and specifies the worst-case toggle rates used for signal integrity purposes. The Power Toggle Rate assignment is used to specify the expected time-averaged toggle rate, and is used by the PowerPlay Power Analyzer to estimate time-averaged power consumption.

MTBF Optimization

In addition to reporting synchronization register chains and MTBF values found in the design, the Quartus II software can also protect these registers from optimizations that might negatively impact MTBF and can optimize the register placement and routing if the MTBF is too low. Synchronization register chains must first be explicitly identified as synchronizers, as described in "Identifying Synchronizers for Metastability Analysis" on page 7–4. Altera recommends that you set **Synchronizer Identification** to **Forced If Asynchronous** for all registers that are part of a synchronizer chain.

Optimization algorithms, such as register duplication and logic retiming in physical synthesis, are not performed on identified synchronization registers. The Fitter protects the number of synchronization registers specified by the **Synchronizer Register Chain Length** option described in the next section.

In addition, the Fitter optimizes identified synchronizers for improved MTBF, by placing and routing the registers to increase the output setup slacks of synchronization registers. Adding slack in the synchronizer chain increases the available settling time for a potentially metastable signal, which improves the chance that the signal will resolve to a known value, and exponentially increases the design MTBF. The Fitter optimizes the number of synchronization registers specified by the **Synchronizer Register Chain Length** option described in the next section.

Metastability optimization is on by default. To view or change the option, on the Assignments menu, click **Settings**. Under **Fitter Settings**, click **More Settings**. From the **More Settings** dialog box, you can turn on or off the **Optimize Design for Metastability** option. To turn the optimization on or off with Tcl, use the following command:

```
set_global_assignment -name OPTIMIZE_FOR_METASTABILITY <ON|OFF>
```

Synchronization Register Chain Length

The **Synchronization Register Chain Length** option specifies how many registers should be protected from optimizations that might reduce MTBF for each register chain, and controls how many registers should be optimized to increase MTBF with the **Optimize Design for Metastability** option. For example, if the **Synchronization Register Chain Length** option is set to **2**, optimizations such as register duplication or logic retiming are prevented from being performed on the first two registers in all identified synchronization chains. The first two registers are also optimized to improve MTBF when the **Optimize Design for Metastability** option is turned on.

The default setting for the **Synchronization Register Chain Length** option is **2**. The first register of a synchronization chain is always protected from operations that might reduce MTBF, but you should set the protection length to protect more of the synchronizer chain. Altera recommends that you set this option to the maximum length of synchronization chains you have in your design so that all synchronization registers are preserved and optimized for MTBF.

To change the global **Synchronization Register Chain Length** option, on the Assignments menu, click **Settings**. Under **Analysis & Synthesis Settings**, click **More Settings**. From the **More Settings** dialog box, you can set the **Synchronization Register Chain Length**.

You can also set the **Synchronization Register Chain Length** on a node or an entity in the Assignment Editor. You can set this value on the first register in a synchronization chain to specify how many registers to protect and optimize in this chain. This individual setting is useful if you want to protect and optimize extra registers that you have created in a specific synchronization chain that has low MTBF, or optimize less registers for MTBF in a specific chain where the maximum frequency or timing performance is not being met.

To make the global setting with Tcl, use the following command:

```
set_global_assignment -name SYNCHRONIZATION_REGISTER_CHAIN_LENGTH
<number of registers>
```

To apply the assignment to a design instance or the first register in a specific chain with Tcl, use the following command:

```
set_instance_assignment -name SYNCHRONIZATION_REGISTER_CHAIN_LENGTH
<number of registers> -to <register or instance name>
```

Reducing Metastability Effects

You can check your design's metastability MTBF in the Metastability Summary report described in "Metastability Report" on page 7–7. As discussed in the "Introduction", you should determine an acceptable target MTBF given the context of your entire system and the fact that MTBF calculations are statistical estimates. A high metastability MTBF (such as hundreds or thousands of years between metastability failures) indicates a more robust design.

This section provides guidelines to ensure complete and accurate metastability analysis, and some suggestions to follow if the Quartus II metastability reports calculate an unacceptable MTBF value. The Timing Optimization Advisor (available from the Tools menu) gives similar suggestions in the Metastability Optimization section.

Apply Complete System-Centric Timing Constraints for the TimeQuest Timing Analyzer

To enable the Quartus II metastability features, make sure that the TimeQuest Timing Analyzer is used for timing analysis.

Ensure that the design is fully timing constrained and that it meets its timing requirements. If the synchronization chain does not meet its timing requirements, the MTBF can not be calculated. If the clock domain constraints are set up incorrectly, the signal transfers between circuitry in unrelated or asynchronous clock domains may not be identified correctly.

Use industry-standard system-centric I/O timing constraints instead of using FPGA-centric timing constraints. As described in "How Timing Constraints Affect Synchronizer Chain Identification and Metastability Analysis" on page 7–6, you should use `set_input_delay` constraints in place of `set_max_delay` constraints to associate each input port with a clock domain to help eliminate false positives during synchronization register identification.

Force the Identification of Synchronization Registers

Use the guidelines in "Identifying Synchronizers for Metastability Analysis" on page 7–4 to ensure the software reports and optimizes the appropriate register chains.

In summary, identify synchronization registers with the **Synchronizer Identification** set to **Forced If Asynchronous** in the Assignment Editor. If there are any registers that the software detects as synchronous but you want to be analyzed for metastability, apply the **Forced** setting to the first synchronizing register. Set **Synchronizer Identification** to **Off** for registers that are not synchronizers for asynchronous signals or unrelated clock domains.

To help you find the synchronizers in your design, you can set the global **Synchronizer Identification** setting on the **TimeQuest Timing Analyzer** page of the **Settings** dialog box to **Auto** to generate a list of all the possible synchronization chains in your design.

Set the Synchronizer Data Toggle Rate

The MTBF calculations assume the data being synchronized is switching at a toggle rate of 12.5% of the source clock frequency. To obtain a more accurate MTBF for a specific chain or all chains in your design, set the **Synchronizer Toggle Rate** as described in "Synchronizer Data Toggle Rate in MTBF Calculation" on page 7–9.

Optimize Metastability During Fitting

Ensure that the **Optimize Design for Metastability** setting described in "MTBF Optimization" on page 7–9 is turned on.

Increase the Length of Synchronizers to Protect and Optimize

Increase the Synchronizer Chain Length parameter to the maximum length of synchronization chains in your design, as described in "Synchronization Register Chain Length" on page 7–10. If you have synchronization chains longer than 2 identified in your design, you can protect the entire synchronization chain from operations that might reduce MTBF and allow metastability optimizations to improve the MTBF.

Set Fitter Effort to Standard Fit instead of Auto Fit

If your design MTBF is too low after following the previous guidelines in this section, you can try increasing the **Fitter effort** to perform more metastability optimization. The default **Auto Fit** setting reduces the Fitter's effort after meeting the design's timing and routing requirements to reduce compilation time. This effort reduction can result in less metastability optimization if the timing requirements are easy to meet. If **Auto Fit** reduces Fitter effort during your design compilation, setting the **Fitter effort** to **Standard Fit** might improve the design's MTBF results. On the Assignments menu, click **Settings**. On the **Fitter Settings** page, set **Fitter effort** to **Standard Fit**.

If Possible, Increase the Number of Stages Used in Synchronizers

Designers commonly use two registers in a synchronization chain to minimize the occurrence of metastable events, and Altera recommends using a standard of three registers for better metastability protection. However, using chains of length two or even three may not be enough to produce a high enough MTBF when the design runs at high clock and data frequencies.

If a synchronization chain is reported to have a low MTBF, consider adding an additional register stage to your synchronization chain. This additional stage increases the settling time of the synchronization chain, allowing more opportunity for the signal to resolve to a known state during a metastable event. Additional settling time increases the MTBF of the chain and improves the robustness of your design. Of course, adding a synchronization stage does introduce an additional stage of latency on the signal.

If you use the Altera FIFO megafunction with separate read and write clocks to cross clock domains, increase the metastability protection (and latency) for better MTBF. In the MegaWizard™ Plug-In Manager for the DCFIFO function, choose the **Best metastability protection, best fmax, unsynchronized clocks** option to add 3 or more synchronization stages. You can increase the number of stages to more than 3 using the **How many sync stages?** setting.

If Possible, Select a Faster Speed Grade Device

The design MTBF depends on process parameters of the device used. Faster devices are less susceptible to metastability issues. If the design MTBF falls significantly below the target MTBF, switching to a faster speed grade can improve the MTBF substantially.

Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ↵
```

The *Quartus II Scripting Reference Manual* includes the same information in PDF form.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. Refer to the *Quartus II Settings File Reference Manual* for information about all settings and constraints in the Quartus II software. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Identifying Synchronizers for Metastability Analysis

To apply the global Synchronizer Identification assignment described on page "Identifying Synchronizers for Metastability Analysis" on page 7–4, use the following command:

```
set_global_assignment -name SYNCHRONIZER_IDENTIFICATION
<OFF|AUTO|"FORCED IF ASYNCHRONOUS">
```

To apply the **Synchronizer Identification** assignment to a specific register or instance, use the following command:

```
set_instance_assignment -name SYNCHRONIZER_IDENTIFICATION
<AUTO|"FORCED IF ASYNCHRONOUS"|FORCED|OFF> -to <register or instance
name>
```

Synchronizer Data Toggle Rate in MTBF Calculation

To specify a toggle rate for MTBF calculations as described on page "Synchronizer Data Toggle Rate in MTBF Calculation" on page 7–9, use the following command:

```
set_instance_assignment -name SYNCHRONIZER_TOGGLE_RATE <toggle rate in
transitions/second> -to <register name>
```

report_metastability TimeQuest and Tcl Command

If you use a command-line or scripting flow, you can generate the metastability analysis reports described in "Metastability Report" on page 7–7 outside of the Quartus II and TimeQuest user interfaces. Table 7–1 describes the options for the `report_metastability` TimeQuest and Tcl command.

Table 7–1. report_metastabilty Command Options

Option	Description
`-append`	If output is sent to a file, this option appends the result to that file. Otherwise, the file is overwritten.
`-file <name>`	Sends the results to an ASCII or HTML file. The extension specified in the file name determines the file type—either ***.txt** or ***.html**.
`-panel_name <name>`	Sends the results to the panel and specifies the name of the new panel.
`-stdout`	Indicates the report be sent to the standard output, via messages. This option is required only if you have selected another output format, such as a file, and would also like to receive messages.

MTBF Optimization

To ensure that metastability optimization described on page "MTBF Optimization" on page 7–9 is turned on (or to turn it off), use the following command:

```
set_global_assignment -name OPTIMIZE_FOR_METASTABILITY <ON|OFF>
```

Synchronization Register Chain Length

To globally set the number of registers in a synchronization chain to be protected and optimized as described on page "Synchronization Register Chain Length" on page 7–10, use the following command:

```
set_global_assignment -name SYNCHRONIZATION_REGISTER_CHAIN_LENGTH
<number of registers>
```

To apply the assignment to a design instance or the first register in a specific chain, use the following command:

```
set_instance_assignment -name SYNCHRONIZATION_REGISTER_CHAIN_LENGTH
<number of registers> -to <register or instance name>
```

Conclusion

Altera's Quartus II software provides industry-leading analysis and optimization features to help you manage metastability in your FPGA designs. Set up your Quartus II project with the appropriate constraints and settings to enable the software to analyze, report, and optimize the design MTBF. Take advantage of these features in the Quartus II software and follow the guidelines in this chapter as required to make your design more robust with respect to metastability.

8. Best Practices for Incremental Compilation Partitions and Floorplan Assignments

QII51017-9.0.0

Introduction

The Quartus® II incremental compilation feature allows you to partition a design, compile partitions separately, and reuse results for unchanged partitions. It provides the following benefits:

- Reduces compilation times by as much as 70%
- Preserves performance for unchanged design blocks
  - Provides repeatable results and reduces the number of compilations
- Enables true team-based design

This document provides a set of guidelines to help you partition your design to take advantage of Quartus II incremental compilation, and to help you create a design floorplan (using LogicLock™ regions) to support the flow.

This document contains the following sections:

- "Overview: Incremental Compilation"
- "Why Plan Partitions and Floorplan Assignments for Incremental Compilation?" on page 8–4
- "Creating Design Partitions: General Partitioning Guidelines" on page 8–6
- "Creating Design Partitions: Design Guidelines" on page 8–9
- "Creating Design Partitions: Consider Additional Design Suggestions" on page 8–23
- "Checking Partition Quality" on page 8–29
- "Introduction to Design Floorplans" on page 8–35
- "Creating a Design Floorplan: Placement Guidelines" on page 8–38
- "Checking Floorplan Quality" on page 8–43
- "Recommended Design Flows and Application Examples" on page 8–45
- "Potential Issues with Creating Partitions and Floorplan Assignments" on page 8–47

Overview: Incremental Compilation

Quartus II incremental compilation is an optional compilation flow that enhances the default Quartus II compilation. If you do not divide up your design for incremental compilation, your design is compiled using the default "flat" compilation flow. This section provides an overview of the incremental flow, and highlights several best practices.

For details about feature usage and application examples, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

The following procedure outlines the general Quartus II incremental compilation flow:

1. Set up your design hierarchy and source code to support partitioning along logical hierarchy boundaries. If you use a third-party synthesis tool, set up your tool to generate separate netlist files.
2. Create design partition assignments in the Quartus II software to specify which hierarchy blocks are compiled independently as partitions (including empty partitions for any missing or incomplete logic blocks).
3. When the design is compiled, Quartus II Analysis and Synthesis and the Fitter create separate netlists for each partition. These netlists are internal post-synthesis and post-fit database representations of the design.
4. Select which netlist type to preserve for each partition. You can reuse the synthesis or fitting netlist, or instruct the software to resynthesize the source files. You can also import compilation results from another project as part of a bottom-up design flow, as described in "Top-Down versus Bottom-Up Compilation Flows" on page 8–3.
5. After part of the design changes, the software recompiles only the required partitions and merges the new compilation results with existing netlists for other partitions, according to the settings from step 4.

In some cases, as described in "Introduction to Design Floorplans" on page 8–35, you should create a design floorplan with placement assignments to constrain each part of the design to a specific region of the device.

Choosing the Netlist Type and Fitter Preservation Level

You must specify which post-compilation netlist you want to use in subsequent compilations by specifying a Netlist Type setting for each partition. For post-fit netlists, you also specify a Fitter Preservation Level setting to indicate the amount of fitting information you want to preserve. Use the following general guidelines for these standard Netlist Type settings:

- Source File: Use this setting to resynthesize the source code (with any new assignments and replace any previous synthesis or Fitter results)
  - If you modify the design source, the software automatically resynthesizes the appropriate partitions with standard Netlist Type settings, so setting the partition to **Source File** is optional in this case
  - Most assignments do not trigger an automatic recompilation, so setting the partition to **Source File** is optional in this case
- Post-Synthesis (default): Use this setting to re-fit the design (with any new Fitter assignments) but preserve the synthesis results

 © March 2009 Altera Corporation

- Post-Fit: Use this setting to preserve placement and performance results
  - The default setting for post-fit is to preserve placement and reroute the entire design; this usually allows the router to find the best routing for all partitions given their placement on the design, and gives very good performance preservation
- Post-Fit with Fitter Preservation Level set to **Placement and Routing**: Use these settings to reserve routing, only if necessary
  - Use post-fit with routing if necessary to meet the timing requirements for specific partitions

Top-Down versus Bottom-Up Compilation Flows

The Quartus II incremental compilation feature supports both top-down and bottom-up compilation flows, and combinations of the two. The design flow affects how much impact design partitions have on the design optimization.

For more information about the different types of incremental design flows and example applications, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

With top-down compilation, one designer performs placement and routing on the entire design in one Quartus II project, although different designers or IP providers can create and verify HDL code separately, or you can optimize critical design blocks or IP cores before adding the rest of the design. Bottom-up design flows allow individual designers or IP providers to complete the optimization of their design in separate Quartus II projects, and then export the lower-level design partitions for import and integration into the top-level project.

A top-down flow is generally simpler to perform than its bottom-up counterpart. For example, having to export and import lower-level designs is eliminated. In addition, a top-down approach provides the design software with information about the entire design so it can perform some global placement and routing optimizations. Therefore, it is often easier to ensure good quality of results with a top-down flow than with a bottom-up flow.

The Quartus II incremental compilation feature is very flexible and supports numerous design methodologies. You can mix top-down and bottom-up flows within a single project. If the top-level design includes one or more design blocks that are optimized by different designers or IP providers, you can import those blocks (using a bottom-up methodology) into a project that also includes partitions for a top-down incremental methodology. In addition, as you perform timing closure for a design, you can create a subproject for one block of the design to be optimized by another designer in a separate Quartus II project, and pass information about the rest of the design to the subproject to obtain the best results.

By following a mixed design methodology, you can take advantage of the team-based capabilities of a bottom-up flow while maintaining the advantages of a top-down flow for most of the design logic.

Bottom-up incremental compilation is not supported in HardCopy® ASIC migration flows. You cannot use a bottom-up methodology if you want to migrate to a HardCopy ASIC. The Revision Compare feature requires that the HardCopy and FPGA netlists are the same, and all operations performed on one revision must also occur on the other revision. Unfortunately, using the bottom-up flow and importing partitions does not support this requirement.

Generating Bottom-Up Design Partition Scripts for Project Management

If you are using a bottom-up or team-based methodology, you can create design partition scripts to pass top-level constraints (such as floorplan assignments or optimization constraints) to the designers of lower-level blocks.

The bottom-up design partition scripting feature provides a project manager interface for managing resource and timing budgets in the top-level design. This interface makes it easier for designers of lower-level modules to implement the instructions from the project lead, and avoid conflicts between projects when importing and incorporating the projects into the top-level design. Using the scripts also helps reduce the need for further optimization to the designs after integration and improves overall designer productivity and team collaboration.

The feature creates Tcl files that each designer can run to set up a project and makefiles for designers who use a make environment. To use this feature, first set up the top-level project with appropriate constraints and floorplan assignments to be passed to lower levels. Then generate design partition scripts after successful compilation of the top-level design. (You can perform a Fast Synthesis and Early Timing Estimation instead of full compilation to reduce compilation time.) The top-level design can have empty partitions when you generate the scripts. To generate the scripts, on the Project menu, click **Generate Bottom-Up Design Partition Scripts** and set the appropriate options.

For details about using these scripts, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Why Plan Partitions and Floorplan Assignments for Incremental Compilation?

Incremental compilation flows require more up-front planning than flat compilations. For example, you might have to structure your source code or design hierarchy to ensure that logic is grouped correctly for optimization. It is easier to implement the correct logic grouping early in the design cycle than to restructure the code later. Incremental compilation generally requires that you be more rigorous about following good design practices than flat compilations.

Planning involves setting up the design logic for partitioning and may involve planning placement assignments to create a floorplan. Not all design flows require floorplan assignments. If you decide to add floorplan assignments later, when the design is close to completion, well-planned partitions make floorplan creation much easier. Poor partition or floorplan assignments can hurt design area utilization and performance, making timing closure more difficult.

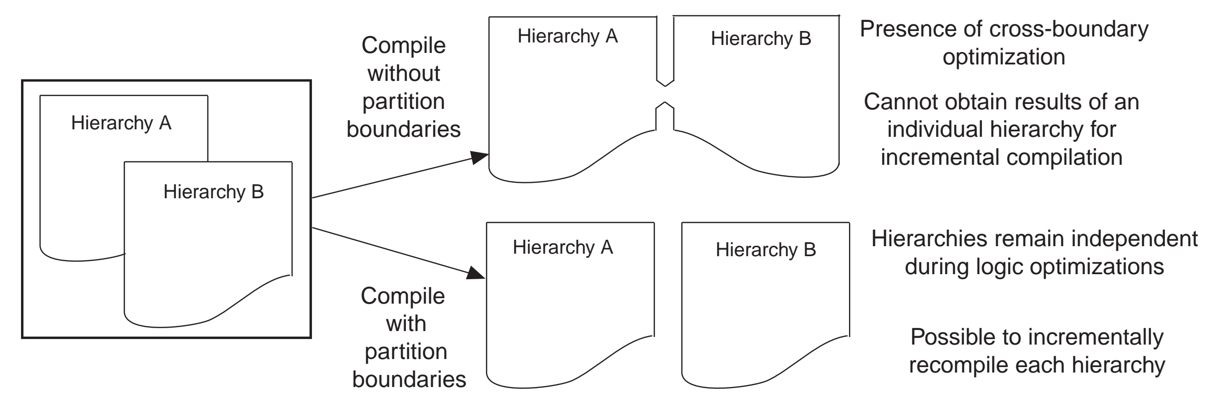
 © March 2009 Altera Corporation

As FPGA devices get larger and more complex, following good design practices becomes more important for all design flows.These planning issues are similar to the requirements for a multiple-chip solution if you were using smaller devices, although planning for one chip is much easier. Adhering to the recommended synchronous design practices makes designs more robust and easier to debug. Using an incremental compilation flow adds additional steps and requirements to your project, but can provide significant benefits in design productivity by preserving the performance of critical blocks and reducing compilation times.

Partition Boundaries and Optimization

If there are any cross-boundary optimizations between partitions, the software cannot obtain separate results for each individual partition. Figure 8–1 describes this effect in more detail. To allow the software to synthesize and place each partition independently, the logical hierarchical boundaries between partitions are treated as hard boundaries for logic optimization. It is important to understand this effect so that you can effectively plan your design partitions.

Figure 8–1. Effects of Partition Boundaries during Logic Optimization



To avoid cross-boundary optimizations, the software synthesizes each partition without using any information about logic contained in other partitions. In a flat compilation, the software uses unconnected signals, constants, inversions, and other design information to perform optimizations. When you partition a design, these types of optimizations do not take place on partition I/O ports. Good design partitions do not rely on these types of logic optimizations.

When all partitions are placed together, the Fitter can perform *placement* optimizations on the design as a whole to optimize the placement of cross-partition paths. (However, the Fitter can never perform any logic optimizations such as physical synthesis across the partition boundary.) When partitions are fit separately in a bottom-up flow or if some partitions use previous post-fitting results, the Fitter does not place and route the entire cross-boundary path at the same time and cannot fully optimize placement across the partition boundaries. Good design partitions can be placed independently because cross-partition paths are not the critical timing paths in the design.

Because cross-boundary logic and placement optimizations cannot occur, the quality of results may decrease as the number of partitions increases. Although more partitions allow for greater reduction in compilation time, you might want to limit the number of partitions to prevent degradation in the quality of results. Creating good design partitions and good floorplan location assignments helps improve the performance results for cross-partition paths. Guidelines for creating these assignments are discussed in the following sections.

Creating Design Partitions: General Partitioning Guidelines

The first stage in planning your design partitions is to organize your source code so that it supports good partition assignments. Although you can assign any hierarchical block of your design as a design partition, following the design guidelines presented in this section ensures better results. This section includes the following topics:

- "Plan Design Hierarchy and Source Design Files" on page 8–6
- "Partition Design by Functionality and Block Size" on page 8–8
- "Partition Design by Clock Domain and Timing Criticality" on page 8–8
- "Consider What Is Changing" on page 8–8

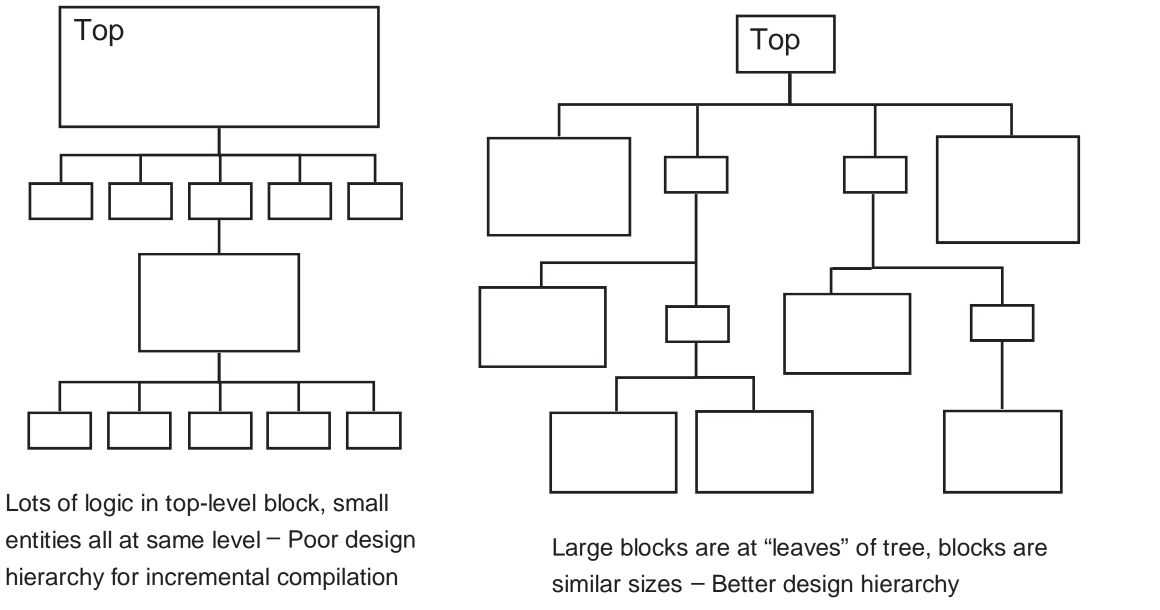
Plan Design Hierarchy and Source Design Files

Start by planning the entities in the design hierarchy. When you assign a hierarchical instance as a design partition, the partition includes the assigned instance and any entities instantiated below it that are not defined as separate partitions. You cannot group separate hierarchical entities into one partition. Take advantage of the design hierarchy to provide flexibility for partitioning and to support different design flows. Keep logic in the "leaves" of the hierarchy tree instead of having a lot of logic at the top level of the design. Doing so ensures that you can isolate partitions if required.

Create entities that can lead to partitions of approximately equal size. For example, do not instantiate a lot of small entities at the same hierarchy level because it will be difficult to group them to form reasonably sized partitions.

Figure 8–2 represents the logic blocks in a design hierarchy. The left side does not follow the recommendations for entity organization, while the right side provides much more flexibility for creating good partitions.

Figure 8–2. Design Hierarchy Recommendations



Create each entity in an independent file. The compiler uses a file checksum to detect changes, and automatically recompiles a partition if its source file changes (for standard Netlist Type settings). If the design entities for two partitions are defined in the same file, changes to the logic in one partition trigger recompilation for both partitions.

Design dependencies also affect which partitions are compiled when a source file changes. If two partitions rely on the same lower-level entity definition, changes in that lower level affect both partitions. Commands such as VHDL `use` and Verilog HDL `` `include `` create dependencies between files, so that changes to one file can trigger recompilations in all dependent files. Avoid these types of file dependencies if they are not required. The **Partition Dependent Files** report for each partition in the **Analysis & Synthesis** folder of the Compilation Report lists which files contribute to each partition.

For more details about what changes trigger an automatic recompilation, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Using Partitions with Third-Party Synthesis Tools

Incremental compilation works well with third-party synthesis tools in addition to Quartus II integrated synthesis. If you use a third-party synthesis tool, set up your tool to create a separate Verilog Quartus Mapping File (**.vqm**) or EDIF Input File (**.edf**) netlist for each hierarchical partition. In the Quartus II software, assign the top-level entity from each netlist to be a design partition. The **.vqm** or **.edf** netlist file is treated as the source file for the partition in the Quartus II software.

For more details about incremental synthesis in third-party tools, refer to your tool vendor's documentation or the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Partition Design by Functionality and Block Size

Initially, partition your design along functional boundaries. In a top-level system block diagram, each block often is a natural design partition. Typically, each block of a system is relatively independent and has more signal interaction internally than interaction between blocks, which helps reduce optimizations between partition boundaries. Keeping functional blocks together means that synthesis and fitting can optimize related logic as a whole, which can lead to improved optimization.

Consider how many partitions you want to maintain in your design to determine how large each partition should be. How much compilation time reduction you want to achieve is also a factor, because compiling small partitions is typically faster than compiling large partitions.

There is no minimum size for partitions; however, having too many partitions can reduce the quality of results by limiting optimization. Ensure that the design partitions are not too small. As a general guideline, each partition should be more than ~2,000 logic elements (LEs) or adaptive logic modules (ALMs). If your design is not yet complete when you partition the design, use previous designs to help you estimate the size that each block is likely to be.

Partition Design by Clock Domain and Timing Criticality

Consider which clock in your design feeds the logic in each partition. If possible, keep clock domains within one partition. When a clock signal is isolated to one partition, it reduces dependence on other partitions for timing optimization. Isolating a clock domain to one partition also allows better use of regional clock routing networks if the partition logic is going to be constrained to one region of the design. In addition, limiting the number of clocks within each partition simplifies the timing requirements for each partition during optimization. Use an appropriate subsystem to handle any clock domain transfers (such as a synchronization circuit, dual-port RAM, or FIFO). You can include this logic inside the partition at one side of the transfer.

Try to isolate timing-critical logic from logic that you expect to meet its timing requirements easily. Doing so allows you to preserve the satisfactory results for non-critical partitions and focus optimization iterations on just the timing-critical portions of the design to minimize compilation time.

Consider What Is Changing

When assigning partitions, think about what is changing in the design. Is there any intellectual property (IP) or reused logic for which the source code will not change during future design iterations? If so, define the logic in its own partition so that you can compile once and immediately preserve the results, and you will not have to compile that part of the design again. Is some logic being tuned or optimized, or are specifications changing for part of the design? If so, define changing logic in its own partition so that you can recompile only the changing part while the rest of the design stays the same.

As a general rule, create partitions to isolate logic that will change from logic that will not change. Partitioning a design in this way maximizes the preservation of unchanged logic and minimizes compilation time.

Creating Design Partitions: Design Guidelines

Follow the partitioning guidelines presented in this section when creating or modifying the HDL code for each design block that you might want to assign as a design partition. Not all of these recommendations have to be followed exactly to be successful with incremental compilation, but adhering to as many as possible maximizes your chances of success.

This section includes the following topics:

- "Register Partition Inputs and Outputs" on page 8–9
- "Minimize Cross-Partition-Boundary I/O" on page 8–10
- "Avoid the Need for Logic Optimization Across Partitions" on page 8–11

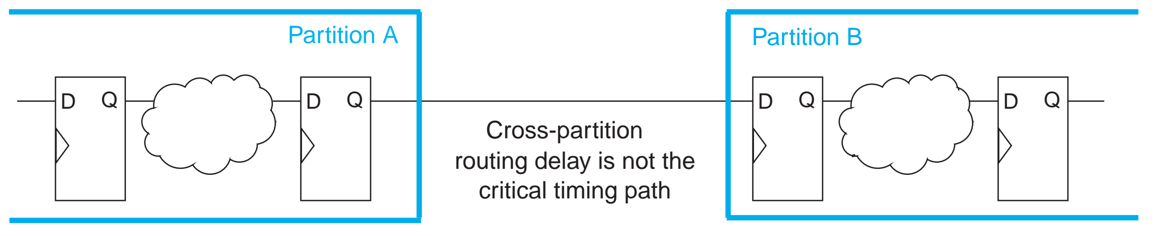
This last subsection includes examples of the types of optimizations that are prevented by partition boundaries, and describes how you can structure or modify your partitions to avoid such optimizations.

Register Partition Inputs and Outputs

Use registers at partition input and output connections that are potentially timing-critical. Registers minimize the delays on inter-partition paths, and prevent the need for cross-boundary logic optimizations.

If every partition boundary has a register as shown in Figure 8–3, every register-to-register timing path between partitions includes only routing delay. Therefore, the timing paths between partitions are likely not timing-critical, and the Fitter can generally place each partition independently from other partitions. This advantage makes it easier to create floorplan location assignments for each separate partition, and is especially important for bottom-up flows in which each partition is placed completely independently. In addition, the partition boundary does not affect combinational logic optimization because each register-to-register logic path is contained within a single partition.

Figure 8–3. Registering Partition I/O



If a design cannot include both input and output registers for each partition due to latency or resource utilization concerns, choose to register one end of each connection. If you register every partition output, for example, the combinational logic that occurs in each cross-partition path is included in one partition so that it can be optimized together.

It is also good synchronous design practice to include registers for every output of a design block. Registered outputs ensure that the input timing performance for each design block is controlled exclusively within the destination logic block.

The statistics described in “Partition Statistics Report” on page 8–33 list how many I/Os are registered or unregistered. The Incremental Compilation Advisor described on page 8–43 lists the unregistered ports for each partition.

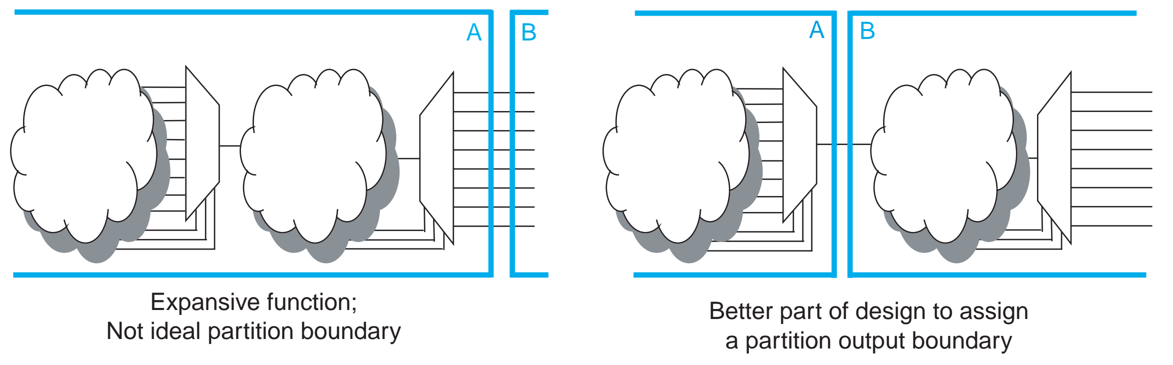
Minimize Cross-Partition-Boundary I/O

Minimize the number of I/O paths that cross between partition boundaries to keep logic paths within a single partition for optimization. Doing so makes partitions more independent for both logic and placement optimization.

This guideline is most important for the timing-critical and high-speed connections between partitions, especially in cases where the input and output of each partition is not registered. Slow connections that are not timing-critical are acceptable because they should not impact the overall timing performance of the design. If there are timing-critical paths between partitions, rework the partitions to avoid these inter-partition paths.

When dividing your design into partitions, consider the types of functions at the partition boundaries. Figure 8–4 shows an expansive function with more outputs than inputs on the left side, which makes a poor partition boundary, and a better place to assign the partition boundary that minimizes cross-partition I/Os on the right side. Adding registers to one or both sides of the cross-partition path in this example would improve the partition quality even more.

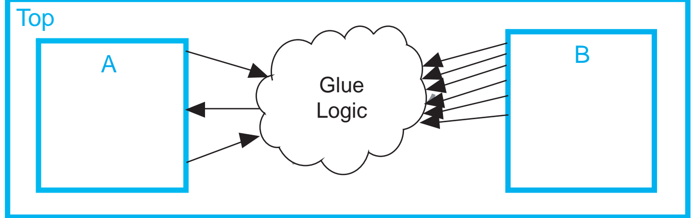
Figure 8–4. Minimizing I/O between Partitions by Moving the Partition Boundary



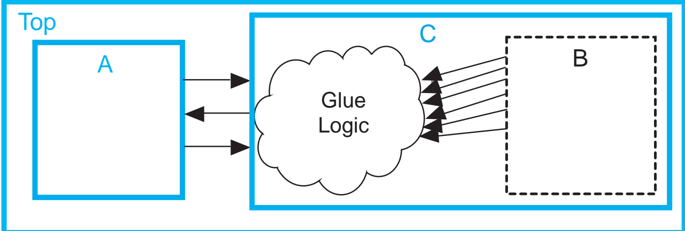
Another way to minimize connections between partitions is to avoid using combinational “glue logic” between partitions. You can often move the logic to the partition at one end of the connection to keep more logic paths within one partition. For example, the bottom diagram in Figure 8–5 includes a new level of hierarchy C that is defined as a partition instead of block B. It is clear that there are fewer I/O connections between partitions A and C than between partitions A and B in the top diagram.

Figure 8–5. Minimizing I/O between Partitions by Modifying Glue Logic

Many cross-partition paths: Poor design partition assignment



Fewer cross-partition paths: Better partitions



The statistics described in "Partition Statistics Report" on page 8–33 list the number of I/O ports as well as the number of inter-partition connections for each partition. The Incremental Compilation Advisor described on "Incremental Compilation Advisor" on page 8–43 lists the number of intra-partition (within a partition) and inter-partition (between partitions) timing edges.

Avoid the Need for Logic Optimization Across Partitions

As discussed in "Partition Boundaries and Optimization" on page 8–5, partition boundaries prevent logic optimizations across partitions. Remember this rule: Logic cannot be optimized or merged across a partition boundary.

To ensure correct and optimal logic optimization, follow the guidelines in this section. In some cases, especially if part of the design is already complete or comes from another designer, these guidelines may not have been followed when the source code was created. These guidelines are not mandatory to implement an incremental compilation flow, but can improve the quality of results. If assigning a partition affects resource utilization or timing performance of a design block as compared to the flat design, it might be due to one of the issues described in this section. Many of the examples provide suggestions for making simple changes to your design or hierarchy to move the partition boundary and improve your results.

These guidelines ensure that your design does not require any logic optimization across partitions:

- "Keep Logic in the Same Partition for Optimization and Merging"
- "Keep Constants in the Same Partition as Logic" on page 8–13
- "Avoid Unconnected Partition I/O" on page 8–14
- "Avoid Signals That Drive Multiple Partition I/O or Connect I/O Together" on page 8–14

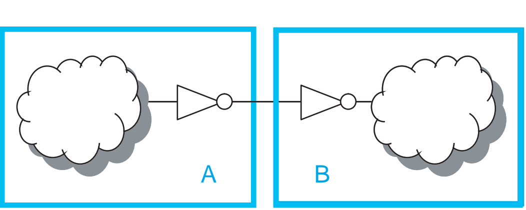
- "Invert Clocks in Destination Partitions" on page 8–16
- "Connect I/O Directly to I/O Register for Packing Across Partition Boundaries" on page 8–16
- "Do Not Use Internal Tri-States" on page 8–20
- "Include All Tri-State and Enable Logic in the Same Partition" on page 8–20
- "Include Bidirectional I/O Registers in the Same Partition" on page 8–21

Keep Logic in the Same Partition for Optimization and Merging

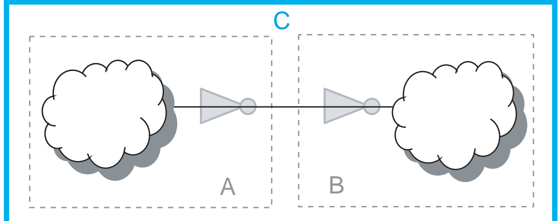
If any design logic requires logic optimization or merging to obtain optimal results, ensure all the logic is part of the same partition.

If a combinational logic path is split across two partitions, the logic cannot be optimized or merged into one logic cell in the device. This effect can result in an extra logic cell in the path, increasing the logic delay. As a very simple example, consider two inverters on the same signal in two different partitions, A and B, as shown in the left side of Figure 8–6. To maintain correct incremental functionality, these two inverters cannot be removed from the design during optimization because they occur in different design partitions. The software cannot use information about other partitions when it compiles each partition, because each partition is allowed to change independently from the other. On the right side of the figure, a new hierarchy block C has been created and defined as a partition to group the logic in blocks A and B instead of having two separate partitions. With the logic contained in one partition, the software can optimize the logic and remove the two inverters (shown in gray color), which reduces the delay for that logic path. Removing two inverters is not a significant reduction in resource utilization because inversion logic is readily available in Altera device architecture; however, it is a good demonstration of the types of logic optimization that are prevented by partition boundaries.

Figure 8–6. Keeping Logic in the Same Partition for Optimization



Inverters in separate partitions A and B cannot be removed from design: Poor design partition assignment



Inverters in same partition C can be removed: Better partition

In a flat design, the Quartus II Fitter can also merge logical instantiations into the same physical device resource. With incremental compilation, logic defined in different partitions cannot be merged to use the same physical device resource.

For example, the Fitter can merge two single-port RAMs from a design into one dedicated RAM block in the device. If the two RAMs are defined in different partitions, the Fitter cannot merge them into one dedicated device RAM block.

This limitation is a concern only if merging is required to fit the design in the target device. Therefore, you are more likely to encounter this issue during troubleshooting than during planning, if your design uses more logic than is available in the device.

Merging PLLs and Transceivers (GXB)

Multiple instances of the ALTPLL megafunction can use the same PLL resource on the device. Similarly, GXB transceiver instances can share high-speed serial interface (HSSI) resources in the same quad as other instances.

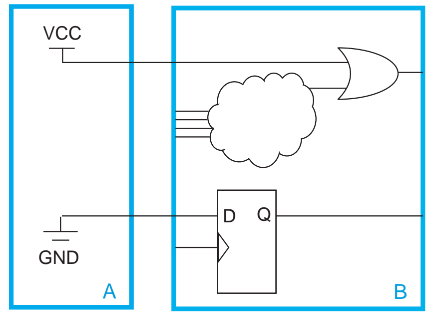
The Fitter can merge multiple instantiations of these blocks into the same device resource, even if it requires optimization across partitions (beginning with the Quartus II software version 7.2). Therefore, there are no restrictions for PLLs and high-speed transceiver blocks when setting up partitions.

Keep Constants in the Same Partition as Logic

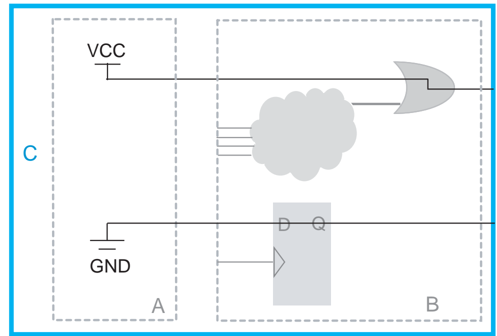
Because the software cannot optimize across a partition boundary, constants are not propagated across partition boundaries. A signal that is constant (1/V_{CC} or 0/GND) in one partition cannot affect another partition.

For example, the left side of Figure 8–7 shows part of a design in which partition A defines some signals as constants (and assumes that the other input connections come from elsewhere in the design and are not shown in the figure). Constants like this could appear due to parameter/generic settings or configurations with parameters, setting a bus to a specific set of values, or could result from optimizations that occur within a group of logic. Because the blocks are independent, the software cannot optimize the logic in block B based on the information from block A. The right side of Figure 8–7 shows a new partition C that groups the logic in blocks A and B, instead of having the two separate partitions. Within the single partition, the software can use the constants to optimize and remove much of the logic in block B (shown in gray color).

Figure 8–7. Keeping Constants in the Same Partition as the Logic They Feed



Connections to constants in another partition:
Poor design partition assignment



Constants in same partition C are used to optimize:
Better partition

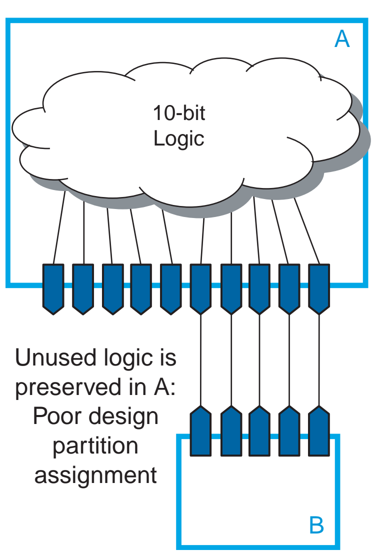
The statistics described in “Partition Statistics Report” on page 8–33 list how many input ports are fed by GND or V_{CC}. The Incremental Compilation Advisor described on page 8–43 lists the ports.

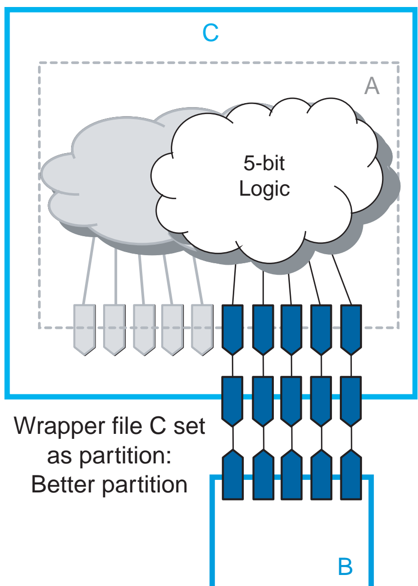
Avoid Unconnected Partition I/O

When a port is left unconnected, optimizations might be able to remove logic driving that port and improve results, similar to a constant connection. However, these optimizations are not allowed across partitions in incremental compilation, because they would create cross-partition dependence. Connect ports to an appropriate node or remove them from the partition. If you know a port will not be used, consider defining a wrapper module with a port interface that reflects this fact.

For example, the left side of Figure 8–8 shows a design that has a 10-bit function defined in partition A, but has only 5 bits connected in partition B. In a flat design, you would expect the logic for the other unused 5 bits to be removed during synthesis. With incremental compilation, synthesis does not remove the unused logic from partition A because partition B is allowed to change independently from partition A. Therefore, you could later connect all 10 bits in partition B and use all 10 bits from partition A. In this case, if you know that you will not use the other 5 bits of partition A, you should remove the unconnected ports and replace them with ground signals inside A. You can create a new wrapper file in the design hierarchy to do this, as shown on the right side of the figure. A new partition C contains the logic from A but includes only the 5 output ports required for connection with partition B. Within this new partition C, the logic for the unused 5 bits can be removed from the design, reducing area utilization.

Figure 8–8. Avoiding Unconnected Partition I/O by Creating a Wrapper File





The statistics described in “Partition Statistics Report” on page 8–33 list how many I/Os are unconnected. The Incremental Compilation Advisor described on page 8–43 lists the unconnected ports.

Avoid Signals That Drive Multiple Partition I/O or Connect I/O Together

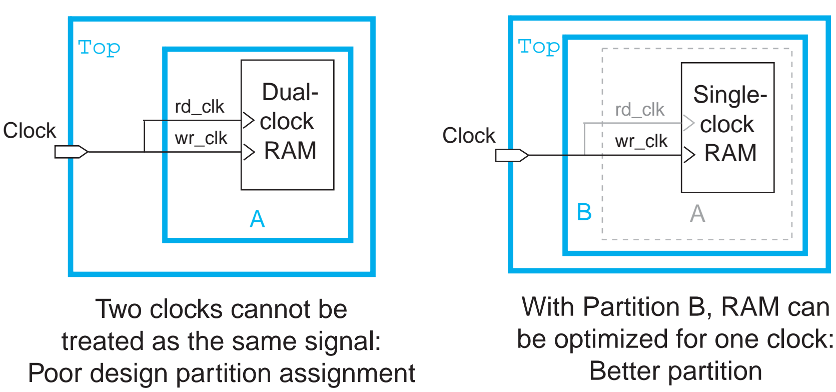
Do not use the same signal to drive multiple ports of a single partition or directly connect two ports of a partition.

If the same signal drives multiple ports of a partition, or if two ports of a partition are directly connected, those ports are logically equivalent. However, because the software has no information about connections made in another partition (including the Top partition), the compilation cannot take advantage of the equivalence. This restriction usually results in sub-optimal results.

If your design has these types of connections, redefine the partition boundaries to remove the affected ports. If one signal from a higher-level partition feeds two input ports of the same partition, feed the one signal into the partition and then make the two connections within the partition. If an output port drives an input port of the same partition, the connection can be made internally without going through any I/O ports. If an input port drives an output port directly, the connection can likely be implemented without the ports in the lower-level partition by connecting the signals in a higher-level design partition.

Figure 8–9 shows an example of one signal driving more than one port. The left diagram shows a design where a single clock signal is used to drive both the read and write clocks of a RAM block. Because the RAM block is compiled as a separate partition A, the RAM block is implemented as though there are two unique clocks. If you know that the port connectivity will not change (that is, the ports will always be driven by the same signal in the Top partition in this case), redefine the port interface so there is only a single port that can drive both connections inside the partition. You can create a wrapper file to define a partition that has fewer ports, as shown in the diagram on the right side. With the single clock fed into the partition, the RAM can be optimized into a single-clock RAM instead of a dual-clock RAM. Single-clock RAM can provide better performance in the device architecture. In addition, partition A might use two global routing lines for the two copies of the clock signal. Partition B can use one global line that fans out to all destinations. Using just the single port connection prevents overuse of global routing resources.

Figure 8–9. Preventing One Signal from Driving Multiple Partition Inputs



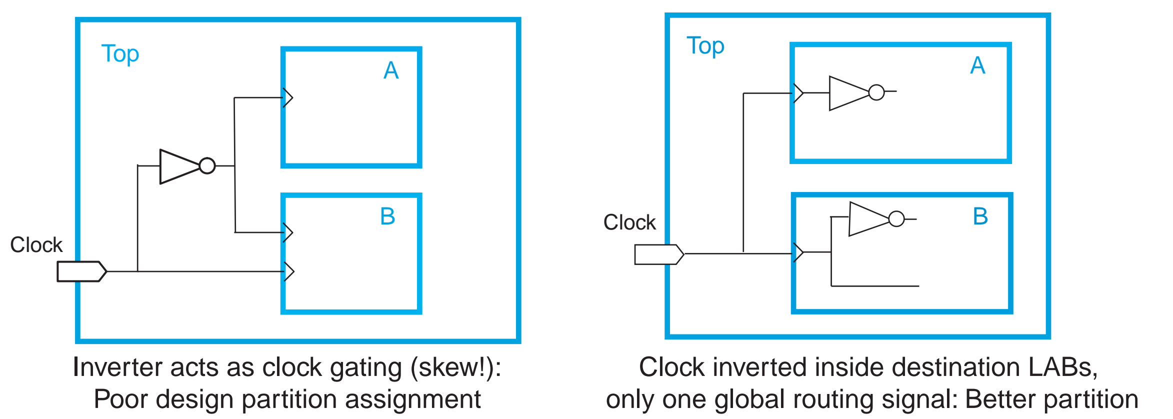
The Incremental Compilation Advisor described on "Incremental Compilation Advisor" on page 8–43 lists partition ports that have the same driving signal, and ports that are directly connected together.

Invert Clocks in Destination Partitions

For best results, clock inversion should be done in the destination logic array block (LAB), because each LAB contains clock inversion circuitry in the device architecture. In a flat compilation, the software can optimize a clock inversion to propagate it to the destination LABs regardless of where the inversion takes place in the design hierarchy. However, clock inversion cannot propagate through a partition boundary to take advantage of the inversion architecture in the destination LABs.

With partition boundaries as shown on the left side of Figure 8–10, the Quartus II software uses logic to invert the signal in the partition that defines the inversion (the Top partition in this example), and then routes the signal on a global clock resource to its destinations (in partitions A and B). The inverted clock acts as a gated clock with high skew. A better solution is to invert the clock signal in the destination partitions as shown on the right side of the figure. In this case the correct logic and routing resources can be used, and the signal is not a gated clock.

Figure 8–10. Inverting Clock Signal in Destination Partitions



Notice that this diagram also shows another example of a single pin feeding two ports of a partition boundary. In the left diagram, partition B does not have the information that the clock and inverted clock come from the same source. In the right diagram, partition B has more information to help optimize the design because the clock is connected as one port of the partition.

Connect I/O Directly to I/O Register for Packing Across Partition Boundaries

Cross-partition register packing of I/O registers is allowed in certain cases where your input and output pins exist in the top-level hierarchy (and the Top partition), but the corresponding I/O registers exist in other partitions.

The following specific circumstances are required for input pin cross-partition register packing:

- The input pin feeds exactly one register.
- The path between the input pin and register includes only input ports of partitions that have one fan-out each.

The following specific circumstances are required for output register cross-partition register packing:

- The register feeds exactly one output pin.

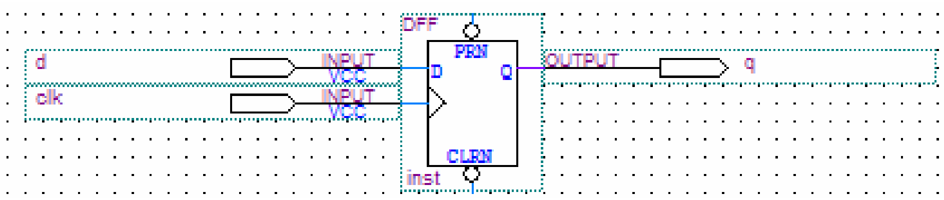
- The output pin is fed by only one signal.
- The path between the register and output pin includes only output ports of partitions that have one fan-out each.

The following examples of I/O register packing illustrate this point using block diagram file (**.bdf**) schematics to describe the design logic.

Example 1—Output Register in Partition Feeding Multiple Output Pins

In this example, a subdesign contains a single register, as shown in Figure 8–11.

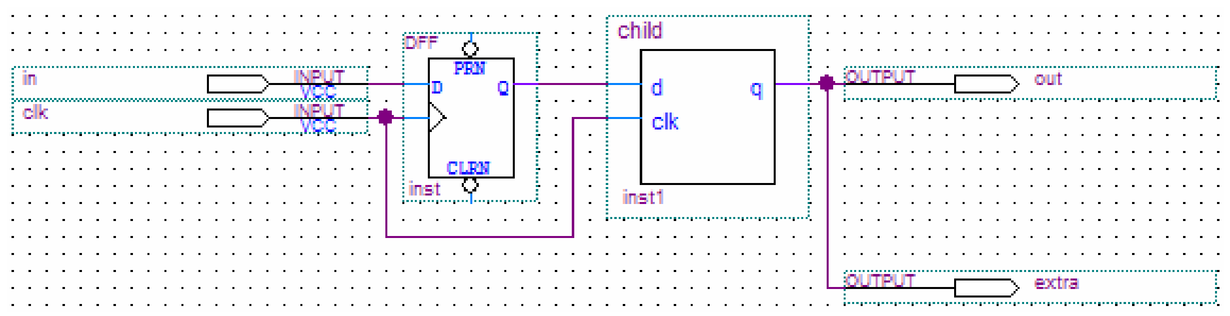
Figure 8–11. Subdesign with One Register, Designated as a Separate Partition



If the top-level design instantiates the subdesign with a single fan-out directly feeding an output pin, and designates the subdesign as a separate design partition, the Quartus II software can perform cross-partition register packing because the single partition port feeds the output pin directly.

In this example, the top-level design instantiates the subdesign as an output register with more than one fan-out signal, as shown in Figure 8–12.

Figure 8–12. Top-Level Design Instantiating the Subdesign in Figure 8–11 with Two Output Pins



In this case, the software does not perform output register packing. If there is a **Fast Output Register** assignment on pin `out`, the software issues a warning that the Fitter cannot pack the node to an I/O pin because the node and the I/O cell are connected across a design partition boundary.

This type of cross-partition register packing is not permitted because it requires modification to the interface of the subdesign partition. To perform incremental compilation, the software must preserve the interface of design partitions.

To allow the software to pack the register in the subdesign from Figure 8–11 with the output pin `out` in Figure 8–12, restructure your HDL code so that output registers directly connects output pins by making one of the following changes:

- Place the register in the same partition as the output pin. The simplest option is to move the register from the subdesign partition into the partition containing the output pin. This guarantees that the Fitter can optimize the two nodes without violating any partition boundaries.
- Duplicate the register in your subdesign HDL as in Figure 8–13 so that each register feeds only one pin, then connect the extra output pin to the new port in the top-level design as shown in Figure 8–14. This converts the cross-partition register packing into the simplest case where each register has a single fan-out.

Figure 8–13. Modified Subdesign from Figure 8–11 with Two Output Registers and Two Output Ports

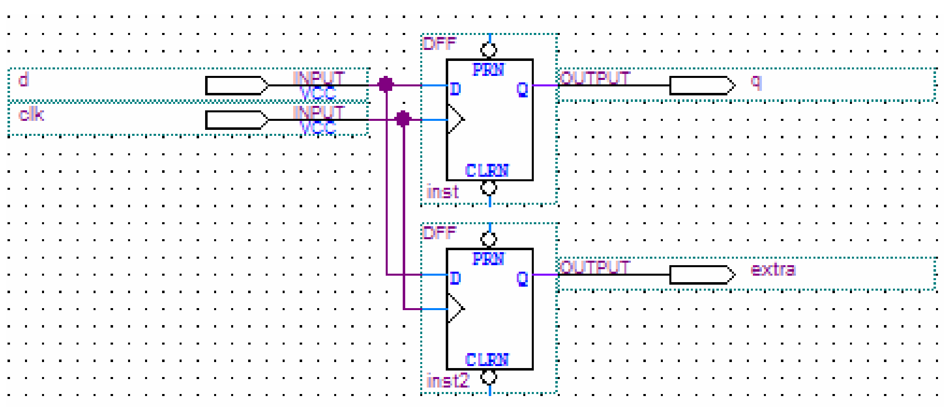


Figure 8–14. Modified Top-Level Design from Figure 8–12 Connecting Two Output Ports to Output Pins

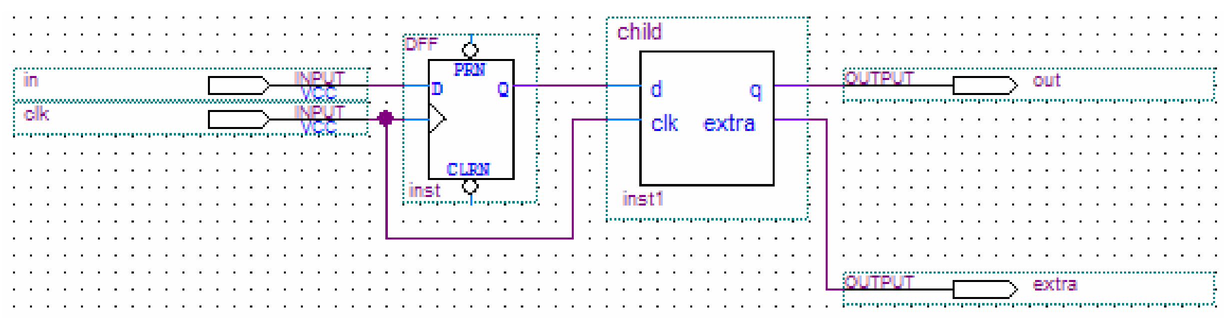

Example 2—Input Register in Partition Fed by an Inverted Input Pin or Output Register in Partition Feeding an Inverted Output Pin

In this example, a subdesign designated as a separate partition contains a register, as shown in Figure 8–11. The top-level design in Figure 8–15 instantiates the subdesign as an input register with the input pin inverted. The top-level design in Figure 8–16 instantiates the subdesign as an output register with the signal inverted before feeding an output pin.

Figure 8–15. Top-Level Design Instantiating the Subdesign in Figure 8–11 as an Input Register with an Inverted Input Pin

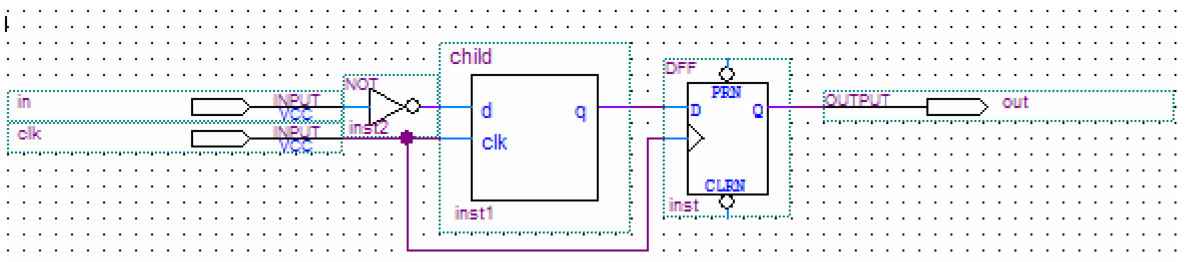

Figure 8–16. Top-Level Design Instantiating the Subdesign in Figure 8–11 as an Output Register Feeding an Inverted Output Pin

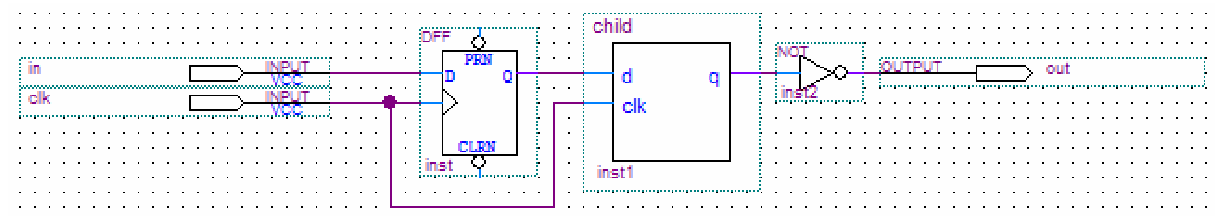


In these cases, the software does not perform register packing. If there is a **Fast Input Register** assignment on pin `in` in Figure 8–15 or a **Fast Output Register** assignment on pin `out` in Figure 8–16, the software issues a warning that the Fitter cannot pack the node to an I/O pin because the node and I/O cell are connected across a design partition boundary.

This type of register packing is not permitted because it requires moving logic across a design partition boundary to place into a single I/O device atom. To perform register packing, either the register must be moved out of the subdesign partition or the inverter must be moved into the subdesign partition to be implemented in the register.

To allow the software to pack the register in the subdesign from Figure 8–11 with the input pin `in` in Figure 8–15 or the output pin `out` in Figure 8–16, restructure your HDL code to place the register in the same partition as the inverter by making one of the following changes:

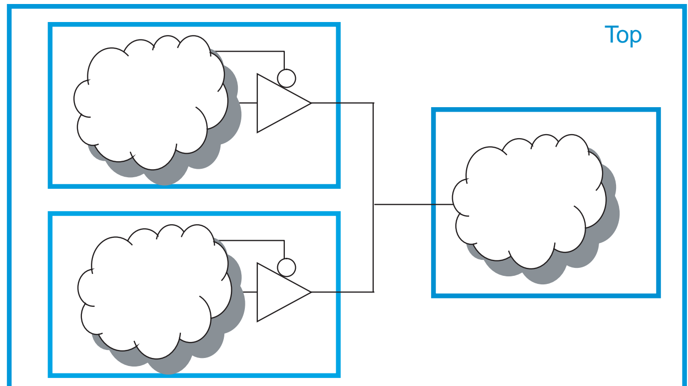
- Move the register from the subdesign partition into the top-level partition containing the pin. This ensures that the Fitter can optimize the I/O register and inverter without violating any partition boundaries.
- Move the inverter from the top-level block into the subdesign, then connect the subdesign directly to a pin in the top-level design. This allows the Fitter to optimize the inverter into the register implementation, so the register is directly connected to a pin, which enables register packing.

Do Not Use Internal Tri-States

Internal tri-state signals are not recommended for FPGAs because the device architecture does not include internal tri-state logic. If designs do use internal tri-states in a flat design (with no partitions), the tri-state logic is typically converted to OR gates or multiplexing logic. But if tri-state logic occurs on a hierarchical partition boundary, the software cannot convert the logic to combinational gates because the partition could be connected to a top-level device I/O through another partition.

Figure 8–17 shows a design with partitions that are not supported for incremental compilation due to the internal tri-state output logic on the partition boundaries. Instead of using internal tri-state logic for partition outputs, implement the correct logic to select between the two signals. Doing so is good practice even when there are no partitions, because such logic explicitly defines the behavior for the internal signals instead of relying on the software to convert the tri-state signals into logic.

Figure 8–17. Unsupported Internal Tri-State Signals



Design results in Quartus II error message:
The software cannot synthesize this
design and maintain incremental functionality

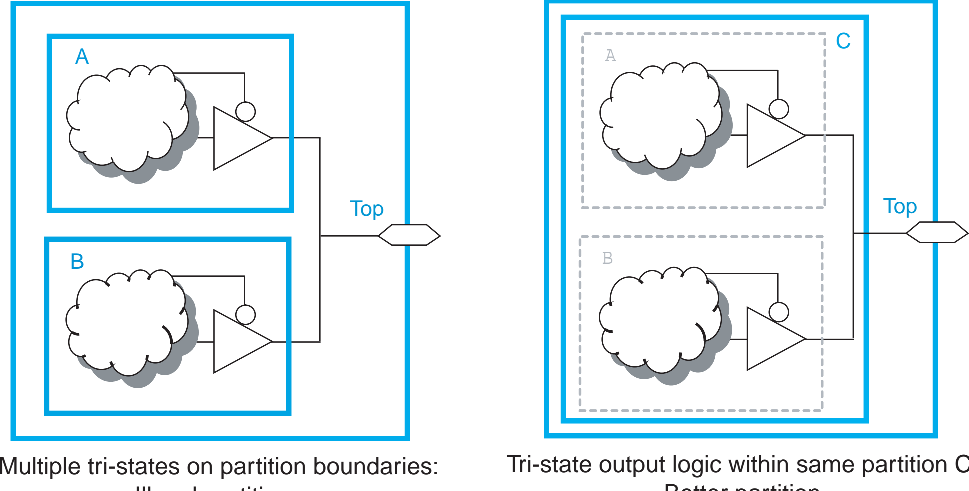
Do not use tri-state signals or bidirectional ports on hierarchical partition boundaries, unless the port is connected directly to a top-level I/O pin on the device. If you must use internal tri-state logic, ensure that all the control and destination logic is contained in the same partition, in which case the software can convert the internal tri-state signals into multiplexing logic like in a flat design. If possible, you should avoid using internal tri-state logic in any Altera FPGA design to ensure that you get the desired implementation when the design is compiled for the target device architecture.

Include All Tri-State and Enable Logic in the Same Partition

When multiple output signals use tri-state logic to drive a device output pin, the Quartus II software merges the logic into one tri-state output pin. The software cannot merge tri-state outputs into one output pin if any of the tri-state logic occurs on a partition boundary. Similarly, output pins with an output enable signal cannot be packed into the device I/O cell if the output enable logic is part of a different partition from the output register. To allow register packing for output pins with an output enable signal, structure your HDL code or design partition assignments so that the register and enable logic are defined in the same partition.

Figure 8–18 shows a design with tri-state output signals that feed a device bidirectional I/O pin (assuming that the input connection feeds elsewhere in the design and is not shown in the figure). On the left side of the figure, the tri-state output signals appear as the outputs of two separate partitions. In this case, the software cannot implement the specified logic and maintain incremental functionality. On the right side, another level of hierarchy C has been created to group the logic from blocks A and B. With this single partition C, the Quartus II software can merge the two tri-state output signals and implement them in the tri-state logic available in the device I/O element.

Figure 8–18. Including All Tri-State Output Logic in the Same Partition



Include Bidirectional I/O Registers in the Same Partition

For a bidirectional partition port that feeds a bidirectional I/O pin at the top level, all the logic that forms the bidirectional I/O cell must reside in the same partition. This guideline applies to the Stratix II family, Cyclone® II family, and all older Altera device families that include I/O registers. In addition, as discussed in the previous two recommendations, the I/O logic must feed the I/O pin without any intervening logic.

In Figure 8–19, for the software to implement all three registers in the I/O element along with the tri-state logic, all the I/O logic must be defined inside the same partition. The logic connected to the registers can occur in the same partition or any other partition; only the I/O registers must be grouped with the tri-state logic definition. The bidirectional I/O port of the partition must be directly connected to the bidirectional device pin at the top level. The signal can go through several partition boundaries if necessary, as long as the connection path contains no logic.

Figure 8–19. Including All Bidirectional I/O Registers in the Same Partition

Bidirectional logic is within one partition, and I/O logic directly feeds I/O pin

Summary of Guidelines Related to Logic Optimization Across Partitions

Follow the guidelines presented in this section to ensure that your design does not require any logic optimization across partitions:

- Keep logic in the same partition for optimization and merging
- Keep constants in the same partition as logic
- Avoid unconnected partition I/O
- Avoid signals that drive multiple partition I/O or connect I/O together
- Invert clocks in destination partitions
- Connect I/O directly to I/O register for packing across partition boundaries
- Do not use internal tri-states
- Include all tri-state and enable logic in the same partition
- Include bidirectional I/O registers in the same partition

Remember that these guidelines are not strict rules to implement an incremental compilation flow, but can improve the quality of results. When creating source design code, keep these guidelines in mind and organize your HDL code to support good partition boundaries. For designs that are already complete, assess whether assigning a partition affects the resource utilization or timing performance of a design block as compared to the flat design, and make the appropriate changes to your design or hierarchy to improve your results.

Creating Design Partitions: Consider Additional Design Suggestions

This section includes several additional design practices that may improve success in incremental compilation flows, if they are applicable to your design:

- "Balance Logic Resources" on page 8–23
- "Balance Global Routing Signals and Clock Networks if Required" on page 8–24
- "Assign Virtual Pins in Bottom-Up Flows" on page 8–25
- "Perform Timing Budgeting if Required" on page 8–26
- "Consider a Cascaded Reset Structure" on page 8–26
- "Drive Clocks Directly in Bottom-Up Flows" on page 8–28
- "Recreate PLLs for Lower-Level Partitions if Required in Bottom-Up Flows" on page 8–28

Balance Logic Resources

When using incremental compilation, the software synthesizes each partition separately with no data about the resources used in other partitions. This means that device resources could be overused in the individual partitions during synthesis, thus, the design may not fit in the target device when the partitions are merged.

In a bottom-up design flow in which designers optimize their lower-level designs and export them to a top-level design, the software places and routes each partition separately. In some cases, partitions can use conflicting resources when combined at the top level.

For example, in the standard synthesis flow, the Quartus II Compiler can perform automated resource balancing for DSP blocks or RAM blocks and convert some of the logic into regular logic cells to prevent overuse. Without data about DSP and RAM blocks used in other partitions, it is possible for the logic in each separate partition to maximize the use of a particular device resource.

To avoid these effects, you may have to perform manual resource balancing across partitions. This is more applicable to bottom-up design flows, because top-down compilation usually handles resource balancing without any user intervention.

To prevent overuse of device resources such as DSP or RAM blocks, you may be able to manually balance the resources. You can use the Quartus II synthesis options to control inference of megafunctions that use the DSP or RAM blocks. You can also use the MegaWizard™ Plug-In Manager to customize your RAM or DSP megafunctions to use regular logic instead of the dedicated hardware blocks.

To assign a number of DSP or RAM resources for each partition, use the following logic options to specify the maximum number of dedicated logic blocks that the software can use in the specified partition: **Maximum DSP Block Usage**, **Maximum Number of M4K/M9K Memory Blocks**, or **Maximum Number of M-RAM/M144K Memory Blocks**. You can set these options globally for all partitions. To set an option for all partitions, on the Assignments menu, click **Settings**. Under **Category**, select **Analysis & Synthesis Settings**. Click **More Settings,** and in the **Existing option settings** list, select the appropriate option. You can also set the option for a specific partition using the Assignment Editor. Select the assignment name, apply it to the root

entity of a partition, and set an integer as the value. The partition-specific assignment overrides the global assignment, if any. However, *each* partition that does not have a partition-specific assignment can use the number of DSP or RAM blocks set by the global assignment. Be aware that this behavior can lead to over-allocation of dedicated logic blocks, eventually resulting in a no-fit error.

For more information about resource balancing when using Quartus II synthesis, refer to the "Megafunction Inference Control" section in the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*. For more tips about resource balancing and reducing resource utilization, refer to the appropriate "Resource Utilization Optimization Techniques" section in the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*.

It is often helpful to create a LogicLock region to isolate the placement of each partition, especially in bottom-up flows, to minimize the chance that the logic in more than one partition uses the same logic resource. However, there are situations in which partition placement may still cause conflicts at the top level. For example, you can design a partition one way in a lower-level design (such as using an M-RAM memory block) and then instantiate it in two different ways in the top level (such as one using an M-RAM block and another using an M4K block). In this case, you can export a post-fit netlist with no placement information from the lower-level design and allow the software to refit the logic at the top level.

Balance Global Routing Signals and Clock Networks if Required

If your design is very complex and has many clocks, you may have to allocate global routing resources between the different design partitions. In most cases, you do not have to allocate routing because the software finds the best solution for the global signals.

Global routing signals can cause conflicts when multiple projects are imported into a top-level design. The Quartus II software automatically promotes high fan-out signals to use global routing resources available in the device. Lower-level partitions can use the same global routing resources, thus causing conflicts at the top level. In addition, LAB placement depends on whether the inputs to the logic cells within the LAB are using a global clock signal. Therefore, problems can occur if a design does not use a global signal in the lower-level design, but does use a global signal in the top-level design.

To avoid these problems, the project lead can first determine which partitions use which type of global routing signals. Each designer of a lower-level partition can then assign the appropriate type of global signals manually and prevent other signals from using global routing resources, or set a maximum number of clocks for the partition.

You can use the **Global Signal** assignment to force or prevent the use of a global routing line, making the assignment to a clock source node or signal. You can also assign certain types of global clock resources in some device families, such as regional clocks that cover only part of the device. Alternatively, designers of lower-level partitions can specify the number of clocks allowed in the project using the maximum clocks allowed options. On the Assignments menu, click **Settings**. Under **Category**,

select **Fitter Settings**. Click **More Settings**, and in the **Existing option settings** list, select the appropriate option. Choose **Maximum number of clocks of any type allowed**, or use the **Maximum number of global clocks allowed**, **Maximum number of regional clocks allowed**, and **Maximum number of periphery clocks allowed** options to restrict the number of clock resources of a given type in the project.

You can view the resource coverage of regional clocks in the Chip Planner, and then align LogicLock regions that constrain partition placement with available global clock routing resources. For example, if the LogicLock region for a particular partition is limited to one device quadrant, that partition's clock can use a regional clock routing type that covers only one device quadrant. If all partition logic is available, the project lead can compile the entire design at the top level with floorplan assignments to allow the use of regional clocks that span only a part of the chip. You can use the Fitter's results to make assignments when optimizing the lower-level partitions in separate Quartus II projects.

If you require more control when planning a design with imported partitions, you can assign a specific signal to use a particular clock network in Stratix II devices and newer device families by assigning the clock control block instance called CLKCTRL. Use the **Global Clock CLKCTRL Location** logic option. You can make a point-to-point assignment from a clock source node to a destination node, or a single-point assignment to a clock source node. Set the assignment value to the name of the clock control block: `CLKCTRL_G`<*global network number*> to choose one of the global routing networks or `CLKCTRL_R`<*regional network number*> to choose one of the dedicated regional routing networks in the device.

If you want to disable the automatic global promotion performed in the Fitter to prevent other signals from being placed on global (or regional) routing networks, turn off the **Auto Global Clock** and **Auto Global Register Control Signals** options. On the Assignments menu, click **Settings**. On the **Fitter Settings** page, click **More Settings** and change the settings to **Off**.

If you are performing a bottom-up flow using design partition scripts, the software can automatically write the commands to pass global constraints and turn off the automatic options. For more information, refer to "Generating Bottom-Up Design Partition Scripts for Project Management" on page 8–4.

Alternatively, to avoid problems when importing, direct the Fitter to discard the placement and routing of the imported netlist by setting the Fitter preservation level property of the partition to Netlist Only. With this option, the Fitter reassigns all the global signals for this particular partition when compiling the top-level design.

Assign Virtual Pins in Bottom-Up Flows

Virtual pins map lower-level design I/Os to internal cells. Use them when the number of I/Os on a lower-level design exceeds the device I/O count, and to increase the timing accuracy of cross-partition paths.

Make a **Virtual Pin** assignment in the Assignment Editor for lower-level design I/Os that will become internal nodes in the top level. Leave clock pins mapped to I/O pins to ensure proper routing.

You can specify locations for the virtual pins that correspond to the placement of other partitions. You can also make timing assignments to the virtual pins to define a timing budget, as described in the following section.

Virtual pins are created automatically from the top-level design if you use the **Generate Bottom-Up Design Partition Scripts** command. The scripts place the virtual pins to correspond with other partitions' placement from the top-level design. Refer to "Generating Bottom-Up Design Partition Scripts for Project Management" on page 8–4 for details.

Perform Timing Budgeting if Required

If you optimize lower-level partitions independently and import them to the top level, or compile with empty partitions, any unregistered paths that cross between partitions are not optimized as an entire path. In these cases, the Compiler has no information about the placement of the logic that connects to the I/O ports. If the logic in one partition is placed far away from logic in another partition, the routing delay between the logic can lead to problems in meeting the timing requirements. You can reduce this effect by ensuring that input and output ports of the partitions are registered whenever possible.

To ensure that the Compiler correctly optimizes the input and output logic in each partition, you may be required to perform some manual timing budgeting. For each unregistered timing path that crosses between partitions, make timing assignments on the corresponding I/O path in each partition to constrain both ends of the path to the budgeted timing delay. Assigning a timing budget for each part of the connection ensures that the Compiler optimizes the paths appropriately.

When performing manual timing budgeting in a lower-level partition for I/O ports that become internal partition connections in a top-level design, you can assign location and/or timing constraints to the virtual pin that represents each connection to further improve the quality of the timing budget. Refer to the previous section for a description of virtual pins.

If you are performing a bottom-up flow using the design partition scripts, the software can write I/O timing budget constraints automatically for virtual pins. Refer to "Generating Bottom-Up Design Partition Scripts for Project Management" on page 8–4 for details.

Consider a Cascaded Reset Structure

Designs typically have a global asynchronous reset signal where a top-level signal feeds all partitions. To minimize skew for the high fan-out signal, the global reset signal is typically placed onto a global routing resource.

In some cases, having one global reset signal can lead to recovery and removal time problems. This issue is not specific to incremental flows; it could be applicable in any large high-speed design. For incremental flows, the global reset signal also creates a timing dependency between the Top partition and lower-level partitions.

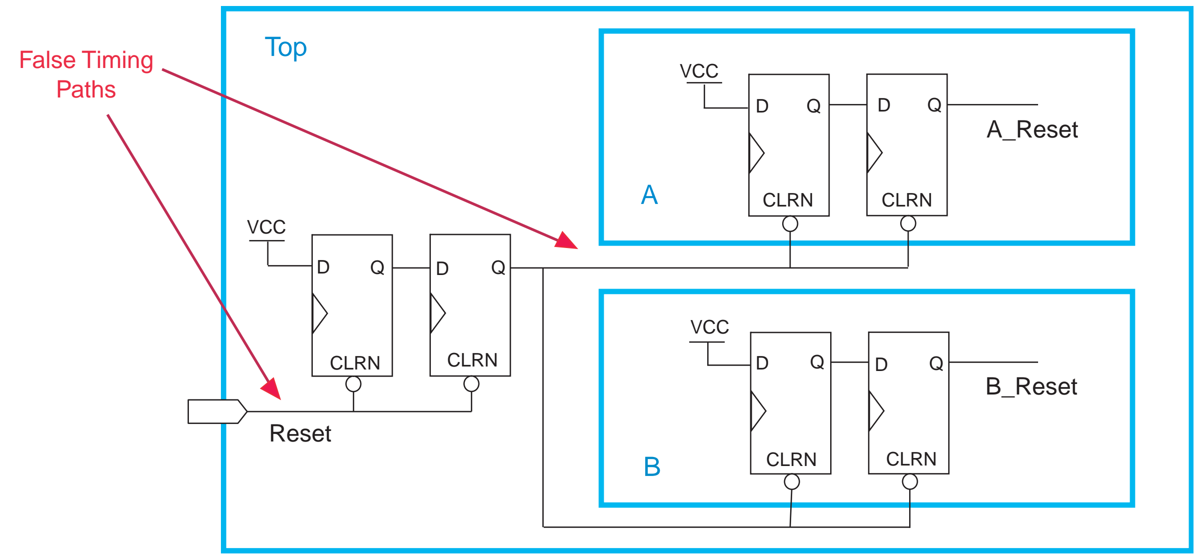
For incremental compilation, minimizing the impact of global structures is helpful. To isolate each partition, consider adding reset synchronizers. By using cascaded reset structures, the design intent is to reduce the inter-partition fan-out of the reset signal, thereby minimizing the effect of the global signal. Reducing the fan-out of the global reset signal also provides more flexibility in routing the cascaded signals, and may help recovery and removal times in some cases.

This suggestion can help in large designs, regardless of whether you are using incremental compilation. However, if one global signal can feed all the logic in its domain and meet recovery and removal times, you probably do not have to follow this recommendation. It is more relevant for high-performance designs where meeting timing on the reset logic can be challenging. Isolating each partition and allowing more flexibility in global routing structures is an additional advantage in incremental flows.

If you add additional reset synchronizers to your design, it adds latency to the reset path, so be sure that this is acceptable in your design. In addition, parts of the design may come out of reset in different clock cycles. You can balance the latency or add hand-shaking logic between partitions, if necessary, to accommodate these differences.

Figure 8–20 shows a cascaded reset structure. The signal is first synchronized as it comes on the chip, following good synchronous design practices. This logic means the design asynchronously resets, but synchronously releases from reset to avoid any race conditions or metastability problems. Then, to minimize the impact of global structures, the circuit employs a divide-and-conquer approach for the reset structure. By implementing a cascaded reset structure, each partition's reset paths are independent. This reduces the effect of inter-partition dependency because the inter-partition reset signals can now be treated as false paths for timing analysis. In some cases, the partition's reset signal can be placed on local lines to reduce the delay added by routing to a global routing line. In other cases, the signal can be routed on a regional or quadrant clock signal.

Figure 8–20. Cascaded Reset Structure



This circuit as one that may help you achieve timing closure and partition independence for your global reset signal. Evaluate the circuit and consider how it works for your design.

Drive Clocks Directly in Bottom-Up Flows

In bottom-up flows, the drive partition clock inputs directly with device clock input pins.

Connecting the clock signal directly avoids any timing analysis difficulties with gated clocks. Clock gating is never recommended for FPGA designs because of potential glitches and clock skew. Clock gating can cause trouble especially in bottom-up flows because the lower-level partitions have no information about any gating that takes place at the top level or in another partition. If a gated clock is required in a partition, perform the gating within that partition, as described for clock inversion in "Invert Clocks in Destination Partitions" on page 8–16.

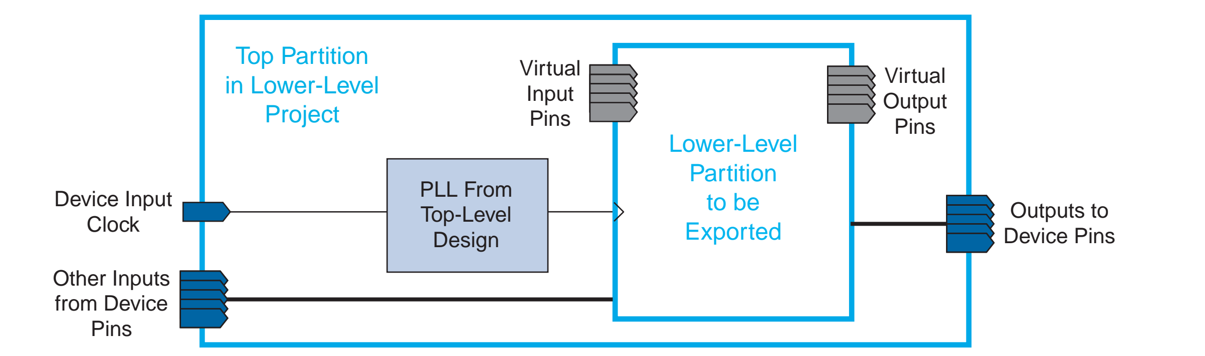
Direct connections to input clock pins also allows design partition scripts to send constraints from the top-level device pin to the lower-level partitions.

Recreate PLLs for Lower-Level Partitions if Required in Bottom-Up Flows

If you use a PLL in your top-level design and connect it to lower-level partitions, the lower-level partitions do not have information about the multiplication, phase shift, or compensation delays for the PLL. To accommodate the PLL timing, you can make appropriate timing assignments in your lower-level Quartus II project to ensure that clocks are not left unconstrained or constrained with an incorrect frequency. Alternatively, you can manually duplicate the top-level PLL (or other derived clock logic) in the lower-level design file to ensure that you have the correct PLL parameters and clock delays for complete, accurate timing analysis.

Include a copy of the top-level PLL in your lower-level project as shown in Figure 8–21, and create a design partition for the rest of the lower-level design logic that will be exported to the top level. When the design is complete, you can export just the lower-level partition, without exporting any auxiliary PLL components to the top-level design. When you use the feature to export a partition within a project, the software exports any hierarchy under the specified partition into the Quartus II Exported Partition (**.qxp**) file but does not include logic defined outside the partition (the PLL in this example).

Figure 8–21. Recreating a Top-Level PLL in a Lower-Level Partition



Checking Partition Quality

This section provides an overview of tools you can use as you make partitions in the Quartus II software. Take advantage of these tools to assess your partition quality, and use the information to improve your design or assignments as required to achieve the best results.

Incremental Compilation Advisor

You can use the Incremental Compilation Advisor to check that your design follows the recommendations for creating design partitions that are presented in this document.

On the Tools menu, point to **Advisors** and click **Incremental Compilation Advisor**. Recommendations are split into General Recommendations that apply to all compilation flows and Bottom-Up Design Recommendations that apply to bottom-up design methodologies. Each recommendation provides an explanation, describes the effect of the recommendation, and provides the action required to make the suggested change.

To check whether the design follows the recommendations, go to the **Timing Independent Recommendations** page or the **Timing Dependent Recommendations** page (for the TimeQuest Timing Analyzer or the Classic Timing Analyzer), and click **Check Recommendations**. For large designs, these operations can take a few minutes.

After you check the design, a symbol appears next to each recommendation that indicates whether or not your design follows that particular recommendation. Refer to the Legend on the **How to use the Incremental Compilation Advisor** page in the Incremental Compilation Advisor for more information.

In some items, there is a link to the appropriate Quartus II settings page where you can make a suggested change to assignments or settings. For many items, if your design does not follow the recommendation, the Check Recommendations operation creates a table that lists any nodes or paths in the design that could be improved.

For example, if not all of the partition I/O ports follow the Register All Ports recommendation, the Incremental Compilation Advisor displays a list of unregistered ports with the partition name and the source and destination nodes for the port. When the Incremental Compilation Advisor provides a list of nodes, you can right-click on a node and click **Locate** to cross-probe to other Quartus II features such as the RTL Viewer, Chip Planner, or the design source code in the text editor.

Opening a new TimeQuest report resets the Incremental Compilation Advisor results, so you must rerun the Check Recommendations process.

Design Partition Planner

The Design Partition Planner allows you to view design connectivity and hierarchy, and can assist you in creating effective design partitions that follow the guidelines in this document. You can also use the Design Partition Planner to optimize design performance, by isolating and resolving failing paths on a partition-by-partition basis.

To view a design and create design partitions, first compile the design, or perform Analysis and Synthesis. On the Tools menu, click **Design Partition Planner**. The design is displayed as a single top-level design block, containing its lower-level instances as boxes.

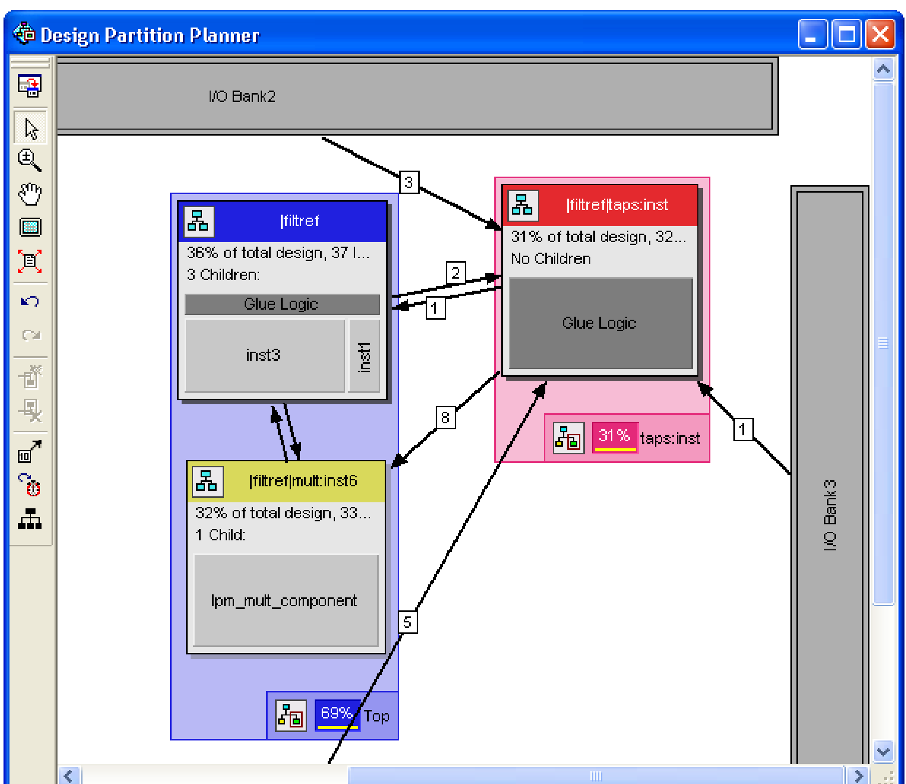
To show connectivity between blocks, extract instances from the top-level design block. Click on a design block and drag it into the surrounding white space, or right-click an entity and click **Extract from Parent** on the Shortcut menu.

When you extract entities, connection bundles are drawn between entities, showing the number of connections existing between pairs of entities. When you have extracted a design block that you want to set as a design partition, right-click on that design block and click **Create Design Partition**.

The Design Partition Planner also has an Auto-Partition feature that creates partitions based on the size and connectivity of the hierarchical design blocks. Right-click on the design block you want to partition (such as the top-level design hierarchy), and choose **Auto-Partition**. You can then analyze and adjust the partition assignments as required.

Figure 8–22 shows the Design Partition Planner after making a design partition assignment to one instance (in the pale red shaded box), and dragging another instance away from the top-level block within the same partition (two design blocks in the pale blue shaded box). The figure shows the number of connections between each partition and information about the size of each design instance.

Figure 8–22. Design Partition Planner



To switch between connectivity display mode and hierarchical display mode, click **Hierarchy Display** on the View menu. Alternately, to switch temporarily to a view-only hierarchy display, click and hold the hierarchy icon in the top-left corner of any entity.

To control the way the connection bundles are displayed, right-click in the white space and choose **Bundle Configuration**. For example, you can remove the connection lines between partitions and I/O banks by turning off **Display connections to I/O banks**. You can also use the settings on the **Connection Counting** tab to adjust how the connections are counted in the bundles.

To optimize design performance, it is desirable to confine failing paths within individual design partitions, so that there are no failing paths passing between partitions, as discussed in earlier sections. The following steps allow you to view the critical timing paths from a TimeQuest Timing Analysis:

1. Open the TimeQuest Timing Analyzer and perform a timing analysis on the design.
2. In the Design Partition Planner, click **Show Timing Data** on the View menu.

In the top-level entity, child entities containing failing paths are marked by a small red dot in the upper right corner of the entity box.

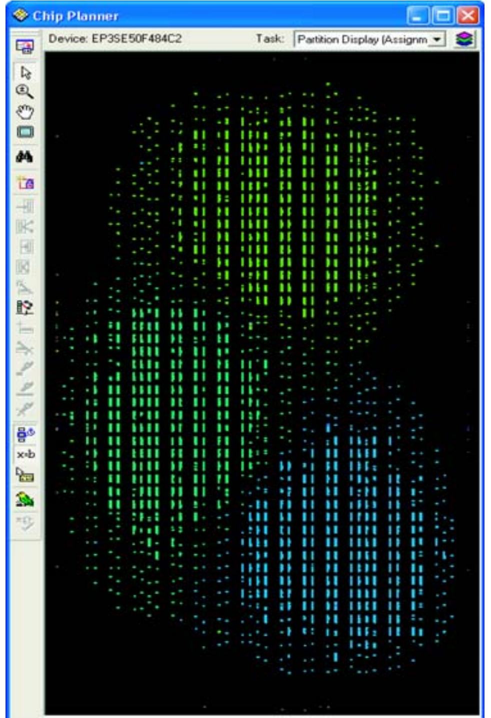
For more details about how to use the Design Partition Planner to analyze your design and create partitions, refer to "Using the Design Partition Planner" in the Quartus II Help.

Floorplan Partition Coloring

After making a set of partition assignments, it can be useful to view how the partitions are placed in the device. The Chip Planner can display nodes for each partition in a different color.

After compilation, in the Chip Planner **Task** list, select **Partition Display (Assignment)**, as shown in Figure 8–23. In this figure, you can see that the three different-colored partitions are grouped in three fairly independent areas of the device.

Figure 8–23. Partition Display in the Chip Planner Showing Three Partitions with Different Color Shades



Viewing Design Partition Planner and Floorplan Side-by-Side

You can view the Design Partition Planner together with the Chip Planner's Partition Planner, to analyze natural placement groupings in the floorplan view. This information can help you decide whether the design blocks should be grouped together in one partition, or whether they will make good partitions for the next compilation. It can also help determine whether the logic can easily be constrained by a LogicLock region to create a design floorplan. If logic naturally groups together when compiled without placement constraints, you can probably assign a reasonably sized LogicLock region to constrain the placement for future compilations. You can experiment by extracting different design blocks in the Design Partition Planner and viewing the placement results of those design blocks from the last compilation.

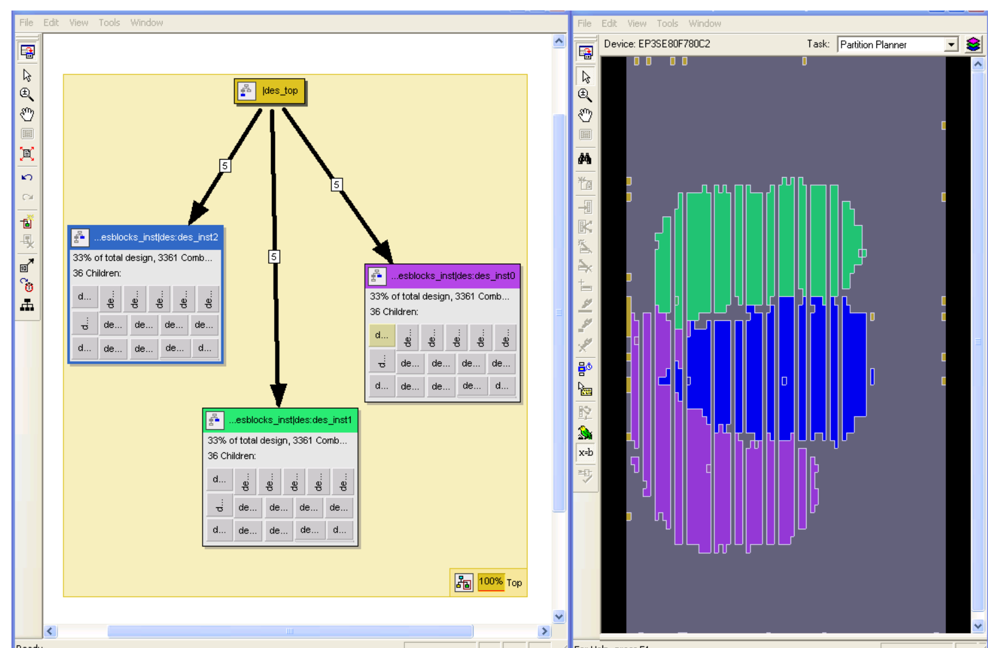
Open the Design Partition Planner, then open the Chip Planner and select the **Partition Planner** task in the **Task** list. This task selection displays the physical locations of design entities using the same colors as the Design Partition Planner display. For ease of viewing, drag and size the Chip Planner and Design partition Planner windows so they are side-by-side.

In the Design Partition Planner, extract instances of interest from their parents using the drag and drop method or the **Extract from Parent** command. Evaluate the physical locations of instances in the Chip Planner and the connectivity between instances displayed in the Design Partition Planner. An entity is generally not suitable to be set as a separate design partition or constrained in a LogicLock region if the Chip Planner shows it to be physically dispersed over a noncontiguous area of the device

after compilation. You can use the Design Partition Planner as described in “Design Partition Planner” on page 8–29 to analyze the design connections. For child instances that are unsuitable to be set as separate design partitions or placed in LogicLock regions, return those instances to their parent using the drag and drop method or the **Collapse to Parent** command.

Figure 8–24 shows a design displayed in both viewers, with different colors for the top-level design and the three major design instances.

Figure 8–24. Top-Level Design and Three Major Instances Shown in Both Viewers



Partition Statistics Report

You can view statistics about design partitions in the **Partition Merge Partition Statistics** compilation report and the **Statistics** tab in the **Design Partitions Properties** dialog box. These reports are useful when optimizing your design partitions in a top-down compilation flow, or when you are compiling the full top-level design in a bottom-up compilation flow, to ensure that the partitions meet the guidelines discussed in this document.

The **Partition Statistics** page under the **Partition Merge** folder of the Compilation Report lists statistics about each partition. The statistics for each partition (each row in the table) include the number of logic cells it contains, as well as the number of input and output pins and how many are registered. This report also lists how many ports are unconnected, or driven by a constant V_{CC} or GND. You can use this information to assess whether you have followed the guidelines for partition boundaries.

You can also view statistics about the resource and port connections for a particular partition on the **Statistics** tab of the **Design Partition Properties** dialog box. On the Assignments menu, click **Design Partitions Window**. Right-click on a partition and click **Properties** to open the dialog box. Click **Show All Partitions** to view all the partitions in the same report. The Design Partition Properties report also shows statistics for the Internal Congestion: Total Connections and Registered Connections. This represents how many signals are connected within the partition. It then lists the inter-partition connections for each partition, which helps you see how partitions are connected to each other.

Report Partition Timing in the TimeQuest Timing Analyzer

The TimeQuest Timing Analyzer includes a diagnostic report called Report Partitions, and the `report_partitions` SDC command. The resulting Partition Timing Overview lists the design partitions and provides the number of failing paths and the worst case timing slack within that partition. The function also creates a Partition Timing Details table that lists the number of failing paths and worst-case slack from each partition to the others.

You can use this report to analyze where the critical timing paths in the design are with respect to design partitions. If a certain partition contains many failing paths, or failing inter-partition paths, you may be able to change your partitioning scheme and improve your timing performance.

For more information about the TimeQuest `report_timing` command, see the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Ensure Partition Assignments Do Not Impact the Quality of Results

There is often a trade-off between compilation time and quality of results when you vary the number of partitions in a project. You can ensure that you limit any negative effect on the quality of results by following an iterative methodology during the partitioning process. In any incremental compilation flow in which you can compile the source code for every partition during the partition planning phase, Altera recommends the following iterative flow:

1. Start with a complete design that is not partitioned and has no location or LogicLock assignments.
2. To perform a placement and timing analysis estimate, on the Processing menu, point to **Start** and click **Start Early Timing Estimate**.

   You must perform Analysis and Synthesis and Partition Merge before performing an Early Timing Estimate.

   To run a full compilation instead of the Early Timing Estimate, on the Processing menu, click **Start Compilation**.
3. Record the quality of results from the Compilation Report (f_{MAX}, area, and any other relevant results).
4. Create design partitions following the guidelines described in this chapter.
5. Perform another Early Timing Estimate or a full compilation.

6. Record the quality of results from the Compilation Report. If the quality of results is significantly worse than those obtained in the previous compilation, repeat step 4 through step 6 to change your partition assignments and use a different partitioning scheme.
7. Even if the quality of results is acceptable, you can repeat step 4 through step 6 by further dividing a large partition into several smaller partitions. Doing so improves compilation time in future incremental compilations. You can repeat this step until you achieve a good trade-off point (that is, all critical paths are localized within partitions, the quality of results is not negatively affected, and the size of each partition is reasonable).

Introduction to Design Floorplans

A floorplan represents the layout of the physical resources on the device. The expressions "creating a design floorplan" and "floorplanning" describe the process of mapping the logical design hierarchy onto physical regions in the device floorplan.

In the Quartus II software, LogicLock regions are used to constrain blocks of a design to a particular region of the device. LogicLock regions represent a rectangular area of the device with a user-defined or Fitter-defined size and location on the device layout.

For more information about design floorplans and LogicLock regions, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

The Difference between Logical Partitions and Physical Regions

Design partitions are "logical" entities based on the design hierarchy. LogicLock regions are "physical" placement assignments that constrain logic to a rectangular region on the device.

It is a common misconception that logic from a design partition is always grouped together on the device when you use incremental compilation. This is not true. Logic from a partition can be placed anywhere in the device if it is not constrained to a LogicLock region. A logical design partition does not refer to any physical area of the device and does not directly control *where* instances are placed on the device.

If you want to control the placement of the logic from a design partition and isolate it to a particular part of the device, you can assign the logical design partition to a physical region in the device floorplan with a LogicLock region assignment. Creating a design floorplan by assigning design partitions to LogicLock regions is recommended to improve the quality of results and avoid placement conflicts in many situations for incremental compilation. Refer to "Why Create a Floorplan?" on page 8–36 for details.

Another misconception is that LogicLock assignments are used to preserve placement results for incremental compilation. This is also not true. LogicLock regions only *constrain* logic to a physical region of the device. Incremental compilation does not use LogicLock assignments or any location assignments to preserve the placement results; it simply reuses the results stored in the database netlist from the previous compilation.

Why Create a Floorplan?

Floorplan location planning can be important for a design that uses full incremental compilation, for the following two reasons:

- To avoid resource conflicts between partitions, predominantly when importing partitions from another Quartus II project
- To ensure a good quality of results when recompiling individual partitions in top-down flows

Why Create a Floorplan in Bottom-Up Flows?

Creating a design floorplan is required if you want to preserve placement for lower-level partitions in a bottom-up flow to avoid resource conflicts between partitions.

Location assignments for each partition ensure that there are no placement conflicts between different partitions. If there are no LogicLock region assignments, or if LogicLock regions are set to auto-size or floating, no device resources are specifically allocated for the logic associated with the region. If you do not clearly define this resource budget, logic placement can conflict when you import the partitions in a bottom-up flow.

Why Create a Floorplan in Top-Down Flows?

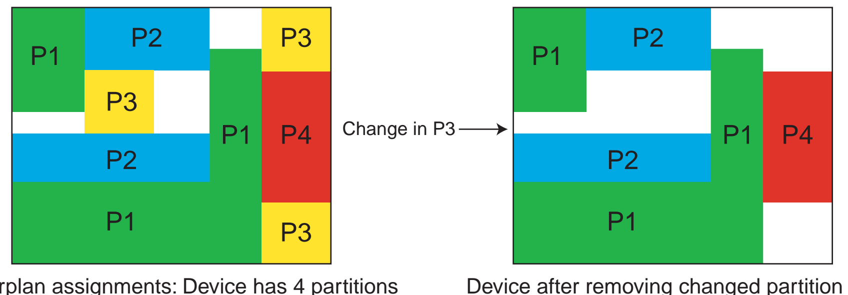
Creating a floorplan is highly recommended for timing-critical partitions to maintain good quality of results when the design changes.

Floorplan assignments are not required for non-critical partitions in a top-down flow. The logic for partitions that are not timing-critical (such as simple top-level glue logic) can be placed anywhere in the device on each recompilation if that is best for your design.

Design floorplan assignments prevent the situation in which the Fitter must place a partition in an area of the device where most resources are already used by other partitions. A LogicLock region provides a reasonable region to re-place logic after a change, so the Fitter does not have to scatter logic throughout the available space in the device.

Figure 8–25 illustrates the problems associated with refitting designs that do not have floorplan location assignments. It shows the initial placement of a four-partition design (P1-P4) without any floorplan location assignments. The second part of the figure shows the device if a change occurs to P3. After removing the logic for the changed partition, the Fitter must replace and reroute the new logic for P3 using the scattered white space shown in Figure 8–25. The placement of the post-fit netlists for other partitions forces the Fitter to implement P3 with the device resources that have not already been used.

Figure 8–25. Representation of Device Floorplan without Location Assignments



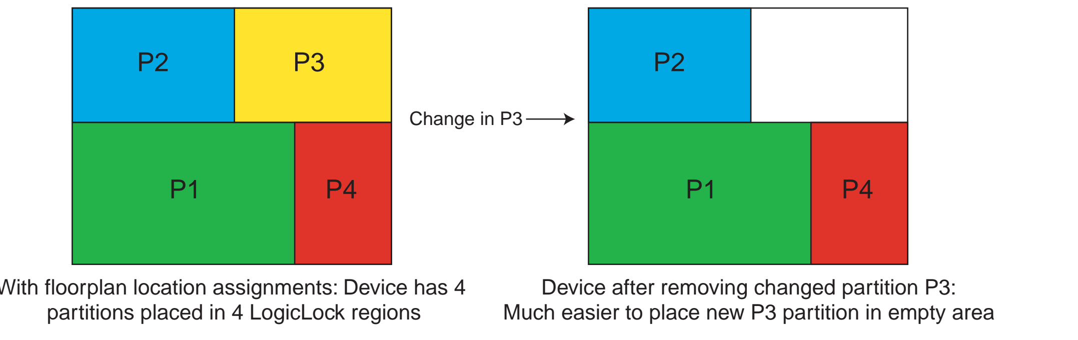
No floorplan assignments: Device has 4 partitions and the logic is placed throughout

Device after removing changed partition P3: New P3 must be placed in empty areas

The Fitter must work harder because of the more difficult physical constraints, and as a result, compilation time often increases. The Fitter might not be able to find any legal placement for the logic in partition P3, even if it could in the initial compilation. In addition, if the Fitter can find a legal placement, the quality of results often decreases in these cases, sometimes dramatically, because the new partition is now scattered throughout the device.

Figure 8–26 shows the initial placement of a four-partition design with floorplan location assignments. Each partition has been assigned to a LogicLock region. The second part of the figure shows the device after partition P3 is removed. This placement presents a much more reasonable task to the Fitter and yields better results.

Figure 8–26. Representation of Device Floorplan with Location Assignments



With floorplan location assignments: Device has 4 partitions placed in 4 LogicLock regions

Device after removing changed partition P3: Much easier to place new P3 partition in empty area

Altera recommends that you create a LogicLock floorplan assignment for any timing-critical blocks that will be recompiled as you make changes to the design.

When to Create a Floorplan

It is important that you plan early to incorporate partitions into the design, and ensure that each design partition follows the partitioning guidelines. You can make the floorplan assignments at different stages of the design flow, early or late in the flow. These guidelines help ensure better results when you start creating floorplan location assignments.

Early Floorplan

An early floorplan is created before the design stage. You can plan an early floorplan at the top level of a team-based design to give each designer a portion of the device resources. Doing so allows each designer to create the logic for their design partition without conflicting with other logic. Each design partition can be implemented independently and integrated later in the top-level project.

You can use an early floorplan as a rough draft of a floorplan for top-down flows as well, to roughly divide up the design partitions into LogicLock regions while iterating through the design cycle.

In a top-down flow, or after you have integrated the first version of all design partitions in a bottom-up flow, you can use the design information and Quartus II features to tune and improve the floorplan, as described in the following section.

Late Floorplan

A late floorplan is created or modified after the design has been created, when the code is close to complete and the design structure is likely to remain stable. When the design is complete, you can take advantage of the Quartus II analysis features to check the floorplan quality. To tune the floorplan, you can perform iterative compilations as required and assess the results of different assignments.

It may not be possible to create a good-quality late floorplan if you do not create partitions in the early stages of the design.

Creating a Design Floorplan: Placement Guidelines

The following guidelines are key to creating a good design floorplan:

- Capture correct resources in each region
- Use good region placement to maintain design performance compared to flat compilation

It is a common misconception that creating a floorplan enhances timing performance, as compared to a flat compilation with no location assignments. The Quartus II Fitter does not usually require guidance to get optimal results for a full design.

Floorplan assignments can help maintain good performance when designs change incrementally, as described in “Why Create a Floorplan in Top-Down Flows?” on page 8–36. However, bad placement assignments can often hurt performance results, as compared to a flat compilation, because the assignments limit the options for the Fitter. Investing some time to find good region placement is required to match the performance of a full flat compilation.

Use the following general strategy to create a floorplan:

1. Divide the design into partitions.
2. Assign the partitions to LogicLock Regions.
3. Compile the design.
4. Analyze the results.
5. Modify the placement and size of regions as required.

You may have to iterate through these steps several times to find the best combination of design partitions and LogicLock regions that meet the design's resource and timing goals.

For details about performing these steps, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Assigning Partitions to LogicLock Regions

To create a full floorplan: Create a LogicLock region for each partition (including the top-level) to assign all logic to a place in the device.

To create a partial floorplan: Create a LogicLock region for any critical or often-changing partitions.

Before compiling the design with new LogicLock assignments, ensure the affected partitions' Netlist Type is set so that the Fitter does not reuse previous placement results.

In most cases, each LogicLock region should contain logic from only one partition. This organization helps prevent resource conflicts in a bottom-up design and can lead to better performance preservation when locking down parts of a project in a top-down design.

The software is flexible and does allow exceptions to this rule. For example, you can place more than one partition in the same LogicLock region if the partitions are tightly connected. For best results, ensure that you recompile all such partitions every time the logic in one partition changes. In addition, if a partition contains multiple lower-level entities, you can place those entities in different areas of the device with multiple LogicLock regions (even though they are defined in the same partition).

You can use the **Reserved** LogicLock option to ensure that you avoid any conflicts with other logic which is not locked into any LogicLock region. This option prevents other logic from being placed in the region, and is useful if you have empty partitions at any point during your design flow, so that you can reserve space in the floorplan. Do not make reserved regions too large, to prevent unused area, because no other logic can be placed in a region with the **Reserved** LogicLock option.

How to Size and Place Regions

In an early floorplan, assign physical locations based on design specifications. Use information about the connections between partitions, the partition size, and the type of device resources required.

In a late floorplan when the design is complete, you can use Fitter-chosen regions as a guideline. Start with the default Auto size and Floating origin location. After compilation, lock the size and origin location. Instead of a full compilation, you can use the **Start Early Timing Estimate** command to perform a fast placement.

Alternatively, in a late floorplan, you can specify the size based on the synthesis results and use Fitter-chosen locations. Right-click on a region in the **LogicLock Regions** dialog box, and choose **Set to Estimated Size**. Like the previous option, start with Floating origin location. After compilation, lock the origin location. Again, instead of a full compilation, you can use the **Start Early Timing Estimate** command to perform a fast placement. You can also enable the **Fast Synthesis Effort** setting to reduce synthesis time.

After a compilation or early timing estimate, you should save the Fitter's size and/or origin location. Click on each LogicLock region in the LogicLock Regions Window while holding the Ctrl key to select all regions (including the top-level region). Right-click on the last selected LogicLock region and click **Set Size and Origin to Previous Fitter Results**.

It is important that you use the Fitter-chosen locations only as a starting point to give the regions a good fixed size and location. Ensure that all LogicLock regions in the design have a fixed size and have their origin locked to a specific location on the chip. On average, regions with fixed size and location yield better timing performance than auto-sized regions.

Modifying Region Size and Origin

After you have saved the Fitter's results from an initial compilation for a late floorplan, modify the regions using your knowledge of the design to set a specific size and location. If you have a good understanding of how the design fits together, you can often improve upon the regions placed in the initial compilation. In an early floorplan, you can use the guidelines in this section to set the size and origin, even though there is no initial Fitter placement for a basis.

The easiest way to move and resize regions is to drag the region location and borders in the Chip Planner. Ensure you select the **User-Defined** region in the floorplan (as opposed to the **Fitter-Placed** region from the last compilation) so that you can change the region.

Generally, you can keep the Fitter-determined relative placement of the regions, but make adjustments if required to meet timing performance. If you find that the Early Timing Estimate did not result in good relative placements, try performing a full compilation so that the Fitter can optimize for a full placement and routing.

If two LogicLock regions have several connections between them, ensure they are placed near each other to improve timing performance. By placing connected regions near each other, the Fitter has more opportunity to optimize inter-region paths when both partitions are recompiled. Reducing the criticality of inter-region paths also allows the Fitter more flexibility when placing the other logic in each region.

If resource utilization is low in the overall device, enlarge the regions. Doing so usually improves the final results because it gives the Fitter more freedom to place additional or modified logic added to the partition during future incremental compilations. It also allows room for optimizations such as pipelining and physical synthesis logic duplication.

Try to have each region evenly full, with the same "fullness" that the complete design would have without LogicLock regions. As a very rough suggestion, try to have each region approximately 75% full.

Allow more area for regions that are densely populated, because overly congested regions can lead to poor results. Allow more empty space for timing-critical partitions to improve results. However, do not make regions too large for their logic. Regions that are too large can result in wasted resources and also lead to suboptimal results.

Ideally, almost the entire device should be covered by LogicLock regions if all partitions are assigned to regions.

Regions should not overlap in the device floorplan. This is a requirement in bottom-up flows and a recommendation in top-down flows. In a bottom-up flow, if two partitions are allocated an overlapping portion of the chip, each may independently claim some common resources in this region. This leads to resource conflicts when importing bottom-up results into a final top-level design. In a top-down flow, overlapping regions give more difficult constraints to the Fitter and can lead to reduced quality of results.

You can create hierarchical LogicLock regions to ensure that the logic in a child partition is physically placed inside the LogicLock region for its parent partition. This can be useful when the parent partition does not contain registers at the boundary with the lower-level child partition and has a lot of signal connectivity. To create a hierarchical relationship between regions in the LogicLock Regions Window, drag and drop the child region to the parent region.

I/O Connections

Consider I/O timing when placing regions. Using I/O registers can minimize I/O timing problems, and using boundary registers on partitions can minimize problems connecting regions or partitions. However, I/O timing might still be a concern. It is most important for bottom-up flows where each partition is compiled independently, because the Fitter can optimize the placement for paths between partitions if the partitions are compiled at the same time.

Place regions close to the appropriate I/O, if necessary. For example, DDR memory interfaces have very strict placement rules to meet timing requirements. Incorporate any specific placement requirements into your floorplan as required. It is best to create LogicLock regions for internal logic only, and provide pin location assignments for external device I/O pins (instead of including the I/O cells in a LogicLock region to control placement).

LogicLock Resource Exclusions

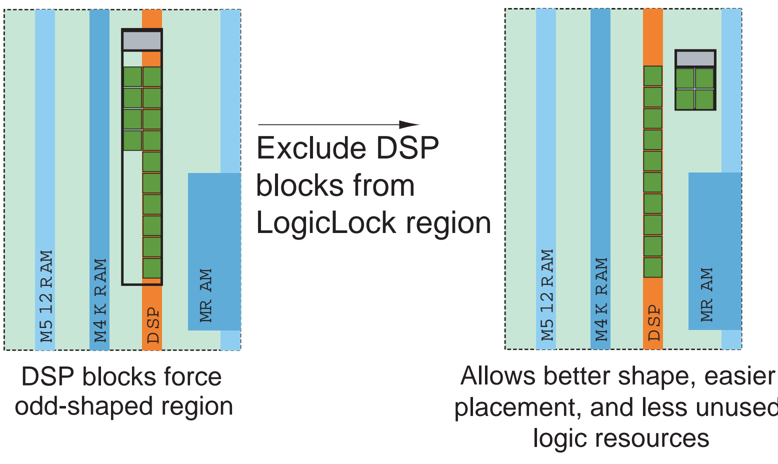
You can exclude certain resource types from a LogicLock region to manage the ratio of logic to dedicated DSP and RAM resources in the region.

If your design contains memory or digital signal processing (DSP) elements, you may want to exclude these elements from the LogicLock region. LogicLock resource exceptions prevent elements of certain types from being assigned to a region. Therefore, those elements are not required to be placed inside the region boundaries. The option does not *prevent* them from being placed inside the region boundaries unless the region's **Reserved** property is turned on.

Resource exceptions are useful in cases where it is difficult to place rectangular regions for design blocks that contain memory and DSP elements, because of their placement in columns throughout the device floorplan. Exclude RAMs, DSPs, or logic cells to give the Fitter more flexibility with region sizing and placement. Excluding RAM or DSP elements can help to resolve no-fit errors that are caused by regions

spanning too many resources, especially for designs that are memory-intensive, DSP-intensive, or both. Figure 8–27 shows an example of a design with an odd-shaped region to accommodate DSP blocks for a region that does not contain very much logic. The right side of the figure shows the result after excluding DSP blocks from the region. The region can be placed more easily without wasting logic resources. The DSP blocks are placed outside the region.

Figure 8–27. LogicLock Resource Exclusion Example



To view any resource exceptions, right-click in the LogicLock Regions Window and click **Properties**. In the **LogicLock Region Properties** dialog box, highlight the design element (module/entity) in the **Members** box and click **Edit**. To set up a resource exception, click the browse button under **Excluded element types**, then turn on the design element types to be excluded from the region. You can choose to exclude combinational logic or registers from logic cells, or any of the sizes of TriMatrix memory blocks, or DSP blocks.

If the excluded logic is in its own lower-level design entity (even if it is within the same design partition), you can assign the entity to a separate LogicLock region to constrain its placement in the device.

You can also use this feature with the LogicLock **Reserved** property to reserve specific resources for logic that will be added to the design.

Creating Non-Rectangular Regions

To constrain placement to non-rectangular areas of the device, you can limit entity placement to a sub-area of a LogicLock region. To do so, construct a LogicLock hierarchy by creating child regions inside of parent regions, and then use the **Reserved** option to control which logic can be placed inside these child regions.

Setting a region's **Reserved** option to **On** prevents the Fitter from placing nodes that are not assigned to the region inside the boundary of the region. Setting a region's **Reserved** option to **Limited** prevents the Fitter from placing nodes that are assigned to the immediate parent LogicLock region's hierarchy inside the boundary of the region. Any other logic can be placed inside the region. To create non-rectangular

regions for a specific entity, you can place child LogicLock regions inside a parent region and set the **Reserved** setting of the child regions to **Limited**. The child region prevents the parent region hierarchy from using that area of the device floorplan, but leaves it open for the rest of the design. You can assign other LogicLock regions to cover that area of the device if required.

For more information and examples of creating non-rectangular regions with the **Reserved** property, refer to *Examples of Using Limited Reserved Status to Constrain LogicLock Location Assignments* in the Quartus II Help.

Checking Floorplan Quality

This section provides an overview of tools that you can use as you create a floorplan in the Quartus II software. Take advantage of these tools to assess your floorplan quality and use the information to improve your design or assignments as required to achieve the best results.

Incremental Compilation Advisor

You can use the Incremental Compilation Advisor to check that your design follows the recommendations for creating floorplan location assignments that are presented in this document. Refer to “Incremental Compilation Advisor” on page 8–29 for more information.

LogicLock Region Resource Estimates

You can view resource estimates included in a LogicLock region to determine the region’s resource coverage. You can use this estimate before compilation to check region size. Using this estimate helps ensure adequate resources when you are sizing or moving regions.

Right-click in the LogicLock Regions Window, choose **Properties**, and select the **Size & Origin** tab. Specify a size and an origin to see the **Available resources** estimate in the dialog box.

LogicLock Region Properties Statistics Report

The LogicLock Region Properties Statistics are similar to the Design Partition Properties described in “Partition Statistics Report” on page 8–33, but include resource usage details after compilation.

The statistics report the number of resources used and the total resources covered by the region. The statistics also list the number of I/O connections and how many I/Os are registered (good), as well as the number of internal connections and the number of inter-region connections (bad).

Right-click in the LogicLock Regions Window, choose **Properties** and select the **Statistics** tab. Click **Show All Regions** to see all regions displayed in the same report.

Critical Path Settings for Chip Planner

The **Critical Path Settings** dialog box allows you to display the most critical paths from the Timing Analyzer report in the Chip Planner floorplan view. You can specify a threshold for which paths to highlight in the Chip Planner. Use this information to identify inter-region critical paths and improve your partition or floorplan assignments.

Locate the Quartus II TimeQuest Timing Analyzer Path in the Chip Planner

In the TimeQuest user interface, you can locate a specific path in the Chip Planner to view its placement. Perform a report timing operation (for example, report timing for all paths with less than 0 ns slack). Right-click in the detailed path report (**Data Path** tab) for a specific path and choose **Locate Path**. Click **OK** to choose the Chip Planner.

Inter-Region Connection Bundles

The Chip Planner can display bundles of connections between LogicLock regions, with filtering options that allow you to choose the relevant data for display. These bundles can help you visualize how many connections there are between each LogicLock region, to improve floorplan assignments, or to change partition assignments if required.

With the Chip Planner open, on the View menu, click **Generate Inter-region Bundles**.

Routing Utilization

The Chip Planner includes a mode to display a color map of routing congestion. This display helps identify areas of the chip that are too tightly packed.

In the Chip Planner, click the Layer Settings icon next to the **Task** list. Change the **Background Color Map** to **Routing Utilization** (the default is Block Utilization).

The darker-colored LAB blocks indicate higher routing congestion. Move your mouse pointer over a LAB to see a tool tip that reports the logic and routing utilization information.

Ensure Floorplan Assignments Do Not Impact Quality of Results

The end results of design partitioning and floorplan creation differ from design to design. However, it is important to evaluate your results to ensure that your scheme is successful. Compare the results before creating your floorplan location assignments to the results after doing so. Consider using another scheme if any of the following guidelines are not met:

- You should see no degradation in f_{MAX} after the design is partitioned and floorplan location assignments are created. In many cases, a slight increase in f_{MAX} is possible
- The area increase should be no more than 5% after the design is partitioned and floorplan location assignments are created
- The time spent in the routing stage should not significantly increase

The amount of compilation time spent in the routing stage is reported in the Messages window by an Info message that indicates the elapsed time for Fitter routing operations. If you notice a dramatic increase in routing time, the floorplan location assignments may be creating substantial routing congestion. In this case, decrease the number of LogicLock regions. Doing so typically reduces the compilation time in subsequent incremental compilations and may also improve design performance.

Recommended Design Flows and Application Examples

This section provides design flows for partitioning and creating a design floorplan during common timing closure and team-based design scenarios. Each flow describes the situation in which it should be used, and gives a step-by-step description of the commands required to implement the flow.

Create a Floorplan for the Entire Design in a Top-Down Flow

Use this flow for top-down incremental compilation designs in which you would like to assign a floorplan location for each design block that is assigned as a separate partition. This is the standard floorplan procedure described in the *Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*. A full floorplan ensures that partitions do not interact as they are changed and recompiled—each partition has its own area of the device floorplan.

To create a LogicLock region for each design partition, use the following general methodology:

1. On the Assignments menu, click **Design Partitions Window** and ensure that all partitions have their Netlist Type set to **Source File** or **Post-Synthesis**. If the Netlist Type is set to **Post-Fit**, floorplan location assignments are not used when recompiling the design.
2. Create a LogicLock region for each partition (including the top-level entity, which is automatically considered a partition).
3. On the Processing menu, point to **Start** and click **Start Early Timing Estimate** to place auto-sized, floating-location LogicLock regions.

   You must perform Analysis and Synthesis, and Partition Merge before performing an Early Timing Estimate.

   To run a full compilation instead of the Early Timing Estimate, on the Processing menu, click **Start Compilation**.
4. On the Assignments menu, click **LogicLock Regions Window**, and click on each LogicLock region while holding the Ctrl key to select all regions (including the top-level region).
5. Right-click on the last selected LogicLock region, and click **Set Size and Origin to Previous Fitter Results**.
6. If required, modify the size and location with the LogicLock Regions Window or the Chip Planner. For example, make the regions bigger to fill up the device and allow for future logic changes.

7. On the Processing menu, point to **Start** and click **Start Early Timing Estimate** to estimate the timing performance of your design with these LogicLock regions.
8. Repeat step 6 and 7 until you are satisfied with the quality of results for your design floorplan. On the Processing menu, click **Start Compilation** to run a full compilation.

Create a Floorplan as the Project Lead in a Bottom-Up Flow

Use this approach when you have several lower-level subdesigns that will be implemented separately by different designers. The subdesign designers want to optimize their designs independently and pass the results on to you, the project lead.

As the project lead in this scenario, perform the following steps to prepare the design for a successful bottom-up design methodology with early floorplan planning:

1. Create a new Quartus II project that will ultimately contain the full implementation of the entire design.
2. To prepare for the bottom-up methodology, create a “skeleton” of the design that defines the hierarchy for the subdesigns that will be implemented by separate designers. Consider the partitioning guidelines in this chapter while determining the design hierarchy.
3. Make project-wide settings. Select the device, make global assignments for clocks and device I/O ports, and make any global signal constraints to specify which signals can use global routing resources.
4. Make design partition assignments for each major subdesign and set the Netlist Type for each design partition that will be imported to **Empty** in the Design Partitions window.
5. Create LogicLock regions for each of the lower-level partitions to create a design floorplan. This floorplan should consider the connectivity between partitions and estimates of the size of each partition based on any initial implementation numbers and knowledge of the design specifications. Use the guidelines described in this chapter to choose a size and location for each LogicLock region.
6. On the Project menu, click **Generate Bottom-Up Design Partition Scripts**, or run the script generator from a Tcl prompt or the command prompt.
7. Make changes to the default script options as desired. Altera recommends that you pass all the default constraints, including LogicLock regions, for all partitions and virtual pin location assignments. Altera further recommends that you add a maximum delay timing constraint for the virtual I/O connections in each partition to help timing closure during integration at the top level. If lower-level projects have not already been created by the other designers, use the partition script to set up the projects so that you can easily take advantage of makefiles.
8. Provide each lower-level designer with the Tcl file to create their project with the appropriate constraints. If you are using makefiles, provide the makefile for each partition.

Create a Floorplan Assignment for One Design Block with Difficult Timing

Use this flow when you have one timing-critical design block that requires more optimization than the rest of your design. You can take advantage of incremental compilation to reduce your compilation time without creating a full design floorplan.

In this scenario, you may not have to create floorplan assignments for the entire design. You can create a region to constrain the location of your critical design block, and allow the rest of the logic to be placed anywhere else in the device. Use the following general methodology:

1. Divide up your design into partitions to reduce compilation time. Consider the guidelines in this chapter while determining the partition boundaries. Ensure that you isolate the timing-critical logic in a separate design partition.
2. Define a LogicLock region for the timing-critical design partition. Ensure that you capture the correct amount of device resources in the region. Turn on the **Reserved** property to prevent any other logic from being placed in the region.
   - If the design block is not complete, reserve space in the design floorplan based on your knowledge of the design specifications, connectivity between design blocks, and estimates of the size of the partition based on any initial implementation numbers.
   - If the critical design block has initial source code ready, compile the design as in the scenario "Create a Floorplan for the Entire Design in a Top-Down Flow" on page 8–45 to place the LogicLock region. Save the Fitter-determined size and origin, then enlarge the region to provide more flexibility and allow for future design changes.
3. As the rest of the design is completed, and the device fills up, the timing-critical region has a reserved area of the floorplan. When you make changes to the design block, the logic can be re-placed in the same part of the device, which helps ensure good quality of results.

Potential Issues with Creating Partitions and Floorplan Assignments

There are some limitations and restrictions on using incremental compilation and using certain design flows with certain Altera features.

Refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook* for complete details about restrictions and limitations.

Consider documented limitations and restrictions as you plan your design flow and select partitions. Most limitations and restrictions do not affect most users, but it is helpful to know if you must modify your partitions or design flow to accommodate certain restrictions.

There are also possible utilization effects due to partitioning and creating a floorplan. These are described in the following subsections. Consider these effects if your design is close to using all of the device resources before adding partition or floorplan assignments.

Logic and Resource Utilization Effects

Partitions can increase resource utilization due to cross-partition optimization limitations. Floorplan assignments can increase resource utilization because regions sometimes lead to unused logic. Follow the recommendations in this document to reduce these effects.

If your device is very full with the flat version of design, you might not be able to use a complete incremental flow for the entire design. You can use a "partial" incremental flow instead to get compilation time and performance preservation benefits for key parts of the design. Focus on creating partitions and floorplan assignments for timing-critical or often-changing blocks to get the most benefit out of the feature.

Routing Utilization Effects

Partitions and floorplan assignments typically increase routing utilization compared to a flat design. Follow the recommendations in this document to reduce the effect.

If long compilation times are due to routing congestion, you might not be able to use incremental flows to reduce compilation time. Focus on creating partitions and floorplan assignments for parts of the design that are not routing-critical to get some benefit.

You can also use incremental compilation to lock routing for routing-critical blocks only (with other partitions empty), and then compile the rest of the design after the critical block meets its requirements.

Review the Fitter Messages to check how much time is spent during routing optimizations and to see the percentage of routing utilization. This information helps highlight routing issues.

Conclusion

Incremental compilation provides a number of benefits, especially to large, complex designs. To take advantage of the feature, it is worth spending some time to create quality partition and floorplan assignments.

Follow the guidelines to set up your design hierarchy and source code for incremental compilation. Keep partitions independent of each other and do not rely on any cross-boundary logic optimizations.

Floorplan location assignments are required for bottom-up flows and are recommended for timing-critical partitions in top-down flows. Follow the guidelines to create and modify LogicLock regions to create good placement assignments for your design partitions.

Take advantage of the numerous Quartus II software tools to assess partition quality and analyze the floorplan to make good partition and LogicLock location assignments. Remember that you do not have to follow all the guidelines exactly to implement an incremental compilation design flow, but following the guidelines can maximize your chances of success.

Revision History

Table 8–1 shows the revision history for this chapter.

Table 8–1. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Added I/O register packing examples from *Incremental Compilation for Hierarchical and Team-Based Designs* chapter ■ Moved "Incremental Compilation Advisor" section ■ Added "Viewing Design Partition Planner and Floorplan Side-by-Side" section ■ Updated Figure 8–22 ■ Chapter 8 was previously Chapter 7 in software release 8.1.	Updated for the Quartus II software version 9.0 release.
November 2008 v8.1.0	Changed to 8-1/2 x 11 page size. No change to content.	Updated for the Quartus II software version 8.1 release.
May 2007 v8.0.0	Initial release.	This content of this chapter is based on information that was contained in Application Note 470.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

Section III. Synthesis

As programmable logic devices (PLDs) become more complex and require increased performance, advanced design synthesis has become an important part of the design flow. In the Quartus® II software you can use the Analysis and Synthesis module of the Compiler to analyze your design files and create the project database. You can also use other EDA synthesis tools to synthesize your designs, and then generate EDIF netlist files or Verilog Quartus Mapping Files (**.vqm**) that you can use with the Quartus II software. This section explains the options that are available for each of these flows and how they are supported in the Quartus II, version 9.0 software.

This section includes the following chapters:

- Chapter 9, Quartus II Integrated Synthesis
- Chapter 10, Synopsys Synplify Support
- Chapter 11, Mentor Graphics Precision Synthesis Support
- Chapter 12, Mentor Graphics LeonardoSpectrum Support
- Chapter 13, Analyzing Designs with Quartus II Netlist Viewers

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

9. Quartus II Integrated Synthesis

QII51008-9.0.0

Introduction

As programmable logic designs become more complex and require increased performance, advanced synthesis has become an important part of the design flow. The Quartus® II software includes advanced integrated synthesis that fully supports VHDL and Verilog HDL, as well as Altera®-specific design entry languages, and provides options to control the synthesis process. With this synthesis support, the Quartus II software provides a complete, easy-to-use solution.

This chapter documents the design flow and language support in the Quartus II software. It explains how you can use incremental compilation to reduce your compilation time, how you can improve synthesis results with Quartus II synthesis options, and how you can control the inference of architecture-specific megafunctions. This chapter also explains some of the node-naming conventions used during synthesis to help you better understand your synthesized design and the messages issued during synthesis to improve your HDL code. Scripting techniques for applying all the options and settings described are also provided.

This chapter contains the following sections:

- "Design Flow" on page 9–2
- "Language Support" on page 9–4
- "Incremental Compilation" on page 9–20
- "Quartus II Synthesis Options" on page 9–22
- "Analyzing Synthesis Results" on page 9–69
- "Analyzing and Controlling Synthesis Messages" on page 9–70
- "Node-Naming Conventions in Quartus II Integrated Synthesis" on page 9–74
- "Scripting Support" on page 9–80

This chapter provides examples of how to use attributes described within the chapter, but does not cover specific coding examples.

For examples of Verilog HDL and VHDL code synthesized for specific logic functions, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*. For information about coding with primitives that describe specific low-level functions in Altera devices, refer to the *Designing With Low-Level Primitives User Guide*.

Design Flow

The Quartus II Analysis and Synthesis process includes Quartus II integrated synthesis, which fully supports Verilog HDL and VHDL languages as well as Altera-specific languages, and supports major features in the SystemVerilog language (refer to "Language Support" on page 9–4 for details). This stage of the compilation flow performs logic synthesis to optimize design logic and performs technology mapping to implement the design logic using device resources, such as logic elements (LEs) or adaptive logic modules (ALMs) and other dedicated logic blocks. This stage also generates the single project database that integrates all the design files in a project (including any netlists from third-party synthesis tools).

You can use the Analysis and Synthesis stage of the Quartus II compilation to perform any of the following levels of Analysis and Synthesis:

- Analyze Current File—Parse the current design source file to check for syntax errors. This command does not report on many semantic errors that require further design synthesis. On the Processing menu, click **Analyze Current File**.
- Analysis & Elaboration—Check a design for syntax and semantic errors and perform elaboration to identify the design hierarchy. On the Processing menu, point to **Start** and click **Start Analysis & Elaboration**.
- Analysis & Synthesis—Perform complete Analysis and Synthesis on a design, including technology mapping. On the Processing menu, point to **Start** and click **Start Analysis & Synthesis**. This is the most commonly used command and is part of the full compilation flow.

The Quartus II design and compilation flow using Quartus II integrated synthesis consists of the following steps:

1. Create a project in the Quartus II software and specify the general project information, including the top-level design entity name. On the File menu, click **New Project Wizard**.
2. Create design files in the Quartus II software or with a text editor.
3. On the Project menu, click **Add/Remove Files in Project** and add all design files to your Quartus II project using the **Files** page of the **Settings** dialog box.
4. Specify compiler settings that control the compilation and optimization of the design during synthesis and fitting. For synthesis settings, refer to "Quartus II Synthesis Options" on page 9–22. Add timing constraints to specify the timing requirements.
5. Compile the design in the Quartus II software. To synthesize the design, on the Processing menu, point to **Start**, and click **Start Analysis & Synthesis**.

   ☞ On the Processing menu, click **Start Compilation** to run a complete compilation flow including placement, routing, creation of a programming file, and timing analysis.

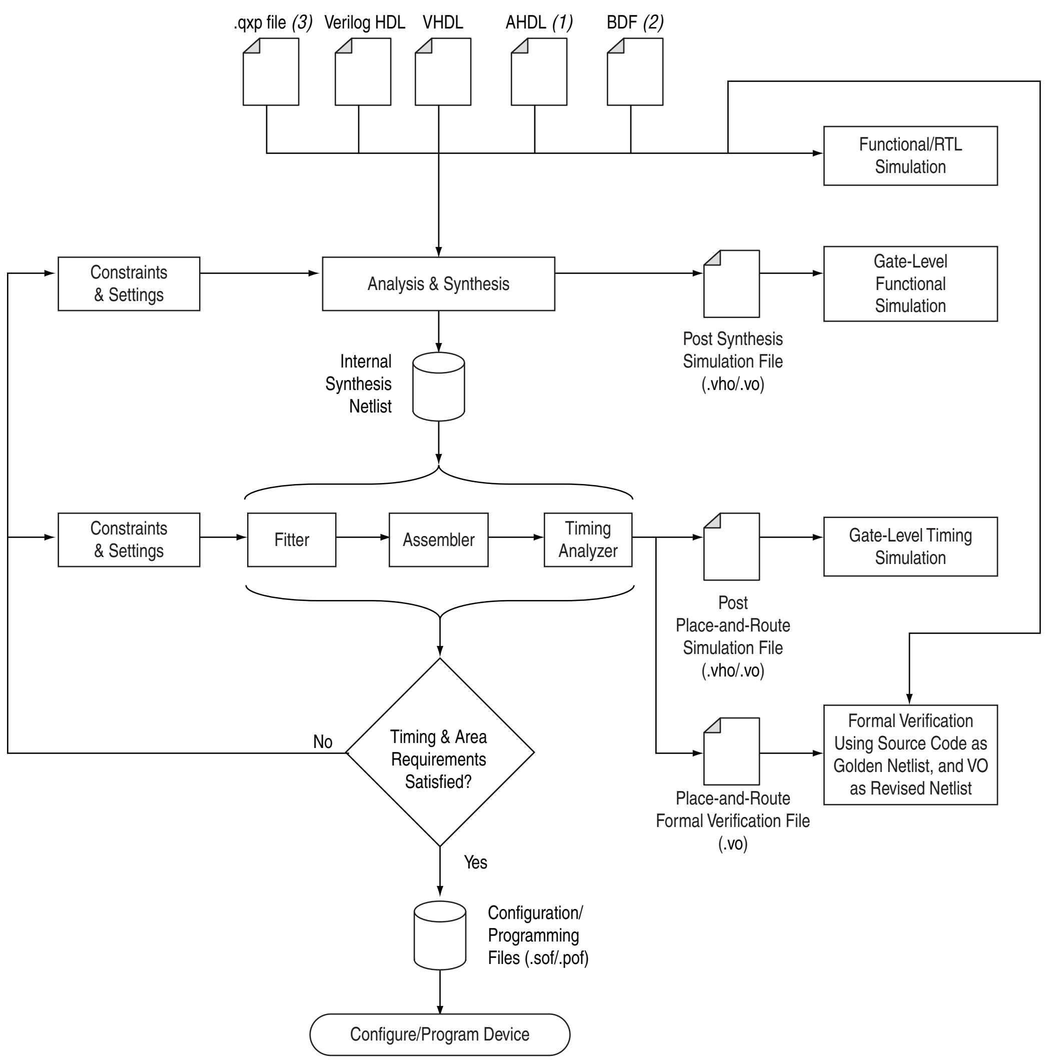
6. After obtaining synthesis and place-and-route results that meet your requirements, program or configure the Altera device.

The software provides netlists that allow you to perform functional simulation and gate-level timing simulation in the Quartus II simulator or a third-party simulator, perform timing analysis in a third-party timing analysis tool in addition to the TimeQuest Timing Analyzer or Classic Timing Analyzer, and/or perform formal verification in a third-party formal verification tool. The Quartus II software also provides many additional analysis and debugging features.

For more information about creating a project, compilation flow, and other features in the Quartus II software, refer to the Quartus II Help. For an overall summary of Quartus II features, refer to the *Introduction to the Quartus II Software* manual.

Figure 9–1 shows the basic design flow using Quartus II integrated synthesis.

Figure 9–1. Quartus II Design Flow Using Quartus II Integrated Synthesis



Notes to Figure 9–1:

(1) AHDL is the Altera Hardware Description Language.

(2) BDF is Altera's schematic Block Design File format (**.bdf**).

(3) The Quartus II eXported Partition (**.qxp**) file is a precompiled netlist that can be used as a design source file. For more information, refer to "Quartus II eXported Partition (.qxp) File as Source" on page 9–21.

Language Support

This section explains the Quartus II software's integrated synthesis support for HDL and schematic design entry, as well as graphical state machine entry, and explains how to specify the Verilog HDL or VHDL language version used in your design. It also documents language features such as Verilog HDL macros, initial constructs and memory system tasks, and VHDL libraries. "Design Libraries" on page 9–12 describes how to compile and reference design units in different custom libraries and "Using Parameters/Generics" on page 9–16 describes how to use parameters or generics and pass them between different languages.

To ensure that the software reads all associated project files, add each file to your Quartus II project. To add files to your project in the Quartus II GUI, on the Project menu, click **Add/Remove Files In Project**. Design files can be added to the project in any order. You can mix all supported languages and netlists generated by third-party synthesis tools in a single Quartus II project.

Verilog HDL Support

The Quartus II compiler's Analysis and Synthesis module supports the following Verilog HDL standards:

- Verilog-1995 (IEEE Standard 1364-1995)
- Verilog-2001 (IEEE Standard 1364-2001)
- SystemVerilog-2005 (IEEE Standard 1800-2005) (not all constructs are supported)

For complete information about specific Verilog HDL syntax features, and language constructs, refer to the Quartus II Help.

The Quartus II compiler uses the Verilog-2001 standard by default for files that have the extension **.v**, and the SystemVerilog standard for files that have the extension **.sv**.

The Verilog HDL code samples provided in this document follow the Verilog-2001 standard unless otherwise specified.

To specify a default Verilog HDL version for all files, perform the following steps:

1. On the Assignments menu, click **Settings**.
2. In the **Settings** dialog box, under **Category**, expand **Analysis & Synthesis Settings**, and select **Verilog HDL Input**.
3. On the **Verilog HDL Input** page, under **Verilog version**, select the appropriate Verilog HDL version, then click **OK**.

You can override the default Verilog HDL version for each Verilog HDL design file by performing the following steps:

1. On the Project menu, click **Add/Remove Files in Project**. The **Settings** dialog box appears.
2. On the **Files** page, select the appropriate file in the list and click the **Properties** button.

 © March 2009 Altera Corporation

3. In the **HDL Version** list, select **SystemVerilog_2005**, **Verilog_2001**, or **Verilog_1995** and click **OK**.

You can also control the Verilog HDL version inside a design file using the `VERILOG_INPUT_VERSION` synthesis directive, as shown in Example 9–1. This directive overrides the default HDL version and any HDL version specified in the **File Properties** dialog box.

Example 9–1. Controlling the Verilog HDL Input Version with a Synthesis Directive

```
// synthesis VERILOG_INPUT_VERSION <language version>
```

The variable *<language version>* takes one of the following values:

- `VERILOG_1995`
- `VERILOG_2001`
- `SYSTEMVERILOG_2005`

When the software reads a `VERILOG_INPUT_VERSION` synthesis directive, the current language version changes as specified until the end of the file, or until the next `VERILOG_INPUT_VERSION` directive is reached.

You cannot change the language version in the middle of a Verilog HDL module.

For more information about specifying synthesis directives, refer to “Synthesis Directives” on page 9–27.

If you use scripts to add design files, you can use the `-HDL_VERSION` command to specify the HDL version for each design file. Refer to “Adding an HDL File to a Project and Setting the HDL Version” on page 9–80.

The Quartus II software support for Verilog HDL is case-sensitive in accordance with the Verilog HDL standard. The Quartus II software supports the compiler directive `` `define``, in accordance with the Verilog HDL standard.

The Quartus II software supports the `include` compiler directive to include files with absolute paths (with either “/” or “\” as the separator), or relative paths (relative to project root, user libraries, or current file location). When searching for a relative path, the Quartus II software initially searches relative to the project directory. If the software cannot find the file, it then searches relative to all user libraries, and finally relative to the directory location of the current file.

Verilog-2001 Support

The Quartus II software does not support Verilog-2001 libraries and configurations.

SystemVerilog Support

The Quartus II software supports the following SystemVerilog constructs:

- Parameterized interfaces, generic interfaces, and `modport` constructs
- Packages
- `Extern` module declarations
- Built-in data types `logic`, `bit`, `byte`, `shortint`, `longint`, `int`

- Unsized integer literals `'0`, `'1`, `'x`, `'z`, `'X`, and `'Z`
- Structure data types using `struct`
- Ports and parameters with unrestricted data types
- User-defined types using `typedef`
- Global declarations of task/functions/parameters/types (does not support global variables)
- Coding constructs `always_comb`, `always_latch`, `always_ff`
- Continuous assignments to nodes other than `nets`, and procedural assignments to nodes other than `reg`
- Enumeration methods `First`, `Last`, `Next(n)`, `Prev(n)`, `Num`, and `Name`
- Assignment operators `+=`, `-=`, `*=`, `/=`, `%=`, `&=`, `|=`, `^=`, `<<=`, `>>=`, `<<<=`, and `>>>=`
- Increment `++` and decrement `--`
- Jump statements `return`, `break`, and `continue`
- Enhanced `for` loop (declare loop variables inside initial condition)
- `Do-while` loop and local loop constructs
- Assignment patterns
- Keywords `unique` and `priority` in case statements
- Default values for function/task arguments
- Closing labels
- Extensions to directives `` `define `` and `` `include ``
- Expression size system function `$bits`
- Array query system functions `$dimensions`, `$unpacked_dimensions`, `$left`, `$right`, `$high`, `$low`, `$increment`, `$size`
- Packed array (include multidimensional packed array)
- Unpacked array (include single-valued range dimension)
- Implicit port connections with **.name** and **.***

Quartus II integrated synthesis also parses, but otherwise ignores, SystemVerilog assertions.

Designs written to comply with the Verilog-2001 standard might not compile successfully using the SystemVerilog setting because the SystemVerilog standard adds a number of new reserved keywords. For a list of reserved words in each language standard, refer to the Quartus II Help.

Initial Constructs and Memory System Tasks

The Quartus II software infers power-up conditions from Verilog HDL `initial` constructs. The software creates power-up settings for variables, including RAM blocks. If the Quartus II software encounters non-synthesizable constructs in an `initial` block, it generates an error. To avoid such errors, enclose non-synthesizable constructs (such as those intended only for simulation) in `translate_off` and `translate_on` synthesis directives, as described in "Translate Off and On / Synthesis Off and On" on page 9–62. Synthesis of initial constructs enables the power-up state of the synthesized design to match, as closely as possible, the power-up state of the original HDL code in simulation.

Initial blocks do not infer power-up conditions in some third-party EDA synthesis tools. If you are converting between synthesis tools, ensure that your power-up conditions are set correctly.

Quartus II integrated synthesis supports the `$readmemb` and `$readmemh` system tasks to initialize memories. Example 9–2 shows an initial construct that initializes an inferred RAM with `$readmemb`.

Example 9–2. Verilog HDL Code: Initializing RAM with the readmemb Command

```
reg [7:0] ram[0:15];
initial
begin
$readmemb("ram.txt", ram);
end
```

When creating a text file to use for memory initialization, specify the address using the format @*<location>* on a new line, then specify the memory word such as `110101` or `abcde` on the next line. Example 9–3shows a portion of a memory initialization file for the RAM in Example 9–2.

Example 9–3. Text File Format: Initializing RAM with the readmemb Command

```
@0
00000000
@1
00000001
@2
00000010
…
@e
00001110
@f
00001111
```

Verilog HDL Macros

The Quartus II software fully supports Verilog HDL macros, which you can define with the `'define` compiler directive in your source code. You can also define macros in the GUI or on the command line.

Setting a Verilog HDL Macro Default Value in the GUI

To specify a macro in the GUI, on the Assignments menu, click **Settings**. In the **Category** list, expand **Analysis & Synthesis Settings** and select **Verilog HDL Input**. Under **Verilog HDL macro**, type the macro name in the **Name** box, the value in the **Setting** box, and click **Add**.

Setting a Verilog HDL Macro Default Value on the Command Line

To set a default value for a Verilog HDL macro on the command line, use the `--verilog_macro` option, as shown in Example 9–4.

Example 9–4. Command Syntax for Specifying a Verilog HDL Macro

```
quartus_map <Design name> --verilog_macro= "<Macro name>=<Macro setting>" ↵
```

The command in Example 9–5 has the same effect as specifying `` `define a 2 `` in the Verilog HDL source code.

Example 9–5. Specifying a Verilog HDL Macro a = 2

```
quartus_map my_design --verilog_macro="a=2" ↵
```

To specify multiple macros, you can repeat the option more than once, as in Example 9–6.

Example 9–6. Specifying Verilog HDL Macros a = 2 and b = 3

```
quartus_map my_design --verilog_macro="a=2" --verilog_macro="b=3" ↵
```

VHDL Support

The Quartus II compiler's Analysis and Synthesis module supports the following VHDL standards:

- VHDL 1987 (IEEE Standard 1076-1987)
- VHDL 1993 (IEEE Standard 1076-1993)

For information about specific VHDL syntax features and language constructs, refer to the Quartus II Help.

The Quartus II compiler uses the VHDL 1993 standard by default for files that have the extension **.vhdl** or **.vhd**.

The VHDL code samples provided in this document follow the VHDL 1993 standard.

To specify a default VHDL version for all files, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, expand **Analysis & Synthesis Settings** and select **VHDL Input**.
3. On the **VHDL Input** page, under **VHDL version**, select the appropriate version, then click **OK**.

You can override the default VHDL version for each VHDL design file by performing the following steps:

1. On the Project menu, click **Add/Remove Files in Project**. The **Settings** dialog box appears.
2. On the **Files** page, select the appropriate file in the list and click **Properties**.
3. In the HDL version list, select **VHDL93** or **VHDL87** and click **OK**.

You can also specify the VHDL version for each design file using the VHDL_INPUT_VERSION synthesis directive, as shown in Example 9–7. This directive overrides the default HDL version and any HDL version specified in the **File Properties** dialog box.

Example 9–7. Controlling the VHDL Input Version with a Synthesis Directive

```
--synthesis VHDL_INPUT_VERSION <language version>
```

The variable <*language version*> takes one of the following values:

- VHDL87
- VHDL93

When the software reads a VHDL_INPUT_VERSION synthesis directive, it changes the current language version as specified until the end of the file, or until it reaches the next VHDL_INPUT_VERSION directive.

You cannot change the language version in the middle of a VHDL design unit.

For more information about specifying synthesis directives, refer to "Synthesis Directives" on page 9–27.

If you use scripts to add design files, you can use the -HDL_VERSION command to specify the HDL version for each design file. Refer to "Adding an HDL File to a Project and Setting the HDL Version" on page 9–80.

The Quartus II software reads default values for registered signals defined in the VHDL code and converts the default values into power-up level settings. This enables the power-up state of the synthesized design to match, as closely as possible, the power-up state of the original HDL code in simulation.

VHDL Standard Libraries and Packages

The Quartus II software includes the standard IEEE libraries and a number of vendor-specific VHDL libraries. For information about organizing your own design units into custom libraries, refer to "Design Libraries" on page 9–12.

The **IEEE** library includes the standard VHDL packages std_logic_1164, numeric_std, numeric_bit, and math_real. The **STD** library is part of the VHDL language standard and includes the packages standard (included in every project by default) and textio. For compatibility with older designs, the Quartus II software also supports the following vendor-specific packages and libraries:

- Synopsys packages such as std_logic_arith and std_logic_unsigned in the **IEEE** library

- Mentor Graphics® packages such as `std_logic_arith` in the **ARITHMETIC** library
- Altera primitive packages `altera_primitives_components` (for primitives such as `GLOBAL` and `DFFE`) and `maxplus2` (for legacy support of MAX+PLUS® II primitives) in the **ALTERA** library
- Altera megafunction packages `altera_mf_components` and `stratixgx_mf_components` in the **ALTERA_MF** library (for Altera-specific megafunctions including LCELL), and `lpm_components` in the **LPM** library for library of parameterized modules (LPM) functions.

For a complete listing of library and package support, refer to the Quartus II Help.

Beginning with the Quartus II software version 5.1, you should import component declarations for Altera primitives such as `GLOBAL` and `DFFE` from the `altera_primitives_components` package and not the `altera_mf_components` package.

VHDL wait Constructs

The Quartus II software supports only a single VHDL `wait until` statement in a process block. Other VHDL wait constructs, such as `wait for`, or `wait on` statements, or processes with multiple `wait` statements, are not synthesizable.

Example 9–8 is a VHDL code example of a supported `wait until` construct.

Example 9–8. VHDL Code: Supported wait until Construct

```
architecture dff_arch of ls_dff is
begin
output: process begin
wait until (CLK'event and CLK='1');
Q <= D;
Qbar <= not D;
end process output;
end dff_arch;
```

Example 9–9 is a VHDL code example of unsupported `wait for` construct. The process block a with `wait for`, or `wait on` statement is not synthesizable.

Example 9–9. VHDL Code: Unsupported wait for Construct

```
process
begin
CLK <= '0';
wait for 20 ns;
CLK <= '1';
wait for 12 ns;
end process;
```

The process block with multiple `wait until` statements is not synthesizable. Example 9–10 shows an example of multiple `wait until` statements in a process block.

Example 9–10. Multiple wait until Statements in a Process Block

```
output: process begin
wait until (CLK'event and CLK='1');
Q <= D;
Qbar <= not D;

wait until (CLK'event and CLK='0');
Q <= 0;
Qbar <= 1;
end process output;
```

AHDL Support

The Quartus II compiler's Analysis and Synthesis module fully supports the Altera Hardware Description Language (AHDL).

AHDL designs use Text Design Files (**.tdf**). You can import AHDL Include Files (**.inc**) into a **.tdf** file with an AHDL `include` statement. Altera provides **.inc** files for all megafunctions shipped with the Quartus II software.

For information about specific AHDL syntax features and language constructs, refer to the Quartus II Help.

The AHDL language does not support the synthesis directives or attributes described in this chapter.

Schematic Design Entry Support

The Quartus II compiler's Analysis and Synthesis module fully supports Block Design Files (**.bdf**) for schematic design entry.

You can use the Quartus II software's Block Editor to create and edit **.bdf** files and open Graphic Design Files (**.gdf**) imported from the MAX+PLUS II software. Use the Symbol Editor to create and edit Block Symbol Files (**.bsf**) and open MAX+PLUS II Symbol Files (**.sym**). You can read and edit these legacy MAX+PLUS II formats with the Quartus II Block and Symbol Editors; however, the Quartus II software saves them as **.bdf** or **.bsf** files.

For information about creating and editing schematic designs, refer to the Quartus II Help.

Schematic entry methods do not support the synthesis directives or attributes described in this chapter.

State Machine Editor

The Quartus II software supports graphical state machine entry. To create a new finite state machine (FSM) design, on the File menu, click **New**. In the **New** dialog box, expand the **Design Files** list and choose **State Machine File**.

In the editor, you can use the State Machine Wizard to step you through the state machine creation. Click the **State Machine Wizard** icon. Specify the reset information, define the input ports, states, and transitions, and then define the output ports and output conditions. Click **Finish** to create the state machine diagram.

You can also create the state machine diagram using the editor GUI. Use the icons or right-click menu options to insert new input and output signals and create states in the schematic display. To specify transitions, select the **Transition Tool** and click on the source state, then drag the mouse to the destination state. Double-click on a transition to specify the transition equation, using a syntax that conforms to Verilog HDL. Double-click on a state to open the **State Properties** dialog box, where you can change the state name, specify whether it acts as the reset state, and change the incoming and outgoing transition equations.

To view and edit state machine information in a table format, click the **State Machine Table** icon.

The state machine diagram is saved as a State Machine File (**.smf**). When you have finished defining the state machine logic, create a Verilog HDL or VHDL design file by clicking the **Generate HDL File** icon. You can then instantiate the state machine in your design using any design entry language.

For more information about creating and editing state machine diagrams, refer to the Quartus II Help.

Design Libraries

By default, the Quartus II software compiles all design files into the work library. If you do not specify a design library, or if a file refers to a library that does not exist, or if the library does not contain a referenced design unit, the software searches the work library. This behavior allows the Quartus II software to compile most designs with minimal setup. (Creating separate custom design libraries is optional.)

To compile your design files into specific libraries (for example, when you have two or more functionally different design entities that share the same name), you can specify a destination library for each design file in various ways, as described in the following subsections:

- "Specifying a Destination Library Name in the Settings Dialog Box"
- "Specifying a Destination Library Name in the Quartus II Settings File or Using Tcl"

When the Quartus II compiler analyzes the file, it stores the analyzed design units in the file's destination library.

Beginning with the Quartus II software version 6.1, a design can contain two or more entities with the same name if they are compiled into separate libraries.

When compiling a design instance, the Quartus II software initially searches for the entity in the library associated with the instance (which is the work library if no other library is specified). If the entity definition is not found, the software searches for a unique entity definition in all design libraries. If more than one entity with the same name is found, the software generates an error. If your design uses multiple entities with the same name, you must compile the entities into separate libraries.

In VHDL, there are several ways to associate an instance with a particular entity, as described in "Mapping a VHDL Instance to an Entity in a Specific Library". In Verilog HDL, BDF schematic entry, AHDL, as well as VQM and EDIF netlists, use different libraries for each of the entities that have the same name, and compile the instantiation into the same library as the appropriate entity.

Specifying a Destination Library Name in the Settings Dialog Box

To specify a library name for one of your design files, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Files**. The **Files** page appears.
3. Select the file in the **File Name** list.
4. Click **Properties**.
5. In the **File Properties** dialog box, select the type of design file from the **Type** list.
6. Type the desired library name in the **Library** field.
7. Click **OK**.

Specifying a Destination Library Name in the Quartus II Settings File or Using Tcl

You can specify the library name with the `-library` option to the <*language type*>`_FILE` assignment in the Quartus II Settings File (**.qsf**) or with Tcl commands.

For example, the following **.qsf** file or Tcl assignments specify that the Quartus II software analyze **my_file.vhd** and store its contents (design units) in the VHDL library **my_lib**, and analyze the Verilog HDL file **my_header_file.h** and store its contents in a library called **another_lib**. Refer to Example 9–11.

Example 9–11. Specifying a Destination Library Name

```
set_global_assignment -name VHDL_FILE my_file.vhd -library my_lib
set_global_assignment -name VERILOG_FILE my_header_file.h -library another_lib
```

For more information about Tcl scripting, refer to "Scripting Support" on page 9–80.

Specifying a Destination Library Name in a VHDL File

You can use the `library` synthesis directive to specify a library name in your VHDL source file. This directive takes a single string argument: the name of the destination library. Specify the `library` directive in a VHDL comment prior to the context clause for a primary design unit (that is, a package declaration, an entity declaration, or a configuration), using one of the supported keywords for synthesis directives, that is, `altera`, `synthesis`, `pragma`, `synopsys`, or `exemplar`.

For more information about specifying synthesis directives, refer to "Synthesis Directives" on page 9–27.

The `library` directive overrides the default library destination **work**, the library setting specified for the current file through the **Settings** dialog box, any existing **.qsf** file setting, any setting made through the Tcl interface, or any prior `library` directive in the current file. The directive remains effective until the end of the file or the next `library` synthesis directive.

Example 9–12 uses the `library` synthesis directive to create a library called **my_lib** that contains the design unit `my_entity`.

Example 9–12. Using the Library Synthesis Directive

```
-- synthesis library my_lib
library ieee;
use ieee.std_logic_1164.all;
entity my_entity(...)
end entity my_entity;
```

You can specify a single destination library for all the design units in a given source file by specifying the library name in the **Settings** dialog box, editing the **.qsf** file, or using the Tcl interface. Using the `library` directive to change the destination VHDL library within a source file gives you the option of organizing the design units in a single file into different libraries, rather than just a single library.

The Quartus II software produces an error if you use the library directive within a design unit.

Mapping a VHDL Instance to an Entity in a Specific Library

The VHDL language provides a number of ways to map or bind an instance to an entity in a specific library, as described in the following subsections.

Direct Entity Instantiation

In the direct entity instantiation method, the instantiation refers to an entity in a specific library, as shown in Example 9–13.

Example 9–13. VHDL Code: Direct Entity Instantiation

```
entity entity1 is
port(...);
end entity entity1;

architecture arch of entity1 is
begin
inst: entity lib1.foo
port map(...);
end architecture arch;
```

Component Instantiation—Explicit Binding Instantiation

There is more than one mechanism for binding a component to an entity. In an explicit binding indication, you bind a component instance to a specific entity, as shown in Example 9–14.

© March 2009 Altera Corporation

Example 9–14. VHDL Code: Binding Instantiation

```
entity entity1 is
port(...);
end entity entity1;

package components is
component entity1 is
port map (...);
end component entity1;
end package components;

entity top_entity is
port(...);
end entity top_entity;

use lib1.components.all;
architecture arch of top_entity is
-- Explicitly bind instance I1 to entity1 from lib1
for I1: entity1 use entity lib1.entity1
port map(...);
end for;
begin
I1: entity1 port map(...);
end architecture arch;
```

Component Instantiation—Default Binding

If you do not provide an explicit binding indication, a component instance is bound to the nearest visible entity with the same name. If no such entity is visible in the current scope, the instance is bound to the entity in the library in which the component was declared. For example, if the component is declared in a package in library `MY_LIB`, an instance of the component is bound to the entity in library `MY_LIB`. The portions of code in Example 9–15 and Example 9–16 show this instantiation method.

Example 9–15. VHDL Code: Default Binding to the Entity in the Same Library as the Component Declaration

```
use mylib.pkg.foo; -- import component declaration from package “pkg”
in                 -- library “mylib”
architecture rtl of top
...
begin
-- This instance will be bound to entity “foo” in library “mylib”
inst: foo
port map(...);
end architecture rtl;
```

Example 9–16. VHDL Code: Default Binding to the Directly Visible Entity

```
use mylib.foo; -- make entity "foo" in library "mylib" directly visible
architecture rtl of top
component foo is
generic (...)
port (...);
end component;
begin
-- This instance will be bound to entity "foo" in library "mylib"
inst: foo
port map(...);
end architecture rtl;
```

Using Parameters/Generics

This section describes how parameters (called generics in VHDL) are supported in the Quartus II software, and how you can pass these parameters between different design languages.

You can enter default parameter values for your design in the **Default Parameters** box in the **Analysis & Synthesis Settings** page of the **Settings** dialog box. Default parameters allow you to specify the parameter overrides for your top-level entity. In AHDL, parameters are inherited, so any default parameters apply to all AHDL instances in the design. You can also specify parameters for instantiated modules in a **.bdf** file. To modify parameters in a **.bdf** instance, double-click on the parameter value box for the instance symbol, or right-click on the symbol and choose **Properties**, then click the **Parameters** tab. For these GUI-based entry methods, information about how parameter values are interpreted, and recommendations about the format you should use, refer to "Setting Default Parameter Values and BDF Instance Parameter Values".

You can specify parameters for instantiated modules in your design source files, using the syntax provided for that language. Some designs instantiate entities in a different language; for example, they might instantiate a VHDL entity from a Verilog HDL design file. You can pass parameters or generics between VHDL, Verilog HDL, AHDL, and BDF schematic entry, and from EDIF or VQM to any of these languages. In most cases, you do not have to do anything special to pass parameters from one language to another. However, in some cases you might have to specify the type of parameter you are passing. In those cases, you should follow certain guidelines to ensure that the parameter value is interpreted correctly. Refer to "Passing Parameters Between Two Design Languages" on page 9–18 for parameter type rules.

Setting Default Parameter Values and BDF Instance Parameter Values

Default parameter values and BDF instance parameter values do not have an explicitly declared type. In most cases, the Quartus II software can correctly infer the type from the value without ambiguity. For example, "`ABC`" is interpreted as a string, `123` as an integer, and `15.4` as a floating-point value. In other cases, such as when the instantiated subdesign language is VHDL, the Quartus II software uses the type of the parameter/generic in the instantiated entity to determine how to interpret the value, so that a value of `123` is interpreted as a string if the VHDL parameter is of type

string. In addition, you can set the parameter value in a format that is legal in the language of the instantiated entity. For example, to pass an unsized bit literal value from BDF to Verilog HDL, you can use `'1` as the parameter value, and to pass a 4-bit binary vector from BDF to Verilog HDL, you can use `4'b1111` as the parameter value.

In a few cases, the Quartus II software cannot infer the correct type of parameter value. To avoid ambiguity, specify the parameter value in a type-encoded format where the first or first and second character of the parameter indicate the type of the parameter, and the rest of the string indicates the value in a quoted sub-string. For example, to pass a binary string `1001` from BDF to Verilog HDL, you cannot simply use the value `1001`, because the Quartus II software interprets it as a decimal value. You also cannot use the string `"1001"`, because the Quartus II software interprets it as an ASCII string. You must use the type-encoded string `B"1001"` for the Quartus II software to interpret the parameter value correctly. Table 9–1 provides a list of valid parameter strings and shows how they are interpreted within the Quartus II software. Altera recommends using the type-encoded format only when necessary to resolve ambiguity.

Table 9–1. Valid Parameter Strings and How They are Interpreted

Parameter String	Quartus II Parameter Type, Format, and Value
`S"abc"`, `s"abc"`	String value abc
`"abc123"`, `"123abc"`	String value abc123 or 123abc
`F"12.3"`, `f"12.3"`	Floating point number 12.3
`-5.4`	Floating point number -5.4
`D"123"`, `d"123"`	Decimal number 123
`123`, `-123`	Decimal number 123, -123
`X"ff"`, `H"ff"`	Hexadecimal value FF
`Q"77"`, `O"77"`	Octal value 77
`B"1010"`, `b"1010"`	Unsigned binary value 1010
`SB"1010"`, `sb"1010"`	Signed binary value 1010
`R"1"`, `R"0"`, `R"X"`, `R"Z"`, `r"1"`, `r"0"`, `r"X"`, `r"Z"`	Unsized bit literal
`E"apple"`, `e"apple"`	Enum type, value name is apple
`P"1 unit"`	Physical literal, the value is (1, unit)
`A(...)`, `a(...)`	Array type or record type, whose content is determined by the string (...)

Beginning in Quartus II software version 8.1, you can select the parameter type using the pull-down list in the **Parameter** tab of the **Symbol Properties** dialog box. You can select the parameter types for global parameters or global constants. The Quartus II software supports the following parameter types:

- **Unsigned Integer**
- **Signed Integer**
- **Unsigned Binary**
- **Signed Binary**
- **Octal**

- **Hexadecimal**
- **Float**
- **Enum**
- **String**
- **Boolean**
- **Char**
- **Untyped/Auto**

If you do not specify the parameter type, the Quartus II software interprets the parameter value and defines the parameter type. Altera recommends specifying parameter type by selecting from the pull-down list to avoid ambiguity.

If you open a **.bdf** file in the Quartus II software version 8.1 and above, the software automatically updates the parameter types of old symbol blocks by interpreting the parameter value based on the language-independent format. If the parameter value type is not recognized, the parameter type is set as untyped. You can specify the parameter type as described in the preceding list.

Passing Parameters Between Two Design Languages

When passing a parameter between two different languages, a design block that is higher in the design hierarchy instantiates a lower-level subdesign block and provides parameter information. It is essential that the parameter be correctly interpreted by the subdesign language (the design entity that is instantiated). Based on the information provided by the higher-level design and the value format, and sometimes by the parameter type of the subdesign entity, the Quartus II software interprets the type and value of the passed parameter.

When passing a parameter whose value is an enumerated type value or literal from a language that does not support enumerated types to one that does (for example, from Verilog HDL to VHDL), it is essential that the enumeration literal is spelled correctly in the higher-level design. The parameter value is passed as a string literal, and it is up to the language of the lower-level design to correctly convert the string literal into the correct enumeration literal.

If the lower-level language is SystemVerilog, it is essential that the `enum` value is used in the correct case. In SystemVerilog, it is recommended that two enumeration literals do not only differ in case. For example, `enum {item, ITEM}` is not a good choice of item names because these names can create confusion among users and it is more difficult to pass parameters from case-insensitive HDLs, such as VHDL.

Arrays have different support in different design languages. For details about the array parameter format, refer to the **Parameter** section in the Analysis & Synthesis Report of a design that contains array parameters or generics.

The following code shows examples of passing parameters from one design entry language to a subdesign written in another language. Example 9–17 shows a VHDL subdesign that is instantiated into a top-level Verilog HDL design in Example 9–18. Example 9–19 shows a Verilog HDL subdesign that is instantiated in a top-level VHDL design in Example 9–20.

Example 9–17. VHDL Parameterized Subdesign Entity

```
type fruit is (apple, orange, grape);
entity vhdl_sub is
generic (
name : string := "default",
width : integer := 8,
number_string : string := "123",
f : fruit := apple,
binary_vector : std_logic_vector(3 downto 0) := "0101",
signed_vector : signed (3 downto 0) := "1111");
```

Example 9–18. Verilog HDL Top-Level Design Instantiating and Passing Parameters to VHDL Entity from Example 9–17

```
vhdl_sub inst (...);
defparam inst.name = "lower";
defparam inst.width = 3;
defparam inst.num_string = "321";
defparam inst.f = "grape"; // Must exactly match enum value
defparam inst.binary_vector = 4'b1010;
      defparam inst.signed_vector = 4'sb1010;
```

Example 9–19. Verilog HDL Parameterized Subdesign Module

```
module veri_sub (...)
parameter name = "default";
parameter width = 8;
parameter number_string = "123";
parameter binary_vector = 4'b0101;
parameter signed_vector = 4'sb1111;
```

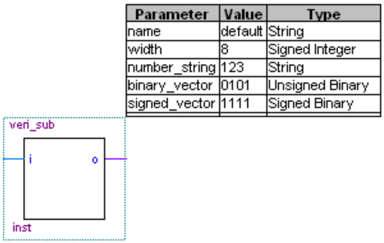
Example 9–20. VHDL Top-Level Design Instantiating and Passing Parameters to the Verilog HDL Module from Example 9–19

```
inst:veri_sub
generic map (
name => "lower",
width => 3,
number_string => "321"
binary_vector = "1010"
signed_vector = "1010")
```

To use an HDL subdesign such as the one shown in Example 9–19 in a top-level BDF design, you must first generate a symbol for the HDL file, as shown in Figure 9–2. Open the HDL file in the Quartus II software, and then, on the File menu, point to **Create/Update** and click **Create Symbol Files for Current File**.

To modify parameters on a BDF instance, double-click on the parameter value box for the instance symbol, or right-click on the symbol and choose **Properties**, then click the **Parameters** tab.

Figure 9–2. BDF Top-Level Design Instantiating and Passing Parameters to the Verilog HDL Module from Example 9–19.



Parameter	Value	Type
name	default	String
width	8	Signed Integer
number_string	123	String
binary_vector	0101	Unsigned Binary
signed_vector	1111	Signed Binary

Incremental Compilation

The incremental compilation feature in the Quartus II software manages a design hierarchy for incremental design by allowing you to divide the design into multiple partitions. Incremental compilation ensures that when a design is compiled, only those partitions of the design that have been updated are resynthesized, reducing compilation time and runtime memory usage. This also means that node names are maintained during synthesis for all registered and combinational nodes in unchanged partitions. You can perform incremental synthesis by setting the Netlist Type for all design partitions to **Post-Synthesis**.

You can also preserve the placement (and optionally routing) information for unchanged partitions. This feature allows you to preserve performance of unchanged blocks in your design and reduces the time required for placement and routing, which significantly reduces your design compilation time.

Partitions for Preserving Hierarchical Boundaries

A design partition represents a portion of the design that you want to synthesize and fit incrementally.

The **Preserve Hierarchical Boundary** logic option is available only in Quartus II software versions 8.1 and earlier. Incremental compilation maintains the hierarchical boundaries of design partitions, so you should use design partitions if you want to preserve hierarchical boundaries through the synthesis and fitting process.

Beginning with Quartus II software version 9.0, if you want to preserve the **Optimization Technique** and **Restructure Multiplexers** logic options set in any entity, you must create new partitions for the particular entity instead of using the **Preserve Hierarchical Boundary** logic option. If you have settings applied to specific existing design hierarchies, particularly those created in the Quartus II software versions before 9.0, you must create a design partition for the design hierarchy so that synthesis can optimize the design instance independently and preserve the hierarchical boundaries. Similarly, if you are performing formal verification, you must use partitions with incremental compilation to ensure that no optimizations occur across specific design hierarchies.

Parallel Synthesis

The **Parallel Synthesis** option is one of the Analysis and Synthesis options that you can use to reduce compilation time for synthesis. The feature enables the Quartus II software to use multi-processors to synthesize multiple partitions in parallel.

This feature is available only if the following requirements are met:

- The number of processors allowed is greater than 1

You can specify the maximum number of processors allowed under **Parallel Compilation** options in the **Compilation Process Settings** page of the **Settings** dialog box.

- Incremental compilation is enabled and your design has two or more partitions
- **Timing Driven Synthesis** is not enabled
- **Physical Synthesis** is not enabled
- **Parallel Synthesis** is enabled using one of the following procedures:

To enable parallel synthesis, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, click **Analysis & Synthesis Settings** and click **More Settings** to select **Parallel Synthesis**.

You can also set the **Parallel Synthesis** option using the following Tcl command:

```
set_global_assignment -name parallel_synthesis on
```

You can view all messages generated during the parallel synthesis in the Message console. Messages from different partitions are interleaved at runtime, but the **Partition Column** displays the partition ID of the partition that has a message. After compilation, you can sort the messages by **Partition Column**—effectively grouping all the messages from a particular partition. To display the partition column, right click on the message console, point to **Message Column** and select **Show Partition Column**. You can also display the **Partition** column on the Tools menu, by clicking **Options** and selecting **Messages** in the **Category** list. In the Messages page, turn on **Show the Partition column**.

If you use the command line, you can differentiate among the interleaved messages by turning on the **Show partition that generated the message** option in **Messages** page. This option shows the partition ID in parenthesis for each message.

Quartus II eXported Partition (.qxp) File as Source

You can use a Quartus II eXported Partition (**.qxp**) file as a source file beginning with Quartus II software version 8.1. The **.qxp** file contains the precompiled design netlist exported from another Quartus II project, or from a design partition within the project, and fully defines the entity. Project team members or IP providers can use a **.qxp** file to send their design to the project lead, instead of sending the original HDL source code. Using this file preserves the previous compilation results and instance-specific assignments. Not all global assignments can be used in a different Quartus II project. You can override the assignments for the entity in the **.qxp** file by applying assignments in the full top-level project.

A **.qxp** file instance that is not assigned as a design partition does not preserve placement and routing results. If you want to preserve the placement (and optionally routing) results from another project or compilation, you must import a post-fitting **.qxp** file into a design partition in your project using the bottom-up incremental compilation flow.

Perform the following steps to create a **.qxp** file:

1. On the Project menu, click **Export Design Partition**.
2. In the **Export file** box, type the name of the **.qxp** file. By default, the directory path and file name are the same as the current project.
3. You can also select the Partition hierarchy to export. By default, the Top partition (the entire project) is exported, but you can choose to export the compilation results of any partition hierarchy in the project.
4. Under **Netlist to export**, select either **Post-fit netlist** or **Post-synthesis netlist**. The default is **Post-fit netlist**. For post-fit netlists, turn on or off the **Export routing** option as required.
5. Click **OK**. The Quartus II software creates the **.qxp** file in the specified directory.

The Quartus II software adds the file into the project and **.qxp** file into a specific library. The design entity in the **.qxp** file can also be instantiated multiple times in the design.

For more information about exporting design partitions and using **.qxp** files, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*

Quartus II Synthesis Options

The Quartus II software offers a number of options to help you control the synthesis process and achieve optimal results for your design. "Setting Synthesis Options" on page 9–24 describes the **Analysis & Synthesis Settings** page of the **Settings** dialog box, where you can set the most common global settings and options, and defines the following three types of synthesis options: Quartus II logic options, synthesis attributes, and synthesis directives. The other subsections describe the following common synthesis options in the Quartus II software, and provide HDL examples of how to use each option, where applicable:

- Major Optimization Settings
  - "Optimization Technique" on page 9–28
  - "Speed Optimization Technique for Clock Domains" on page 9–28
  - "PowerPlay Power Optimization" on page 9–31
  - "Restructure Multiplexers" on page 9–34
  - "Synthesis Effort" on page 9–35

- Settings Related to Timing Constraints
  - "Optimization Technique" on page 9–28
  - "Speed Optimization Technique for Clock Domains" on page 9–28
  - "Auto Gated Clock Conversion" on page 9–29
  - "Timing-Driven Synthesis" on page 9–30
  - "SDC Constraint Protection" on page 9–31
- State Machine Settings and Enumerated Types
  - "State Machine Processing" on page 9–36
  - "Manually Specifying State Assignments Using the syn_encoding Attribute" on page 9–37
  - "Manually Specifying Enumerated Types Using the enum_encoding Attribute" on page 9–39
  - "Safe State Machines" on page 9–41
- Register Power-Up Settings
  - "Power-Up Level" on page 9–42
  - "Power-Up Don't Care" on page 9–43
- Controlling, Preserving, Removing, and Duplicating Logic and Registers
  - "Limiting DSP Block Usage in Partitions" on page 9–32
  - "Remove Duplicate Registers" on page 9–44
  - "Remove Redundant Logic Cells" on page 9–44
  - "Preserve Registers" on page 9–44
  - "Disable Register Merging/Don't Merge Register" on page 9–45
  - "Noprune Synthesis Attribute/Preserve Fan-out Free Register Node" on page 9–46
  - "Keep Combinational Node/Implement as Output of Logic Cell" on page 9–46
  - "Don't Retime, Disabling Synthesis Netlist Optimizations" on page 9–47
  - "Don't Replicate, Disabling Synthesis Netlist Optimizations" on page 9–48
  - "Maximum Fan-Out" on page 9–49
  - "Controlling Clock Enable Signals with Auto Clock Enable Replacement and direct_enable" on page 9–50
  - "Auto Gated Clock Conversion" on page 9–29
  - To preserve design hierarchy, refer to "Partitions for Preserving Hierarchical Boundaries" on page 9–20

- Megafunction Inference Options
  - "Megafunction Inference Control" on page 9–51
  - "RAM Style and ROM Style—for Inferred Memory" on page 9–53
  - "Turning Off Add Pass-Through Logic to Inferred RAMs/ no_rw_check Attribute Setting" on page 9–54
  - "RAM Initialization File—for Inferred Memory" on page 9–57
  - "Multiplier Style—for Inferred Multipliers" on page 9–58
- Controlling Synthesis with Other Synthesis Directives
  - "Full Case" on page 9–60
  - "Parallel Case" on page 9–61
  - "Translate Off and On / Synthesis Off and On" on page 9–62

  - "Read Comments as HDL" on page 9–63
- Specifying I/O-Related Assignments
  - "Use I/O Flipflops" on page 9–64
  - "Specifying Pin Locations with chip_pin" on page 9–65
- Setting Quartus II Logic Options in Your HDL Source Code
  - "Using altera_attribute to Set Quartus II Logic Options" on page 9–66

Setting Synthesis Options

You can set synthesis options in the **Settings** dialog box, or with logic options in the Quartus II software, or you can use synthesis attributes and directives within the HDL source code.

Analysis & Synthesis Settings Page of the Settings Dialog Box

On the Assignments menu, click **Settings**. The **Settings** dialog box appears. In the **Category** list, select **Analysis & Synthesis Settings**. The **Analysis & Synthesis Settings** page allows you to set global synthesis options that apply to the entire project. These options are described in later subsections.

Beginning with Quartus II software version 9.0, some of the advanced synthesis settings can be set in the **Physical Synthesis Optimization** page under **Compilation Process Settings**.

For more information about Physical Synthesis options, refer to the *Netlist Optimizations and Physical Synthesis* chapter in volume 2 of the *Quartus II Handbook*.

© March 2009 Altera Corporation

Quartus II Logic Options

Quartus II logic options control many aspects of the synthesis and place-and-route process. To set logic options in the Quartus II GUI, on the Assignments menu, click **Assignment Editor**. You can also use a corresponding Tcl command. Quartus II logic options allow you to set instance or node-specific assignments without editing the source HDL code. Logic options can be used with all design entry languages supported by the Quartus II software.

For more information about using the Assignment Editor, refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook*.

Synthesis Attributes

The Quartus II software supports synthesis attributes for Verilog HDL and VHDL, also commonly called pragmas. These attributes are not standard Verilog HDL or VHDL commands; synthesis tools use attributes to control the synthesis process in a particular manner. Attributes always apply to a specific design element, and are applied in the HDL source code. Some synthesis attributes are also available as Quartus II logic options via the Quartus II GUI or with Tcl. Each attribute description in this chapter indicates whether there is a corresponding setting or logic option that can be set in the GUI; some attributes can be specified only with HDL synthesis attributes.

Attributes specified in your HDL code are not visible in the Assignment Editor or in the **.qsf** file. Assignments or settings made through the Quartus II GUI, the **.qsf** file, or the Tcl interface take precedence over assignments or settings made with synthesis attributes in your HDL code. The Quartus II software generates warning messages if invalid attributes are found, but does not generate an error or stop the compilation. This behavior is required because attributes are specific to various design tools, and attributes not recognized in the Quartus II software might be intended for a different EDA tool. The Quartus II software lists the attributes specified in your HDL code in the Source assignments table in the Analysis & Synthesis report.

The Verilog-2001, SystemVerilog, and VHDL language definitions provide specific syntax for specifying attributes, but in Verilog-1995, you must embed attribute assignments in comments. You can enter attributes in your code using the syntax in Example 9–21 through Example 9–24, where *<attribute>*, *<attribute type>*, *<value>*, *<object>*, and *<object type>* are variables, and the entry in brackets is optional. The examples in this chapter demonstrate each syntax form.

Verilog HDL is case-sensitive; therefore, synthesis attributes are also case-sensitive.

Example 9–21. Synthesis Attributes in Verilog-1995

```
// synthesis <attribute> [ = <value> ]
or
/* synthesis <attribute> [ = <value> ] */
```

Verilog-1995 comment-embedded attributes, as shown in Example 9–21, must be used as a suffix to (that is, placed after) the declaration of an item and must appear before the semicolon when one is required.

You cannot use the open one-line comment in Verilog HDL when a semicolon is required at the end of the line, because it is not clear to which HDL element the attribute applies. For example, you cannot make an attribute assignment such as `reg r; // synthesis` *<attribute>* because the attribute could be read as part of the next line.

To apply multiple attributes to the same instance in Verilog-1995, separate the attributes with spaces, as follows:

`//synthesis` *<attribute1>* [= *<value>*] *<attribute2>* [= *<value>*]

For example, to set the `maxfan` attribute to `16` (Refer to "Maximum Fan-Out" on page 9–49 for details) and set the `preserve` attribute (refer to "Preserve Registers" on page 9–44 for details) on a register called `my_reg`, use the following syntax:

```
reg my_reg /* synthesis maxfan = 16 preserve */;
```

In addition to the `synthesis` keyword shown above, the keywords `pragma`, `synopsys`, and `exemplar` are supported for compatibility with other synthesis tools. The keyword `altera` is also supported, which allows you to add synthesis attributes that will be recognized only by Quartus II integrated synthesis and not by other tools that recognize the same synthesis attribute.

Because formal verification tools do not recognize the `exemplar`, `pragma`, and `altera` keywords, avoid using these attribute keywords when using formal verification.

Example 9–22. Synthesis Attributes in Verilog-2001 and SystemVerilog

```
(* <attribute> [ = <value> ] *)
```

Verilog-2001 attributes, as shown in Example 9–22, must be used as a prefix to (that is, placed before) a declaration, module item, statement, or port connection, and used as a suffix to (that is, placed after) an operator or a Verilog HDL function name in an expression.

Because formal verification tools do not recognize the syntax, the Verilog-2001 attribute syntax is not supported when using formal verification.

To apply multiple attributes to the same instance in Verilog-2001 or SystemVerilog, separate the attributes with commas, as shown in Example 9–23:

Example 9–23. Applying Multiple Attributes

```
(* <attribute1> [ = <value1>], <attribute2> [ = <value2> ] *)
```

For example, to set the `maxfan` attribute to `16` (refer to "Maximum Fan-Out" on page 9–49 for details) and set the `preserve` attribute (refer to "Preserve Registers" on page 9–44 for details) on a register called `my_reg`, use the following syntax:

```
(* preserve, maxfan = 16 *) reg my_reg;
```

© March 2009 Altera Corporation

Example 9–24. Synthesis Attributes in VHDL

```
attribute <attribute> : <attribute type> ;
attribute <attribute> of <object> : <object type> is <value>;
```

VHDL attributes, as shown in Example 9–24, declare the attribute type and then apply it to a specific object. For VHDL designs, all supported synthesis attributes are declared in the `altera_syn_attributes` package in the **Altera** library. You can call this library from your VHDL code to declare the synthesis attributes, as follows:

```
LIBRARY altera;
USE altera.altera_syn_attributes.all;
```

Synthesis Directives

The Quartus II software supports synthesis directives, also commonly called compiler directives or pragmas. You can include synthesis directives in Verilog HDL or VHDL code as comments. These directives are not standard Verilog HDL or VHDL commands; synthesis tools use directives to control the synthesis process in a particular manner. Directives do not apply to a specific design node but change the behavior of the synthesis tool from the point where they occur in the HDL source code. Other tools, such as simulators, ignore these directives and treat them as comments.

You can enter synthesis directives in your code using the syntax shown in Example 9–25 and Example 9–26, where *<directive>* and *<value>* are variables, and the entry in brackets is optional. Notice that for synthesis directives there is no = sign before the value; this is different than the syntax for synthesis attributes. The examples in this chapter demonstrate each syntax form.

Verilog HDL is case-sensitive; therefore, all synthesis directives are also case-sensitive.

Example 9–25. Verilog HDL Code: Synthesis Directives

```
// synthesis <directive> [ <value> ]
or
/* synthesis <directive> [ <value> ] */
```

Example 9–26. VHDL Code: Synthesis Directives

```
-- synthesis <directive> [ <value> ]
```

In addition to the `synthesis` keyword shown above, the `pragma`, `synopsys`, and `exemplar` keywords are supported in both Verilog HDL and VHDL for compatibility with other synthesis tools. The keyword `altera` is also supported, which allows you to add synthesis directives that are recognized only by Quartus II integrated synthesis and not by other tools that recognize the same synthesis directives.

Because formal verification tools ignore keywords `exemplar`, `pragma`, and `altera`, avoid using these directive keywords when you are using formal verification to prevent mismatches with the Quartus II results.

Optimization Technique

The **Optimization Technique** logic option specifies the goal for logic optimization during compilation; that is, whether to attempt to achieve maximum speed performance or minimum area usage, or a balance between the two. Table 9–2 lists the settings for this logic option, which you can apply only to a design entity. You can also set this logic option for your whole project on the **Analysis & Synthesis Settings** page in the **Settings** dialog box. If you want to set this logic option for an entity, you must create a design partition for the entity before setting the **Optimization Technique** logic option. Beginning in Quartus II version 9.0, this option is ignored when set on an entity that is not a design partition.

Table 9–2. Optimization Technique Settings

Setting	Description
Area	The compiler makes the design as small as possible to minimize resource usage.
Speed	The compiler chooses a design implementation that has the fastest f_{MAX}.
Balanced *(1)*	The compiler maps part of the design for area and part for speed, providing better area utilization than optimizing for speed, with only a slightly slower f_{MAX} than optimizing for speed.

Note to Table 9–2:

(1) The balanced optimization technique is not supported for all device families.

The default setting varies by device family and is generally optimized for the best area/speed trade-off. Results are design-dependent and vary depending on which device family you use.

Speed Optimization Technique for Clock Domains

The **Speed Optimization Technique for Clock Domains** logic option specifies that all combinational logic in or between the specified clock domain(s) is optimized for speed.

When this option is set on a particular clock signal, all the logic in this clock domain is optimized for speed during synthesis. The remainder of the design in other clock domains is synthesized with the project-wide **Optimization Technique** that is set in the **Analysis & Synthesis Settings** page. The option can also be set from one clock to another clock signal, in which case the logic in paths from registers in the first clock domain to registers in the second clock domain are synthesized for speed. The advantage of using this option over the project-wide setting to optimize for speed is that there is less penalty to the area of the design because a smaller part of the circuit is optimized for speed. This can also have a positive effect on clock speed. This option also has an advantage over setting the **Optimization Technique** on a design entity because that option forces the hierarchical blocks to be synthesized separately. Doing so can increase area and decrease performance due to the lack of optimizations across hierarchies. The **Speed Optimization Technique for Clock Domains** option does not treat hierarchical entities separately, and can optimize across hierarchical boundaries for logic within the same clock domain.

This option is useful if you have one or more clock domains that do not meet your timing requirements. When there are failing paths within a clock domain, the option can be set on the clock of that clock domain. When there are failing paths between clock domains, the option can be set from one clock domain to the other clock domain.

This option is available for the following device families: Arria® GX, Stratix® series, Cyclone® series, HardCopy® II, HardCopy Stratix, and MAX® II.

Auto Gated Clock Conversion

Clock gating is a common optimization technique used in ASIC designs to minimize power consumption. You can use the **Auto Gated Clock Conversion** option to optimize your prototype ASIC designs by converting gated clocks into clock enables when you use FPGAs in your ASIC prototyping. The automatic conversion of gated clocks to clock enables is more efficient than manually modifying source code. However, this feature should not be used when migrating FPGA designs to HardCopy ASICs. The **Auto Gated Clock Conversion** option automatically converts qualified gated clocks (base clocks as defined in the SDC assignments) to clock enables. To use **Auto Gated Clock Conversion**, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Analysis & Synthesis Settings**. The **Analysis & Synthesis Settings** page appears.
3. Click **More Settings**. The **More Analysis & Synthesis Settings** dialog box appears.
4. Under **Option**, in the **Name** list, select **Auto Gated Clock Conversion** and in the **Setting** list, select **On**.
5. Click **OK**.
6. Click **OK** again.

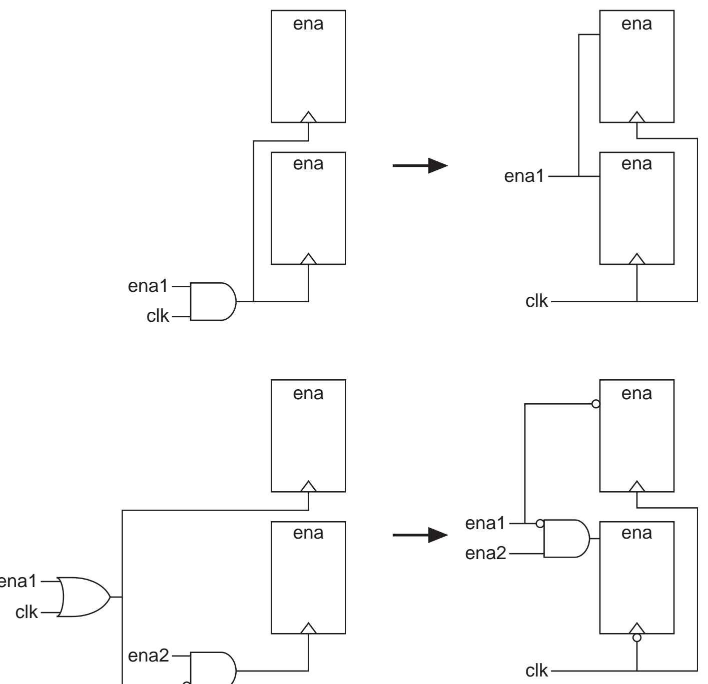
This feature is available only for the TimeQuest Timing Analyzer and supports the following device families: Arria II GX, Arria GX, Stratix series (except for Stratix) and Cyclone series (except for Cyclone), HardCopy II, and MAX II devices.

The gated clock conversion occurs when the following conditions are met:

- Only one base clock drives a gated-clock
- For one set of gating input values, the value output of the gated clock remains constant and does not change as the base clock changes
- For one value of the base clock, changes in the gating inputs do not change the value output for the gated clock

The feature supports combinational gates in clock gating network. Figure 9–3 shows examples of gated clock conversions.

Figure 9–3. Gated Clock Conversion



This feature does not support registers in RAM, DSP blocks, or I/O related WYSIWYG. The gated clock conversion does not support multiple design partitions from incremental compilation where the gated clock and base clock are not in the same hierarchical partition because the gated-clock conversion cannot trace the base clock from the gated clock. Thus, base clocks and gated clocks must be in the same hierarchical design partition. If a gated clock that is derived from a root gated clock of a multiple cascaded gated clock cannot be converted, the whole gated clock tree will not be converted, because each conversion is based on a gated clock tree instead of every gated clock.

The **Info** tab in the Messages window lists all the converted gated clocks. You can view a list of converted and non-converted gated clocks from the Compilation Report under the **Optimization Results** of the Analysis & Synthesis Report. The reasons for non-converted gated clocks are listed in the **Gated Clock Conversion Details** table.

Timing-Driven Synthesis

The **Timing-Driven Synthesis** option specifies whether synthesis should use the design's SDC timing constraints to better optimize the circuit. This feature enables synthesis to take into account the SDC timing constraints to focus on the truly critical parts of the design when optimizing for performance. Altera recommends using **Timing-Driven Synthesis** with **Optimization Technique Balanced**. When you turn on **Timing-Driven Synthesis**, Synthesis improves logic depth on parts of the design that require meeting performance requirements at the cost of area increase. Compared to **Optimization Technique** option for speed, **Timing-Driven Synthesis** gets similar performance but saves area.

To use the **Timing-Driven Synthesis** option, perform the following steps:

1. On the Assignment menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Analysis & Synthesis Settings**. In the **Analysis & Synthesis Settings** page, select **Timing-Driven Synthesis**.

The feature is available only for the TimeQuest Timing Analyzer and supports Arria II GX, Arria GX, Stratix series (except Stratix devices) and Cyclone series (except Cyclone devices), and HardCopy II devices. Altera recommends that you select a specific device for timing-driven synthesis to have the most accurate timing information. When auto device is selected, timing-driven synthesis uses the smallest device for the selected family to obtain timing information.

SDC Constraint Protection

The **SDC constraint protection** option allows you to preserve timing constraints when you use the TimeQuest Timing Analyzer. The feature checks on register merging and retiming. It prevents register merging on registers with incompatible SDC constraints and prevents register retiming on constrained registers. It helps maintain the validity of SDC constraints throughout compilation. To use the **SDC constraint protection** option, perform the following steps:

1. On the Assignment menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Analysis & Synthesis Settings**. The **Analysis & Synthesis Settings** page appears.
3. Click **More Settings**. The **More Settings** dialog box appears.
4. Under **Option**, in the **Name** list, select **SDC constraint protection** and in the **Setting** list, select **On**.

This feature is available only for the TimeQuest Timing Analyzer and supports the following device families: Arria GX, Stratix series (except Stratix devices), Cyclone series (except Cyclone devices), HardCopy II, and MAX II devices.

PowerPlay Power Optimization

This logic option controls the power-driven compilation setting of Analysis and Synthesis and determines how aggressively Analysis and Synthesis optimizes the design for power. On the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**. This displays the **Analysis & Synthesis Settings** page. The following three settings are available for the **PowerPlay Power Optimization** option:

- **Off**—Analysis and Synthesis does not perform any power optimizations.
- **Normal Compilation**—Analysis and Synthesis performs power optimizations, without reducing design performance.
- **Extra Effort**—Analysis and Synthesis performs additional power optimizations, which can reduce design performance.

This logic option is available for the following device families: Arria GX, Stratix series, Cyclone series, HardCopy II, and MAX II.

For more information about optimizing your design for power utilization, refer to the *Power Optimization* chapter in volume 2 of the *Quartus II Handbook*. For information about analyzing your power results, refer to the *PowerPlay Power Analysis* chapter in volume 3 of the *Quartus II Handbook*.

Limiting DSP Block Usage in Partitions

One important step of Analysis and Synthesis is resource balancing. In this step, Quartus II integrated synthesis looks at the digital signal processing (DSP) block used in the design and balances it against the resources available in the targeted device that are converting the DSP blocks that cannot fit in the device into equivalent logic. For incremental compilation, each partition has a separate balancing step.

By default, the Quartus II integrated synthesis looks at the targeted device information to find out the number of DSP blocks available for use. However, in incremental compilation, each partition looks at the device information independently and consequently assumes that it has all the DSP blocks in the device available for use. This can result in over-allocation of DSP blocks in the design, which means that the total number of DSP blocks used by all the partitions is greater than the number of DSP blocks available in the device. This can eventually lead to a no-fit error during the fitting process.

To avoid this, Altera recommends that you set the **Maximum DSP Block Usage** assignment on each partition to manually limit the number of DSP blocks used. You can set this assignment on a partition using the Assignment Editor by selecting the **Maximum DSP Block Usage** assignment, and setting it on the root of a partition. Set any positive integer as the value of this assignment. If this assignment is set on a name other than a partition root, the Quartus II integrated synthesis gives an error.

The **Maximum DSP Block Usage** assignment is available only for supported device families. Refer to the Quartus II Help for a list of the devices.

For more information about using the Assignment Editor, refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook.*

You can also set this assignment globally as a project-wide option by performing the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Analysis & Synthesis Settings**. The **Analysis & Synthesis Settings** page appears.
3. Click **More Settings**. The **More Analysis & Synthesis Settings** dialog box appears.
4. From the pull-down menu, point to **Maximum DSP Block Usage**, and from the **Settings** pull-down menu, select your desired value.

The partition-specific assignment overrides the global assignment, if any. However, each partition that does not have a partition-specific **Maximum DSP Block Usage** assignment limits the number of the DSP blocks to the value set by the global assignment. This can also lead to over-allocation of DSP blocks. Therefore, Altera recommends that you always set this assignment on each partition when you use the incremental compilation.

Manually limiting the DSP blocks usage is also useful for HardCopy II device migration, where the number of DSP blocks that can be implemented in a HardCopy II device is more than the number of DSP blocks that can be implemented in its equivalent Stratix II device.

In Quartus II software version 8.1 and later, the floorplan aware synthesis feature enables you to use LogicLock regions to define resource allocation for DSPs and RAMs before setting the maximum resource allocation assignment.

For more information about using LogicLock regions to create a floorplan for incremental compilation, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*, or refer to the Quartus II Help.

Altera recommends that you always use LogicLock assignments first before setting the maximum resource allocation assignments per partition. However, this recommendation might not affect the resource balancing if you manually assign nodes in a partition to different LogicLock regions and if there are some unassigned nodes which fall in the root LogicLock region where nodes are often from more than one partition. Thus, you can move the unassigned nodes to the defined LogicLock regions in the respective partitions and use the floorplan aware synthesis feature for better DSP and RAM balancing.

The floorplan aware synthesis feature is turned on by default. If you do not want the software to consider the LogicLock floorplan constraints when performing DSP and RAM balancing, you can turn off the floorplan aware synthesis feature. Set the **Use LogicLock Constraints During Resource Balancing** option to **Off** in the **Analysis & Synthesis Settings** page by clicking **More Settings**.

DSP balancing converts extra DSP blocks in the design into equivalent logic to meet Fitter requirements where the number of DSP blocks in design is less than or equal to the number of DSP blocks available. RAM balancing converts RAMs from one RAM type to another to meet Fitter requirements where the RAM block utilization of each RAM type is within limits of the available blocks for each RAM type. The floorplan aware synthesis option also allows you to specify maximum resources for different RAM types, such as **Maximum Number of M4K/M9K Memory Blocks**, **Maximum Number of M512 Memory Blocks**, or **Maximum Number of M-RAM/M144K Memory Blocks**.

You can specify the maximum DSP and RAM resource allocation by performing the following steps:

1. On the Assignment menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Analysis & Synthesis Settings**. The **Analysis & Synthesis Settings** page appears.
3. Click **More Settings**. The **More Settings** dialog box appears.
4. Under **Option**, in the **Name** list, select **Maximum DSP Block Usage** or **Maximum Number** <*block type*> **Memory Blocks** and specify the resource count in the **Setting** list.
5. Click **OK**.
6. Click **OK**.

HardCopy II devices have limited RAM blocks and there is no assignment to limit the RAM blocks usage in the HardCopy II device migration. Thus, Altera recommends that the maximum resource options are set to the default value of **-1 (UNLIMITED)** for the migration flow.

You can view the DSP and RAM block usage after balancing from the Compilation Report.

Restructure Multiplexers

This option specifies whether the Quartus II software should extract and optimize buses of multiplexers during synthesis.

This option is useful if your design contains buses of fragmented multiplexers. This option restructures multiplexers more efficiently for area, allowing the design to implement multiplexers with a reduced number of LEs or ALMs. This option is available for the following device families: Arria GX, Stratix series, Cyclone series, HardCopy II, and MAX II.

The **Restructure Multiplexers** option works on entire trees of multiplexers. Multiplexers may arise in different parts of the design through Verilog HDL or VHDL constructs such as the "`if`," "`case`," or "`?:`" statements. When multiplexers from one part of the design feed multiplexers in another part of the design, trees of multiplexers are formed. Multiplexer buses occur most often as a result of multiplexing together vectors in Verilog HDL, or `STD_LOGIC_VECTOR` signals in VHDL. The **Restructure Multiplexers** option identifies buses of multiplexer trees that have a similar structure. When it is turned on, the **Restructure Multiplexers** option optimizes the structure of each multiplexer bus for the target device to reduce the overall amount of logic used in the design.

Results of the multiplexer optimizations are design dependent, but area reductions as high as 20% are possible. The option can negatively affect your design's f_{MAX}.

Table 9–3 lists the settings for the logic option, which you can apply only to a design entity individual node, or to an entity that is a design partition. Beginning in Quartus II version 9.0, this option is only valid when set on an entity that is a design partition. You can also specify this option on the **Analysis & Synthesis Settings** page in the **Settings** dialog box for your whole project by clicking **More Settings** and setting the option value.

Table 9–3. Restructure Multiplexer Settings

Setting	Description
On	Enables multiplexer restructuring to minimize your design area. This setting can reduce the f_{MAX}.
Off	Disables multiplexer restructuring to avoid possible reductions in f_{MAX}.
Auto (Default)	Allows the compiler to determine whether to enable the option based on your other Quartus II synthesis settings. The option is **On** when the **Optimization Technique** option is set to **Area**, **Balanced**, or **Speed**. When the **Optimization Technique** option is set to **Speed**, Quartus II integrated synthesis attempts to restructure the multiplexers selectively and makes a good trade-off between area and f_{MAX}.

After you have compiled your design, you can view multiplexer restructuring information in the **Multiplexer Restructuring Statistics** report in the **Multiplexer Statistics** folder under **Analysis & Synthesis Optimization Results** in the **Analysis & Synthesis** section of the Compilation Report. Table 9–4 describes the information that is listed in the **Multiplexer Restructuring Statistics** report table for each bus of multiplexers.

Table 9–4. Multiplexer Information in the Multiplexer Restructuring Statistics Report

Heading	Description
Multiplexer Inputs	The number of different choices that are multiplexed together.
Bus Width	The width of the bus in bits.
Baseline Area	An estimate of how many logic cells are required to implement the bus of multiplexers (before any multiplexer restructuring takes place). This estimate can be used to identify any large multiplexers in the design.
Area if Restructured	An estimate of how many logic cells are required to implement the bus of multiplexers if **Multiplexer Restructuring** is applied.
Saving if Restructured	An estimate of how many logic cells are saved if **Multiplexer Restructuring** is applied.
Registered	An indication of whether registers are present on the multiplexer outputs. **Multiplexer Restructuring** uses the secondary control signals of a register (such as synchronous clear and synchronous load) to further reduce the amount of logic required to implement the bus of multiplexers.
Example Multiplexer Output	The name of one of the multiplexers' outputs. This name can help determine where in the design the multiplexer bus originated.

For more information about optimizing for multiplexers, refer to the *Multiplexers* section of the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

Synthesis Effort

This option specifies the overall synthesis effort level in the Quartus II software. The level can be either **Fast** or **Auto**.

Auto is the default, which means synthesis goes through the normal flow and tries to optimize your design as much as possible.

When the effort level is set to **Fast**, Quartus II integrated synthesis skips a number of steps to make synthesis run much faster (at the cost of performance and resource utilization). This option is especially useful if you perform an early timing estimate. The early timing estimate feature gives you preliminary timing estimates before running a full compilation, which results in a quicker iteration time; therefore, you can save significant compilation time to get a good estimation of the final timing of your design.

Altera recommends using the **Fast** synthesis effort level with the Fitter early timing estimate feature. When the **Fast** synthesis effort level is used with the full Fitter, the Fitter runtime might increase because fast synthesis produces a netlist that is slightly harder for the Fitter to route as compared to the netlist from a normal synthesis.

To set the **Synthesis Effort** option from the Quartus II GUI, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.

2. Under **Category**, click **Analysis & Synthesis Settings**. The **Analysis & Synthesis Settings** page appears.
3. Click **More Settings**.
4. Next to **Name**, from the pull-down menu, select **Synthesis Effort**.
5. Next to **Setting**, from the pull-down menu, select **Auto** or **Fast**. Click **OK**.
6. Click **OK** to close the **Settings** dialog box.

To set the **Synthesis Effort** option at the command line, use the `--effort` option, as shown in Example 9–27.

Example 9–27. Command Syntax for Specifying Synthesis Effort Option

```
quartus_map <Design name> --effort= "auto | fast"
```

If you want to run fast synthesis with the Fitter **Early Timing Estimate** option, use the command shown in Example 9–28. This command runs the full flow with Timing Analysis.

Example 9–28. Command Syntax for running fast synthesis with Early Timing Estimate Option

```
quartus_sh --flow early_timing_estimate_with_synthesis <Design name>
```

You can also run this flow from the Tasks pane in the Quartus II software. Select and expand **Compile Design**, then **Analysis & Synthesis**. Double-click **Early Timing Estimate** to start the flow.

State Machine Processing

This logic option specifies the processing style used to compile a state machine. Table 9–5 lists the settings for this logic option, which you can apply to a state machine name or to a design entity containing a state machine. You can also set this option for your whole project on the **Analysis & Synthesis Settings** page in the **Settings** dialog box.

Table 9–5. State Machine Processing Settings

Setting	Description
Auto (Default)	Allows the compiler to choose what it determines to be the best encoding for the state machine
Minimal Bits	Uses the least number of bits to encode the state machine
One-Hot	Encodes the state machine in the one-hot style. See the example below for details.
User-Encoded	Encodes the state machine in the manner specified by the user
Sequential	Uses a binary encoding in which the first enumeration literal in the Enumeration Type has encoding `0`, the second `1`, and so on.
Gray	Uses an encoding in which the encodings for adjacent enumeration literals differ by exactly one bit. An N-bit gray code can represent 2^N values.
Johnson	Uses an encoding similar to a gray code, in which each state only has one bit different from its neighboring states. Each state is generated by shifting the previous state's bits to the right by 1; the most significant bit of each state is the negation of the least significant bit of the previous state. An N-bit Johnson code can represent at most 2N states but requires less logic than a gray encoding.

The default state machine encoding, which is **Auto**, uses one-hot encoding for FPGA devices and minimal-bits encoding for CPLDs. These settings achieve the best results on average, but another encoding style might be more appropriate for your design, so this option allows you to control the state machine encoding.

For guidelines to ensure that your state machine is inferred and encoded correctly, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

For one-hot encoding, the Quartus II software does not guarantee that each state has one bit set to one and all other bits to zero. Quartus II integrated synthesis creates one-hot register encoding by using standard one-hot encoding and then inverting the first bit. This results in an initial state with all zero values, and the remaining states have two 1 values. Quartus II integrated synthesis encodes the initial state with all zeros for the state machine power-up because all device registers power up to a low value. This encoding has the same properties as true one-hot encoding: each state can be recognized by the value of one bit. For example, in a one-hot-encoded state machine with five states including an initial or reset state, the software uses the following register encoding:

```
State 0     0 0 0 0 0
State 1     0 0 0 1 1
State 2     0 0 1 0 1
State 3     0 1 0 0 1
State 4     1 0 0 0 1
```

If the **State Machine Processing** logic option is set to **User-Encoded** in a Verilog HDL design, the software starts with the original design values for the state constants. For example, a Verilog HDL design can contain a declaration such as the following example:

```
parameter S0 = 4'b1010, S1 = 4'b0101, ...
```

If the software infers states `S0, S1,...` it uses the encoding `4'b1010, 4'b0101,...`. If necessary, the software inverts bits in a user-encoded state machine to ensure that all bits of the reset state of the state machine are zero.

To assign your own state encoding with the **User-Encoded** setting of the **State Machine Processing** option in a VHDL design, you must apply specific binary encoding to the elements of an enumerated type because enumeration literals have no numeric values in VHDL. Use the `syn_encoding` synthesis attribute to apply your encoding values. Refer to "Manually Specifying State Assignments Using the syn_encoding Attribute" for more information.

For information about the **Safe State Machine** option, refer to "Safe State Machines" on page 9–41.

Manually Specifying State Assignments Using the syn_encoding Attribute

The Quartus II software infers state machines from enumerated types and automatically assigns state encoding based on "State Machine Processing" on page 9–36. With this logic option, you can choose the value **User-Encoded** to use the encoding from your HDL code. However, in standard VHDL code, you cannot specify user encoding in the state machine description because enumeration literals have no numeric values in VHDL.

To assign your own state encoding for the **User-Encoded State Machine Processing** setting, use the `syn_encoding` synthesis attribute to apply specific binary encodings to the elements of an enumerated type or to specify an encoding style. The Quartus II software can implement Enumeration Types with the different encoding styles shown in Table 9–6.

Table 9–6. syn_encoding Attribute Values

Attribute Value	Description
"default"	Use an encoding based on the number of enumeration literals in the Enumeration Type. If there are fewer than five literals, use the "sequential" encoding. If there are more than five but fewer than 50 literals, use a "one-hot" encoding. Otherwise, use a "gray" encoding.
"sequential"	Use a binary encoding in which the first enumeration literal in the Enumeration Type has encoding 0, the second 1, and so on.
"gray"	Use an encoding in which the encodings for adjacent enumeration literals differ by exactly one bit. An N-bit gray code can represent 2^N values.
"johnson"	Use an encoding similar to a gray code. An N-bit Johnson code can represent at most 2N states but requires less logic than a gray encoding.
"one-hot"	The default encoding style requiring N bits, where N is the number of enumeration literals in the Enumeration Type.
"compact"	Use an encoding with the fewest bits.

The `syn_encoding` attribute must follow the enumeration type definition but precede its use.

In Example 9–29, the `syn_encoding` attribute associates a binary encoding with the states in the enumerated type `count_state`. In this example, the states are encoded with the following values: zero = "11", one = "01", two = "10", three = "00".

Example 9–29. Specifying User-Encoded States with the syn_encoding Attribute in VHDL

```
ARCHITECTURE rtl OF my_fsm IS
   TYPE count_state is (zero, one, two, three);
   ATTRIBUTE syn_encoding : STRING;
   ATTRIBUTE syn_encoding OF count_state : TYPE IS "11 01 10 00";
   SIGNAL present_state, next_state : count_state;
BEGIN
```

You can also use the `syn_encoding` attribute in Verilog HDL to direct the synthesis tool to use the encoding from your HDL code, instead of using the **State Machine Processing** option.

The `syn_encoding` value "user" instructs the Quartus II software to encode each state with its corresponding value from the Verilog HDL source code. By changing the values of your state constants, you can change the encoding of your state machine.

Example 9–30. Specifying User-Encoded States with the syn_encoding Attribute in Verilog-2001

```
(* syn_encoding = "user" *) reg [1:0] state;
parameter init = 0, last = 3, next = 1, later = 2;
always @ (state) begin
case (state)
init:
out = 2'b01;
next:
out = 2'b10;
later:
out = 2'b11;
last:
out = 2'b00;
endcase
end
```

In Example 9–30, the states are encoded as follows:

```
init = "00"
last = "11"
next = "01"
later = "10"
```

Without the `syn_encoding` attribute, the Quartus II software would encode the state machine based on the current value of the **State Machine Processing** logic option.

If you are also specifying a safe state machine (as described in "Safe State Machines" on page 9–41), separate the encoding style value in the quotation marks with the safe value with a comma, as follows: "`safe, one-hot`" or "`safe, gray`".

Manually Specifying Enumerated Types Using the enum_encoding Attribute

By default, the Quartus II software one-hot encodes all user-defined Enumerated Types. With the `enum_encoding` attribute, you can specify the logic encoding for an Enumerated Type and override the default `one-hot` encoding to improve the logic efficiency.

If an Enumerated Type represents the states of a state machine, using the `enum_encoding` attribute to specify a manual state encoding prevents the compiler from recognizing state machines based on the Enumerated Type. Instead, the compiler processes these state machines as "regular" logic using the encoding specified by the attribute, and they are not listed as state machines in the Report window for the project. If you want to control the encoding for a recognized state machine, use the **State Machine Processing** logic option and the `syn_encoding` synthesis attribute.

To use the `enum_encoding` attribute in a VHDL design file, associate the attribute with the Enumeration Type whose encoding you want to control. The `enum_encoding` attribute must follow the Enumeration Type Definition but precede its use. In addition, the attribute value must be a string literal that specifies either an arbitrary user encoding or an encoding style of `"default"`, `"sequential"`, `"gray"`, `"johnson"`, or `"one-hot"`.

An arbitrary user encoding consists of a space-delimited list of encodings. The list must contain as many encodings as there are enumeration literals in your Enumeration Type. In addition, the encodings must all have the same length, and each encoding must consist solely of values from the `std_ulogic` type declared by the `std_logic_1164` package in the **IEEE** library. In the code fragment of Example 9–31, the `enum_encoding` attribute specifies an arbitrary user encoding for the Enumeration Type `fruit`.

Example 9–31. Specifying an Arbitrary User Encoding for Enumerated Type

```
type fruit is (apple, orange, pear, mango);
attribute enum_encoding : string;
attribute enum_encoding of fruit : type is "11 01 10 00";
```

In this example, the enumeration literals are encoded as:

```
apple   = "11"
orange  = "01"
pear    = "10"
mango   = "00"
```

You might want to specify an encoding style, rather than a manual user encoding, especially when the Enumeration Type has a large number of enumeration literals. The Quartus II software can implement Enumeration Types with the different encoding styles shown in Table 9–7.

Table 9–7. enum_encoding Attribute Values

Attribute Value	Description
`"default"`	Use an encoding based on the number of enumeration literals in the Enumeration Type. If there are fewer than five literals, use the `"sequential"` encoding. If there are more than five but fewer than 50 literals, use a `"one-hot"` encoding. Otherwise, use a `"gray"` encoding.
`"sequential"`	Use a binary encoding in which the first enumeration literal in the Enumeration Type has encoding `0`, the second `1`, and so on.
`"gray"`	Use an encoding in which the encodings for adjacent enumeration literals differ by exactly one bit. An N-bit gray code can represent 2^N values.
`"johnson"`	Use an encoding similar to a gray code. An N-bit Johnson code can represent at most 2^N states but requires less logic than a gray encoding.
`"one-hot"`	The default encoding style requiring *N* bits, where *N* is the number of enumeration literals in the Enumeration Type.

Observe that in Example 9–31, the `enum_encoding` attribute manually specified a gray encoding for the Enumeration Type `fruit`. This example could be written more concisely by specifying the `"gray"` encoding style instead of a manual encoding, as shown in Example 9–32.

Example 9–32. Specifying the “gray” Encoding Style or Enumeration Type

```
type fruit is (apple, orange, pear, mango);
attribute enum_encoding : string;
attribute enum_encoding of fruit : type is "gray";
```

Safe State Machines

The **Safe State Machine** option and corresponding `syn_encoding` attribute value `safe` specify that the software should insert extra logic to detect an illegal state and force the state machine's transition to the reset state.

It is possible for a finite state machine to enter an illegal state—meaning the state registers contain a value that does not correspond to any defined state. By default, the behavior of the state machine that enters an illegal state is undefined. However, you can set the `syn_encoding` attribute to `safe` or use the **Safe State Machine** logic option if you want the state machine to recover deterministically from an illegal state. Use this option if you have asynchronous inputs to your state machine. The most common cause of this situation is a state machine that has control inputs that come from another clock domain, such as the control logic for a clock-crossing FIFO, because the state machine must have inputs from another clock domain. An alternative is to add synchronizer registers to the inputs.

The `safe` state machine value does not use any user-defined default logic from your HDL code that corresponds to unreachable states. Verilog HDL and VHDL allow you to explicitly specify a behavior for all states in the state machine, including unreachable states. However, synthesis tools detect if state machine logic is unreachable and minimize or remove the logic. Any flag signals or logic used in the design to indicate such an illegal state are also removed. If the state machine is implemented as safe, the recovery logic forces its transition from an illegal state to the reset state.

The **Safe State Machine** option can be set globally, or on individual state machines. To set this option, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Analysis & Synthesis Settings**. The **Analysis & Synthesis Settings** page appears.
3. Click **More Settings**. The **More Analysis & Synthesis Settings** dialog box appears.
4. In the **Existing option settings** list, select **Safe State Machine**.
5. Under **Option**, in the **Setting** list, select **On**.
6. Click **OK**.
7. Click **OK** to close the **Settings** dialog box.

You can also use the Assignment Editor to turn on the **Safe State Machine** option for specific state machines.

You can set the `syn_encoding` `safe` attribute on a state machine in HDL, as shown in Example 9–33 through Example 9–35.

Example 9–33. Verilog HDL Code: a Safe State Machine Attribute

```
reg [2:0] my_fsm /* synthesis syn_encoding = "safe" */;
```

Example 9–34. Verilog-2001 Code: a Safe State Machine Attribute

```
(* syn_encoding = "safe" *) reg [2:0] my_fsm;
```

Example 9–35. VHDL Code: a Safe State Machine Attribute

```
ATTRIBUTE syn_encoding OF my_fsm : TYPE IS "safe";
```

If you are also specifying an encoding style (as described in "Manually Specifying State Assignments Using the syn_encoding Attribute" on page 9–37), separate the encoding style value in the quotation marks with the `safe` value with a comma, as follows: `"safe, one-hot"` or `"safe, gray"`.

Safe state machine implementation can result in a noticeable area increase for the design. Therefore, Altera recommends that you set this option only on the critical state machines in the design where the safe mode is required, such as a state machine that uses inputs from asynchronous clock domains. You can also reduce the necessity of this option by correctly synchronizing inputs coming from other clock domains.

If the `safe` state machine assignment is made on an instance that is not recognized as a state machine, or an entity that contains a state machine, the software takes no action. You must restructure the code so that the instance is recognized and properly inferred as a state machine.

For guidelines to ensure that your state machine is inferred correctly, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

Power-Up Level

This logic option causes a register (flipflop) to power up with the specified logic level, either **High** (1) or **Low** (0). Registers in the device core hardware power up to 0 in all Altera devices. For the register to power up with a logic level High specified using this option, the compiler performs an optimization referred to as NOT-gate push back on the register. NOT-gate push back adds an inverter to the input and the output of the register so that the reset and power-up conditions appear to be high and the device operates as expected. The register itself still powers up low, but the register output is inverted so the signal arriving at all destinations is high. This option is available for all Altera devices supported by the Quartus II software except MAX® 3000A and MAX 7000S devices.

The **Power-Up Level** option supports wildcard characters, and you can apply this option to any register, registered logic cell WYSIWYG primitive, or to a design entity containing registers if you want to set the power level for all registers in the design entity. If this option is assigned to a registered logic cell WYSIWYG primitive, such as an atom primitive from a third-party synthesis tool, you must turn on the **Perform WYSIWYG Primitive Resynthesis** logic option for it to take effect. You can also apply the option to a pin with the logic configurations described in the following list:

- If this option is turned on for an input pin, the option is transferred automatically to the register that is driven by the pin if the following conditions are present:
  - There is no logic, other than inversion, between the pin and the register
  - The input pin drives the data input of the register
  - The input pin does not fan-out to any other logic

- If this option is turned on for an output or bidirectional pin, it is transferred automatically to the register that feeds the pin, if the following conditions are present:
  - There is no logic, other than inversion, between the register and the pin
  - The register does not fan-out to any other logic

Inferred Power-Up Levels

Quartus II integrated synthesis reads default values for registered signals defined in Verilog HDL and VHDL code, and converts the default values into Power-Up Level settings. The software also synthesizes variables that are assigned values in Verilog HDL initial blocks into power-up conditions. Synthesis of these default and initial constructs enables the design's synthesized behavior to match, as closely as possible, the power-up state of the HDL code during a functional simulation.

For example, the following register declarations all set a power-up level of V_{CC} or a logic value "1":

```
signal q : std_logic = '1';  -- power-up to VCC

reg q = 1'b1;  // power-up to VCC

reg q;
initial begin q = 1'b1; end  // power-up to VCC
```

For more information about NOT-gate push back, the power-up states for Altera devices, and how the power-up level is affected by set and reset control signals, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

Power-Up Don't Care

This logic option allows the compiler to optimize registers in the design that do not have a defined power-up condition. This option is turned on by default.

For example, your design might have a register with its D input tied to V_{CC}, and with no clear signal or other secondary signals. If this option is enabled, the compiler can choose for the register to power up to V_{CC}. Therefore, the output of the register is always V_{CC}. The compiler can remove the register and connect its output to V_{CC}. If you turn this option off or if you set a **Power-Up Level** assignment of **Low** for this register, the register transitions from GND to V_{CC} when the design starts up on the first clock signal. Thus, the register is not stuck at V_{CC} and cannot be removed. Similarly, if the register has a clear signal, it is not removed because after the clear is asserted, the register transitions again to GND and back to V_{CC}.

If the compiler performs a Power-Up Don't Care optimization that allows it to remove a register, it issues a message indicating it is doing so.

This project-wide option does not apply to registers that have the **Power-Up Level** logic option set to either **High** or **Low**.

Remove Duplicate Registers

If you turn on this logic option, the compiler removes registers that are identical to another register. If two registers generate the same logic, the compiler removes the second one, and the first one fans out to the second one's destinations. Also, if the deleted register has different logic option assignments, the compiler ignores them. This option is turned on by default.

Typically, you should use this option only if you want to prevent the compiler from removing duplicate registers. That is, you should use this option only with the **Off** setting. You can apply this option to an individual register or a design entity that contains registers.

Remove Redundant Logic Cells

This logic option removes redundant `LCELL` primitives or WYSIWYG cells. The option is off by default to preserve logic cells that have been used intentionally. If you turn on this option, the compiler optimizes a circuit for area and speed. You can set this option globally or apply it to individual nodes and entities. If you turn on the option at the global level, you can use the `keep` attribute or **Implement as Output of Logic Cell** logic option to preserve specific wire signals or nodes (refer to "Keep Combinational Node/Implement as Output of Logic Cell" on page 9–46).

Preserve Registers

This attribute and logic option directs the compiler not to minimize or remove a specified register during synthesis optimizations or register netlist optimizations. Optimizations can eliminate redundant registers and registers with constant drivers; this option prevents a register from being reduced to a constant or merged with a duplicate register. This option can preserve a register so you can observe it during simulation or with the SignalTap II Embedded Logic Analyzer. Additionally, it can preserve registers if you are creating a preliminary version of the design in which secondary signals are not specified. You can also use the attribute to preserve a duplicate of an I/O register so that one copy can be placed in an I/O cell and the second can be placed in the core. By default, the software might remove one of the two duplicate registers. In this case, the `preserve` attribute can be added to both registers to prevent this.

This option cannot preserve registers that have no fan-out. To prevent the removal of registers with no fan-out, refer to "Noprune Synthesis Attribute/Preserve Fan-out Free Register Node" on page 9–46.

The **Preserve Registers** option prevents a register from being inferred as a state machine.

You can set the **Preserve Registers** logic option in the Quartus II GUI or you can set the `preserve` attribute in your HDL code, as shown in Example 9–36 through Example 9–38. In these examples, the `my_reg` register is preserved.

In addition to `preserve`, the Quartus II software supports the `syn_preserve` attribute name for compatibility with other synthesis tools.

Example 9–36. Verilog HDL Code: syn_preserve Attribute

```
reg my_reg /* synthesis syn_preserve = 1 */;
```

Example 9–37. Verilog-2001 Code: syn_preserve Attribute

```
(* syn_preserve = 1 *) reg my_reg;
```

The `= 1` after the `preserve` in Example 9–36 and Example 9–37 is optional, because the assignment uses a default value of `1` when it is specified.

Example 9–38. VHDL Code: preserve Attribute

```
signal my_reg : stdlogic;
attribute preserve : boolean;
attribute preserve of my_reg : signal is true;
```

Disable Register Merging/Don't Merge Register

This logic option and attribute prevents the specified register from being merged with other registers and prevents other registers from being merged with the specified register. When applied to a design entity, it applies to all registers in the entity.

You can use this option to instruct the compiler to correctly use your timing constraints for the register during synthesis. For example, if the register has a multicycle constraint, this option prevents the compiler from merging other registers into the specified register, avoiding unintended timing effects and functional differences.

This option differs from the **Preserve Register** option because it does not prevent a register with constant drivers or a redundant register from being removed. In addition, this option prevents other registers from merging with the specified register.

You can set the **Disable Register Merging** logic option in the Quartus II GUI, or you can set the `dont_merge` attribute in your HDL code, as shown in Example 9–39 through Example 9–41. In these examples, the `my_reg` register is prevented from merges.

Example 9–39. Verilog HDL Code: dont_merge Attribute

```
reg my_reg /* synthesis dont_merge */;
```

Example 9–40. Verilog-2001 Code: dont_merge Attribute

```
(* dont_merge *) reg my_reg;
```

Example 9–41. VHDL Code: dont_merge Attribute

```
signal my_reg : stdlogic;
attribute dont_merge : boolean;
attribute dont_merge of my_reg : signal is true;
```

Noprune Synthesis Attribute/Preserve Fan-out Free Register Node

This synthesis attribute and corresponding logic option direct the compiler to preserve a fan-out-free register through the entire compilation flow. This is different from the **Preserve Registers** option, which prevents a register from being reduced to a constant or merged with a duplicate register. Standard synthesis optimizations remove nodes that do not directly or indirectly feed a top-level output pin. This option can retain a register so you can observe it in the Simulator or the SignalTap II Embedded Logic Analyzer. Additionally, it can retain registers if you are creating a preliminary version of the design in which the registers' fan-out logic is not specified. This option is supported for inferred registers in the Arria GX, Stratix series, Cyclone series, and MAX II device families.

You can set the **Preserve Fan-out Free Register Node** logic option in the Quartus II GUI, or you can set the `noprune` attribute in your HDL code, as shown in Example 9–42 though Example 9–44. In these examples, the `my_reg` register is preserved.

You must use the `noprune` attribute instead of the logic option if the register has no immediate fan-out in its module or entity. If you do not use the synthesis attribute, registers with no fan-out are removed (or "pruned") during Analysis and Elaboration before the logic synthesis stage applies any logic options. If the register has no fan-out in the full design, but has fan-out within its module or entity, you can use the logic option to retain the register through compilation.

The attribute name `syn_noprune` is supported for compatibility with other synthesis tools.

Example 9–42. Verilog HDL Code: syn_noprune Attribute

```
reg my_reg /* synthesis syn_noprune */;
```

Example 9–43. Verilog-2001 Code: noprune Attribute

```
(* noprune *) reg my_reg;
```

Example 9–44. VHDL Code: noprune Attribute

```
signal my_reg : stdlogic;
attribute noprune: boolean;
attribute noprune of my_reg : signal is true;
```

Keep Combinational Node/Implement as Output of Logic Cell

This synthesis attribute and corresponding logic option direct the compiler to keep a wire or combinational node through logic synthesis minimizations and netlist optimizations. A wire that has a `keep` attribute or a node that has the **Implement as Output of Logic Cell** logic option applied becomes the output of a logic cell in the final synthesis netlist, and the name of the logic cell will be the same as the name of the wire or node. You can use this directive to make combinational nodes visible to the SignalTap II Embedded Logic Analyzer.

The option cannot keep nodes that have no fan-out. Node names cannot be maintained for wires with tri-state drivers, or if the signal feeds a top-level pin of the same name (in this case, the node name is changed to a name such as <*net name*>`~buf0`).

You can set the **Implement as Output of Logic Cell** logic option in the Quartus II GUI, or you can set the `keep` attribute in your HDL code, as shown in Example 9–45 through Example 9–47. In these examples, the compiler maintains the node name `my_wire`.

In addition to `keep`, the Quartus II software supports the `syn_keep` attribute name for compatibility with other synthesis tools.

Example 9–45. Verilog HDL Code: keep Attribute

```
wire my_wire /* synthesis keep = 1 */;
```

Example 9–46. Verilog-2001 Code: keep Attribute

```
(* keep = 1 *) wire my_wire;
```

Example 9–47. VHDL Code: syn_keep Attribute

```
signal my_wire: bit;
attribute syn_keep: boolean;
attribute syn_keep of my_wire: signal is true;
```

Don't Retime, Disabling Synthesis Netlist Optimizations

This attribute disables synthesis retiming optimizations on the specified register. When applied to a design entity, it applies to all registers in the entity.

You can use this option to turn off retiming optimizations and prevent node name changes so that the compiler can correctly use your timing constraints for the register.

You can set the **Netlist Optimizations** logic option to **Never Allow** in the Quartus II GUI to disable retiming along with other synthesis netlist optimizations, or you can set the `dont_retime` attribute in your HDL code, as shown in Example 9–48 through Example 9–50. In these examples, the `my_reg` register is prevented from being retimed.

Example 9–48. Verilog HDL Code: dont_retime Attribute

```
reg my_reg /* synthesis dont_retime */;
```

Example 9–49. Verilog-2001 Code: dont_retime Attribute

```
(* dont_retime *) reg my_reg;
```

Example 9–50. VHDL Code: dont_retime Attribute

```
signal my_reg : std_logic;
attribute dont_retime : boolean;
attribute dont_retime of my_reg : signal is true;
```

For compatibility with third-party synthesis tools, Quartus II integrated synthesis also supports the attribute `syn_allow_retiming`. To disable retiming, set `syn_allow_retiming` to `0` (Verilog HDL) or `false` (VHDL). This attribute does not have any effect when set to `1` or `true`.

Don't Replicate, Disabling Synthesis Netlist Optimizations

This attribute disables synthesis replication optimizations on the specified register. When applied to a design entity, it applies to all registers in the entity.

You can use this option to turn off register replication (or duplication) optimizations so that the compiler can use your timing constraints for the register.

You can set the **Netlist Optimizations** logic option to **Never Allow** in the Quartus II GUI to disable replication along with other synthesis netlist optimizations, or you can set the `dont_replicate` attribute in your HDL code, as shown in Example 9–51 through Example 9–53. In these examples, the `my_reg` register is prevented from being replicated.

Example 9–51. Verilog HDL Code: dont_replicate Attribute

```
reg my_reg /* synthesis dont_replicate  */;
```

Example 9–52. Verilog-2001 Code: dont_replicate Attribute

```
(* dont_replicate *) reg my_reg;
```

Example 9–53. VHDL Code: dont_replicate Attribute

```
signal my_reg : std_logic;
attribute dont_replicate : boolean;
attribute dont_replicate of my_reg : signal is true;
```

For compatibility with third-party synthesis tools, Quartus II integrated synthesis also supports the attribute `syn_replicate`. To disable replication, set `syn_replicate` to `0` (Verilog HDL) or `false` (VHDL). This attribute does not have any effect when set to `1` or `true`.

© March 2009 Altera Corporation

Maximum Fan-Out

This attribute and logic option directs the compiler to control the number of destinations fed by a node. The compiler duplicates a node and splits its fan-out until the individual fan-out of each copy falls below the maximum fan-out restriction. You can apply this option to a register or a logic cell buffer, or to a design entity that contains these elements. You can use this option to reduce the load of critical signals, which can improve performance. You can use the option to instruct the compiler to duplicate (or replicate) a register that feeds nodes in different locations on the target device. Duplicating the register can allow the Fitter to place these new registers closer to their destination logic, minimizing routing delay.

This option is available for all devices supported in the Quartus II software except MAX 3000, MAX 7000, FLEX 10K®, and ACEX® 1K devices. To turn off the option for a given node if the option is set at a higher level of the design hierarchy, in the **Netlist Optimizations** logic option, select **Never Allow**. If not disabled by the **Netlist Optimizations** option, the maximum fan-out constraint is honored as long as the following conditions are met:

- The node is not part of a cascade, carry, or register cascade chain
- The node does not feed itself
- The node feeds other logic cells, DSP blocks, RAM blocks, and/or pins through data, address, clock enable, and so on, but not through any asynchronous control ports (such as asynchronous clear)

The software does not create duplicate nodes in these cases, either because there is no clear way to duplicate the node, or to avoid the possible situation in which small differences in timing could produce functional differences in the implementation (in the third condition above where asynchronous control signals are involved). If the constraint cannot be applied because one of these conditions is not met, the Quartus II software issues a message indicating that it ignored maximum fan-out assignment. To instruct the software not to check the node’s destinations for possible problems like the third condition, you can set the **Netlist Optimizations** logic option to **Always Allow** for a given node.

If you have enabled any of the Quartus II netlist optimizations that affect registers, add the `preserve` attribute to any registers to which you have set a `maxfan` attribute. The `preserve` attribute ensures that the registers are not affected by any of the netlist optimization algorithms, such as register retiming.

For details about netlist optimizations, refer to the *Netlist Optimizations and Physical Synthesis* chapter in volume 2 of the *Quartus II Handbook*.

You can set the **Maximum Fan-Out** logic option in the Quartus II GUI; this option supports wildcard characters. You can also set the `maxfan` attribute in your HDL code, as shown in Example 9–54 through Example 9–56. In these examples, the compiler duplicates the `clk_gen` register, so its fan-out is not greater than 50.

In addition to `maxfan`, the Quartus II software supports the `syn_maxfan` attribute name for compatibility with other synthesis tools.

Example 9–54. Verilog HDL Code: syn_maxfan Attribute

```
reg clk_gen /* synthesis syn_maxfan = 50 */;
```

Example 9–55. Verilog-2001 Code: maxfan Attribute

```
(* maxfan = 50 *) reg clk_gen;
```

Example 9–56. VHDL Code: maxfan Attribute

```
signal clk_gen : stdlogic;
attribute maxfan : signal ;
attribute maxfan of clk_gen : signal is 50;
```

Controlling Clock Enable Signals with Auto Clock Enable Replacement and direct_enable

The **Auto Clock Enable Replacement** logic option allows the software to find logic that feeds a register and move the logic to the register's clock enable input port. The option is on by default. You can set this option to **Off** for individual registers or design entities to solve fitting or performance issues with designs that have many clock enables. Turning the option off prevents the software from using the register's clock enable port. The software implements the clock enable functionality using multiplexers in logic cells.

If specific logic is not automatically moved to a clock enable input with the **Auto Clock Enable Replacement** logic option, you can instruct the software to use a direct clock enable signal. Applying the `direct_enable` attribute to a specific signal instructs the software to use the clock enable port of a register to implement the signal. The attribute ensures that the clock enable port is driven directly by the signal, and the signal is not optimized or combined with any other logic.

Example 9–57 through Example 9–59 show how to set this attribute to ensure that the signal is preserved and used directly as a clock enable.

In addition to `direct_enable`, the Quartus II software supports the `syn_direct_enable` attribute name for compatibility with other synthesis tools.

Example 9–57. Verilog HDL Code: direct_enable attribute

```
wire my_enable /* synthesis direct_enable = 1 */ ;
```

Example 9–58. Verilog-2001 Code: syn_direct_enable attribute

```
(* syn_direct_enable *) wire my_enable;
```

Example 9–59. VHDL Code: direct_enable attribute

```
attribute direct_enable: boolean;
attribute direct_enable of my_enable: signal is true;
```

Megafunction Inference Control

The Quartus II compiler automatically recognizes certain types of HDL code and infers the appropriate megafunction. The software uses the Altera megafunction code when compiling your design, even when you do not specifically instantiate the megafunction. The software infers megafunctions to take advantage of logic that is optimized for Altera devices. The area and performance of such logic can be better than the results obtained by inferring generic logic from the same HDL code.

Additionally, you must use megafunctions to access certain architecture-specific features, such as RAM, DSP blocks, and shift registers that generally provide improved performance compared with basic logic cells.

For details about coding style recommendations when targeting megafunctions in Altera devices, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

The Quartus II software provides options to control the inference of certain types of megafunctions, as described in the following subsections.

Multiply-Accumulators and Multiply-Adders

Use the **Auto DSP Block Replacement** logic option to control DSP block inference for multiply-accumulations and multiply-adders. This option is turned on by default. To disable inference, turn off this option for your whole project on the **Analysis & Synthesis Settings** page of the **Settings** dialog box, or disable the option for a specific block with the Assignment Editor.

Any registers that the software maps to the ALTMULT_ACCUM and ALTMULT_ADD megafunctions and places in DSP blocks are not available in the Simulator because their node names do not exist after synthesis.

Shift Registers

Use the **Auto Shift Register Replacement** logic option to control shift register inference. This option is turned on by default. To disable inference, turn off this option for your whole project on the **Analysis & Synthesis Settings** page of the **Settings** dialog box by clicking **More Settings** and setting the option to **Off**. You can also disable the option for a specific block with the Assignment Editor. The software might not infer small shift registers because small shift registers typically do not benefit from implementation in dedicated memory. However, you can use the **Allow Any Shift Register Size for Recognition** logic option to instruct synthesis to infer a shift register even when its size is considered too small.

The registers that the software maps to the ALTSHIFT_TAPS megafunction and places in RAM are not available in the Simulator because their node names do not exist after synthesis.

The **Auto Shift Register Replacement** logic option is turned off automatically when a formal verification tool is selected on the **EDA Tool Settings** page. The software issues a warning and lists shift registers that would have been inferred if no formal verification tool was selected in the compilation report. To allow the use of a megafunction for the shift register in the formal verification flow, you can either instantiate a shift register explicitly using the MegaWizard™ Plug-In Manager or make the shift register into a black box in a separate entity/module.

RAM and ROM

Use the **Auto RAM Replacement** and **Auto ROM Replacement** logic options to control RAM and ROM inference, respectively. These options are turned on by default. To disable inference, turn off the appropriate option for your whole project on the **Analysis & Synthesis Settings** page of the **Settings** dialog box by clicking **More Settings** and setting the option to **Off**. You can also disable the option for a specific block with the Assignment Editor.

Although inferred shift registers are implemented in RAM blocks, you cannot turn off the **Auto RAM Replacement** option to disable shift register replacement. Use the **Auto Shift Register Replacement** option (refer to “Shift Registers”).

The software might not infer very small RAM or ROM blocks because very small memory blocks can typically be implemented more efficiently by using the registers in the logic. However, you can use the **Allow Any RAM Size for Recognition** and **Allow Any ROM Size for Recognition** logic options to instruct synthesis to infer a memory block even when its size is considered too small.

The **Auto ROM Replacement** logic option is automatically turned off when a formal verification tool is selected in the **EDA Tool Settings** page. A warning is issued and a report panel lists ROMs that would have been inferred if no formal verification tool was selected. To allow the use of a megafunction for the shift register in the formal verification flow, you can either instantiate a ROM explicitly using the MegaWizard Plug-In Manager or create a black box for the ROM in a separate entity/module.

Although formal verification tools do not support inferred RAM blocks, because of the importance of inferring RAM in many designs, the **Auto RAM Replacement** logic option remains on when a formal verification tool is selected in the **EDA Tool Settings** page. The Quartus II software automatically performs black box instance for any module or entity that contains a RAM block that is inferred. The software issues a warning and lists the black box that is created in the compilation report. This block box allows formal verification tools to proceed; however, the entire module or entity containing the RAM cannot be verified in the tool. Altera recommends that you explicitly instantiate RAM blocks in separate modules or entities so that as much logic as possible can be verified by the formal verification tool.

 © March 2009 Altera Corporation

RAM to Logic Cell Conversion

The **Auto RAM to Logic Cell Conversion** option allows Quartus II integrated synthesis to convert RAM blocks that are small in size to logic cells if the logic cell implementation is deemed to give better quality of results. Only single-port or simple-dual port RAMs with no initialization files can be converted to logic cells. This option is off by default. You can set this option globally or apply it to individual RAM nodes. You can enable this option by turning on the appropriate option for your whole project in the **More Analysis & Synthesis Settings** dialog box.

For the FLEX 10K, APEX series, Arria GX, and the Stratix series of devices, the software uses the following rules to determine whether a RAM should be placed in logic cells or a dedicated RAM block:

- If the number of words is less than 16, use a RAM block if the total number of bits is greater than or equal to 64
- If the number of words is greater than or equal to 16, use a RAM block if the total number of bits is greater than or equal to 32
- Otherwise, implement the RAM in logic cells

For the Cyclone series of devices, the software uses the following rules:

- If the number of words is greater than or equal to 64, use a RAM block
- If the number of words is greater than or equal to 16 and less than 64, use a RAM block if the total number of bits is greater than or equal to 128
- Otherwise, implement the RAM in logic cells

RAM Style and ROM Style—for Inferred Memory

These attributes specify the implementation for an inferred RAM or ROM block. You can specify the type of TriMatrix embedded memory block to be used, or specify the use of standard logic cells (LEs or ALMs). The attributes are supported only for device families with TriMatrix embedded memory blocks.

The `ramstyle` and `romstyle` attributes take a single string value. The values "`M512`", "`M4K`", "`M-RAM`", "`MLAB`", "`M9K`", and "`M144K`" (as applicable for the target device family) indicate the type of memory block to use for the inferred RAM or ROM. If you set the attribute to a block type that does not exist in the target device family, the software generates a warning and ignores the assignment. The value `logic` indicates that the RAM or ROM should be implemented in regular logic rather than dedicated memory blocks. You can set the attribute on a module or entity, in which case it specifies the default implementation style for all inferred memory blocks in the immediate hierarchy. You can also set the attribute on a specific signal (VHDL) or variable (Verilog HDL) declaration, in which case it specifies the preferred implementation style for that specific memory, overriding the default implementation style.

If you specify a value of `logic`, the memory still appears as a RAM or ROM block in the RTL Viewer, but it is converted to regular logic during a later synthesis step.

In addition to `ramstyle` and `romstyle`, the Quartus II software supports the `syn_ramstyle` attribute name for compatibility with other synthesis tools.

Example 9–60 through Example 9–62 specify that all memory in the module or entity my_memory_blocks should be implemented using a specific type of block.

Example 9–60. Verilog-1995 Code: Applying a romstyle Attribute to a Module Declaration

```
module my_memory_blocks (...) /* synthesis romstyle = "M4K" */;
```

Example 9–61. Verilog-2001 Code: Applying a ramstyle Attribute to a Module Declaration

```
(* ramstyle = "M512" *) module my_memory_blocks (...);
```

Example 9–62. VHDL Code: Applying a romstyle Attribute to an Architecture

```
architecture rtl of my_ my_memory_blocks is
attribute romstyle : string;
attribute romstyle of rtl : architecture is "M-RAM";
begin
```

Example 9–63 through Example 9–65 specify that the inferred memory my_ram or my_rom should be implemented using regular logic instead of a TriMatrix memory block.

Example 9–63. Verilog-1995 Code: Applying a syn_ramstyle Attribute to a Variable Declaration

```
reg [0:7] my_ram[0:63] /* synthesis syn_ramstyle = "logic" */;
```

Example 9–64. Verilog-2001 Code: Applying a romstyle Attribute to a Variable Declaration

```
(* romstyle = "logic" *) reg [0:7] my_rom[0:63];
```

Example 9–65. VHDL Code: Applying a ramstyle Attribute to a Signal Declaration

```
type memory_t is array (0 to 63) of std_logic_vector (0 to 7);
signal my_ram : memory_t;
attribute ramstyle : string;
attribute ramstyle of my_ram : signal is "logic";
```

Turning Off Add Pass-Through Logic to Inferred RAMs/ no_rw_check Attribute Setting

Setting the no_rw_check value for the ramstyle attribute, or turning off the corresponding global **Add Pass-Through Logic to Inferred RAMs** logic option indicates that your design does not depend on the behavior of the inferred RAM when there are reads and writes to the same address in the same clock cycle. If you specify the attribute or turn off the logic option, the Quartus II software can choose a read-during-write behavior instead of using the read-during-write behavior of your HDL source code.

In some cases, an inferred RAM must be mapped into regular logic cells because it has a read-during-write behavior that is not supported by the TriMatrix memory blocks in your target device. In other cases, the Quartus II software must insert extra logic to mimic read-during-write behavior of the HDL source, increasing the area of your design and potentially reducing its performance. In these cases, you can use the

attribute to specify that the software can implement the RAM directly in a TriMatrix memory block without using logic. You can also use the attribute to prevent a warning message for dual-clock RAMs in the case that the inferred behavior in the device does not exactly match the read-during-write conditions described in the HDL code.

For more information about recommended styles for inferring RAM and some of the issues involved with different read-during-write conditions, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

To set the **Add Pass-Through Logic to Inferred RAMs** logic option through the Quartus II GUI, click **More Settings** on the **Analysis & Synthesis Settings** page of the **Settings** dialog box. Example 9–66 and Example 9–67 use two addresses and normally require extra logic after the RAM to ensure that the read-during-write conditions in the device match the HDL code. If you don't require a defined read-during-write condition in your design, this extra logic is not required. With the `no_rw_check` attribute, Quartus II integrated synthesis won't generate the extra logic.

Example 9–66. Verilog HDL Inferred RAM Using no_rw_check Attribute

```
module ram_infer (q, wa, ra, d, we, clk);
    output [7:0] q;
    input [7:0] d;
    input [6:0] wa;
    input [6:0] ra;
    input we, clk;
    reg [6:0] read_add;
    (* ramstyle = "no_rw_check" *) reg [7:0] mem [127:0];
    always @ (posedge clk) begin
        if (we)
            mem[wa] <= d;
        read_add <= ra;
    end
    assign q = mem[read_add];
endmodule
```

Example 9–67. VHDL Inferred RAM Using no_rw_check Attribute

```
LIBRARY ieee;
USE ieee.std_logic_1164.ALL;

ENTITY ram IS
    PORT (
        clock: IN STD_LOGIC;
        data: IN STD_LOGIC_VECTOR (2 DOWNTO 0);
        write_address: IN INTEGER RANGE 0 to 31;
        read_address: IN INTEGER RANGE 0 to 31;
        we: IN STD_LOGIC;
        q: OUT STD_LOGIC_VECTOR (2 DOWNTO 0));
END ram;

ARCHITECTURE rtl OF ram IS
    TYPE MEM IS ARRAY(0 TO 31) OF STD_LOGIC_VECTOR(2 DOWNTO 0);
    SIGNAL ram_block: MEM;
    ATTRIBUTE ramstyle : string;
    ATTRIBUTE ramstyle of ram_block : signal is "no_rw_check";
    SIGNAL read_address_reg: INTEGER RANGE 0 to 31;
BEGIN
    PROCESS (clock)
    BEGIN
        IF (clock'event AND clock = '1') THEN
            IF (we = '1') THEN
                ram_block(write_address) <= data;
            END IF;
            read_address_reg <= read_address;
        END IF;
    END PROCESS;
    q <= ram_block(read_address_reg);
END rtl;
```

You can use a ramstyle attribute with the MLAB value so that the Quartus II software can infer a small RAM block and place it in an MLAB.

This attribute is also useful in cases where some asynchronous RAM blocks might be coded with read-during-write behavior that does not match the Stratix III architecture. Thus, the device behavior would not exactly match the behavior described in the code. If the difference in behavior is acceptable in your design, use the ramstyle attribute with the `no_rw_check` value to specify that the software should not check the read-during-write behavior when inferring the RAM. When this attribute is set, Quartus II integrated synthesis allows the behavior of the output to be different when the asynchronous read occurs on an address that had a write on the most recent clock edge. That is, functional HDL simulation results will not match the hardware behavior if you write to an address that is being read.

To include both attributes, set the value of the ramstyle attribute to "`MLAB, no_rw_check`".

Example 9–68 and Example 9–69 show the method of setting two values to the ramstyle attribute using a small asyncronous RAM block, with the ramstyle synthesis attribute set so that the memory can be implemented in the MLAB memory block and the read-during-write behavior is not important. Without the attribute, this design requires 512 registers and 240 ALUTs. With the attribute, the design requires 8 memory ALUTs and just 15 registers.

© March 2009 Altera Corporation

Example 9–68. Verilog HDL Inferred RAM Using no_rw_check and MLAB Attributes

```
module async_ram (
    input   [5:0] addr,
    input   [7:0] data_in,
    input         clk,
    input         write,
    output  [7:0] data_out );

   (* ramstyle = "MLAB, no_rw_check" *) reg [7:0] mem[0:63];

   assign  data_out = mem[addr];

   always @ (posedge clk)
   begin
      if (write)
         mem[addr] = data_in;
   end
endmodule
```

Example 9–69. VHDL Inferred RAM Using no_rw_check and MLAB Attributes

```
LIBRARY ieee;
USE ieee.std_logic_1164.ALL;
ENTITY ram IS
   PORT (
      clock: IN STD_LOGIC;
      data: IN STD_LOGIC_VECTOR (2 DOWNTO 0);
      write_address: IN INTEGER RANGE 0 to 31;
      read_address: IN INTEGER RANGE 0 to 31;
      we: IN STD_LOGIC;
      q: OUT STD_LOGIC_VECTOR (2 DOWNTO 0));
END ram;

ARCHITECTURE rtl OF ram IS
   TYPE MEM IS ARRAY(0 TO 31) OF STD_LOGIC_VECTOR(2 DOWNTO 0);
   SIGNAL ram_block: MEM;
   ATTRIBUTE ramstyle : string;
   ATTRIBUTE ramstyle of ram_block : signal is "MLAB , no_rw_check";
   SIGNAL read_address_reg: INTEGER RANGE 0 to 31;
BEGIN
   PROCESS (clock)
   BEGIN
      IF (clock'event AND clock = '1') THEN
         IF (we = '1') THEN
            ram_block(write_address) <= data;
         END IF;
         read_address_reg <= read_address;
      END IF;
   END PROCESS;
   q <= ram_block(read_address_reg);
END rtl;
```

RAM Initialization File—for Inferred Memory

The `ram_init_file` attribute specifies the initial contents of an inferred memory in the form of a Memory Initialization File (**.mif**). The attribute takes a string value containing the name of the RAM initialization file.

Example 9–70. Verilog-1995 Code: Applying a ram_init_file Attribute

```
reg [7:0] mem[0:255] /* synthesis ram_init_file
= " my_init_file.mif" */;
```

Example 9–71. Verilog-2001 Code: Applying a ram_init_file Attribute

```
(* ram_init_file = "my_init_file.mif" *) reg [7:0] mem[0:255];
```

Example 9–72. VHDL Code: Applying a ram_init_file Attribute

```
type mem_t is array(0 to 255) of unsigned(7 downto 0);
signal ram : mem_t;
attribute ram_init_file : string;
attribute ram_init_file of ram :
signal is "my_init_file.mif";
```

In VHDL, you can also initialize the contents of an inferred memory by specifying a default value for the corresponding signal. In Verilog HDL, you can use an initial block to specify the memory contents. Quartus II integrated synthesis automatically converts the default value into a **.mif** file for the inferred RAM.

Multiplier Style—for Inferred Multipliers

The `multstyle` attribute specifies the implementation style for multiplication operations (`*`) in your HDL source code. You can use this attribute to specify whether you prefer the compiler to implement a multiplication operation in general logic or dedicated hardware, if available in the target device.

The `multstyle` attribute takes a string value of `"logic"` or `"dsp"`, indicating a preferred implementation in logic or in dedicated hardware, respectively. In Verilog HDL, apply the attribute to a module declaration, a variable declaration, or a specific binary expression containing the `*` operator. In VHDL, apply the synthesis attribute to a signal, variable, entity, or architecture.

Specifying a `multstyle` of `"dsp"` does not guarantee that the Quartus II software can implement a multiplication in dedicated DSP hardware. The final implementation depends on several conditions, including the availability of dedicated hardware in the target device, the size of the operands, and whether or not one or both operands are constant.

In addition to `multstyle`, the Quartus II software supports the `syn_multstyle` attribute name for compatibility with other synthesis tools.

When applied to a Verilog HDL module declaration, the attribute specifies the default implementation style for all instances of the `*` operator in the module. For example, in the following code examples, the multstyle attribute directs the Quartus II software to implement all multiplications inside module `my_module` in dedicated multiplication hardware.

Example 9–73. Verilog-1995 Code: Applying a multstyle Attribute to a Module Declaration

```
module my_module (...) /* synthesis multstyle = "dsp" */;
```

Example 9–74. Verilog-2001 Code: Applying a multstyle Attribute to a Module Declaration

```
(* multstyle = "dsp" *) module my_module(...);
```

When applied to a Verilog HDL variable declaration, the attribute specifies the implementation style to be used for a multiplication operator whose result is directly assigned to the variable. It overrides the `multstyle` attribute associated with the enclosing module, if present. In Example 9–75 and Example 9–76, the `multstyle` attribute applied to variable `result` directs the Quartus II software to implement `a * b` in general logic rather than dedicated hardware.

Example 9–75. Verilog-2001 Code: Applying a multstyle Attribute to a Variable Declaration

```
wire [8:0] a, b;
(* multstyle = "logic" *) wire [17:0] result;
assign result = a * b;  //Multiplication must be
                        //directly assigned to result
```

Example 9–76. Verilog-1995 Code: Applying a multstyle Attribute to a Variable Declaration

```
wire [8:0] a, b;
wire [17:0] result /* synthesis multstyle = "logic" */;
assign result = a * b;  //Multiplication must be
                        //directly assigned to result
```

When applied directly to a binary expression containing the `*` operator, the attribute specifies the implementation style for that specific operator alone and overrides any `multstyle` attribute associated with the target variable or enclosing module. In Example 9–77, the `multstyle` attribute indicates that `a * b` should be implemented in dedicated hardware.

Example 9–77. Verilog-2001 Code: Applying a multstyle Attribute to a Binary Expression

```
wire [8:0] a, b;
wire [17:0] result;
assign result = a * (* multstyle = "dsp" *) b;
```

You cannot use Verilog-1995 attribute syntax to apply the `multstyle` attribute to a binary expression.

When applied to a VHDL entity or architecture, the attribute specifies the default implementation style for all instances of the `*` operator in the entity or architecture. In Example 9–78, the `multstyle` attribute directs the Quartus II software to use dedicated hardware, if possible, for all multiplications inside architecture `rtl` of entity `my_entity`.

Example 9–78. VHDL Code: Applying a multstyle Attribute to an Architecture

```
architecture rtl of my_entity is
   attribute multstyle : string;
   attribute multstyle of rtl : architecture is "dsp";
begin
```

When applied to a VHDL signal or variable, the attribute specifies the implementation style to be used for all instances of the * operator whose result is directly assigned to the signal or variable. It overrides the `multstyle` attribute associated with the enclosing entity or architecture, if present. In Example 9–79, the `multstyle` attribute associated with signal `result` directs the Quartus II software to implement `a * b` in general logic rather than dedicated hardware.

Example 9–79. VHDL Code: Applying a multstyle Attribute to a Signal or Variable

```
signal a, b : unsigned(8 downto 0);
signal result : unsigned(17 downto 0);

attribute multstyle : string;
attribute multstyle of result : signal is "logic";
result <= a * b;
```

Full Case

A Verilog HDL case statement is considered full when its case items cover all possible binary values of the case expression or when a default case statement is present. A `full_case` attribute attached to a case statement header that is not full forces the unspecified states to be treated as a "don't care" value. VHDL case statements must be full, so the attribute does not apply to VHDL.

Using this attribute on a case statement that is not full avoids the latch inference problems discussed in the *Design Recommendations for Altera Devices and the Quartus II Design Assistant* chapter in volume 1 of the *Quartus II Handbook*.

Latches have limited support in formal verification tools. It is important to ensure that you do not infer latches unintentionally; for example, through an incomplete case statement when using formal verification. Formal verification tools do support the `full_case` synthesis attribute (with limited support for attribute syntax, as described in "Synthesis Attributes" on page 9–25).

When you use the `full_case` attribute, there is a potential cause for a simulation mismatch between Verilog HDL functional and post-Quartus II simulation because unknown case statement cases can still function like latches during functional simulation. For example, a simulation mismatch can occur with the code in Example 9–80 when `sel` is `2'b11` because a functional HDL simulation output behaves like a latch while the Quartus II simulation output behaves like "don't care."

Altera recommends making the case statement "full" in your regular HDL code, instead of using the `full_case` attribute.

The case statement in Example 9–80 is not full because not all binary values for `sel` are specified. Because the `full_case` attribute is used, synthesis treats the output as "don't care" when the `sel` input is `2'b11`.

Example 9–80. Verilog HDL Code: a full_case Attribute

```
module full_case (a, sel, y);
   input [3:0] a;
   input [1:0] sel;
   output y;
   reg y;
   always @ (a or sel)
   case (sel) // synthesis full_case
      2'b00: y=a[0];
      2'b01: y=a[1];
      2'b10: y=a[2];
   endcase
endmodule
```

Verilog-2001 syntax also accepts the statements in Example 9–81 in the `case` header instead of the comment form shown in Example 9–80.

Example 9–81. Verilog-2001 Syntax for the full_case Attribute

```
(* full_case *) case (sel)
```

Parallel Case

The `parallel_case` attribute indicates that a Verilog HDL case statement should be considered parallel; that is, only one case item can be matched at a time. Case items in Verilog HDL case statements might overlap. To resolve multiple matching case items, the Verilog HDL language defines a priority relationship among case items in which the case statement always executes the first case item that matches the case expression value. By default, the Quartus II software implements the extra logic required to satisfy this priority relationship.

Attaching a `parallel_case` attribute to a case statement's header allows the Quartus II software to consider its case items as inherently parallel; that is, at most one case item matches the case expression value. Parallel case items reduce the complexity of the generated logic.

In VHDL, the individual choices in a case statement might not overlap, so they are always parallel and this attribute does not apply.

Use this attribute only when the `case` statement is truly parallel. If you use the attribute in any other situation, the generated logic will not match the functional simulation behavior of the Verilog HDL.

Altera recommends that you avoid using the `parallel_case` attribute, due to the possibility of introducing mismatches between Verilog HDL functional and post-Quartus II simulation.

If you specify SystemVerilog-2005 as the supported Verilog HDL version for your design, you can use the SystemVerilog keyword `unique` to achieve the same result as the `parallel_case` directive without causing simulation mismatches.

Example 9–82 shows a casez statement with overlapping case items. In functional HDL simulation, the three case items have a priority order that depends on the bits in sel. For example, sel[2] takes priority over sel[1], which takes priority over sel[0]. However, the synthesized design can simulate differently because the parallel_case attribute eliminates this priority order. If more than one bit of sel is high, more than one output (a, b, or c) is high as well, a situation that cannot occur in functional HDL simulation.

Example 9–82. Verilog HDL Code: a parallel_case Attribute

```
module parallel_case (sel, a, b, c);
    input [2:0] sel;
    output a, b, c;
    reg a, b, c;
    always @ (sel)
    begin
        {a, b, c} = 3'b0;
        casez (sel) // synthesis parallel_case
            3'b1??: a = 1'b1;
            3'b?1?: b = 1'b1;
            3'b??1: c = 1'b1;
        endcase
    end
endmodule
```

Verilog-2001 syntax also accepts the statements shown in Example 9–83 in the case (or casez) header instead of the comment form, as shown in Example 9–82.

Example 9–83. Verilog-2001 Syntax

```
(* parallel_case *) casez (sel)
```

Translate Off and On / Synthesis Off and On

The translate_off and translate_on synthesis directives indicate whether the Quartus II software or a third-party synthesis tool should compile a portion of HDL code that is not relevant for synthesis. The translate_off directive marks the beginning of code that the synthesis tool should ignore; the translate_on directive indicates that synthesis should resume. You can also use the synthesis_on and synthesis_off directives as a synonym for translate on and off.

A common use of these directives is to indicate a portion of code that is intended for simulation only. The synthesis tool reads synthesis-specific directives and processes them during synthesis; however, third-party simulation tools read the directives as comments and ignore them. Example 9–84 and Example 9–85 show these directives.

Example 9–84. Verilog HDL Code: Translate Off and On

```
// synthesis translate_off
parameter tpd = 2;    // Delay for simulation
#tpd;
// synthesis translate_on
```

Example 9–85. VHDL Code: Translate Off and On

```
-- synthesis translate_off
use std.textio.all;
-- synthesis translate_on
```

If you wish to ignore a portion of code in Quartus II integrated synthesis only, you can use the Altera-specific attribute keyword `altera`. For example, use the `// altera translate_off` and `// altera translate_on` directives to direct Quartus II integrated synthesis to ignore a portion of code that is intended only for other synthesis tools.

Ignore translate_off and synthesis_off Directives

The **Ignore translate_off and synthesis_off directives** logic option directs Quartus II integrated synthesis to ignore the `translate_off` and `synthesis_off` directives described in the previous section. This allows you to compile code that was previously intended to be ignored by third-party synthesis tools; for example, megafunction declarations that were treated as black boxes in other tools but can be compiled in the Quartus II software. To set the **Ignore translate_off and synthesis_off directives** logic option, click **More Settings** on the **Analysis & Synthesis Settings** page of the **Settings** dialog box.

Read Comments as HDL

The `read_comments_as_HDL` synthesis directive indicates that the Quartus II software should compile a portion of HDL code that is commented out. This directive allows you to comment out portions of HDL source code that are not relevant for simulation, while instructing the Quartus II software to read and synthesize that same source code. Setting the `read_comments_as_HDL` directive to `on` marks the beginning of commented code that the synthesis tool should read; setting the `read_comments_as_HDL` directive to `off` indicates the end of the code.

You can use this directive with `translate_off` and `translate_on` to create one HDL source file that includes both a megafunction instantiation for synthesis and a behavioral description for simulation.

Because formal verification tools do not recognize the `read_comments_as_HDL` directive, it is not supported when you are using formal verification.

In Example 9–86 and Example 9–87, the commented code enclosed by `read_comments_as_HDL` is visible to the Quartus II compiler and is synthesized.

Because synthesis directives are case-sensitive in Verilog HDL, you must match the case of the directive, as shown in the following examples.

Example 9–86. Verilog HDL Code: Read Comments as HDL

```
// synthesis read_comments_as_HDL on
// my_rom lpm_rom (.address (address),
//                  .data    (data));
// synthesis read_comments_as_HDL off
```

Example 9–87. VHDL Code: Read Comments as HDL

```
-- synthesis read_comments_as_HDL on
-- my_rom : entity lpm_rom
--   port map (
--    address => address,
--    data    => data,       );
-- synthesis read_comments_as_HDL off
```

Use I/O Flipflops

This attribute directs the Quartus II software to implement input, output, and output enable flipflops (or registers) in I/O cells that have fast, direct connections to an I/O pin, when possible. Applying the `useioff` synthesis attribute can improve I/O performance by minimizing setup, clock-to-output, and clock-to-output enable times. This synthesis attribute is supported using the **Fast Input Register**, **Fast Output Register**, and **Fast Output Enable Register** logic options that can also be set in the Assignment Editor.

For more information about which device families support fast input, output, and output enable registers, refer to the device family data sheet, device handbook, or the Quartus II Help.

The `useioff` synthesis attribute takes a Boolean value and can only be applied to the port declarations of a top-level Verilog HDL module or VHDL entity (it is ignored if applied elsewhere). Setting the value to `1` (Verilog HDL) or `TRUE` (VHDL) instructs the Quartus II software to pack registers into I/O cells. Setting the value to `0` (Verilog HDL) or `FALSE` (VHDL) prevents register packing into I/O cells.

In Example 9–88 and Example 9–89, the `useioff` synthesis attribute directs the Quartus II software to implement the registers `a_reg`, `b_reg`, and `o_reg` in the I/O cells corresponding to the ports `a`, `b`, and `o`, respectively.

Example 9–88. Verilog HDL Code: the useioff Attribute

```
module top_level(clk, a, b, o);
       input clk;
       input [1:0] a, b /* synthesis useioff = 1 */;
       output [2:0] o /* synthesis useioff = 1 */;
       reg [1:0] a_reg, b_reg;
       reg [2:0] o_reg;
       always @ (posedge clk)
       begin
           a_reg <= a;
           b_reg <= b;
           o_reg <= a_reg + b_reg;
       end
       assign o = o_reg;
endmodule
```

Verilog-2001 syntax also accepts the type of statements shown in Example 9–89 and Example 9–90 instead of the comment form shown in Example 9–88.

Example 9–89. Verilog-2001 Code: the useioff Attribute

```
(* useioff = 1 *)   input [1:0] a, b;
(* useioff = 1 *)   output [2:0] o;
```

Example 9–90. VHDL Code: the useioff Attribute

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.numeric_std.all;
entity useioff_example is
   port (
      clk  : in  std_logic;
      a, b : in  unsigned(1 downto 0);
      o    : out unsigned(1 downto 0));
   attribute useioff : boolean;
   attribute useioff of a : signal is true;
   attribute useioff of b : signal is true;
   attribute useioff of o : signal is true;
end useioff_example;
architecture rtl of useioff_example is
   signal o_reg, a_reg, b_reg : unsigned(1 downto 0);
begin
   process(clk)
   begin
      if (clk = '1' AND clk'event) then
          a_reg <= a;
          b_reg <= b;
          o_reg <= a_reg + b_reg;
      end if;
   end process;
o <= o_reg;
end rtl;
```

Specifying Pin Locations with chip_pin

This attribute enables you to assign pin locations in your HDL source. The attribute can be used only on the ports of the top-level entity or module in the design, and cannot be used to assign pin locations from entities at lower levels of the design hierarchy. You can assign pins only to single-bit or one-dimensional bus ports in your design.

For single-bit ports, the value of the `chip_pin` attribute is the name of the pin on the target device, as specified by the device's pin table.

In addition to `chip_pin`, the Quartus II software supports the `altera_chip_pin_lc` attribute name for compatibility with other synthesis tools. When using this attribute in other synthesis tools, some older device families require an "@" symbol in front of each pin assignment. In the Quartus II software, the "@" is optional.

Example 9–91 through Example 9–93 show different ways of assigning input pin `my_pin1` to Pin C1 and `my_pin2` to Pin 4 on a different target device.

Example 9–91. Verilog-1995 Code: Applying Chip Pin to a Single Pin

```
input my_pin1 /* synthesis chip_pin = "C1" */;
input my_pin2 /* synthesis altera_chip_pin_lc = "@4" */;
```

Example 9–92. Verilog-2001 Code: Applying Chip Pin to a Single Pin

```
(* chip_pin = "C1" *) input my_pin1;
(* altera_chip_pin_lc = "@4" *) input my_pin2;
```

Example 9–93. VHDL Code: Applying Chip Pin to a Single Pin

```
entity my_entity is
port(my_pin1: in std_logic; my_pin2: in std_logic;…);
end my_entity;
attribute chip_pin : string;
attribute altera_chip_pin_lc : string;
attribute chip_pin of my_pin1 : signal is "C1";
attribute altera_chip_pin_lc of my_pin2 : signal is "@4";
```

For bus I/O ports, the value of the chip pin attribute is a comma-delimited list of pin assignments. The order in which you declare the port's range determines the mapping of assignments to individual bits in the port. To leave a particular bit unassigned, simply leave its corresponding pin assignment blank.

Example 9–94 assigns `my_pin[2]` to `Pin_4`, `my_pin[1]` to `Pin_5`, and `my_pin[0]` to `Pin_6`.

Example 9–94. Verilog-1995 Code: Applying Chip Pin to a Bus of Pins

```
input [2:0]  my_pin /* synthesis chip_pin = "4, 5, 6" */;
```

Example 9–95 reverses the order of the signals in the bus, assigning `my_pin[0]` to `Pin_4` and `my_pin[2]` to `Pin_6` but leaves `my_pin[1]` unassigned.

Example 9–95. Verilog-1995 Code: Applying Chip Pin to Part of a Bus

```
input [0:2]  my_pin /* synthesis chip_pin = "4, ,6" */;
```

Example 9–96 assigns `my_pin[2]` to Pin `4` and `my_pin[0]` to Pin `6`, but leaves `my_pin[1]` unassigned.

Example 9–96. VHDL Code: Applying Chip Pin to Part of a Bus of Pins

```
entity my_entity is
port(my_pin: in std_logic_vector(2 downto 0);…);
end my_entity;

attribute chip_pin of my_pin: signal is "4, , 6";
```

Using altera_attribute to Set Quartus II Logic Options

This attribute enables you to apply Quartus II options and assignments to an object in your HDL source code. You can set this attribute on an entity, architecture, instance, register, RAM block, or I/O pin. You cannot set it on an arbitrary combinational node such as a net. With `altera_attribute`, you can control synthesis options from your HDL source even when the options lack a specific HDL synthesis attribute (such as many of the logic options presented earlier in this chapter). You can also use this attribute to pass entity-level settings and assignments to phases of the compiler flow beyond Analysis and Synthesis, such as Fitting.

Assignments or settings made through the Quartus II GUI, the **.qsf** file, or the Tcl interface take precedence over assignments or settings made with the `altera_attribute` synthesis attribute in your HDL code.

The syntax for setting this attribute in HDL is the same as the syntax for other synthesis attributes, as shown in "Synthesis Attributes" on page 9–25.

The attribute value is a single string containing a list of **.qsf** file variable assignments separated by semicolons, as shown in Example 9–97.

Example 9–97. variable Assignments Separated by Semicolons

```
-name <variable_1> <value_1>;-name <variable_2> <value_2>[;…]
```

If the Quartus II option or assignment includes a target, source, and/or section tag, use the syntax in Example 9–98 for each **.qsf** file variable assignment.

Example 9–98. Syntax for Each .qsf File Variable Assignment

```
-name <variable> <value>
-from <source> -to <target> -section_id <section>
```

The syntax for the full attribute value, including the optional target, source, and section tags for two different **.qsf** file assignments, is shown in Example 9–99.

Example 9–99. Syntax for Fill Attribute Value

```
" -name <variable_1> <value_1> [-from <source_1>] [-to <target_1>] [-section_id \
<section_1>]; -name <variable_2> <value_2> [-from <source_2>] [-to <target_2>] \
[-section_id <section_2>] "
```

If a variable's assigned value is a string of text, you must use escaped quotes around the value in Verilog HDL, or double-quotes in VHDL, as in the following examples (using non-existent variable and value terms):

Verilog HDL

```
"VARIABLE_NAME \"STRING_VALUE\""
```

VHDL

```
"VARIABLE_NAME ""STRING_VALUE"""
```

To find the **.qsf** file variable name or value corresponding to a specific Quartus II option or assignment, you can make the option setting or assignment in the Quartus II GUI and then note the changes in the **.qsf** file. You can also refer to the *Quartus II Settings File Reference Manual*, which documents all variable names.

Example 9–100 through Example 9–102 use `altera_attribute` to set the power-up level of an inferred register.

For inferred instances, you cannot apply the attribute to the instance directly, so you should apply the attribute to one of the instance's output nets. The Quartus II software moves the attribute to the inferred instance automatically.

Example 9–100. Verilog-1995 Code: Applying Altera Attribute to an Instance

```
reg my_reg /* synthesis altera_attribute = "-name POWER_UP_LEVEL HIGH"
*/;
```

Example 9–101. Verilog-2001 Code: Applying Altera Attribute to an Instance

```
(* altera_attribute = "-name POWER_UP_LEVEL HIGH" *) reg my_reg;
```

Example 9–102. VHDL Code: Applying Altera Attribute to an Instance

```
signal my_reg : std_logic;
attribute altera_attribute : string;
attribute altera_attribute of my_reg: signal is "-name POWER_UP_LEVEL
HIGH";
```

Example 9–103 through Example 9–105 use the `altera_attribute` to disable the **Auto Shift Register Replacement** synthesis option for an entity. To apply the Altera Attribute to a VHDL entity, you must set the attribute on its architecture rather than on the entity itself.

Example 9–103. Verilog-1995 Code: Applying Altera Attribute to an Entity

```
module my_entity(…) /* synthesis altera_attribute = "-name
AUTO_SHIFT_REGISTER_RECOGNITION OFF" */;
```

Example 9–104. Verilog-2001 Code: Applying Altera Attribute to an Entity

```
(* altera_attribute = "-name AUTO_SHIFT_REGISTER_RECOGNITION OFF" *)
module my_entity(…) ;
```

Example 9–105. VHDL Code: Applying Altera Attribute to an Entity

```
entity my_entity is
-- Declare generics and ports
end my_entity;
architecture rtl of my_entity is
attribute altera_attribute : string;
-- Attribute set on architecture, not entity
attribute altera_attribute of rtl: architecture is "-name
AUTO_SHIFT_REGISTER_RECOGNITION OFF";
begin
-- The architecture body
end rtl;
```

You can also use `altera_attribute` for more complex assignments involving more than one instance. In Example 9–106 through Example 9–108, the `altera_attribute` is used to cut all timing paths from `reg1` to `reg2`, equivalent to this Tcl or QSF command:

```
set_instance_assignment -name CUT ON -from reg1 -to reg2 ↵
```

Example 9–106. Verilog-1995 Code: Applying Altera Attribute with -to

```
reg reg2;
reg reg1 /* synthesis altera_attribute = "-name CUT ON -to reg2" */;
```

Example 9–107. Verilog-2001 Code: Applying Altera Attribute with -to

```
reg reg2;
(* altera_attribute = "-name CUT ON -to reg2" *) reg reg1;
```

Example 9–108. VHDL Code: Applying Altera Attribute with -to

```
signal reg1, reg2 : std_logic;
attribute altera_attribute: string;
attribute altera_attribute of reg1 : signal is "-name CUT ON -to reg2";
```

You can specify either the `-to` option or the `-from` option in a single `altera_attribute`; integrated synthesis automatically sets the remaining option to the target of the `altera_attribute`. You can also specify wildcards for either option. For example, if you specify "`*`" for the `-to` option instead of `reg2` in these examples, the Quartus II software cuts all timing paths from `reg1` to every other register in this design entity.

The `altera_attribute` can be used only for entity-level settings, and the assignments (including wildcards) apply only to the current entity.

Analyzing Synthesis Results

After you have performed synthesis, you can check your synthesis results in the **Analysis & Synthesis** section of the Compilation Report and the Project Navigator.

Analysis and Synthesis Section of the Compilation Report

The Compilation Report, which provides a summary of results for the project, appears after a successful compilation, or you can choose it from the Processing menu. After Analysis and Synthesis, before the Fitter begins, the Summary information provides a summary of utilization based on synthesis data, before Fitter optimizations have occurred. Synthesis-specific information is listed in the **Analysis & Synthesis** section.

There are various report sections under Analysis and Synthesis, including a list of the source files read for the project, the resource utilization by entity after synthesis, and information about state machines, latches, optimization results, and parameter settings.

For more information about each report section, refer to the Quartus II Help.

Project Navigator

The **Hierarchy** tab of the Project Navigator provides a summary of resource information about the entities in the project. After Analysis and Synthesis, before the Fitter begins, the Project Navigator provides a summary of utilization based on synthesis data, before Fitter optimizations have occurred.

If you hold your mouse pointer over one of the entities in the **Hierarchy** tab, a tooltip appears that shows parameter information for each instance.

Analyzing and Controlling Synthesis Messages

This section provides information about the messages generated during synthesis, and how you can control which messages appear during compilation.

Quartus II Messages

The messages that appear during Analysis and Synthesis describe many of the optimizations that the software performs during the synthesis stage, and provide information about how the design is interpreted. You should always check the messages to analyze **Critical Warnings** and **Warnings**, because these messages can relate to important design problems. It is also useful to read the information messages **Info** and **Extra Info** to get more information about how the software processes your design.

The **Info**, **Extra Info**, **Warning**, **Critical Warning**, and **Error** tabs display messages grouped by type.

You can right-click on a message in the Messages window and get help on the message, locate the source of the message in your design, and manage messages.

You can use message suppression to reduce the number of messages listed after a compilation by preventing individual messages and entire categories of messages from being displayed. For example, if you review a particular message and determine that it is not caused by something in your design that should be changed or fixed, you can suppress the message so it is not displayed during subsequent compilations. This saves time because you see only new messages during subsequent compilations.

You can right-click on an individual message in the Messages window and choose commands in the **Suppress** submenu. Another way to achieve the same goal is to open the Message Suppression Manager. To do this, right-click in the Messages window, point to **Suppress**, and click **Message Suppression Manager**.

For more information about messages and how to suppress them, refer to the *Managing Quartus II Projects* chapter in volume 2 of the *Quartus II Handbook.*

Beginning with Quartus II software version 8.1, you can specify the type of Analysis and Synthesis messages that you want to view by selecting the **Analysis & Synthesis Message Level** option. You can specify the display level by performing the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, click **Analysis & Synthesis Settings**. The **Analysis & Synthesis Settings** page appears.
3. Click **More Settings**. Select the level for the **Analysis & Synthesis Message Level** option.

For more information about the **Analysis & Synthesis Message Level** option, refer to the Quartus II Help File.

VHDL and Verilog HDL Messages

The Quartus II software issues a variety of messages when it is analyzing and elaborating the Verilog HDL and VHDL files in your design. These HDL messages are a subset of all Quartus II messages that help you identify potential problems early in the design process.

HDL messages fall into the following three categories:

- **Info message**—Lists a property of your design.
- **Warning message**—Indicates a potential problem in your design. Potential problems come from a variety of sources, including typos, inappropriate design practices, or the functional limitations of your target device. Though HDL warning messages do not always identify actual problems, you should always investigate code that generates an HDL warning. Otherwise, the synthesized behavior of your design might not match your original intent or its simulated behavior.
- **Error message**—Indicates an actual problem with your design. Your HDL code can be invalid due to a syntax or semantic error, or it might not be synthesizable as written. Consult the Help associated with any HDL error messages for assistance in removing the error from your design.

In Example 9–109, the sensitivity list contains multiple copies of the variable `i`. While the Verilog HDL language does not prohibit duplicate entries in a sensitivity list, it is clear that this design has a typo: Variable `j` should be listed on the sensitivity list to avoid a possible simulation/synthesis mismatch.

Example 9–109. Generating an HDL Warning Message

```
//dup.v
module dup(input i, input j, output reg o);
always @ (i or i)
    o = i & j;
endmodule
```

When processing this HDL code, the Quartus II software generates the following warning message:

```
Warning: (10276) Verilog HDL sensitivity list warning at dup.v(2):
sensitivity list contains multiple entries for "i".
```

In Verilog HDL, variable names are case-sensitive, so the variables `my_reg` and `MY_REG` in Example 9–110 are two different variables. However, declaring variables whose names only differ in case might confuse some users, especially those users who use VHDL, where variables are not case-sensitive.

Example 9–110. Generating HDL Info Messages

```
// namecase.v
module namecase (input i, output o);
    reg my_reg;
    reg MY_REG;
    assign o = i;
endmodule
```

When processing this HDL code, the Quartus II software generates the following informational message:

```
Info: (10281) Verilog HDL information at namecase.v(3): variable name
"MY_REG" and variable name "my_reg" should not differ only in case.
```

In addition, the Quartus II software generates additional HDL info messages to inform you that neither `my_reg` or `MY_REG` are used in this small design:

```
Info: (10035) Verilog HDL or VHDL information at namecase.v(3): object
"my_reg" declared but not used
Info: (10035) Verilog HDL or VHDL information at namecase.v(4): object
"MY_REG" declared but not used
```

The Quartus II software allows you to control how many HDL messages you see during the Analysis and Elaboration of your design files. You can set the HDL Message Level to enable or disable groups of HDL messages, or you can enable or disable specific messages, as described in the following sections.

For more information about synthesis directives and their syntax, refer to "Synthesis Directives" on page 9–27.

Setting the HDL Message Level

The HDL Message Level specifies the types of messages that the Quartus II software displays when it is analyzing and elaborating your design files. Table 9–8 details the information about the HDL message levels.

Table 9–8. HDL Info Message Level

Level	Purpose	Description
Level1	Displays high-severity messages only	If you want to see only those HDL messages that identify likely problems with your design, select Level1. When Level1 is selected, the Quartus II software issues a message only if there is a high probability that it points to an actual problem with your design.
Level2	Displays high-severity and medium-severity messages	If you want to see additional HDL messages that identify possible problems with your design, select Level2. This is the default setting.
Level3	Displays all messages, including low-severity messages	If you want to see all HDL info and warning messages, select Level3. This level includes extra "LINT" messages that suggest changes to improve the style of your HDL code or make it easier to understand.

You should address all issues reported at the **Level1** setting. The default HDL message level is **Level2**.

To set the HDL Message Level in the GUI, on the Assignments menu, click **Settings**. In the **Category** list, click **Analysis & Synthesis Settings**. Set the desired message level from the pull-down menu in the **HDL Message Level** list, and click **OK**.

You can override this default setting in a source file with the `message_level synthesis` directive, which takes the values `level1`, `level2`, and `level3`, as shown in Example 9–111 and Example 9–112.

Example 9–111. Verilog HDL Examples of message_level Directive

```
// altera message_level level1
or
/* altera message_level level3 */
```

Example 9–112. VHDL Code: message_level Directive

```
-- altera message_level level2
```

A `message_level` synthesis directive remains effective until the end of a file or until the next `message_level` directive. In VHDL, you can use the `message_level` synthesis directive to set the HDL Message Level for entities and architectures, but not for other design units. An HDL Message Level for an entity applies to its architectures, unless overridden by another `message_level` directive. In Verilog HDL, you can use the `message_level` directive to set the HDL Message Level for a module.

Enabling or Disabling Specific HDL Messages by Module/Entity

You can enable or disable a specific HDL info or warning message with its Message ID, which is displayed in parentheses at the beginning of the message. Enabling or disabling a specific message overrides its HDL Message Level. This method is different from the message suppression in the Messages window because you can use this method to disable messages for a specific module or entity. This method applies only the HDL messages, and if you disable a message with this method, the message is listed as a Suppressed message in the Quartus II GUI.

To disable specific HDL messages in the GUI, on the Assignments menu, click **Settings**. In the **Category** list, expand **Analysis & Synthesis Settings** and select **Advanced**. In the **Advanced Message Settings** dialog box, add the Message IDs you wish to enable or disable.

To enable or disable specific HDL messages in your HDL, use the `message_on` and `message_off` synthesis directives. Both directives take a space-separated list of Message IDs. You can enable or disable messages with these synthesis directives immediately before Verilog HDL modules, VHDL entities, or VHDL architectures. You cannot enable or disable a message in the middle of an HDL construct.

A message enabled or disabled via a `message_on` or `message_off` synthesis directive overrides its HDL Message Level or any `message_level` synthesis directive. The message remains disabled until the end of the source file or until its status is changed by another `message_on` or `message_off` directive.

Example 9–113. Verilog HDL message_off Directive for Message with ID 10000

```
// altera message_off 10000
or
/* altera message_off 10000 */
```

Example 9–114. VHDL message_off Directive for Message with ID 10000

```
-- altera message_off 10000
```

Node-Naming Conventions in Quartus II Integrated Synthesis

Being able to find the logic node names after synthesis can be useful during verification or while debugging a design. This section provides an overview of the conventions used by the Quartus II software when it names the nodes created from your HDL design. The section focuses on the conventions for Verilog HDL and VHDL code, but AHDL and BDFs are discussed when appropriate.

Whenever possible, Quartus II integrated synthesis uses wire or signal names from your source code to name nodes such as LEs or ALMs. Some nodes, such as registers, have predictable names that typically do not change when a design is resynthesized, although certain optimizations can affect register names. The names of other nodes, particularly LEs or ALMs that contain only combinational logic, can change due to logic optimizations that the software performs.

This section discusses the following topics:

- "Hierarchical Node-Naming Conventions"
- "Node-Naming Conventions for Registers (DFF or D Flipflop Atoms)"
- "Register Changes During Synthesis" on page 9–76
- "Preserving Register Names" on page 9–78
- "Node-Naming Conventions for Combinational Logic Cells" on page 9–78
- "Preserving Combinational Logic Names" on page 9–79

Hierarchical Node-Naming Conventions

To make each name in the design unique, the Quartus II software adds the hierarchy path to the beginning of each name. The "|" separator is used to indicate a level of hierarchy. For each instance in the hierarchy, the software adds the entity name and the instance name of that entity, using the ":" separator between each entity name and its instance name. For example, if a design instantiates entity `A` with the name `my_A_inst`, the hierarchy path of that entity would be `A:my_A_inst`. The full name of any node is obtained by starting with the hierarchical instance path, followed by a "|", and ending with the node name inside that entity, using the following convention:

<entity 0>:*<instance_name 0>*|*<entity 1>*:
<instance_name 1>| . . . |*<instance_name n>*

For example, if entity A contains a register (DFF atom) called `my_dff`, its full hierarchy name would be `A:my_A_inst|my_dff`.

On the **Compilation Process Settings** page of the **Settings** dialog box, click **More Settings** and turn off **Display entity name for node name** to instruct the compiler to generate node names that do not contain the name for each level of the hierarchy. With this option off, the node names use the following convention:

<instance_name 0>|*<instance_name 1>*| . . . |*<instance_name n>*

Node-Naming Conventions for Registers (DFF or D Flipflop Atoms)

In Verilog HDL and VHDL, inferred registers are named after the `reg` or `signal` connected to the output.

© March 2009 Altera Corporation

Example 9–115 is a description of a register in Verilog HDL that creates a DFF primitive called `my_dff_out`:

Example 9–115. Verilog HDL Register

```
wire dff_in, my_dff_out, clk;

always @ (posedge clk)
my_dff_out <= dff_in;
```

Similarly, Example 9–116 is a description of a register in VHDL that creates a DFF primitive called `my_dff_out`.

Example 9–116. VHDL Register

```
signal dff_in, my_dff_out, clk;
process (clk)
begin
if (rising_edge(clk)) then
my_dff_out <= dff_in;
end if;
end process;
```

In AHDL designs, DFF registers are declared explicitly rather than inferred, so the software uses the user-declared name for the register.

For schematic designs using a **.bdf** file, all elements are given a name when they are instantiated in the design, so the software uses the user-defined name for the register or DFF.

In the special case that a wire or signal (such as `my_dff_out` in the preceding examples) is also an output pin of your top-level design, the Quartus II software cannot use that name for the register (for example, cannot use `my_dff_out`) because the software requires that all logic and I/O cells have unique names. In this case, the Quartus II integrated synthesis appends `~reg0` to the register name.

For example, the Verilog HDL code in Example 9–117 produces a register called `q~reg0`:

Example 9–117. Verilog HDL Register Feeding Output Pin

```
module my_dff (input clk, input d, output q);
always @ (posedge clk)
q <= d;
endmodule
```

This situation occurs only for registers driving top-level pins. If a register drives a port of a lower level of the hierarchy, the port is removed during hierarchy flattening and the register retains its original name, in this case, `q`.

Register Changes During Synthesis

On some occasions, you might not be able to find registers that you expect to see in the synthesis netlist. Registers might be removed by logic optimization, or their names might be changed due to synthesis optimization. Common optimizations include inference of a state machine, counter, adder-subtractor, or shift register from registers and surrounding logic. Other common register changes occur when registers are packed into dedicated hardware on the FPGA, such as a DSP block or a RAM block.

This section describes the following factors that can affect register names:

- "Synthesis and Fitting Optimizations"
- "State Machines"
- "Inferred Adder-Subtractors, Shift Registers, Memory, and DSP Functions" on page 9–77
- "Packed Input and Output Registers of RAM and DSP Blocks" on page 9–77
- "Preserving Register Names" on page 9–78
- "Preserving Combinational Logic Names" on page 9–79

Synthesis and Fitting Optimizations

Registers might be removed by synthesis logic optimization if they are not connected to inputs or outputs in the design, or if the logic can be simplified due to constant signal values. Register names might also be changed due to synthesis optimizations, such as when duplicate registers are merged together to reduce resource utilization.

NOT-gate push back optimizations can affect registers that use preset signals. This type of optimization can impact your timing assignments when registers are used as clock dividers. If this situation occurs in your design, change the clock settings to work on the new register name.

Synthesis netlist optimizations often change node names because registers can be combined or duplicated to optimize the design.

For more information about the type of optimizations performed by synthesis netlist optimizations, refer to the *Netlist Optimizations and Physical Synthesis* chapter in volume 2 of the *Quartus II Handbook*.

The Quartus II Compilation Report provides a list of registers that are removed during synthesis optimizations, and a brief reason for the removal. In the **Analysis & Synthesis** folder, open **Optimization Results**, and then open **Register Statistics**, and click on the **Registers Removed During Synthesis** report, and the **Removed Registers Triggering Further Register Optimizations** report. The second report contains a list of registers that are the cause of other registers being removed in the design. It provides a brief reason for the removal, and a list of registers that were removed due to the removal of the initial register.

Synthesis creates synonyms for registers duplicated with the **Maximum Fan-Out** option (or `maxfan` attribute). Therefore, timing assignments applied to nodes that are duplicated with this option are applied to the new nodes as well.

The Quartus II Fitter can also change node names after synthesis (for example, when the Fitter uses register packing to pack a register into an I/O element, or when logic is modified by physical synthesis). The Fitter creates synonyms for duplicated registers so timing analysis can use the existing node name when applying assignments.

You can instruct the Quartus II software to preserve certain nodes throughout compilation so you can use them for verification or making assignments. For more information, refer to "Preserving Register Names" on page 9–78.

State Machines

If a state machine is inferred from your HDL code, the registers that represent the states are mapped into a new set of registers that implement the state machine. Most commonly, the software converts the state machine into a one-hot form where each state is represented by one register. In this case, for Verilog HDL or VHDL designs, the registers are named according to the name of the state register and the states, where possible.

For example, consider a Verilog HDL state machine where the states are `parameter state0 = 1, state1 = 2, state2 = 3`, and where the state machine register is declared as `reg [1:0] my_fsm`. In this example, the three one-hot state registers are named `my_fsm.state0`, `my_fsm.state1`, and `my_fsm.state2`.

In AHDL, state machines are explicitly specified with a machine name. State machine registers are given synthesized names based on the state machine name but not the state names. For example, if a state machine is called `my_fsm` and has four state bits, they might be synthesized with names such as `my_fsm~12`, `my_fsm~13`, `my_fsm~14`, and `my_fsm~15`.

Inferred Adder-Subtractors, Shift Registers, Memory, and DSP Functions

The Quartus II software infers megafunctions from Verilog HDL and VHDL code for logic that forms adder-subtractors, shift registers, RAM, ROM, and arithmetic functions that can be placed in DSP blocks.

For information about inferring megafunctions, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

Because adder-subtractors are part of a megafunction instead of generic logic, the combinational logic exists in the design with different names. For shift registers, memory, and DSP functions, the registers and logic are typically implemented inside the dedicated RAM or DSP blocks in the device. Thus, the registers are not visible as separate LEs or ALMs.

Packed Input and Output Registers of RAM and DSP Blocks

Registers can be packed into the input registers and output registers of RAM and DSP blocks, so that they are not visible as separate registers in LEs or ALMs.

For information about packing registers into RAM and DSP megafunctions, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook.*

Preserving Register Names

You might want to preserve certain register names for verification or debugging, or to ensure that timing assignments are applied correctly. Quartus II integrated synthesis preserves certain nodes automatically if they are likely to be used in a timing constraint.

Use the `preserve` attribute to instruct the compiler not to minimize or remove a specified register during synthesis optimizations or register netlist optimizations. Refer to "Preserve Registers" on page 9–44 for details.

Use the `noprune` attribute to preserve a fan-out-free register through the entire compilation flow. Refer to "Noprune Synthesis Attribute/Preserve Fan-out Free Register Node" on page 9–46 for details.

Use the synthesis attribute `syn_dont_merge` to make sure registers are not merged with other registers, and other registers are not merged with them. Refer to "Disable Register Merging/Don't Merge Register" on page 9–45 for details.

Node-Naming Conventions for Combinational Logic Cells

Whenever possible for Verilog HDL, VHDL, and AHDL code, the Quartus II software uses wire names that are the targets of assignments, but can change the node names due to synthesis optimizations.

For example, consider the Verilog HDL code in Example 9–118. Quartus II integrated synthesis uses the names `c`, `d`, `e`, and `f` for the combinational logic cells that are produced.

Example 9–118. Naming Nodes for Combinational Logic Cells in Verilog HDL

```
wire c;
reg d, e, f;

assign c = a | b;
always @ (a or b)
d = a & b;
always @ (a or b) begin : my_label
e = a ^ b;
end

always @ (a or b)
f = ~(a | b);
```

For schematic designs using a **.bdf** file, all elements are given a name when they are instantiated in the design and the software uses the user-defined name when possible.

Node naming conventions for schematic buses in the Quartus II software version 7.2 and later are different than the MAX+PLUS II software and older versions of the Quartus II software. In most cases, the Quartus II software uses the appropriate naming convention for the design source file. Designs created using the Quartus II software version 7.1 or earlier use the MAX+PLUS II naming convention. Designs created in the Quartus II software version 7.2 and later use the Quartus II naming

 © March 2009 Altera Corporation

convention that matches the behavior of standard HDLs. In some cases, however, a design might contain files created in various versions. To set an assignment for a particular instance in the Assignment Editor, enter the instance name in the **To** field, choose **Block Design Naming** from the **Assignment Name** list, and set the value to **MaxPlusII** or **QuartusII**.

If logic cells, such as those created in Example 9–118, are packed with registers in device architectures such as the Stratix and Cyclone device families, those names might not appear in the netlist after fitting. In other devices, such as newer families in the Stratix and Cyclone series device families, the register and combinational nodes are kept separate throughout the compilation, so these names are more often maintained through fitting.

When logic optimizations occur during synthesis, it is not always possible to retain the initial names as described. In some cases, synthesized names are used, which are the wire names with a tilde (~) and a number appended. For example, if a complex expression is assigned to wire `w` and that expression generates several logic cells, those cells can have names such as `w`, `w~1`, `w~2`, and so on. Sometimes the original wire name `w` is removed, and an arbitrary name such as `rtl~123` is created. It is a goal of Quartus II integrated synthesis to retain user names whenever possible. Any node name ending with ~<*number*> is a name created during synthesis, which can change if the design is changed and re-synthesized. Knowing these naming conventions can help you understand your post-synthesis results and make it easier to debug your design or make assignments.

The software maintains combinational clock logic by making sure nodes that are likely to be a clock are not changed during synthesis. The software also maintains (or "protects") multiplexers in clock trees so that the TimeQuest Timing Analyzer has information about which paths are unate, to allow complete and correct analysis of combinational clocks. Multiplexers often occur in clock trees when the design selects between different clocks. To help analysis of clock trees, the software ensures that each multiplexer encountered in a clock tree is broken into 2:1 multiplexers, and each of those 2:1 multiplexers is mapped into one look-up table (independent of the device family). This optimization might result in a slight increase in area, and for some designs a decrease in timing performance. You can turn off this multiplexer protection with the option **Clock MUX Protection** under **More Settings** on the **Analysis & Synthesis Settings** page of the **Settings** dialog box. This option applies to Arria GX devices, the Stratix and Cyclone series, and MAX II devices.

Preserving Combinational Logic Names

You might want to preserve certain combinational logic node names for verification or debugging, or to ensure that timing assignments are applied correctly.

Use the `keep` attribute to keep a wire name or combinational node name through logic synthesis minimizations and netlist optimizations. Refer to "Keep Combinational Node/Implement as Output of Logic Cell" on page 9–46 for details.

For any internal node in your design clock network, use `keep` to protect the name so that you can apply correct clock settings. Also, set the attribute on combinational logic involved in `cut` assignments and `-through` assignments.

Setting the keep attribute on combinational logic can increase the area utilization and increase the delay of the final mapped logic because it requires the insertion of extra combinational logic. Use the attribute only when necessary.

Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ↵
```

The *Quartus II Scripting Reference Manual* includes the same information in PDF form.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. Refer to the *Quartus II Settings File Reference Manual* for information about all settings and constraints in the Quartus II software. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

You can specify many of the options described in this section either on an instance, global level, or both.

Use the following Tcl command to make a global assignment:

```
set_global_assignment -name <QSF Variable Name> <Value> ↵
```

Use the following Tcl command to make an instance assignment:

```
set_instance_assignment -name <QSF Variable Name> <Value>\ -to
<Instance Name> ↵
```

Adding an HDL File to a Project and Setting the HDL Version

Use the following Tcl assignments to add an HDL or schematic entry design file to your project:

```
set_global_assignment -name VERILOG_FILE <file name>.<v|sv>
set_global_assignment -name SYSTEMVERILOG_FILE <file name>.sv
set_global_assignment -name VHDL_FILE <file name>.<vhd|vhdl>
set_global_assignment -name AHDL_FILE <file name>.tdf
set_global_assignment -name BDF_FILE <file name>.bdf
```

You can use any file extension for design files, as long as you specify the correct language when adding the design file. For example, you can use **.h** for Verilog HDL header files.

To specify the Verilog HDL or VHDL version, use the following option at the end of the VERILOG_FILE or VHDL_FILE command:

```
-HDL_VERSION <language version>
```

The variable <*language version*> takes one of the following values:

- VERILOG_1995
- VERILOG_2001

- SYSTEMVERILOG_2005
- VHDL87
- VHDL93

For example, to add a Verilog HDL file called **my_file** that is written in Verilog-1995, use the following command:

```
set_global_assignment -name VERILOG_FILE my_file.v -HDL_VERSION
VERILOG_1995
```

Quartus II Synthesis Options

Table 9–9 lists the **.qsf** file variable names and applicable values for the settings discussed in this chapter. The **.qsf** file variable name is used in the Tcl assignment to make the setting along with the appropriate value.

Table 9–9. Quartus II Synthesis Options (Part 1 of 3) *(Note 1)*

Setting Name	Quartus II Settings File Variable	Values
Add Pass-Through Logic to Inferred RAMs	ADD_PASS_THROUGH_LOGIC_TO_INFERRED_ RAMS	On/Off
Allow Any RAM Size for Recognition	ALLOW_ANY_RAM_SIZE_FOR_RECOGNITION	On/Off
Allow Any ROM Size for Recognition	ALLOW_ANY_ROM_SIZE_FOR_RECOGNITION	On/Off
Allow Any Shift Register Size for Recognition	ALLOW_ANY_SHIFT_REGISTER_SIZE_FOR_ RECOGNITION	On/Off
Allow Asynchronous Clear Usage For Shift Register Replacement	ALLOW_ACLR_FOR_SHIFT_REGISTER_ RECOGNITION	On/Off
Allow Synchronous Control Signals	ALLOW_SYNCH_CTRL_USAGE	On/Off
Analysis & Synthesis Message Level	SYNTH_MESSAGE_LEVEL	Low/Medium/High
Auto Carry Chains	AUTO_CARRY_CHAINS	On/Off
Auto Clock Enable Replacement	AUTO_CLOCK_ENABLE_RECOGNITION	On/Off
Auto DSP Block Replacement	AUTO_DSP_RECOGNITION	On/Off
Auto Gated Clock Conversion	SYNTH_GATED_CLOCK_CONVERSION	On/Off
Auto Open-Drain Pins	AUTO_OPEN_DRAIN_PINS	On/Off
Auto RAM Block Balancing	AUTO_RAM_BLOCK_BALANCING	On/Off
Auto RAM to Logic Cell Conversion	AUTO_RAM_TO_LCELL_CONVERSION	On/Off
Auto RAM Replacement	AUTO_RAM_RECOGNITION	On/Off
Auto Resource Sharing	AUTO_RESOURCE_SHARING	On/Off
Auto ROM Replacement	AUTO_ROM_RECOGNITION	On/Off
Auto Shift-Register Replacement	AUTO_SHIFT_REGISTER_RECOGNITION	Always/Auto/Off
Block Design Naming	BLOCK_DESIGN_NAMING	Auto/Max+Plus II/ Quartus II
Carry Chain Length	*<device name>*_CARRY_CHAIN_LENGTH	*<Maximum allowable length of a chain>*

Table 9–9. Quartus II Synthesis Options (Part 2 of 3) *(Note 1)*

Setting Name	Quartus II Settings File Variable	Values
Clock MUX Protection	SYNTH_CLOCK_MUX_PROTECTION	On/Off
Create Debugging Nodes for IP Cores	ENABLE_IP_DEBUG	On/Off
DSP Block Balancing	DSP_BLOCK_BALANCING	Auto/DSP Blocks/ Logic Elements/ Off/Simple 18-bit Multipliers/ Simple Multipliers/Width 18-bit Multipliers
Extract Verilog State Machines	EXTRACT_VERILOG_STATE_MACHINES	On/Off
Extract VHDL State Machines	EXTRACT_VHDL_STATE_MACHINES	On/Off
Force Use of Synchronous Clear Signals	FORCE_SYNCH_CLEAR	On/Off
HDL Message Level	HDL_MESSAGE_LEVEL	Level1/Level2/ Level3
Ignore CARRY Buffers	IGNORE_CARRY_BUFFERS	On/Off
Ignore CASCADE Buffers	IGNORE_CASCADE_BUFFERS	On/Off
Ignore GLOBAL Buffers	IGNORE_GLOBAL_BUFFERS	On/Off
Ignore LCELL Buffers	IGNORE_LCELL_BUFFERS	On/Off
Ignore Maximum Fan-Out Assignments	IGNORE_MAX_FANOUT_ASSIGNMENTS	On/Off
Ignore ROW GLOBAL Buffers	IGNORE_ROW_GLOBAL_BUFFERS	On/Off
Ignore SOFT Buffers	IGNORE_SOFT_BUFFERS	On/Off
Ignore translate_off and synthesis_off directives	IGNORE_TRANSLATE_OFF_AND_SYNTHESIS_OFF	On/Off
Ignore Verilog Initial Constructs	IGNORE_VERILOG_INITIAL_CONSTRUCTS	On/Off
Iteration limit for constant Verilog loops	VERILOG_CONSTANT_LOOP_LIMIT	*<Maximum limit to infinite loops before exhaustion of memory>*
Iteration limit for non-constant Verilog loops	VERILOG_NON_CONSTANT_LOOP_LIMIT	*<Maximum limit to infinite loops before exhaustion of memory>*
Limit AHDL Integers to 32 Bits	LIMIT_AHDL_INTEGERS_TO_32_BITS	On/Off
Maximum DSP Block Usage *(2)*	MAX_BALANCING_DSP_BLOCKS	*<Maximum DSP Block Usage Value>*
Maximum Number of M4K/ M9K Memory Blocks	MAX_RAM_BLOCKS_M4K	*<Maximum memory blocks usage>*
Maximum Number of M512 Memory Blocks	MAX_RAM_BLOCKS_M512	*<Maximum memory blocks usage>*
Maximum Number of M-RAM/ M144K Memory Blocks	MAX_RAM_BLOCKS_MRAM	*<Maximum memory blocks usage>*
NOT Gate Push-Back	NOT_GATE_PUSH_BACK	On/Off
Number of Inverted Registers Reported in Synthesis Report	NUMBER_OF_INVERTED_REGISTERS_REPORTED	*<Maximum number of inverted registers>*
Number of Removed Registers Reported in Synthesis Report	NUMBER_OF_REMOVED_REGISTERS_REPORTED	*<Maximum number of inverted registers>*

Table 9–9. Quartus II Synthesis Options (Part 3 of 3) *(Note 1)*

Setting Name	Quartus II Settings File Variable	Values
Optimization Technique	*<device family>*_OPTIMIZATION_TECHNIQUE	Area/Speed/ Balanced
Parallel Synthesis	PARALLEL_SYNTHESIS	On/Off
Perform WYSIWYG Primitive Resynthesis	ADV_NETLIST_OPT_SYNTH_WYSIWYG_REMAP	On/Off
PowerPlay Power Optimization	OPTIMIZE_POWER_DURING_SYNTHESIS	Normal compilation/ Extra effort/Off
Power-Up Don't Care *(2)*	ALLOW_POWER_UP_DONT_CARE	On/Off
Remove Duplicate Registers	REMOVE_DUPLICATE_REGISTERS	On/Off
Remove Redundant Logic Cells *(2)*	REMOVE_REDUNDANT_LOGIC_CELLS	On/Off

Timing Driven Synthesis	SYNTH_TIMING_DRIVEN_SYNTHESIS	On/Off
Use LogicLock Constraints during Resource Balancing	USE_LOGICLOCK_CONSTRAINTS_IN_BALANCING	On/Off

Notes to Table 9–9:

(1) These settings are supported as Global and Instance settings, unless specified.

(2) This setting is only a Global setting.

Assigning a Pin

Use the following Tcl command to assign a signal to a pin or device location:

```
set_location_assignment -to <signal name> <location>
```

For example: `set_location_assignment -to data_input Pin_A3`

Valid locations are pin location names. Some device families also support edge and I/O bank locations. Edge locations are EDGE_BOTTOM, EDGE_LEFT, EDGE_TOP, and EDGE_RIGHT. I/O bank locations include IOBANK_1 to IOBANK_n, where n is the number of I/O banks in a particular device.

Creating Design Partitions for Incremental Compilation

To create a partition, use the following command:

```
set_instance_assignment -name PARTITION_HIERARCHY \
<file name> -to <destination> -section_id <partition name>
```

The <*destination*> should be the entity's short hierarchy path. A *short* hierarchy path is the full hierarchy path without the top-level name, for example: `"ram:ram_unit|altsyncram:altsyncram_component"` (with quotation marks). For the top-level partition, you can use the pipe (|) symbol to represent the top-level entity.

For more information about hierarchical naming conventions, refer to "Node-Naming Conventions in Quartus II Integrated Synthesis" on page 9–74.

The <*partition name*> is the user-designated partition name, which must be unique and less than 1024 characters long. The name can consist only of alphanumeric characters, as well as pipe (|), colon (:), and underscore (_) characters. Altera recommends enclosing the name in double quotation marks (" ").

The <*file name*> is the name used for internally generated netlist files during incremental compilation. Netlists are named automatically by the Quartus II software based on the instance name if you create the partition in the GUI. If you are using Tcl to create your partitions, you must assign a custom file name that is unique across all partitions. For the top-level partition, the specified file name is ignored, and you can use any dummy value. To ensure the names are safe and platform independent, file names must be unique regardless of case. For example, if a partition uses the file name `my_file`, no other partition can use the file name `MY_FILE`. For simplicity, Altera recommends that you base each file name on the corresponding instance name for the partition.

The software stores all netlists in the **db** compilation database directory.

Conclusion

The Quartus II software includes complete Verilog HDL and VHDL language support, as well as support for Altera-specific languages, making it an easy-to-use, standalone solution for Altera designs. You can use the synthesis options available in the software to help you improve your synthesis results, giving you more control over the way your design is synthesized. Use Quartus II reports and messages to analyze your compilation results.

Document Revision History

Table 9–10 shows the revision history for this chapter.

Table 9–10. Document Revision History (Part 1 of 2)

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Updated Table 9–9. ■ Updated the following sections: → “Partitions for Preserving Hierarchical Boundaries” on page 9–20 → “Analysis & Synthesis Settings Page of the Settings Dialog Box” on page 9–24 → “Timing-Driven Synthesis” on page 9–30 → “Turning Off Add Pass-Through Logic to Inferred RAMs/ no_rw_check Attribute Setting” on page 9–54 ■ Added “Parallel Synthesis” on page 9–21 ■ Chapter 9 was previously Chapter 8 in software version 8.1	Updated for Quartus II software version 9.0 release.

Table 9–10. Document Revision History (Part 2 of 2)

November 2008 v8.1.0	■ Changed page size to 8.5” × 11” ■ Restructured chapter by rearranging sections ■ Updated Figure 8–1 ■ Updated Table 8–9 ■ Added Example 8–23 and Example 8–28 ■ Updated the following sections: →“Setting Default Parameter Values and BDF Instance Parameter Values” →“Incremental Compilation” →“Quartus II Synthesis Options” →“Limiting DSP Block Usage in Partitions” →“Synthesis Effort” →“Using altera_attribute to Set Quartus II Logic Options” →“Quartus II Messages” ■ Added the following sections: →“Quartus II eXported Partition (.qxp) File as Source” →“Auto Gated Clock Conversion” →“Timing-Driven Synthesis” →“SDC Constraint Protection”	Updated for Quartus II software version 8.1 release.
May 2008 v8.0.0	■ Adjusted the items listed in “System Verilog Support” ■ Added the section “VHDL wait Constructs and associated Examples” ■ Added the section “Limiting DSP Block Usage in Partitions” ■ Added the section “Synthesis Effort” ■ Added hyperlinks to referenced documents throughout the chapter ■ Minor editorial updates	Updated for Quartus II software version 8.0 release.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

10. Synopsys Synplify Support

QII51009-9.0.0

Introduction

This chapter documents support for the Synopsys Synplify software in the Quartus® II software, as well as key design flows, methodologies, and techniques for achieving good results in Altera® devices. This chapter includes the following topics:

- General design flow with the Synplify and Quartus II software
- Synplify software optimization strategies, including timing-driven compilation settings, optimization options, and Altera-specific attributes
- Exporting designs and constraints to the Quartus II software using NativeLink integration
- Guidelines for Altera megafunctions and library of parameterized module (LPM) functions, instantiating them with the MegaWizard™ Plug-In Manager, and tips for inferring them from hardware description language (HDL) code
- Incremental compilation and block-based design, including the MultiPoint flow in the Synplify Pro and Synplify Premier software

The content in this chapter applies to the Synplify, Synplify Pro, and Synplify Premier software unless otherwise specified. This chapter includes the following sections:

- "Altera Device Family Support"
- "Design Flow" on page 10–2
- "Synplify Optimization Strategies" on page 10–6
- "Exporting Designs to the Quartus II Software Using NativeLink Integration" on page 10–14
- "Guidelines for Altera Megafunctions and Architecture-Specific Features" on page 10–25
- "Incremental Compilation and Block-Based Design" on page 10–37

This chapter assumes that you have set up, licensed, and are familiar with the Synplify software.

Altera Device Family Support

The Synplify software maps synthesis results to Altera device families. The following list shows the Altera device families supported by the Synplify software version C-2009.03, with the Quartus II software version 9.0:

- ACEX® 1K
- APEX™ II, APEX 20K, APEX 20KC, APEX 20KE
- Arria® GX series
- Cyclone® series
- FLEX® 10K, FLEX 6000

- HardCopy® series
- MAX® II
- MAX 7000, MAX 3000
- Stratix® series, Stratix GX series

The Synplify software also supports the Excalibur™ ARM® legacy device that is supported in the Quartus II software only with a specific license requested at www.altera.com/mysupport.

The Synplify software also supports the FLEX 8000 and MAX 9000 legacy devices that are supported only in the Altera MAX+PLUS® II software.

To learn about new device support for a specific Synplify version, refer to the release notes at www.synopsys.com.

Design Flow

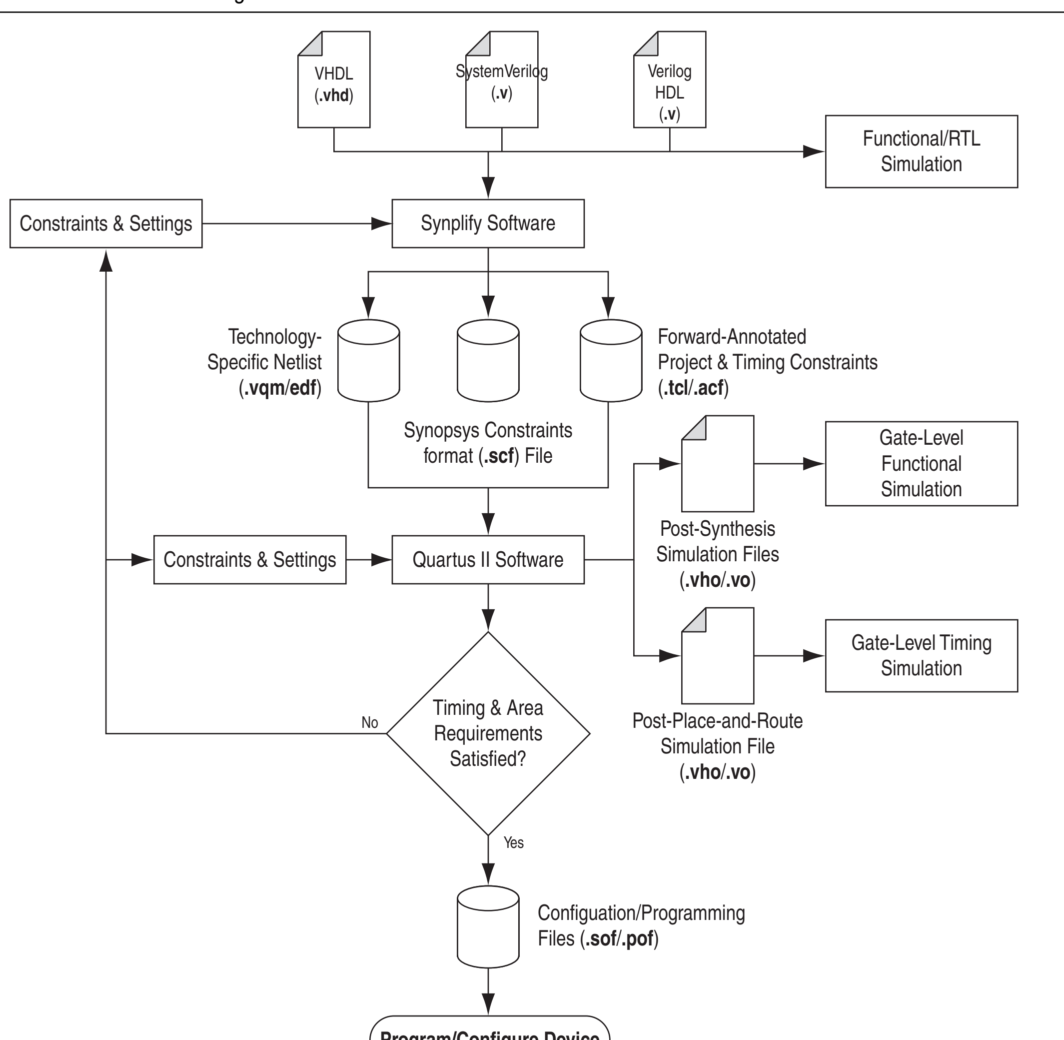
A Quartus II software design flow using the Synplify software consists of the following steps:

1. Create Verilog HDL or VHDL design files.
2. Set up a project in the Synplify software and add the HDL design files for synthesis.
3. Select a target device and add timing constraints and compiler directives in the Synplify software to optimize the design during synthesis.
4. Run synthesis in the Synplify software.
5. Create a Quartus II project and import these files generated by the Synplify software into the Quartus II software. These files are used for placement and routing, and for performance evaluation.
   - The technology-specific Verilog Quartus Mapping File (**.vqm**) netlist or EDIF (**.edf**) netlist for legacy devices also supported in the MAX+PLUS II software
   - The Synopsys Constraints Format (**.scf**) file for TimeQuest timing constraints
   - The tool command language (**.tcl**) constraint file

   Alternatively, you can run the Quartus II software from within the Synplify software. For more detailed information, refer to "Running the Quartus II Software from within the Synplify Software" on page 10–15.
6. After obtaining place-and-route results that meet your requirements, configure or program the Altera device.

Figure 10–1 shows the recommended design flow when using the Synplify and the Quartus II software.

Figure 10–1. Recommended Design Flow



The Synplify software supports VHDL, Verilog HDL, and SystemVerilog source files. However, only the Synplify Pro and Premier software supports mixed synthesis, allowing a combination of VHDL and Verilog HDL or SystemVerilog format source files.

Specify timing constraints and attributes for the design in a Synopsys Constraints File (**.scf**) with the SCOPE window in the Synplify software or directly in the HDL source file. Compiler directives can also be defined in the HDL source file. Many of these constraints are forward-annotated for use by the Quartus II software.

The HDL Analyst that is included in the Synplify software is a graphical tool for generating schematic views of the technology-independent register transfer level (RTL) view netlist (**.srs**) and technology-view netlist (**.srm**) files. You can use the Synplify HDL Analyst to analyze and debug your design visually. The HDL Analyst supports cross probing between the RTL and Technology views, the HDL source code, and the Finite State Machine (FSM) viewer. Synplify HDL Analyst also supports cross-probing between the technology view and the timing report file in the Quartus II software.

A separate license file is required to enable the HDL Analyst in the Synplify software. The Synplify Pro and Premier software include the HDL Analyst.

After synthesis is completed, import the **.vqm** or **.edf** netlist to the Quartus II software for place-and-route. Use the **.tcl** file generated by the Synplify software to forward-annotate your constraints (including device selection) and optionally to set up your project in the Quartus II software.

If you select a Stratix III, Cyclone III, Arria GX, or newer device, the Quartus II software uses the SDC-format timing constraints from the **.scf** file with the TimeQuest Timing Analyzer by default. If you select a Stratix II or Stratix II GX device, you have the option to switch from the Classic Timing Analyzer to the TimeQuest Timing Analyzer by turning on the **Use TimeQuest Timing Analyzer** option in the **Device** tab in the **Implementation Options** dialog box in the Synplify software. For other devices, the Quartus II software uses the Tcl-format timing constraints from the Quartus Setting File (**.qsf**) with the Classic Timing Analyzer. Refer to "Passing TimeQuest SDC Timing Constraints to the Quartus II Software in the .scf File" on page 10–16 for information about manually changing from the TimeQuest Timing Analyzer to the Classic Timing Analyzer in the Quartus II software.

If the area and timing requirements are satisfied, use the files generated by the Quartus II software to program or configure the Altera device. As shown in Figure 10–1, if your area or timing requirements are not met, you can change the constraints in the Synplify software or the Quartus II software and repeat the synthesis. Altera recommends that you provide the timing constraints as much as possible at the Synplify software level and the placement constraints at the Quartus II software level. Repeat the process until the area and timing requirements are met.

While you can perform simulation at various points in the process, you can also perform final timing analysis after placement and routing is complete. You can also perform formal verification at various stages of the design process.

For more information about how the Synplify software supports formal verification, refer to *Section III. Formal Verification* in volume 3 of the *Quartus II Handbook*.

You can also use other options and techniques in the Quartus II software to meet area and timing requirements. One such option is called WYSIWYG Primitive Resynthesis, which can perform optimizations on your **.vqm** netlist within the Quartus II software.

For information about netlist optimizations, refer to the *Netlist Optimizations and Physical Synthesis* chapter in volume 2 of the *Quartus II Handbook*.

In some cases, you might be required to modify the source code if the area and timing requirements cannot be met using options in the Synplify and Quartus II software.

After synthesis, the Synplify software produces several intermediate and output files. Table 10–1 lists these file types.

Table 10–1. Synplify Intermediate and Output Files (Part 1 of 2)

File Extensions	File Description
.srs	Technology-independent RTL netlist that can be read only by the Synplify software
.srm	Technology view netlist

Table 10–1. Synplify Intermediate and Output Files (Part 2 of 2)

File Extensions	File Description
.srr *(1)*	Synthesis Report file
.edf/.vqm	Technology-specific netlist in **.edf** or **.vqm** file format An **.edf** file is created for ACEX 1K, FLEX 10K, FLEX 10KA, FLEX 10KE, FLEX 6000, FLEX 8000, MAX 7000, MAX 9000, and MAX 3000 devices. A **.vqm** file is created for all other Altera device families.
.acf/.tcl	Forward-annotated constraints file containing constraints and assignments. A **.tcl** file for the Quartus II software is created for all devices. The **.tcl** file contains the appropriate Tcl commands to create and set up a Quartus II project and pass placement constraints. If applicable, the MAX+PLUS II assignments are imported from the **.acf** file.
.scf	Synopsys Constraint Format file containing timing constraints for the TimeQuest Timing Analyzer

Note to Table 10–1:

(1) This report file includes performance estimates that are often based on pre-place-and-route information. Use the f_{MAX} reported by the Quartus II software after place-and-route—it is the only reliable source of timing information. This report file includes post-synthesis device resource utilization statistics that might inaccurately predict resource usage after place-and-route. The Synplify software does not account for black box functions nor for logic usage reduction achieved through register packing performed by the Quartus II software. Register packing combines a single register and look-up table (LUT) into a single logic cell, reducing logic cell utilization below the Synplify software estimate. Use the device utilization reported by the Quartus II software after place-and-route.

Output Netlist File Name and Result Format

Specify the output netlist directory location and name for the Synplify software by performing the following steps:

1. On the Project menu, click **Implementation Options**.
2. Click the **Implementation Results** tab.
3. In the **Results Directory** box, type your output netlist file directory location.
4. In the **Result File Name** box, type your output netlist file name.

By default, the directory and file name are set to the project implementation directory and the top-level design module or entity name.

The **Result Format and Quartus Version** options are also available on the **Implementation Results** tab. The **Result Format** list specifies an **.edf** or **.vqm** netlist, depending on your device family. The software creates an **.edf** output netlist file only for ACEX 1K, FLEX 10K, FLEX 10KA, FLEX 10KE, FLEX 6000, FLEX 8000, MAX 7000, MAX 9000, and MAX 3000 devices. For other Altera devices, the software generates a **.vqm**-formatted netlist.

Select the version of the Quartus II software that you are using in the **Quartus Version** list. This option ensures that the netlist is compatible with the software version and supports the newest features. Altera recommends using the latest version of the Quartus II software whenever possible. If your Quartus II software is newer than the versions available in the **Quartus Version** list, check if there is a newer version of the Synplify software available that supports the current Quartus II software version. Otherwise, choose the latest version in the list for the best compatibility.

The **Quartus Version** list is available only after selecting an Altera device.

To set the Quartus II software version used in the Synplify software, perform the following steps:

1. In the Synplify software, on the Project menu, click **Implementation Options**.
2. Click the **Implementation Results** tab, then click **Quartus Version**.
3. Choose the correct version number in the list.

Alternatively, use the following command from the command line:

```
set_option -quartus_version <version number> ↵
```

Synplify Optimization Strategies

As designs become more complex and require increased performance, using different optimization strategies has become important. Combining Synplify software constraints with VHDL and Verilog HDL coding techniques and Quartus II software options can help you obtain the required results.

For additional design and optimization techniques, refer to the *Design Recommendations for Altera Devices and the Quartus II Design Assistant* chapter in volume 1 and the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*.

The Synplify software offers many constraints and optimization techniques to improve your design's performance. The Synplify Pro and Premier software add additional techniques that are not supported in the basic Synplify software. This section provides an overview of some of the techniques you can use to help improve the quality of your results.

For more information about applying the attributes discussed in this section, refer to the *Altera Constraints, Attributes, and Options* chapter of the *Synopsys FPGA Synthesis Reference Manual*.

Using Synplify Premier to Optimize Your Design

Synplify Premier offers additional physical synthesis optimizations than the other Synplify products. After regular logic synthesis, Synplify Premier places and routes the design and attempts to restructure the netlist based on the physical location of the logic in the Altera device. Synplify Premier forward-annotates the design netlist to the Quartus II software to perform the final placement and routing. In the default flow, Synplify Premier also forward-annotates placement information for the critical path(s) in the design, which can improve the compilation time in the Quartus II software.

The physical location annotation file is called <*design name*>**_plc.tcl**. If you call the Quartus II software from the Synplify Premier user interface, the Quartus II software automatically uses this file for the placement information.

The Physical Analyst allows you to examine the placed netlist from Synplify Premier, similar to the HDL Analyst for a logical netlist. You can use this display to analyze and diagnose possible problems.

Implementations in Synplify Pro or Premier

To create different synthesis results without overwriting the other results, in the Synplify Pro or Premier software, on the Project menu, click **New Implementation**. For each implementation, specify the target device, synthesis options, and constraint files. Each implementation generates its own subdirectory that contains all the resulting files, including **.vqm**/**.edf**, **.scf**, and **.tcl** files, from a compilation of the particular implementation. You can then compare the results of the different implementations to find the optimal set of synthesis options and constraints for a design.

Timing-Driven Synthesis Settings

The Synplify software supports timing-driven synthesis with user-assigned timing constraints to optimize the performance of the design. The Synplify software optimizes the design to attempt to meet these constraints.

The Quartus II NativeLink feature allows timing constraints that are applied in the Synplify software to be forward-annotated for the Quartus II software using either a **.tcl** script file or a **.scf** file for timing-driven place and route. Refer to "Passing TimeQuest SDC Timing Constraints to the Quartus II Software in the .scf File" on page 10–16 or "Passing Constraints to the Quartus II Software using Tcl Commands" on page 10–18 for more details about how constraints such as clock frequencies, false paths, and multicycle paths are forward-annotated. This section explains some of the important timing constraints in the Synplify software.

The Synplify Synthesis Report File (**.srr**) contains timing reports of estimated place-and-route delays. The Quartus II software can perform further optimizations on a post-synthesis netlist from third-party synthesis tools. In addition, designs might contain black boxes or intellectual property (IP) functions that have not been optimized by the third-party synthesis software. Actual timing results are obtained only after the design has gone through full placement and routing in the Quartus II software. For these reasons, the Quartus II post place-and-route timing reports provide a more accurate representation of the design. Use the statistics in these reports to evaluate design performance.

Clock Frequencies

For single-clock designs, specify a global frequency when using the push-button flow. While this flow is simple and provides good results, often it does not meet the performance requirements for more advanced designs. You can use timing constraints, compiler directives, and other attributes to help optimize the performance of a design. You can enter these attributes and directives directly in the HDL code. Alternatively, you can enter attributes (not directives) into an **.sdc** file with the SCOPE window in the Synplify software.

Use the SCOPE window to set global frequency requirements for the entire design and individual clock settings. Use the **Clocks** tab in the SCOPE window to specify frequency (or period), rise times, fall times, duty cycle, and other settings. Assigning individual clock settings, rather than over-constraining the global frequency, helps the Quartus II software and the Synplify software achieve the fastest clock frequency for the overall design. The `define_clock` attribute assigns clock constraints.

Multiple Clock Domains

The Synplify software can perform timing analysis on unrelated clock domains. Each clock group is a different clock domain and is treated as unrelated to the clocks in all other clock groups. All the clocks in a single clock group are assumed to be related and the Synplify software automatically calculates the relationship between the clocks. You can assign clocks to a new clock group or put related clocks in the same clock group by using the **Clocks** tab in the SCOPE window or with the `define_clock` attribute.

Input and Output Delays

Specify the input and output delays for the ports of a design in the **Input/Output** tab of the SCOPE window or with the `define_input_delay` and `define_output_delay` attributes. The Synplify software does not allow you to assign the t_{CO} and t_{SU} values directly to inputs and outputs. However, a t_{CO} value can be inferred by setting an external output delay; a t_{SU} value can be inferred by setting an external input delay.

Equation 10–1 illustrates the relationship between t_{CO} and the output delay:

Equation 10–1.

$$t_{CO} = \text{clock period} - \text{external output delay}$$

Equation 10–2 illustrates the relationship between t_{SU} and the input delay:

Equation 10–2.

$$t_{SU} = \text{clock period} - \text{external input delay}$$

When the `syn_forward_io_constraints` attribute is set to 1, the Synplify software passes the external input and output delays to the Quartus II software using NativeLink integration. The Quartus II software then uses the external delays to calculate the maximum system frequency.

Multicycle Paths

Specify any multicycle paths in the design in the **Multi-Cycle Paths** tab of the SCOPE window or with the `define_multicycle_path` attribute. A multicycle path is a path that requires more than one clock cycle to propagate. You must specify which paths are multicycle to avoid having the Quartus II and the Synplify compilers work excessively on a non-critical path. Not specifying these paths can also result in an inaccurate critical path being reported during timing analysis.

False Paths

False paths are paths that should not be considered during timing analysis or which should be assigned low (or no) priority during optimization. Some examples of false paths are slow asynchronous resets and test logic added to the design. Set these paths in the **False Paths** tab of the SCOPE window. Use the `define_false_path` attribute.

FSM Compiler

If the FSM Compiler is turned on, the compiler automatically detects state machines in a design. The compiler can then extract and optimize the state machine. The FSM Compiler analyzes the state machine and decides to implement sequential, gray, or one-hot encoding based on the number of states. It also performs unused-state analysis, optimization of unreachable states, and minimization of transition logic.

If the FSM Compiler is turned off, the compiler does not optimize logic as state machines. The state machines are implemented as coded in the HDL code. Thus, if the coding style for the state machine was sequential, the implementation is also sequential. If the FSM Compiler is turned on, the compiler infers and optimizes the state machines. The implementation is based on the number of states regardless of the coding style in the HDL code.

Use the `syn_state_machine` complier directive to specify or prevent a state machine from being extracted and optimized. To override the default encoding of the FSM Compiler, use the `syn_encoding` directive.

The values for the `syn_encoding` directive are shown in Table 10–2.

Table 10–2. syn_encoding Directive Values

Value	Description
Sequential	Generates state machines with the fewest possible flipflops. Sequential, also called binary, state machines are useful for area-critical designs when timing is not the primary concern.
Gray	Generates state machines where only one flipflop changes during each transition. Gray-encoded state machines tend to be free of glitches.
One-hot	Generates state machines containing one flipflop for each state. One-hot state machines typically provide the best performance and shortest clock-to-output delays. However, one-hot implementations are usually larger than sequential implementations.
Safe	Generates extra control logic to force the state machine to the reset state if an invalid state is reached. You can use the safe value in conjunction with the other three values, which results in the state machine being implemented with the requested encoding scheme and the generation of the reset logic.

Example 10–1 shows sample VHDL code for applying the `syn_encoding` directive.

Example 10–1. Sample VHDL Code for syn_encoding

```
SIGNAL current_state : STD_LOGIC_VECTOR(7 DOWNTO 0);
ATTRIBUTE syn_encoding : STRING;
ATTRIBUTE syn_encoding OF current_state : SIGNAL IS "sequential";
```

The default is to optimize state machine logic for speed and area, but this is potentially undesirable for critical systems. The safe value generates extra control logic to force the state machine to the reset state if an invalid state is reached.

FSM Explorer in Synplify Pro and Premier

The Synplify Pro and Premier software can use FSM Explorer to explore different encoding styles for a state machine automatically, and then implement the best encoding based on the overall design constraints. FSM Explorer uses the FSM Compiler to identify and extract state machines from a design. However, unlike the FSM Compiler that chooses the encoding style based on the number of states, the FSM Explorer tries several different encoding styles before choosing a specific one. The trade-off is that the compilation requires more time to perform the analysis of the state machine, but finds an optimal encoding scheme for the state machine.

Optimization Attributes and Options

The following sections describe other attributes and options that you can modify in the Synplify software to improve your design performance.

Retiming in Synplify Pro and Premier

The Synplify Pro and Premier software can retime a design, which can improve the timing performance of sequential circuits by moving registers (register balancing) across combinational elements. Be aware that retimed registers incur name changes. To retime your design, turn on the **Retiming** option in the **Device** tab in the **Implementation Options** section, or use the `syn_allow_retiming` attribute.

Maximum Fan-Out

When your design has critical path nets with high fan-out, use the `syn_maxfan` attribute to control the fan-out of the net. Setting this attribute for a specific net results in the replication of the driver of the net to reduce overall fan-out. The `syn_maxfan` attribute takes an integer value and applies it to inputs or registers. (The `syn_maxfan` attribute cannot be used to duplicate control signals. The minimum allowed value of the attribute is 4.) Using this attribute might result in increased logic resource utilization, thus putting a strain on routing resources and leading to long compile times and difficult fitting.

If you must duplicate an output register or output enable register, you can create a register for each output pin by using the `syn_useioff` attribute (refer to “Register Packing”).

Preserving Nets

During synthesis, the compiler maintains ports, registers, and instantiated components. However, some nets cannot be maintained to create an optimized circuit. Applying the `syn_keep` directive overrides the optimization of the compiler and preserves the net during synthesis. The `syn_keep` directive takes a Boolean value and can be applied to wires (Verilog HDL) and signals (VHDL). Setting the value to **true** preserves the net through synthesis.

Register Packing

Altera devices allow for the packing of registers into I/O cells. Altera recommends allowing the Quartus II software to make the I/O register assignments. However, you can control register packing with the `syn_useioff` attribute. The `syn_useioff` attribute takes a Boolean value and can be applied to ports or entire modules. Setting the value to **1** instructs the compiler to pack the register into an I/O cell. Setting the value to **0** prevents register packing in both the Synplify and Quartus II software.

Resource Sharing

The Synplify software uses resource sharing techniques during synthesis by default to reduce area. Turning off the **Resource Sharing** option on the **Options** tab of the **Implementation Options** dialog box improves performance results for some designs. You can also turn off the option for a specific module with the `syn_sharing` attribute. If you turn off this option, be sure to check the results to determine if it helps the timing performance. If it does not help, leave **Resource Sharing** turned on.

Preserving Hierarchy

The Synplify software performs cross-boundary optimization by default. This results in the flattening of the design to allow optimization. Use the `syn_hier` attribute to over-ride the default compiler settings. The `syn_hier` attribute takes a string value and applies it to modules, architectures, or both. Setting the value to **hard** maintains the boundaries of a module, architecture, or both, but allows constant propagation. Setting the value to **locked** prevents all cross-boundary optimizations. Use the **locked** setting with the partition setting to create separate design blocks and multiple output netlists for incremental compilation, as described in "Using MultiPoint Synthesis with Incremental Compilation" on page 10–39.

By default, the Synplify software generates a hierarchical **.vqm** file. To flatten the file, set the `syn_netlist_hierarchy` attribute to **0**.

Register Input and Output Delays

The advanced options called `define_reg_input_delay` and `define_reg_output_delay` can speed up paths feeding a register or coming from a register by a specific number of nanoseconds. The Synplify software attempts to meet the global clock frequency goals for a design as well as the individual clock frequency goals (set with `define_clock`). You can use these attributes to add delay to paths feeding into or out of registers to further constrain critical paths. The setting also works with negative numbers, so you can slow down a path that is too highly optimized.

These options are useful to close timing when your design does not meet timing goals because the routing delay after placement and routing exceeds the delay predicted by the Synplify software. Rerun synthesis using these options, specifying the actual routing delay (from place-and-route results) so that the tool can meet the required clock frequency. Synopsys recommends that for best results, do not make these assignments too aggressively. For example, increase the routing delay value but don't use the full routing delay from the last compilation.

In the SCOPE constraint window, use the registers panel with the following entries:

- **Register—**Specifies the name of the register. If you have initialized a compiled design, choose the name from the list.

- **Type**—Specifies whether the delay is an input or output delay.
- **Route**—Shrinks the effective period for the constrained registers by the specified value without affecting the clock period that is forward-annotated to the Quartus II software.

Use the following Tcl command syntax to specify an input or output register delay in nanoseconds.

Example 10–2. Specifying an Input or Output Register Delay Using Tcl Command Syntax

```
define_reg_input_delay {<register>}  -route <delay in ns>
define_reg_output_delay {<register>} -route <delay in ns>
```

syn_direct_enable

This attribute controls the assignment of a clock-enable net to the dedicated enable pin of a register. Using this attribute, you can direct the Synplify mapper to use a particular net as the only clock enable when the design has multiple clock enable candidates.

You can also use this attribute as a compiler directive to infer registers with clock enables. To do so, enter the `syn_direct_enable` directive in your source code, not the SCOPE spreadsheet.

The `syn_direct_enable` data type is Boolean. A value of **1** or **true** enables net assignment to the clock-enable pin. The following is the syntax for Verilog HDL:

```
object /* synthesis syn_direct_enable = 1 */ ;
```

Standard I/O Pad

For certain Altera devices and the equivalent device I/O standard, specify the I/O standard type to use for the I/O pad in the design using the **I/O Standard** panel in the Synplify SCOPE window.

Example 10–3 shows the Synplify SDC syntax for the `define_io_standard` constraint, in which the `delay_type` must be either `input_delay` or `output_delay`.

Example 10–3. Synplify SDC Syntax for the define_io_standard Constraint

```
define_io_standard [-disable|-enable] {<objectName>} -delay_type \
[input_delay|output_delay] <columnTclName>{<value>} [<columnTclName>{<value>}...]
```

For details about supported I/O standards, refer to *Altera I/O Standards* in the *Synopsys FPGA Synthesis Reference Manual.*

Altera-Specific Attributes

The following attributes are for use with specific Altera device features. These attributes are forward-annotated to the Quartus II project and are used during the place-and-route process.

altera_chip_pin_lc

Use this attribute to make pin assignments. This attribute takes a string value and applies it to inputs and outputs. Use the attribute only on the ports of the top-level entity in the design. Do not use this attribute to assign pin locations from entities at lower levels of the design hierarchy.

This attribute is not supported for any of the MAX series devices. In the SCOPE window, select the attribute **altera_chip_pin_lc** and set the value to a pin number or a list of pin numbers.

Example 10–4 shows VHDL code for making location assignments to ACEX 1K and FLEX 10KE devices.

The "@" sign prefix is used to specify pin locations for only ACEX 1K and FLEX 10KE devices. For these devices, pin location assignments are written to the output **.edf** file.

Example 10–4. Making Location Assignments to ACEX 1K and FLEX 10KE Devices, VHDL

```
ENTITY sample (data_in : IN STD_LOGIC_VECTOR (3 DOWNTO 0);
   data_out: OUT STD_LOGIC_VECTOR (3 DOWNTO 0));
ATTRIBUTE altera_chip_pin_lc : STRING;
ATTRIBUTE altera_chip_pin_lc OF data_out : SIGNAL IS "@14, @5,@16, @15";
```

Example 10–5 shows VHDL code for making location assignments for other Altera devices. Pin location assignments for these devices are written to the output Tcl script.

Example 10–5. Making Location Assignments to Other Devices, VHDL

```
ENTITY sample (data_in : IN STD_LOGIC_VECTOR (3 DOWNTO 0);
   data_out: OUT STD_LOGIC_VECTOR (3 DOWNTO 0));
ATTRIBUTE altera_chip_pin_lc : STRING;
ATTRIBUTE altera_chip_pin_lc OF data_out : SIGNAL IS "14, 5, 16, 15";
```

The `data_out` signal is a 4-bit signal; `data_out[3]` is assigned to pin 14 and `data_out[0]` is assigned to pin 15.

altera_implement_in_esb or altera_implement_in_eab

Use these attributes to implement logic in either embedded system blocks (ESBs) or embedded array blocks (EABs) rather than in logic resources to improve area utilization. The modules selected for such implementation cannot have feedback paths, and either all or none of the I/Os must be registered. This attribute takes a boolean value and can be applied to instances. (This option is applicable for devices with ESBs/EABs only. For example, the Stratix device family is not supported by this option. This attribute is ignored for designs targeting devices that do not have ESBs or EABs.)

altera_io_powerup

Use this attribute to define the power-up value of an I/O register that has no set or reset. This attribute takes a string value (**high** | **low**) and applies it to ports that have I/O registers. By default, the power-up value of the I/O is set to **low**.

altera_io_opendrain

Use this attribute to specify open-drain mode I/O ports. This attribute takes a boolean value and applies it to outputs or bidirectional ports for devices that support open-drain mode.

Exporting Designs to the Quartus II Software Using NativeLink Integration

The NativeLink feature in the Quartus II software facilitates the seamless transfer of information between the Quartus II software and EDA tools, and allows you to run other EDA design entry or synthesis, simulation, and timing analysis tools automatically from within the Quartus II software. After a design is synthesized in the Synplify software, a **.vqm** or **.edf** netlist file, an **.scf** file for TimeQuest Timing Analyzer timing constraints, and **.tcl** files are used to import the design into the Quartus II software for place-and-route. You can run the Quartus II software from within the Synplify software or as a stand-alone application. After you have imported the design into the Quartus II software, you can specify different options to further optimize the design.

When you are using NativeLink integration, the path to your project must not contain white space. The Synplify software uses Tcl scripts to communicate with the Quartus II software, and the Tcl language does not accept arguments with white space in the path.

Use NativeLink integration to integrate the Synplify software and Quartus II software with a single GUI for both synthesis and place-and-route operations. NativeLink integration allows you to run the Quartus II software from within the Synplify software GUI or to run the Synplify software from within the Quartus II software GUI.

This section explains the different NativeLink flows and provides details about how constraints are passed to the Quartus II software. This section describes the following topics:

- "Running the Quartus II Software from within the Synplify Software" on page 10–15
- "Using the Quartus II Software to Run the Synplify Software" on page 10–15
- "Running the Quartus II Software Manually Using the Synplify-Generated Tcl Script" on page 10–16
- "Passing TimeQuest SDC Timing Constraints to the Quartus II Software in the .scf File" on page 10–16
- "Passing Constraints to the Quartus II Software using Tcl Commands" on page 10–18

Running the Quartus II Software from within the Synplify Software

To use the Quartus II software from within the Synplify software, you must first verify that the `QUARTUS_ROOTDIR` environment variable contains the Quartus II software installation directory located at <*Altera Design Suite Installation Directory*>**\quartus**. This environment variable is required to use the Synplify and Quartus II software together.

In the Windows operating system, the `QUARTUS_ROOTDIR` variable is set when you open the Quartus II user interface, so it is automatically set to the most recent version you opened in the user interface. If your software installation is located on another machine, ensure that you set this variable correctly. You can change the variable manually using the Control Panel, System icon.

On UNIX and Linux operating systems, the variable is not set automatically, so you must create an environment variable `QUARTUS_ROOTDIR` that points to the <*Altera Design Suite Installation Directory*>**/quartus** location.

Under each implementation in the Synplify Pro software, create a place-and-route implementation called `pr_`<*number*> `Altera Place and Route`. You can create new place and route implementations using the **New P&R** button in the GUI. To run the Quartus II software in command-line mode after each synthesis run, use the text box to turn on the place-and-route implementation. The results of the place and route are written to a log file in the **pr_**<*number*> directory under the current implementation directory.

You can also use the commands in the Quartus II menu to run the Quartus II software at any time following a successful completion of synthesis. In the Synplify software, on the Options menu, click **Quartus II** and then choose one of the following commands:

- **Launch Quartus**—Opens the Quartus II software GUI and creates a Quartus II project with the synthesized output file, forward-annotated timing constraints, and pin assignments. Use this command to configure options for the project and execute any Quartus II commands.
- **Run Background Compile**—Runs the Quartus II software in command-line mode with the project settings from the synthesis run. The results of the place-and-route are written to a log file.

The <*project_name*>**_cons.tcl** file is used to set up the Quartus II project and calls the <*project_name*>**.tcl** file to pass constraints from the Synplify software to the Quartus II software. By default, the <*project_name*>**.tcl** file contains device, timing, and location assignments. If the project is set up to use the TimeQuest Timing Analyzer, the <*project_name*>**.tcl** file contains the command to use the Synplify-generated **.scf** constraints file with TimeQuest instead of using the Tcl constraints with the Classic Timing Analyzer.

Using the Quartus II Software to Run the Synplify Software

You can set up the Quartus II software to run the Synplify software for synthesis using NativeLink integration. This feature allows you to use the Synplify software to quickly synthesize a design as part of a normal compilation in the Quartus II software. When you use this feature, the Synplify software does not use any timing constraints or assignments such as incremental compilation partitions that you have set in the Quartus II software.

For best results, Synopsys recommends that you set constraints in the Synplify software and use the Tcl script to pass these constraints to the Quartus II software, instead of calling Synplify from within the Quartus II software.

To set up Synplify in the Quartus II software, on the Tools menu, click **Options**. In the **Options** dialog box, click **EDA Tool Options** and specify the path of Synplify or Synplify Pro software.

For detailed information about using NativeLink integration with the Synplify software, refer to the Quartus II Help.

Beginning with the Quartus II software version 7.1, running the Synplify software with NativeLink integration is supported on both floating network and node-locked single-PC licenses. Both types of licenses support batch mode compilation.

Running the Quartus II Software Manually Using the Synplify-Generated Tcl Script

You can also use the Quartus II software separately from the Synplify software. To run the Tcl script generated by the Synplify software to set up your project and set up assignments such as the device selection, perform the following steps:

1. Ensure the **.vqm**/**.edf**, **.scf** (if you are using the TimeQuest Timing Analyzer timing constraints), and **.tcl** files are located in the same directory (they are located in the implementation directory by default).
2. In the Quartus II software, on the View menu, point to **Utility Windows** and click **Tcl Console.** The Quartus II Tcl Console opens.
3. At the Tcl Console command prompt, type the following:

```
source <path>/<project name>_cons.tcl ↵
```

Passing TimeQuest SDC Timing Constraints to the Quartus II Software in the .scf File

The TimeQuest Timing Analyzer is a powerful ASIC-style timing analysis tool that validates the timing performance of all logic in your design using an industry standard constraints format, Synopsys Design Constraints (SDC). This section explains how timing constraints set in the Synplify software are passed to the Quartus II software for use with the TimeQuest Timing Analyzer.

The timing constraints you set in the Synplify software are stored in the Synplify Design Constraints (**.sdc**) file. The **.tcl** file always contains all other constraints for the Quartus II software, such as the device specification and any location constraints. The timing constraints are forward-annotated using the **.tcl** file for the Quartus II Classic Timing Analyzer, as described in "Passing Constraints to the Quartus II Software using Tcl Commands" on page 10–18. For the TimeQuest Timing Analyzer, the timing constraints are forward-annotated in the Synopsys Constraints Format (**.scf**) file.

Altera recommends that you use the TimeQuest Timing Analyzer, as specified in the Synplify **.tcl** file that sets up the Quartus II project for the newest devices. However, you can use the Tcl commands for the Classic Timing Analyzer if required. You can manually change from the TimeQuest Timing Analyzer to the Classic Timing Analyzer in the Quartus II software by performing the following steps:

1. From the Assignments menu, click **Settings**.

2. In the **Category** list, select **Timing Analysis Settings**.
3. Under **Timing analysis processing**, select **Use Classic Timing Analyzer during compilation**.
4. Click **OK**.

For additional information about the TimeQuest Timing Analyzer, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Synopsys recommends that you modify constraints using the SCOPE constraint editor window and not through the generated **.sdc**, **.scf**, or **.tcl** file.

The following list of Synplify constraints are converted to the equivalent Quartus II SDC commands and are forward-annotated to the Quartus II software in the **.scf** file:

- `define_clock`
- `define_input_delay`
- `define_output_delay`
- `define_multicycle_path`
- `define_false_path`

All Synplify constraints described in the following sections use the same Synplify commands as described in "Passing Constraints to the Quartus II Software using Tcl Commands" on page 10–18; however, the constraints are mapped to SDC commands for the TimeQuest Timing Analyzer.

For syntax and arguments for these commands, refer to the applicable subsection or refer to Synplify Help. For a list of corresponding commands in the Quartus II software, refer to the Quartus II Help.

Individual Clocks and Frequencies

Specify clock frequencies for individual clocks in the Synplify software with the command `define_clock`. This command is passed to the Quartus II software with `create_clock`.

Input and Output Delay

Specify input delay and output delay constraints in the Synplify software with the commands `define_input_delay` and `define_output_delay`, respectively. These commands are passed to the Quartus II software with `set_input_delay` and `set_output_delay`.

Multicycle Path

Specify a multicycle path constraint in the Synplify software with the command `define_multicycle_path`. This command is passed to the Quartus II software with `set_multicycle_path`.

False Path

Specify a false path constraint in the Synplify software with the command `define_false_path`. This command is passed to the Quartus II software with `set_false_path`.

Passing Constraints to the Quartus II Software using Tcl Commands

This section describes how Synplify constraints are converted to the equivalent Quartus II assignments and are forward-annotated to the Quartus II software with Tcl commands.

This section also describes timing constraints for the Quartus II Classic Timing Analyzer. If you are using the TimeQuest Timing Analyzer, the Quartus II timing constraints described in this section do not apply. Refer to "Passing TimeQuest SDC Timing Constraints to the Quartus II Software in the .scf File" on page 10–16 for information about timing constraints supported by TimeQuest.

Global Signals

The Synplify software automatically promotes clock signals to global routing lines and passes Global Signal assignments to the Quartus II software. The assignments ensure that the same global routing constraints are applied during placement and routing.

The signals promoted to global routing can be different than the ones that the Quartus II software promotes to global routing by default. The Synplify software promotes only clock signals and not other control signals such as reset or enable. By default, without constraints from the Synplify software, the Quartus II software promotes control signals to global routing if they have high fan-out.

Default or Global Clock Frequency

Use the following Synplify command to set the Synplify default or global clock frequency that applies to the entire project:

```
set_option -frequency <frequency>
```

The <*frequency*> is specified in MHz. If a global frequency is not specified, the software uses the default global clock frequency of 1 MHz.

The `set_option` constraint is passed to the Quartus II software with the following command:

```
set_global_assignment -name FMAX_REQUIREMENT <frequency> MHz
```

If a frequency is not specified in the Quartus II software, the software uses the default global clock frequency of 1 GHz.

Individual Clocks and Frequencies

Specify clock frequencies for individual clocks with the following Synplify commands as shown in Example 10–6.

Example 10–6. Specifying Clock Frequencies for Individual Clocks

```
define_clock -name {<clock_name>} -freq <frequency> -clockgroup <clock_group> -rise <rise_time>\
-fall <fall_time>
define_clock -name {<clock_name>} -period <period> -clockgroup <clock_group> -rise <rise_time>\
-fall <fall_time>
```

Table 10–3 shows the command arguments.

 © March 2009 Altera Corporation

Table 10–3. Command Arguments

Argument	Description
`-name`	The <*clock_name*> specifies a design port name or register output signal name and, after synthesis, corresponds to a <*mapped_clock_name*>.
`-freq` *(1)*	The <*frequency*> is specified in MHz.
`-period` *(2)*	The <*period*> is specified in ns.
`-clockgroup`	If the <*clock_group*> is not specified, it defaults to `default_clkgroup`. The Synplify software assumes all clocks belonging to the same clock group are related. If you do not specify a clock group, the clock belongs to the default clock group. Therefore, if you do not specify any clock groups, all the clocks are considered related by default in the software.
`-rise` `-fall`	The <*rise_time*> and <*fall_time*> specify a non-default duty cycle. By default, the Synplify synthesis tool assumes that the clock is a 50% duty cycle clock, with the rising edge at 0 and the falling edge at period/2. If you have another duty clock cycle, you can specify the appropriate **Rise At** and **Fall At** values.

Notes to Table 10–3:

(1) When the <*frequency*> is specified, the Synplify software uses <*fall_time*>and <*frequency*> to calculate the `duty_cycle` with the following formula: `duty_cycle` = (<*fall_time*> – <*rise_time*>) × <*frequency*> / 100.

(2) When the <*period*> is specified, the Synplify software uses <*fall_time*> and <*period*> to calculate the `duty_cycle` with the following formula: `duty_cycle` = 100 × (<*fall_time*> – <*rise_time*>) / <*period*>.

The equivalent Quartus II Classic Timing Analyzer commands depend on how the clock groups are defined. In the Quartus II software, clocks that belong to the same or related clock settings are considered related clocks. Clocks assigned to unrelated clock settings are unrelated clocks. There is a one-to-one correspondence between each Quartus II clock setting and a Synplify clock group.

The following sections describe only the frequency constraints. Use the corresponding constraints for the period.

Virtual Clocks

The Quartus II software supports virtual clocks. If you use the virtual clock setting in the Synplify software, the setting is mapped to a constraint in the Quartus II software.

Route Delay Option

The `-route` option in the Synplify software clock constraints is designed for use in synthesis only if you do not meet timing goals because the routing delay after placement and routing exceeds the delay predicted by the Synplify software. This constraint does not have to be forward-annotated to the Quartus II software.

Multiple Clocks in Different Clock Groups

You can specify clock frequencies for multiple clocks with the Synplify commands shown in Example 10–7.

Example 10–7. Specifying Clock Frequencies for Multiple Clocks

```
define_clock -name {<clock_name1>} -freq <frequency1> -clockgroup <clock_group1> \
-rise <rise_time1> -fall <fall_time1>

define_clock -name {<clock_name2>} -freq <frequency2> -clockgroup <clock_group2> \
-rise <rise_time2> -fall <fall_time2>
```

<clock_group1> and *<clock_group2>* are unique names defined in the Synplify software for base clock settings in the Quartus II Classic Timing Analyzer.

If the clock *<rise_time>* is zero (“0”), multiple separate clocks are passed to the Quartus II software with the commands shown in Example 10–8.

Example 10–8. Quartus II Assignments for Multiple Clocks if the Clock Rise Time is Zero

```
create_base_clock -fmax <frequency1>MHz -duty_cycle <duty_cycle1> \
-target mapped_clock_name1 <base_clock_setting1>

create_base_clock -fmax <frequency2>MHz -duty_cycle <duty_cycle2> \
-target mapped_clock_name2 <base_clock_setting2>
```

If the clock *<rise_time>* is non-zero, multiple separate clocks are passed to the Quartus II software with the following commands shown in Example 10–9.

Example 10–9. Quartus II Assignments for Multiple Clocks if the Clock Rise Time is Not Zero

```
create_base_clock -fmax <frequency1>MHz -duty_cycle <duty cycle1> -no_target <base clock setting1>

create_base_clock -fmax <frequency2>MHz -duty_cycle <duty cycle2> -no_target <base clock setting2>

create_relative_clock -base_clock <base clock setting1> -offset <rise time1>ns \
-duty_cycle <duty cycle1> -multiply <multiply by> -divide <divide by> \
-target <mapped clock name1> <derived clock setting1>

create_relative_clock -base_clock <base clock setting2> -offset <rise time2>ns \
-duty_cycle <duty cycle2> -multiply <multiply by> -divide <divide by> \
-target <mapped clock name2> <derived clock_setting2>
```

Multiple Clocks with Different Frequencies in the Same Clock Group

In the Synplify software, you can specify multiple clocks with relative clock settings in the same clock group with different frequencies, with the commands shown in Example 10–10.

Example 10–10. Specifying Multiple Clocks with Different Frequencies in the Same Clock Group

```
define_clock -name {<clock_name1>} -freq <frequency1> -clockgroup <clock_group1> \
-rise <rise_time1> -fall <fall_time1>

define_clock -name {<clock_name2>} -freq <frequency2> -clockgroup <clock_group2> \
-rise <rise_time2> -fall <fall_time2>
```

When you specify clocks with different frequencies in the same clock group, the software calculates the *<multiply_by>* and the *<divide_by>* factors for relative clock settings from *<frequency1>* and *<frequency2>* in the clock group settings.

If the clock *<rise_time>* is zero, multiple clocks with relative clock settings in the same clock group with different frequencies are passed to the Quartus II software with the commands shown in Example 10–11.

Example 10–11. Quartus II Assignments for Multiple Clocks with Different Frequencies in the Same Clock Group, if the Clock Rise Time is Zero

```
create_base_clock -fmax <frequency1>MHz -duty_cycle <duty_cycle1> \
-target <mapped_clock_name1> <base_clock_setting1>

create_relative_clock -base_clock <base_clock_setting1> -duty_cycle <duty_cycle2> \
-multiply <multiply_by> -divide <divide_by> -target <mapped_clock_name2> <derived_clock_setting2>
```

Inter-Clock Relationships—Delays and False Paths between Clocks

Set a clock-to-clock delay constraint in Synplify with the commands in Example 10–12.

Example 10–12. Specifying Clock-to-Clock Delay Constraints

```
define_clock_delay -fall <clock_name1> -rise <clock_name2> <delay_value>
define_clock_delay -rise <clock_name1> -fall <clock_name2> <delay_value>
define_clock_delay -rise <clock_name1> -rise <clock_name2> <delay_value>
define_clock_delay -fall <clock_name1> -fall <clock_name2> <delay_value>
```

If <*delay_value*> is set to `false`, these constraints in Synplify indicate a false path between the two clocks. If all four rise/fall clock-edge pairs are specified in the Synplify software, the Synplify constraints are mapped to the following constraint in the Quartus II software:

```
set_timing_cut_assignment -from <clock_name1> -to <clock_name2>
```

If all four clock-edge pairs are not specified in Synplify, the constraint cannot be mapped to a constraint for the Quartus II Classic Timing Analyzer.

If <*delay_value*> is set to a value other than `false`, these constraints in Synplify are not mapped to constraints in the Quartus II software. The Quartus II Classic Timing Analyzer does not support clock-edge to clock-edge delay constraints.

False Paths

Specify the false path constraint in the Synplify software with the following command:

```
define_false_path -from <sig_name1> -to <sig_name2>
```

The signals <*sig_name1*> and <*sig_name1*> can be design port names or register instance names.

The **define_false_path** constraint in the Synplify software is mapped to the constraint in the Quartus II software, as shown in the following command:

```
set_timing_cut_assignment -from <sig_name2> -to <sig_name2>
```

The Synplify software can identify pairs of signal sets such that every member of the cross-product of these two sets is a valid false path constraint. Signal groups can be defined in the Quartus II Classic Timing Analyzer with the following commands:

```
timegroup -add_member sig_name1_i <sig_group1>
(for every signal in <sig_group1>)
timegroup -add_member sig_name2_i <sig_group2>
(for every signal in <sig_group2>)
set_timing_cut_assignment -from <sig_group1> -to <sig_group2>
```

If the signals <*sig_name1*> or <*sig_name2*> represent multiple signals such as a wildcard, group, or bus, the constraints can be appropriately expanded for representation in the Quartus II software. The Quartus II software supports wildcard signal names, and signal groups for timing assignments. The Quartus II software does not support bus notation, such as **A[7:4]**.

False Path from a Signal

Specify a false path constraint from a signal in the Synplify software with the following command:

```
define_false_path -from <sig_name>
```

The Quartus II Classic Timing Analyzer does not support "from-only" path specifications. You must also include a "to-path" specification. However, you can specify a wildcard for the `-to` signal. This constraint in Synplify is mapped to the following constraint in the Quartus II software:

```
set_timing_cut_assignment -from <sig_name> -to {*}
```

False Path to a Signal

Specify a false path constraint to a signal in the Synplify software with the following command:

```
define_false_path -to <sig_name>
```

The Quartus II Classic Timing Analyzer does not support "to-only" path specifications. You must include a "from-path" specification. However, you can specify a wildcard for the `-from` signal. This constraint in the Synplify software is mapped to the following constraint in the Quartus II software:

```
set_timing_cut_assignment -from {*} -to <sig_name>
```

False Path through a Signal

Specify a false path constraint through a signal in the Synplify software with the following command:

```
define_false_path -from <sig_name1> -to <sig_name2> \
-through <sig_name3>
```

The Quartus II Classic Timing Analyzer does not support false paths with a "through path" specification. Any constraint in the Synplify software with a `-through` specification is not mapped to a constraint for the Quartus II Classic Timing Analyzer.

Multicycle Paths

Specify a multicycle path constraint in the Synplify software with the following command:

```
define_multicycle_path -from <sig_name1> -to <sig_name2> <clock_cycles>
```

This constraint in the Synplify software is mapped to the following constraint in the Quartus II software:

```
set_multicycle_assignment -from <sig_name1> \
-to <sig_name2> <clock_cycles>
```

If the signals <*sig_name1*> or <*sig_name2*> represent multiple signals such as a wildcard, group, or bus, the constraints can be appropriately expanded for representation in the Quartus II software as described in "False Paths" on page 10–8.

<clock_cycles> is the number of clock cycles for the multicycle path.

Multicycle Path from a Signal

Specify a multicycle path constraint from a signal in the Synplify software with the following command:

```
define_multicycle_path -from <sig_name> <clock_cycles>
```

This constraint is mapped using a wildcard for the `-to` value in the Quartus II Classic Timing Analyzer, similar to the false path constraints:

```
set_multicycle_assignment -from <sig_name> -to {*} <clock_cycles>
```

Multicycle Path to a Signal

Specify a multicycle path constraint to a signal in the Synplify software with the following command:

```
define_multicycle_path -to <sig_name> <clock_cycles>
```

This constraint is mapped using a wildcard for the `-from` value in the Quartus II Classic Timing Analyzer, similar to the false path constraints:

```
set_multicycle_assignment -from {*} -to <sig_name> <clock_cycles>
```

Multicycle Path through a Signal

Specify a multicycle path constraint through a signal in the Synplify software using the following command:

```
define_multicycle_path -from <sig_name1> -to <sig_name2> \
-through <sig_name3> <clock_cycles>
```

The Quartus II Classic Timing Analyzer does not support multicycle paths with a "through path" specification. Any constraint in the Synplify software with a `-through` specification is not mapped to a constraint for the Quartus II Classic Timing Analyzer.

Maximum Path Delays

Specify the maximum path delay relationships between signals in the Synplify software with the following command:

```
define_path_delay -from <sig_name1> -to <sig_name2> -max <delay_value>
```

This constraint in the Synplify software is mapped to the following constraint in the Quartus II software:

```
set_instance_assignment -from <sig_name1> \
-to <sig_name2> -name SETUP_RELATIONSHIP <delay_value>ns
```

The Quartus II Classic Timing Analyzer does not support signal groups or bus notation. It supports only register names for this constraint.

Maximum Path Delay from a Signal

Specify the maximum path delay constraint from a signal in the Synplify software with the following command:

```
define_path_delay -from <sig_name> -max <delay_value>
```

This constraint is mapped using a wildcard for the `-to` value in the Quartus II Classic Timing Analyzer, similar to false path constraints:

```
set_instance_assignment -from <sig_name> -to {*} \
-name SETUP_RELATIONSHIP <delay_value>ns
```

Maximum Path Delay to a Signal

Specify the maximum path delay constraint to a signal in the Synplify software with the following command:

```
define_path_delay -to <sig_name> -max <delay_value>
```

This constraint is mapped using a wildcard for the `-from` value in the Quartus II Classic Timing Analyzer, similar to the false path constraints.

```
set_instance_assignment -from {*}<sig_name> \
-to <sig_name> -name SETUP_RELATIONSHIP <delay_value>ns
```

Maximum Path Delay through a Signal

Specify the maximum path delay constraint through a signal in the Synplify software with the following command:

```
define_path_delay -from <sig_name1> -to <sig_name2> \
-through <sig_name3> -max <delay_value>
```

The Quartus II Classic Timing Analyzer does not support maximum path delay constraints with a "through path" specification. Any constraint in Synplify with a `-through` specification is not mapped to a constraint for the Quartus II Classic Timing Analyzer.

Register Input and Output Delays

These register input delay and register output delay constraints in the Synplify software are for use in synthesis only, and therefore are not forward-annotated to the Quartus II software.

Default External Input Delay

Specify the default input delay constraint in the Synplify software with the following command:

```
define_input_delay -default <delay_value>
```

This constraint is mapped to the following constraint in the Quartus II software:

```
set_input_delay -clock {*} <delay_value> {*}
```

Port-Specific External Input Delay

Specify a port-specific input delay constraint in the Synplify software with the following command:

```
define_input_delay <input_port_name> <delay_value> \
-ref <clock_name>:<clock_edge>
```

The *<clock_edge>* can be set to **`r`** (rising edge) or **`f`** (falling edge).

When the clock edge is **`r`** (rising edge), this constraint is mapped to the following constraint in the Quartus II software:

```
set_input_delay -clock <clock_name> <delay_value> <input_port_name>
```

When the <*clock_edge*> is **f** (falling edge), this constraint is not mapped to a constraint in the Quartus II software. The Quartus II Classic Timing Analyzer does not support the specification of input delays with respect to the falling edge of the clock.

Default External Output Delay

Specify the default output delay constraint in the Synplify software with the following command:

```
define_output_delay -default <delay_value>
```

This constraint is mapped to the following constraint in the Quartus II software:

```
set_output_delay -clock {*} <delay_value> {*}
```

Port-Specific External Output Delay

Specify a port-specific input delay constraint in the Synplify software with the following command:

```
define_output_delay <output_port_name> <delay_value> \
-ref <clock_name>:<clock_edge>
```

The <*clock_edge*> can be set to **r** (rising edge) or **f** (falling edge). When the clock edge is **r** (rising edge), this constraint is mapped to the following constraint in the Quartus II software:

```
set_output_delay -clock <clock_name> <delay_value> <output_port_name>
```

When the clock_edge is **f** (falling edge), this constraint is not mapped to a constraint in the Quartus II software. The Quartus II Classic Timing Analyzer does not support the specification of output delays with respect to the falling edge of the clock.

Guidelines for Altera Megafunctions and Architecture-Specific Features

Altera provides parameterizable megafunctions including LPMs, device-specific Altera megafunctions, IP available as Altera MegaCore® functions, and IP available through the Altera Megafunction Partners Program (AMPP℠). You can use megafunctions and IP functions by instantiating them in your HDL code, or you can infer certain megafunctions from generic HDL code.

If you want to instantiate a megafunction in your HDL code, you can do so with the MegaWizard Plug-In Manager to parameterize the function or by instantiating the function using the port and parameter definition. The MegaWizard Plug-In Manager provides a graphical interface within the Quartus II software for customizing and parameterizing any available megafunction for the design. For more information about the MegaWizard Plug-In Manager flow with the Synplify software, refer to "Instantiating Altera Megafunctions Using the MegaWizard Plug-In Manager" on page 10–26 and "Instantiating Intellectual Property Using the MegaWizard Plug-In Manager and IP Toolbench" on page 10–28.

For more information about specific Altera megafunctions, refer to the Quartus II Help. For more information about IP functions, refer to the appropriate IP documentation.

The Synplify software also automatically recognizes certain types of HDL code and infers the appropriate megafunction when a megafunction provides optimal results. The Synplify software provides options to control inference of certain types of megafunctions, as described in "Inferring Altera Megafunctions from HDL Code" on page 10–31.

For a detailed discussion about instantiating versus inferring megafunctions, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*. This chapter also provides details about using the MegaWizard Plug-In Manager in the Quartus II software and explains the files generated by the wizard, as well as providing coding style recommendations and HDL examples for inferring megafunctions in Altera devices.

Instantiating Altera Megafunctions Using the MegaWizard Plug-In Manager

This section describes how to instantiate Altera megafunctions using the MegaWizard Plug-In Manager.

When you use the MegaWizard Plug-In Manager to set up and parameterize a megafunction, the MegaWizard Plug-In Manager creates a VHDL or Verilog HDL wrapper file <*output file*>**.v|vhd** that instantiates the megafunction.

The Synplify software makes use of the Quartus II timing and resource estimation netlist feature to report more accurate resource utilization and timing performance estimates, and take better advantage of timing-driven optimization than treating the megafunction as a "black box". Include the MegaWizard-generated megafunction variation wrapper file in your Synplify project so the Synplify software has all the information about the megafunction.

There is an option in the MegaWizard Plug-In Manager to generate a netlist for resource and timing estimation. This option is not recommended for the Synplify software because the software generates this information in the background without a separate netlist. If you do create a separate netlist <*output file*>**_syn.v** and use that file in your synthesis project, you must also include the <*output file*>**.v|vhd** file in your Quartus II project.

Make sure to set the correct Quartus II version in the Synplify software before compiling the MegaWizard-generated file so the software uses the correct library definitions for the megafunction. The **Quartus Version** setting must match the version of the Quartus II software used to generate the customized megafunction in the MegaWizard Plug-In Manager.

For details about how to set the Quartus II version in the Synplify software, refer to "Output Netlist File Name and Result Format" on page 10–5.

In addition, ensure that the `QUARTUS_ROOTDIR` environment variable is set to the installation directory location of the correct Quartus II version. The Synplify software uses this information to launch the Quartus II software in the background. The environment variable setting must match the version of the Quartus II software used to generate the customized megafunction in the MegaWizard Plug-In Manager. Refer to "Using the Quartus II Software to Run the Synplify Software" on page 10–15 for details.

Using MegaWizard Plug-In Manager-Generated Verilog HDL Files for Megafunction Instantiation

If you check the <*output file*>**_inst.v** option on the last page of the wizard, the MegaWizard Plug-In Manager generates a Verilog HDL instantiation template file for use in your Synplify design. The instantiation template file, <*output file*>**_inst.v**, helps to instantiate the megafunction variation wrapper file, <*output file*>**.v**, in your top-level design. Include the megafunction variation wrapper file <*output file*>**.v** in your Synplify project. The Synplify software includes the megafunction information in the output **.vqm** netlist file. There is no need to include the MegaWizard-generated megafunction variation wrapper file in your Quartus II project.

Using MegaWizard Plug-In Manager-Generated VHDL Files for Megafunction Instantiation

If you check the <*output file*>**.cmp** and <*output file*>**_inst.vhd** options on the last page of the wizard, the MegaWizard Plug-In Manager generates a VHDL component declaration file and a VHDL instantiation template file for use in your Synplify design. These files can help you instantiate the megafunction variation wrapper file, <*output file*>**.vhd**, in your top-level design. Include <*output file*>**.vhd** in your Synplify project. The Synplify software includes the megafunction information in the output **.vqm** netlist file. There is no need to include the MegaWizard-generated megafunction variation wrapper file in your Quartus II project.

Changing Synplify's Default Behavior for Instantiated Altera Megafunctions

By default, the Synplify software automatically calls the Quartus II software in the background to generate a resource and timing estimation netlist for megafunctions, as described in the previous sections.

You might want to change this behavior to reduce run times in the Synplify software (because generating the netlist files can take several minutes for large designs), or if the Synplify software cannot access your Quartus II software installation to generate the files. Changing this behavior might speed up the compilation time in the Synplify software, but the Quality of Results (QoR) might be reduced.

The Synplify software calls the Quartus II software to generate information in two ways:

- Some megafunctions provide a "clear box" model—Synplify software can fully synthesize this model and include the device architecture-specific primitives in the output **.vqm** netlist file.
- Other megafunctions provide a "grey box" model—Synplify can read the resource information but the netlist does not contain all the logic functionality.

For these functions, the Synplify software uses the logic information for resource and timing estimation and optimization, and then instantiates the megafunction in the output **.vqm** netlist file so the Quartus II software can implement the appropriate device primitives. By default, the Synplify software uses the clear box model when available, and otherwise uses the grey box model. To change this behavior, click **Implementation Options**, and on the **Device** tab, change the Altera Models setting. The default is **on**. To enable clear box models but not grey box, select **clearbox_only**, or to turn off the feature entirely, choose **off**.

Instantiating Intellectual Property Using the MegaWizard Plug-In Manager and IP Toolbench

Many Altera IP functions include a resource and timing estimation netlist that the Synplify software uses to report more accurate resource utilization and timing performance estimates, and take better advantage of timing-driven optimization than a black box function.

To create this netlist file, first select the IP function in the MegaWizard Plug-In Manager and click **Next** to open the IP Toolbench. Click **Step 2: Set Up Simulation**, which sets up all the EDA options. Enable the **Generate netlist** option to generate a netlist for resource and timing estimation. The netlist file is generated when you click **Step 3: Generate**.

The Quartus II software generates a file <*output file*>**_syn.v**. This netlist contains the "grey box" information for resource and timing estimation, but does not contain the actual implementation. Include this netlist file in your Synplify project. Next, include the megafunction variation wrapper file <*output file*>**.v|vhd** in the Quartus II project along with your Synplify **.vqm** output netlist.

If your IP function does not include a resource and timing estimation netlist, the Synplify software must treat the IP function as a black box. In this case, refer to the following subsections for details about creating black boxes.

For information about including Quartus II-specific files in your Synplify project so they are automatically passed to the Quartus II software along with the output **.vqm** file, refer to "Including Files for Quartus II Placement and Routing Only" on page 10–30.

Using Generated Verilog HDL Files for Black Box IP Function Instantiation

Use the `syn_black_box` compiler directive to declare a module as a black box. The top-level design files must contain the IP port mapping and a hollow-body module declaration. Apply the `syn_black_box` directive to the module declaration in the top-level file or a separate file included in the project to instruct the Synplify software that this is a black box. The software compiles successfully without this directive, but reports an additional warning message. Using this directive allows you to add other directives, as discussed in "Other Synplify Software Attributes for Creating Black Boxes" on page 10–29.

Example 10–13 shows a sample top-level file that instantiates **my_verilogIP.v**, which is a simplified customized variation generated by the MegaWizard Plug-In Manager and IP Toolbench.

Example 10–13. Sample Top-Level Verilog HDL Code with Black Box Instantiation of IP

```
module top (clk, count);
   input clk;
   output[7:0]  count;
   my_verilogIP verilogIP_inst (.clock (clk), .q (count));
endmodule
// Module declaration
// The following attribute is added to create a
// black box for this module.
module my_verilogIP (clock, q) /* synthesis syn_black_box */;
   input clock;
   output[7:0]  q;
endmodule
```

Using Generated VHDL Files for Black Box IP Function Instantiation

Use the syn_black_box compiler directive to declare a component as a black box. The top-level design files must contain the megafunction variation component declaration and port mapping. Apply the syn_black_box directive to the component declaration in the top-level file. The software compiles successfully without this directive, but reports an additional warning message. Using this directive allows you to add other directives, such as the ones in the "Other Synplify Software Attributes for Creating Black Boxes" section.

Example 10–14 shows a sample top-level file that instantiates **my_vhdlIP.vhd**, which is a simplified customized variation generated by the MegaWizard Plug-In Manager and IP Toolbench.

Example 10–14. Sample Top-Level VHDL Code with Black Box Instantiation of IP

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;

ENTITY top IS
    PORT (
        clk: IN STD_LOGIC ;
        count: OUT STD_LOGIC_VECTOR (7 DOWNTO 0)
    );
END top;

ARCHITECTURE rtl OF top IS
COMPONENT my_vhdlIP
    PORT (
        clock: IN STD_LOGIC ;
        q: OUT STD_LOGIC_VECTOR (7 DOWNTO 0)
    );
end COMPONENT;
attribute syn_black_box : boolean;
attribute syn_black_box of my_vhdlIP: component is true;
BEGIN
    vhdlIP_inst : my_vhdlIP PORT MAP (
        clock => clk,
        q => count
    );
END rtl;
```

Other Synplify Software Attributes for Creating Black Boxes

Instantiating a function as a black box methodology does not provide the synthesis tool any visibility into the function module. Thus, it does not take full advantage of the synthesis tool's timing-driven optimization. For better timing optimization, especially if the black box does not have registered inputs and outputs, add timing models to black boxes. This can be done by adding the syn_tpd, syn_tsu, and syn_tco attributes. Refer to Example 10–15 for a Verilog HDL example.

Example 10–15. Adding Timing Models to Black Boxes in Verilog HDL

```
module ram32x4(z,d,addr,we,clk);
    /* synthesis syn_black_box syn_tco1="clk->z[3:0]=4.0"
        syn_tpd1="addr[3:0]->z[3:0]=8.0"
        syn_tsu1="addr[3:0]->clk=2.0"
        syn_tsu2="we->clk=3.0" */
    output[3:0]z;
    input[3:0]d;
    input[3:0]addr;
    input we
    input clk
endmodule
```

The following additional attributes are supported by the Synplify software to communicate details about the characteristics of the black box module within the HDL code:

- `syn_resources`—Specifies the resources used in a particular black box
- `black_box_pad_pin`—Prevents mapping to I/O cells
- `black_box_tri_pin`—Indicates a tri-stated signal

For more information about applying these attributes, refer to the *Altera Constraints, Attributes, and Options* chapter of the *Synopsys FPGA Synthesis Reference Manual*.

Including Files for Quartus II Placement and Routing Only

In the Synplify software, you can add files to your project that are used only during placement and routing in the Quartus II software. This can be useful if you have grey boxes or black boxes for Synplify synthesis that require the full design files to be compiled in the Quartus II software.

Add the files to the Synplify project like other source files. Then right-click on the file and click **File options**. Enable the **Use for Place and Route Only** option. You can also set the option in a script using the `-job_owner par` option.

For example, the commands in Example 10–16 define files for a Synplify project that includes a top-level design file, a grey box netlist file, an IP wrapper file, and an encrypted IP file. With these files, the Synplify software writes an empty instantiation of "core" in the **.vqm** file and uses the grey box netlist for resource and timing estimation. The files **core.v** and **core_enc8b10b.v** are not compiled by Synplify and are copied into the place-and-route directory. The Quartus II software compiles these files to implement the "core" IP block.

Example 10–16. Commands to Define Files for a Synplify Project

```
add_file -verilog -job_owner par "core_enc8b10b.v"
add_file -verilog -job_owner par "core.v"
add_file -verilog "core_gb.v"
add_file -verilog "top.v"
```

Inferring Altera Megafunctions from HDL Code

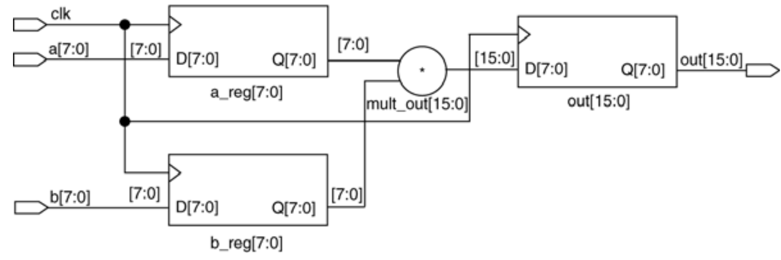
The Synplify software uses Behavior Extraction Synthesis Technology (BEST) algorithms to infer high-level structures such as RAMs, ROMs, operators, FSMs, and DSP multiplication operations. It then keeps the structures abstract for as long as possible in the synthesis process. This allows the use of technology-specific resources to implement these structures by inferring the appropriate Altera megafunction when a megafunction provides optimal results. The following sections outline some of the Synplify-specific details when inferring Altera megafunctions. The Synplify software provides options to control inference of certain types of megafunctions, which is also described in the following sections.

For coding style recommendations and examples for inferring megafunctions in Altera devices, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

Inferring Multipliers

Figure 10–2 shows the HDL Analyst view of an unsigned 8 × 8 multiplier with two pipeline stages after synthesis as seen in HDL Analyst in the Synplify software. This multiplier is converted into an ALTMULT_ADD or ALTMULT_ACCUM megafunction. For devices with DSP blocks, the software might implement the function in a DSP block instead of regular logic, depending on device utilization. For certain devices, the software maps directly to DSP block device primitives instead of instantiating a megafunction in the **.vqm** file.

Figure 10–2. HDL Analyst View of LPM_MULT Megafunction (Unsigned 8 × 8 Multiplier with Pipeline=2)



Resource Balancing

While mapping multipliers to DSP blocks, the Synplify software performs resource balancing for optimum performance.

Altera devices have a fixed number of DSP blocks, which include a fixed number of embedded multipliers. If the design uses more multipliers than are available, the Synplify software automatically maps the extra multipliers to logic elements (LEs), or adaptive logic modules (ALMs).

If a design uses more multipliers than are available in the DSP blocks, the Synplify software maps the multipliers in the critical paths to DSP blocks. Next, any wide multipliers, which might or might not be in the critical paths, are mapped to DSP blocks. Smaller multipliers and multipliers that are not in the critical paths might then be implemented in the logic (LEs or ALMs). This ensures that the design fits successfully in the device.

Controlling the Inferring of DSP Blocks

You can implement multipliers in DSP blocks or in logic in Altera devices that contain DSP blocks. You can control this implementation through attribute settings in the Synplify software.

Signal Level Attribute

You can control the implementation of individual multipliers by using the `syn_multstyle` attribute as shown in the following Verilog HDL code:

```
<signal_name> /* synthesis syn_multstyle = "logic" */;
```

where *signal_name* is the name of the signal.

This setting applies to wires only; it cannot be applied to registers.

Table 10–4 shows the values for the signal level attribute in the Synplify software that controls the implementation of the multipliers in the DSP blocks or LEs.

Table 10–4. Attribute Settings for DSP Blocks in the Synplify Software

Attribute Name	Value	Description
`syn_multstyle`	`lpm_mult`	LPM function inferred and multipliers implemented in DSP blocks
`syn_multstyle`	`logic`	LPM function not inferred and multipliers implemented LEs by the Synplify software
`syn_multstyle`	`block_mult`	DSP megafunction is inferred and multipliers are mapped directly to DSP block device primitives (for supported devices)

Example 10–17 and Example 10–18 show simple Verilog HDL and VHDL code using the `syn_multstyle` attribute.

Example 10–17. Signal Attributes for Controlling DSP Block Inference in Verilog HDL Code

```
module mult(a,b,c,r,en);
    input [7:0] a,b;
    output [15:0] r;
    input [15:0] c;
    input en;
    wire [15:0] temp /* synthesis syn_multstyle="logic" */;

    assign temp = a*b;
    assign r = en ? temp : c;
endmodule
```

Example 10–18. Signal Attributes for Controlling DSP Block Inference in VHDL Code

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.std_logic_unsigned.all;

entity onereg is port (
    r  : out std_logic_vector(15 downto 0);
    en : in std_logic;
    a  : in std_logic_vector(7 downto 0);
    b  : in std_logic_vector(7 downto 0);
    c  : in std_logic_vector(15 downto 0)
    );
end onereg;

architecture beh of onereg is
signal temp : std_logic_vector(15 downto 0);
attribute syn_multstyle : string;
attribute syn_multstyle of temp : signal is "logic";

begin
    temp <= a * b;
    r <= temp when en='1' else c;
end beh;
```

Inferring RAM

When a RAM block is inferred from an HDL design, the software uses an Altera megafunction to target the device memory architecture. For certain devices, the software maps directly to memory block device primitives instead of instantiating a megafunction in the **.vqm** file.

Follow these guidelines for the Synplify software to successfully infer RAM in a design:

- The address line must be at least two bits wide.
- Resets on the memory are not supported. Refer to the device family documentation for information about whether read and write ports must be synchronous.
- Some Verilog HDL statements with blocking assignments might not be mapped to RAM blocks, so avoid blocking statements when modeling RAMs in Verilog HDL.

For certain device families, the `syn_ramstyle` attribute specifies the implementation to use for an inferred RAM. You can apply `syn_ramstyle` globally, to a module, or to a RAM instance, to specify `registers` or `block_ram` values. To turn off RAM inference, set the attribute value to `registers`.

When inferring RAM for certain Altera device families, the Synplify software generates additional bypass logic. This logic is generated to resolve a half-cycle read/write behavior difference between the RTL and post-synthesis simulations. The RTL simulation shows the memory being updated on the positive edge of the clock; the post-synthesis simulation shows the memory being updated on the negative edge of the clock. To eliminate bypass logic, the output of the RAM must be registered. By adding this register, the output of the RAM is seen after a full clock cycle, by which time the update has occurred, thus eliminating the need for bypass logic.

For devices with TriMatrix memory blocks, disable the creation of glue logic by setting the `syn_ramstyle` value to `no_rw_check`. Use `syn_ramstyle` with a value of `no_rw_check` to disable the creation of glue logic in dual-port mode.

Example 10–19 shows sample VHDL code for inferring dual-port RAM.

Example 10–19. VHDL Code for Inferred Dual-Port RAM

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
USE ieee.std_logic_signed.all;

ENTITY dualport_ram IS
PORT ( data_out: OUT STD_LOGIC_VECTOR (7 DOWNTO 0);
    data_in: IN STD_LOGIC_VECTOR (7 DOWNTO 0);
    wr_addr, rd_addr: IN STD_LOGIC_VECTOR (6 DOWNTO 0);
    we: IN STD_LOGIC;
    clk: IN STD_LOGIC);
END dualport_ram;

ARCHITECTURE ram_infer OF dualport_ram IS
TYPE Mem_Type IS ARRAY (127 DOWNTO 0) OF STD_LOGIC_VECTOR (7 DOWNTO 0);
SIGNAL mem: Mem_Type;
SIGNAL addr_reg: STD_LOGIC_VECTOR (6 DOWNTO 0);

BEGIN
    data_out <= mem (CONV_INTEGER(rd_addr));
    PROCESS (clk, we, data_in) BEGIN
        IF (clk='1' AND clk'EVENT) THEN
            IF (we='1') THEN
                mem(CONV_INTEGER(wr_addr)) <= data_in;
            END IF;
        END IF;
    END PROCESS;
END ram_infer;
```

Example 10–20 shows an example of the VHDL code preventing bypass logic for inferring dual-port RAM. The extra latency behavior stems from the inferring methodology and is not required when instantiating a megafunction.

Example 10–20. VHDL Code for Inferred Dual-Port RAM Preventing Bypass Logic

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
USE ieee.std_logic_signed.all;

ENTITY dualport_ram IS
PORT ( data_out: OUT STD_LOGIC_VECTOR (7 DOWNTO 0);
    data_in : IN STD_LOGIC_VECTOR (7 DOWNTO 0);
    wr_addr, rd_addr : IN STD_LOGIC_VECTOR (6 DOWNTO 0);
    we : IN STD_LOGIC;
    clk : IN STD_LOGIC);
END dualport_ram;

ARCHITECTURE ram_infer OF dualport_ram IS
TYPE Mem_Type IS ARRAY (127 DOWNTO 0) OF STD_LOGIC_VECTOR (7 DOWNTO 0);
SIGNAL mem : Mem_Type;
SIGNAL addr_reg : STD_LOGIC_VECTOR (6 DOWNTO 0);
SIGNAL tmp_out : STD_LOGIC_VECTOR(7 DOWNTO 0); --output register

BEGIN
    tmp_out <= mem (CONV_INTEGER(rd_addr));
    PROCESS (clk, we, data_in) BEGIN
        IF (clk='1' AND clk'EVENT) THEN
            IF (we='1') THEN
                mem(CONV_INTEGER(wr_addr)) <= data_in;
            END IF;
            data_out <= tmp_out; --registers output preventing
                                 -- bypass logic generation.
        END IF;
    END PROCESS;
END ram_infer;
```

RAM Initialization

Use Verilog HDL system tasks `$readmemb` or `$readmemh` in your HDL code to initialize RAM memories. The Synplify compiler forward-annotates the initialization values in the **.srs** (technology-independent RTL netlist) file and the mapper generates a corresponding hexadecimal memory initialization (**.hex**) file. One **.hex** file is created for each of the `altsyncram` megafunctions that are inferred in the design. The **.hex** file is associated with the `altsyncram` instance in the **.vqm** file using the `init_file` attribute.

Example 10–21 and Example 10–22 illustrate how RAM memories can be initialized through HDL code and how the corresponding **.hex** file is generated using Verilog HDL.

Example 10–21. Using $readmemb System Task to Initialize an Inferred RAM in Verilog HDL Code

```
initial
begin
    $readmemb("mem.ini", mem);
end

always @(posedge clk)
begin
    raddr_reg <= raddr;
    if(we)
        mem[waddr] <= data;
end
```

Example 10–22. Sample of .vqm Instance Containing Memory Initialization File from Example 10–21

```
altsyncram mem_hex( .wren_a(we), .wren_b(GND),...);

defparam mem_hex.lpm_type = "altsyncram";
defparam mem_hex.operation_mode = "Dual_Port";
...
defparam mem_hex.init_file = "mem_hex.hex";
```

Inferring ROM

When a ROM block is inferred from an HDL design, the software uses an Altera megafunction to target the device memory architecture. For certain devices, the software maps directly to memory block device atoms instead of instantiating a megafunction in the **.vqm** file. Follow these guidelines for the Synplify software to successfully infer ROM in a design:

- The address line must be at least two bits wide.
- The ROM must be at least half full.
- A CASE or IF statement must make 16 or more assignments using constant values of the same width.

Inferring Shift Registers

The software infers shift registers for sequential shift components so that they can be placed in dedicated memory blocks in supported device architectures using the ALTSHIFT_TAPS megafunction.

If required, set the implementation style with the `syn_srlstyle` attribute. If you do not want the components automatically mapped to shift registers, set the value to `registers`. You can set the value globally or on individual modules or registers.

For some designs, turning off shift register inference improves the design performance.

Incremental Compilation and Block-Based Design

As designs become more complex and designers work in teams, a block-based incremental design flow is often an effective design approach. In an incremental compilation flow, you can make changes to part of the design while maintaining the placement and performance of unchanged parts of the design. Design iterations are made dramatically faster by focusing new compilations on particular design partitions and merging results with previous compilation results of other partitions. In a bottom-up or team-based approach, you can perform optimization on individual subblocks and then preserve the results before you integrate the blocks into a final design and optimize it at the top level.

MultiPoint synthesis, which is available for certain device technologies in the Synplify Pro and Premier software, provides an automated block-based incremental synthesis flow. The MultiPoint feature manages a design hierarchy to let you design incrementally and synthesize designs that take too long for top-down synthesis of the entire project. MultiPoint synthesis allows different netlist files to be created for different sections of a design hierarchy and supports the Quartus II incremental compilation methodology. It also ensures that only those sections of a design that have been updated are resynthesized when the design is compiled, reducing synthesis run time and preserving the results for the unchanged blocks. You can change and resynthesize one section of a design without affecting other sections of the design.

You can also partition your design and create different netlist files manually with the Synplify software by creating a separate project for the logic in each partition of the design. Creating different netlist files for each partition of the design also means that each partition can be independent of the others.

Hierarchical design methodologies can improve the efficiency of your design process, providing better design reuse opportunities and fewer integration problems when working in a team environment. When you use these incremental synthesis methodologies, you can take advantage of incremental compilation in the Quartus II software. You can perform placement and routing on only the changed partitions of the design, reducing place-and-route time and preserving your fitting results. Follow the guidelines in this section to help you achieve good results with these methodologies.

The following list shows the general top-down compilation flow when using these features of the Quartus II software:

1. Create Verilog HDL or VHDL design files as in the regular design flow.
2. Determine which hierarchical blocks are to be treated as separate partitions in your design.
3. Set up your design using the MultiPoint feature or separate projects so that a separate netlist file is created for each partition of the design.
4. If using separate projects, disable I/O pad insertion in the implementations for lower-level partitions.
5. Compile and map each partition in the Synplify software, making constraints as you would in the regular design flow.
6. Import the **.vqm** netlist and **.tcl** file for each partition into the Quartus II software and set up the Quartus II project(s) to use incremental compilation.

7. Compile your design in the Quartus II software and preserve the compilation results using the post-fit netlist in incremental compilation.
8. When you make design or synthesis optimization changes to part of your design, resynthesize only the changed partition to generate a new netlist and **.tcl** file. Do not regenerate netlist files for the unchanged partitions.
9. Import the new netlist and **.tcl** file into the Quartus II software and recompile the design in the Quartus II software using incremental compilation.

For more information about creating partitions and using the incremental compilation in the Quartus II software, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Creating a Design with Separate Netlist Files for Incremental Compilation

The first stage of a hierarchical or incremental design flow is to ensure that different parts of your design do not affect each other. Ensure that you have separate netlists for each partition in your design so you can take advantage of incremental compilation in the Quartus II software. If the entire design is in one netlist file, changes in one partition might affect other partitions because of possible node name changes when you resynthesize the design.

To ensure the proper functioning of the synthesis flow, create separate netlist files only for modules and entities. In addition, each module or entity requires its own design file. If two different modules are in the same design file but are defined as being part of different partitions, you cannot maintain incremental compilation since both partitions would have to be recompiled when you change one of the modules.

Altera recommends that you register all inputs and outputs of each partition. This makes logic synchronous and avoids any delay penalty on signals that cross partition boundaries.

If you use boundary tri-states in a lower-level block, the Synplify software pushes (or "bubbles") the tri-states through the hierarchy to the top level to make use of the tri-state drivers on output pins of Altera devices. Because bubbling tri-states requires optimizing through hierarchies, lower-level tri-states are not supported with a block-based compilation methodology. Use tri-state drivers only at the external output pins of the device and in the top-level block in the hierarchy.

For more detailed recommendations about designing your hierarchy and creating partitions, refer to the *Best Practices for Incremental Compilation Partitions and Floorplan Assignments* chapter in volume 1 of the *Quartus II Handbook*.

You can generate multiple **.vqm** netlist files with the MultiPoint synthesis flow in the Synplify Pro and Premier software, or by manually creating separate Synplify projects and creating a black box for each block that you want to be considered as a separate design partition.

In the MultiPoint synthesis flow (Synplify Pro and Premier only), you create multiple **.vqm** netlist files from one easy-to-manage, top-level synthesis project. By using the manual black box method, you have multiple synthesis projects, which might be required for certain team-based or bottom-up designs where a single top-level project is not desired.

After you have created multiple **.vqm** files using one of these two methods, you must create the appropriate Quartus II projects to place-and-route the design.

Using MultiPoint Synthesis with Incremental Compilation

This section describes how to generate multiple **.vqm** files using the Synplify Pro and Premier MultiPoint synthesis flow. You must first set up your constraint file and Synplify options, then apply the appropriate Compile Point settings to write multiple **.vqm** files and create design partition assignments for incremental compilation.

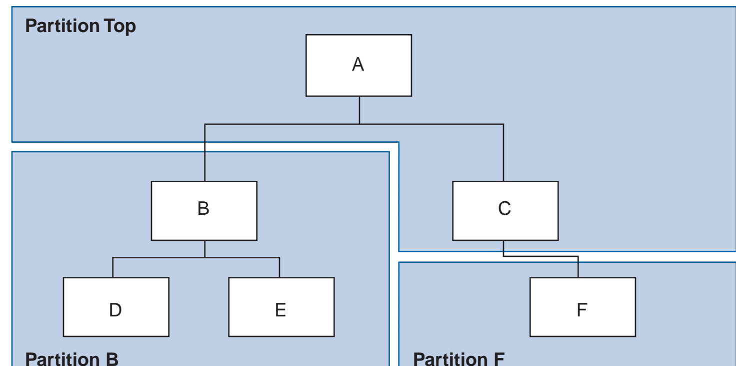
Set Compile Points and Create Constraint Files

The MultiPoint flow lets you segment a design into smaller synthesis units, called "Compile Points." The synthesis software treats each Compile Point as a partition for incremental mapping, which allows you to isolate and work on individual Compile Point modules as independent segments of the larger design without impacting other design modules. A design can have any number of Compile Points, and Compile Points can be nested. The top-level module is always treated as a Compile Point.

Compile Points are optimized in isolation from their parent, which can be another Compile Point or a top-level design. Each block created with a Compile Point is unaffected by critical paths or constraints on its parent or other blocks. A Compile Point is independent, with its own individual constraints. During synthesis, any Compile Points that have not yet been synthesized are synthesized before the top level. Nested Compile Points are synthesized before the parent Compile Points in which they are contained. When you apply the appropriate setting for the Compile Point, a separate netlist is created for that Compile Point, isolating that logic from any other logic in the design.

Figure 10–3 shows an example of a design hierarchy that is split into multiple partitions. The top-level block of each partition can be synthesized as a separate Compile Point.

Figure 10–3. Partitions in a Hierarchical Design



In this case, modules A, B, and F are Compile Points. The top-level Compile Point consists of the top-level block in the design (that is, block A in this example), including the logic that is not defined under another Compile Point. In this example, the design for top-level Compile Point A also includes the logic in one of its subblocks, C. Because block F is defined as its own Compile Point, it is not treated as part of the top-level Compile Point A. Another separate Compile Point B contains the logic in blocks B, D, and E. One netlist is created for the top-level module A and submodule C, another netlist is created for B and its submodules D and E, while a third netlist is created for F.

Apply Compile Points to the module or architecture in the Synplify Pro SCOPE spreadsheet or in the **.sdc** file. You cannot set a Compile Point in the Verilog HDL or VHDL source code. You can set the constraints manually using Tcl or by editing the **.sdc** file, or you can use one of two methods in the GUI, as described in the following subsections.

Defining Compile Points Using .tcl or .sdc Files

To set Compile Points using a **.tcl** or **.sdc** file, use the `define_compile_point` command, as shown in Example 10–23.

Example 10–23. The define_compile_point Command

```
define_compile_point [-disable] {<objname>} -type {locked, partition}
```

In Example 10–23, *objname* represents any module in the design. The Compile Point type `{locked, partition}` indicates that the Compile Point represents a partition for the Quartus II incremental compilation flow.

Each Compile Point has a set of constraint files that begin with the `define_current_design` command to set up the SCOPE environment, as follows:

```
define_current_design {<my_module>}
```

Defining Compile Points in the Top-Level SCOPE Window

The following method requires you to separately create constraint files for the top-level and lower-level Compile Points:

1. In the top-level SCOPE window, select the **Compile Points** tab.
2. Select the modules that you want to define as Compile Points and set **Type** to **locked, partition**.
3. Manually create a constraint file for each module to set constraints for each Compile Point.

Defining Compile Points by Creating a New SCOPE File

When you use the following process, the lower-level constraint file is created automatically:

1. On the File menu, click **New** and choose to create a new **Constraint File**. Or, click the **SCOPE** icon in the tool bar.
2. From the **Select File Type** tab of the **Create a New SCOPE File** dialog box, select **Compile Point**.

3. Select the module you want to designate as a Compile Point and click **OK**. The software automatically sets the Compile Points in the top-level constraint file and creates a lower-level constraint file for each Compile Point.

Additional Considerations for Compile Points

To ensure that changes to a Compile Point do not affect the top-level parent module, disable the **Update Compile Point Timing Data** option in the **Implementation Options** dialog box. If this option is enabled, updates to a child module can impact the top-level module.

You can apply the `syn_allowed_resources` attribute to any Compile Point view to restrict the number of resources for a particular module.

When using Compile Points with incremental compilation, keep the following restrictions in mind:

- To use Compile Points effectively, you must provide timing constraints (timing budgeting) for each Compile Point; the more accurate the constraints, the better your results are. Constraints are not automatically budgeted, so manual time budgeting is essential. Altera recommends that you register all inputs and outputs of each partition. This avoids any logic delay penalty on signals that cross partition boundaries.
- When using the Synplify attribute `syn_useioff` to pack registers in the I/O Elements (IOEs) of Altera devices, these registers must be in the top-level module, not a lower level. Otherwise, you must allow the Quartus II software to perform I/O register packing instead of the `syn_useioff` attribute. You can use the **Fast Input Register** or **Fast Output Register** options, or set I/O timing constraints and turn on **Optimize I/O cell register placement for timing** on the Fitter Settings page of the **Settings** dialog box in the Quartus II software.
- There is no incremental synthesis support for top-level logic; any logic in the top-level is resynthesized during every compilation in the Synplify software.

For more information about using Compile Points and setting Synplify attributes and constraints for both top-level and lower-level Compile Points, refer to the *Synopsys FPGA Synthesis User Guide* and the *Synopsys FPGA Synthesis Reference Manual* in the Synplify software.

Creating a Quartus II Project for Compile Points and Multiple .vqm Files

During compilation, the Synplify Pro and Premier software creates a <*top-level project*>**.tcl** file that provides the Quartus II software with the appropriate constraints and design partition assignments, creating a partition for each **.vqm** file along with the information to set up a Quartus II project. For details about using the Tcl script generated by the Synplify software to set up your Quartus II project and pass your constraints, refer to “Running the Quartus II Software Manually Using the Synplify-Generated Tcl Script” on page 10–16.

Depending on your design methodology, you can create one Quartus II project for all netlists (a top-down placement and routing flow) or a separate Quartus II project for each netlist (a bottom-up placement and routing flow). In a top-down incremental compilation design flow, you create design partition assignments and optionally LogicLock™ floorplan location assignments for each partition in the design within a single Quartus II project. This methodology allows for the best quality of results and performance preservation during incremental changes to your design.

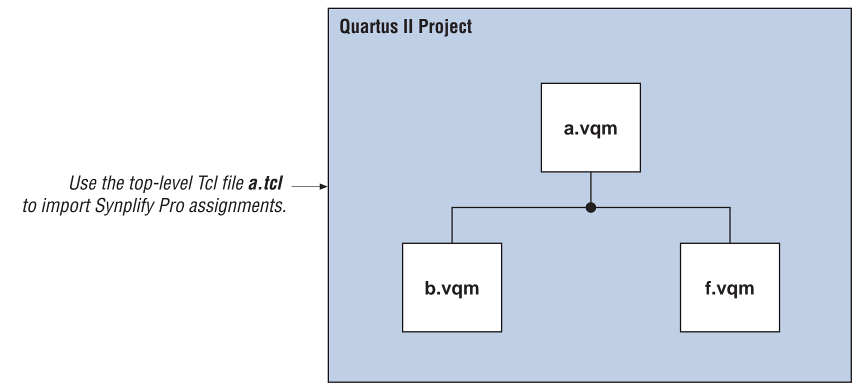
You might require a bottom-up design flow if each partition must be optimized separately, such as in certain team-based design flows. If you use this flow, Altera recommends you create a design floorplan to avoid placement conflicts between each partition. To perform a bottom-up compilation in the Quartus II software, create separate Quartus II projects and import each design partition into a top-level design using the incremental compilation export and import features to maintain placement results.

The following sections describe how to create the Quartus II projects for these two design flows.

Creating a Single Quartus II Project for a Top-Down Incremental Compilation Flow

Use the *<top-level project>***.tcl** file that contains the Synplify assignments for all partitions within the project. This method allows you to import all the partitions into one Quartus II project and optimize all modules within the project at once, taking advantage of the performance preservation and compilation-time reduction incremental compilation offers. Figure 10–4 shows a visual representation of the design flow for the example design in Figure 10–3 on page 10–39.

Figure 10–4. Design Flow Using Multiple .vqm Files with One Quartus II Project



Creating Multiple Quartus II Projects for a Bottom-Up Incremental Compilation Flow

Use the *<lower-level compile point>***.tcl** files that contain the Synplify assignments for each Compile Point. Generate multiple Quartus II projects, one for each partition and netlist in the design. The designers in the project can optimize their own partitions separately within the Quartus II software and export the results for their own partitions. Figure 10–5 shows a visual representation of the design flow for the example design in Figure 10–3 on page 10–39. You can export the optimized sub-designs and then import them into one top-level Quartus II project using incremental compilation to complete the design.

Figure 10–5. Design Flow Using Multiple .vqm Files with Multiple Quartus II Projects

Quartus II Project
a.vqm
*Use the top-level Tcl file **a.tcl** to Import Synplify Pro Assignments*

Quartus II Project
b.vqm
*Use the lower-level Tcl file **b.tcl** to Import Synplify Pro Assignments*

Quartus II Project
f.vqm
*Use the lower-level Tcl file **f.tcl** to Import Synplify Pro Assignments*

Creating Multiple .vqm Files for Incremental Compilation Using Separate Synplify Projects

This section describes how to manually generate multiple **.vqm** files for incremental compilation using black boxes and separate Synplify projects for each design partition. This manual flow is supported in versions of the Synplify software that do not include the MultiPoint Synthesis feature.

Manually Creating Multiple .vqm Files Using Black Boxes

To create multiple **.vqm** files manually in the Synplify software, create a separate project for each low-level module and top-level design that you want to maintain as a separate **.vqm** file for an incremental compilation partition. Implement black box instantiations of lower-level partitions in your top-level project.

When synthesizing the projects for the lower-level modules, perform the following steps:

1. In the **Implementation Options** dialog box, turn on **Disable I/O Insertion** for the target technology.
2. Read the HDL files for the modules.

Modules might include black box instantiations of lower-level modules that are also maintained as separate **.vqm** files.

3. Add constraints with the SCOPE constraint window.
4. Enter the clock frequency to ensure that the sub-design is correctly optimized.
5. In the **Attributes** tab, set **syn_netlist_hierarchy** to **0**.

When synthesizing the top-level design project, perform the following steps:

1. Turn off **Disable I/O Insertion** for the target technology.
2. Read the HDL files for top-level designs.
3. Create black boxes using lower-level modules in the top-level design.

4. Add constraints with the SCOPE constraint window.
5. Enter the clock frequency to ensure that the design is correctly optimized.
6. In the **Attributes** tab, set **syn_netlist_hierarchy** to **0**.

The following sections describe an example of black box implementation to create separate **.vqm** files. Figure 10–3 on page 10–39 shows an example of a design hierarchy that is split into multiple partitions.

The partition top contains the top-level block in the design (block A) and the logic that is not defined as part of another partition. In this example, the partition for top-level block A also includes the logic in one of its sub-blocks, C. Because block F is contained in its own partition, it is not treated as part of the top-level partition A. Another separate partition, B, contains the logic in blocks B, D, and E. In a team-based design, different engineers can work on the logic in different partitions. One netlist is created for the top-level module A and its submodule C, another netlist is created for B and its submodules D and E, while a third netlist is created for F.

To create multiple **.vqm** files for this design, follow these steps:

1. Generate a **.vqm** file for module B. Use **B.v/.vhd**, **D.v/.vhd**, and **E.v/.vhd** as the source files.
2. Generate a **.vqm** file for module F. Use **F.v/.vhd** as the source files.
3. Generate a top-level **.vqm** file for module A. Use **A.v/.vhd** and **C.v/.vhd** as the source files. Ensure that you use black box modules B and F, which were optimized separately in the previous steps.

Creating Black Boxes in Verilog HDL

Any design block that is not defined in the project or included in the list of files to be read for a project are treated as a black box by the software. Use the `syn_black_box` attribute to indicate that you intend to create a black box for the given module. In Verilog HDL, you must provide an empty module declaration for the module that is treated as a black box.

Example 10–24 shows an example of the **A.v** top-level file. Follow the same procedure for lower-level files that also contain a black box for any module beneath the current level hierarchy.

Example 10–24. Verilog HDL Black Box for Top-Level File A.v

```
module A (data_in, clk, e, ld, data_out);
    input data_in, clk, e, ld;
    output [15:0] data_out;

    wire [15:0] cnt_out;

    B U1 (.data_in (data_in),.clk(clk), .ld (ld),.data_out(cnt_out));
    F U2 (.d(cnt_out), .clk(clk), .e(e), .q(data_out));

    // Any other code in A.v goes here.
endmodule

// Empty Module Declarations of Sub-Blocks B and F follow here.
// These module declarations (including ports) are required for black
// boxes.

module B (data_in, clk, ld, data_out) /* synthesis syn_black_box */ ;
    input data_in, clk, ld;
    output [15:0] data_out;
endmodule

module F (d, clk, e, q) /* synthesis syn_black_box */ ;
    input [15:0] d;
    input clk, e;
    output [15:0] q;
endmodule
```

Creating Black Boxes in VHDL

Any design block that is not defined in the project or included in the list of files to be read for a project is treated as a black box by the software. Use the `syn_black_box` attribute to indicate that you intend to treat the given component as a black box. In VHDL, you must have a component declaration for the black box just like any other block in the design.

Although VHDL is not case-sensitive, a **.vqm** (a subset of Verilog HDL) file is case-sensitive. Entity names and their port declarations are forwarded to the **.vqm** file. Black box names and port declarations are also passed to the **.vqm** file. To prevent case-based mismatches, use the same capitalization for black box and entity declarations in VHDL designs.

Example 10–25 shows an example of the **A.vhd** top-level file. Follow this same procedure for any lower-level files that contain a black box for any block beneath the current level of hierarchy.

Example 10–25. VHDL Black Box for Top-Level File A.vhd

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
LIBRARY synplify;
USE synplify.attributes.all;

ENTITY A IS
PORT ( data_in : IN INTEGER RANGE 0 TO 15;
    clk, e, ld : IN STD_LOGIC;
    data_out : OUT INTEGER RANGE 0 TO 15 );
END A;

ARCHITECTURE a_arch OF A IS

COMPONENT B PORT(
    data_in : IN INTEGER RANGE 0 TO 15;
    clk, ld : IN STD_LOGIC;
    d_out : OUT INTEGER RANGE 0 TO 15 );
END COMPONENT;

COMPONENT F PORT(
    d : IN INTEGER RANGE 0 TO 15;
    clk, e: IN STD_LOGIC;
    q : OUT INTEGER RANGE 0 TO 15 );
END COMPONENT;

attribute syn_black_box of B: component is true;
attribute syn_black_box of F: component is true;

-- Other component declarations in A.vhd go here
signal cnt_out : INTEGER RANGE 0 TO 15;

BEGIN

U1 : B
PORT MAP (
    data_in => data_in,
    clk => clk,
    ld => ld,
    d_out => cnt_out );

U2 : F
PORT MAP (
    d => cnt_out,
    clk => clk,
    e => e,
    q => data_out );

-- Any other code in A.vhd goes here

END a_arch;
```

After you have completed the steps described in this section, you have a netlist file for each partition of the design. These files are ready for use with incremental compilation in the Quartus II software.

Creating a Quartus II Project for Multiple .vqm Files

The Synplify software creates a **.tcl** file for each **.vqm** file that provides the Quartus II software with the appropriate constraints and information to set up a project. For details about using the Tcl script generated by the Synplify software to set up your Quartus II project and pass your constraints, refer to "Running the Quartus II Software Manually Using the Synplify-Generated Tcl Script" on page 10–16.

Depending on your design methodology, you can create one Quartus II project for all netlists (a top-down placement and routing flow) or a separate Quartus II project for each netlist (a bottom-up placement and routing flow). In a top-down incremental compilation design flow, you create design partition assignments and optional LogicLock floorplan location assignments for each partition in the design within a single Quartus II project. This methodology allows for the best quality of results and performance preservation during incremental changes to your design. You might require a bottom-up design flow where each partition must be optimized separately, such as in certain team-based design flows.

To perform a bottom-up compilation in the Quartus II software, create separate Quartus II projects and import each design partition into a top-level design using the incremental compilation export and import features to maintain the results.

The following sections describe how to create the Quartus II projects for these two design flows.

Creating a Single Quartus II Project for a Top-Down Incremental Compilation Flow

Use the <*top-level project*>**.tcl** file that contains the Synplify assignments for the top-level design. This method allows you to import all of the partitions into one Quartus II project and optimize all modules within the project at once, taking advantage of the performance preservation and compilation time reduction offered by incremental compilation. Figure 10–6 shows a visual representation of the design flow for the example design in Figure 10–3 on page 10–39.

All of the constraints from the top-level project are passed to the Quartus II software in the top-level **.tcl** file, but any constraints made in the lower-level projects within the Synplify software is not forward-annotated. Enter these constraints manually in your Quartus II project.

Figure 10–6. Design Flow Using Multiple .vqm Files with One Quartus II Project

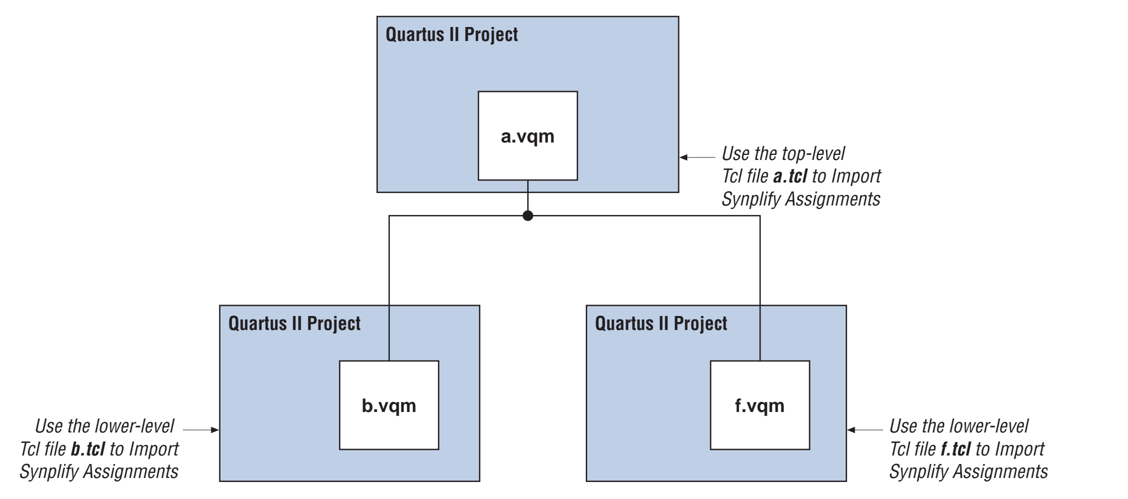
Quartus II Project
a.vqm
b.vqm
f.vqm
*Use **a.tcl** to import top-level Synplify Pro assignments. Enter any lower-level assignments manually.*

Creating Multiple Quartus II Projects for a Bottom-Up Incremental Compilation Flow

Use the **.tcl** file that is created for each **.vqm** file by the Synplify software for each Synplify project. This method generates multiple Quartus II projects, one for each block in the design. The designers in the project can optimize their own blocks separately within the Quartus II software and export the placement of their own blocks. Figure 10–7 shows a visual representation of the design flow for the example in Figure 10–3 on page 10–39.

Designers should create a LogicLock region to create a design floorplan for each block to avoid conflicts between partitions. The top-level designer then imports all the blocks and assignments into the top-level project. This method allows each block in the design to be optimized separately and then imported into one top-level project.

Figure 10–7. Design Flow Using Multiple Synplify Projects and Multiple Quartus II Projects



Performing Incremental Compilation in the Quartus II Software

In a top-down design flow using Multipoint Synthesis, the Synplify software uses the Quartus II top-level **.tcl** file to ensure that the two tools databases stay synchronized. The Tcl creates, changes, or deletes partition assignments in the Quartus II software for Compile Points that you create, change, or delete in Synplify. However, if you create, change, or delete a partition in the Quartus II software, the Synplify software does not change your Compile Point settings. Make any corresponding change in your Synplify project so that you create the correct **.vqm** files.

If you use the NativeLink integration feature described in "Using the Quartus II Software to Run the Synplify Software" on page 10–15, the Synplify software does not use any information about design partition assignments that you have set in the Quartus II software.

If you are creating netlist files using multiple Synplify projects, or if you don't use the Synplify Pro or Premier-generated **.tcl** files to update constraints in your Quartus II project, you must ensure that your Synplify **.vqm** netlists align with your Quartus II partition settings.

After you have set up your Quartus II project with **.vqm** netlist files as separate design partitions, set the appropriate Quartus II options to preserve your compilation results. On the Assignments menu, click **Design Partitions Window**. Change the Netlist Type to **Post-Fit** to preserve the previous compilation's post-fit placement results. To preserve routing results as well, set the **Fitter Preservation Level** to **Placement and Routing**. If you do not make these settings, the Quartus II software does not reuse the placement or routing results from the previous compilation.

You can take advantage of incremental compilation with your Synplify design to reduce compilation time in the Quartus II software and preserve the results for unchanged design blocks.

For more information about using Quartus II incremental compilation, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Conclusion

Advanced synthesis is an important part of the design flow. Taking advantage of the Synopsys Synplify and Altera Quartus II design flows allow you to control how your design files are prepared for the Quartus II place-and-route process, as well as improve performance and optimize a design for use with Altera devices. The methodologies outlined in this chapter can help optimize a design to achieve performance goals and save design time.

Document Revision History

Table 10–5. Document Revision History

Date and Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Added new section "Exporting Designs to the Quartus II Software Using NativeLink Integration" on page 10–14 ■ Minor updates for the Quartus II software version 9.0 release ■ Chapter 10 was previously Chapter 9 in software version 8.1	Updated for the Quartus II software version 9.0 release
November 2008 v8.1.0	■ Changed to 8-1/2 x 11 page size ■ Changed the chapter title from "Synplicity Synplify & Synplify Pro Support" to "Synopsys Synplify Support" ■ Replaced references to Synplicity with references to Synopsys ■ Added information about Synplify Premier ■ Updated supported device list ■ Added SystemVerilog information to Figure 10–1	Updated for the Quartus II software version 8.1 release and the Synplify software version 9.6.2 release.
May 2008 v8.0.0	■ Updated supported device list ■ Updated constraint annotation information for the TimeQuest Timing Analyzer ■ Updated RAM and MAC constraint limitations ■ Revised Table 9–1 ■ Added new section "Changing Synplify's Default Behavior for Instantiated Altera Megafunctions" ■ Added new section "Instantiating Intellectual Property Using the MegaWizard Plug-In Manager and IP Toolbench" ■ Added new section "Including Files for Quartus II Placement and Routing Only" ■ Added new section "Additional Considerations for Compile Points" ■ Removed section "Apply the LogicLock Attributes" ■ Modified Figure 9–4, 9–43, 9–47. and 9–48 ■ Added new section "Performing Incremental Compilation in the Quartus II Software" ■ Numerous text changes and additions throughout the chapter ■ Renamed several sections ■ Updated "Referenced Documents" section	Updated for Quartus II software release, version 8.0, and the Synplify software release, version 9.4.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

11. Mentor Graphics Precision Synthesis Support

QII51011-9.0.0

Introduction

This chapter documents support for the Mentor Graphics Precision RTL Synthesis and Precision RTL Plus Synthesis software in the Quartus II software design flow, as well as key design methodologies and techniques for improving your results for Altera devices.

As programmable logic device (PLD) designs become more complex and require increased performance, advanced synthesis has become an important part of the design flow. When integrated into the Quartus® II design flow, Mentor Graphics® Precision Synthesis can be used to improve performance results for Altera® devices.

The topics discussed in this chapter include:

- "Design Flow" on page 11–2
- "Creating and Compiling a Project in the Precision Synthesis Software" on page 11–6
- "Mapping the Precision Synthesis Design" on page 11–6
- "Synthesizing the Design and Evaluating the Results" on page 11–11
- "Exporting Designs to the Quartus II Software Using NativeLink Integration" on page 11–11
- "Guidelines for Altera Megafunctions and Architecture-Specific Features" on page 11–19
- "Incremental Compilation and Block-Based Design" on page 11–28

This chapter assumes that you have installed and licensed the Precision Synthesis software and the Quartus II software. You must install and license the Precision RTL Plus Synthesis software if you want to use the incremental synthesis feature for incremental compilation and block-based design.

To obtain and license the Precision Synthesis software, refer to the Mentor Graphics website at www.mentor.com. To install and run the Precision Synthesis software and to set up your work environment, refer to the *Precision Synthesis Installation Guide* in the Precision Manuals Bookcase. To access the Manuals Bookcase, in the Precision Synthesis software, click **Help** and select **Open Manuals Bookcase**.

Device Family Support

The following list shows the Altera device families supported by the Mentor Graphics Precision Synthesis software version 2009a when used with the Quartus II software version 9.0:

- ACEX® 1K
- APEX™ II, APEX 20K, APEX 20KC, APEX 20KE
- Arria® GX
- Cyclone® series
- FLEX® series
- HardCopy® series
- MAX® series, MAX II
- Stratix® series, Stratix GX series

The Precision Synthesis software also supports the Excalibur™ ARM® legacy device that is supported in the Quartus II software only with a specific license requested at www.altera.com/mysupport).

The Precision Synthesis software also supports the FLEX 8000 and MAX 9000 legacy devices that are supported only in the Altera MAX+PLUS® II software.

For information about future device support, such as the Arria II GX device family introduced with the Quartus II software version 9.0, contact your Mentor Graphics representative or refer to the Mentor Graphics website at www.mentor.com.

Design Flow

The basic steps in a Quartus II design flow using the Precision Synthesis software include:

1. Create Verilog HDL or VHDL design files.
2. Create a project in the Precision Synthesis software that contains the HDL files for your design, select your target device, and set global constraints. Refer to "Creating and Compiling a Project in the Precision Synthesis Software" on page 11–6 for details about how to create a project in the Precision Synthesis software.
3. Compile the project in the Precision Synthesis software.
4. Add specific timing constraints, optimization attributes, and compiler directives to optimize the design during synthesis.

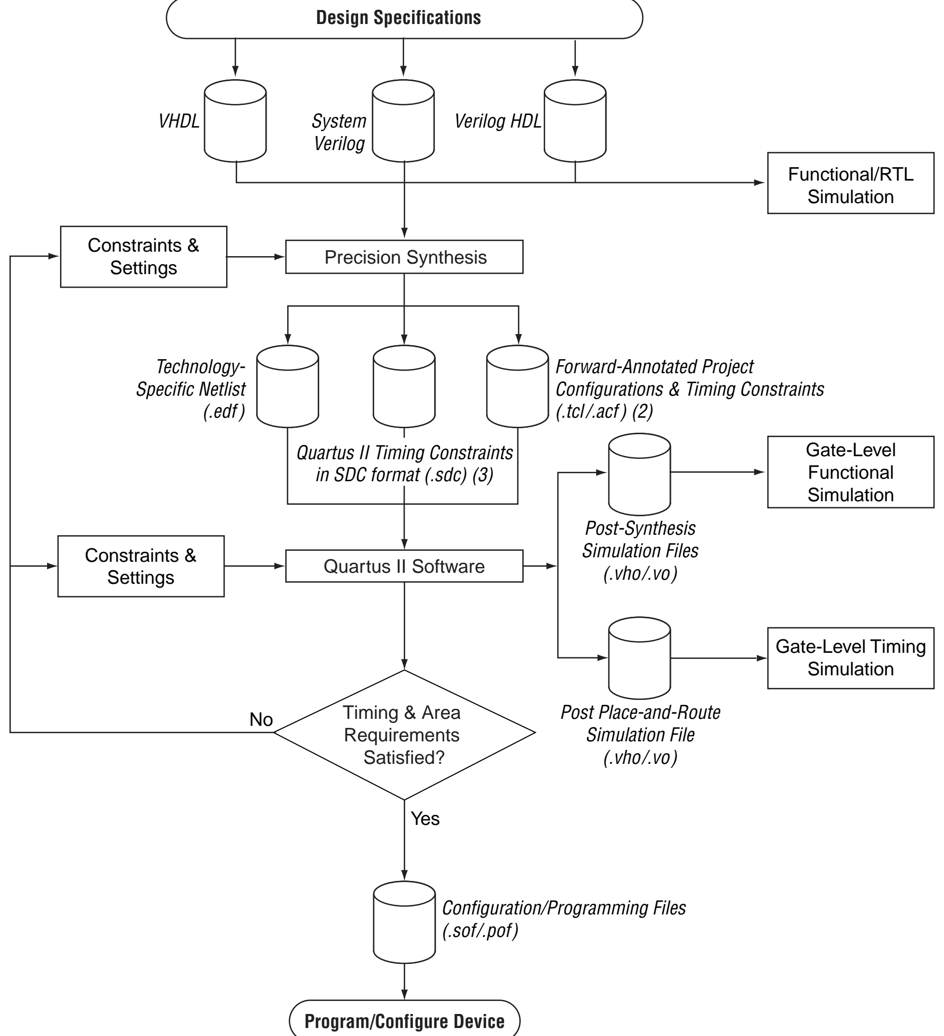
For best results, Mentor Graphics recommends specifying constraints that are as close as possible to actual operating requirements. Properly setting clock and I/O constraints, assigning clock domains, and indicating false and multicycle paths guide the synthesis algorithms more accurately toward a suitable solution in the shortest synthesis time.

5. Synthesize the project in the Precision Synthesis software. With the design analysis capabilities and cross-probing of the Precision Synthesis software, you can identify and improve circuit area and performance issues using pre-layout timing estimates.
6. Create a Quartus II project and import the following files generated by the Precision Synthesis software into the Quartus II project:
   - Technology-specific EDIF (**.edf**) netlist
   - Synopsys Design Constraints (**.sdc**) file for the TimeQuest Timing Analyzer
   - Tool command language (**.tcl**) files to set up your Quartus II project and pass constraints

   You can run the Quartus II software from within the Precision Synthesis software, or launch the Precision Synthesis software using the Quartus II software. Refer to "Running the Quartus II Software from within the Precision Synthesis Software" on page 11–12 and "Using Quartus II Software to Launch the Precision Synthesis Software" on page 11–14 for more detailed information.
7. After obtaining place-and-route results that meet your requirements, configure or program the Altera device.

Figure 11–1 shows the Quartus II design flow using the Precision Synthesis software as described in these steps. The steps are further described in detail in this chapter.

Figure 11–1. Design Flow Using the Precision Synthesis Software and Quartus II Software *(Note 1)*



Notes to Figure 11–1:

(1) Refer to Table 11–1 for details about the files generated by the Precision Synthesis software for the Quartus II design flow.

(2) Some of the constraints from the Precision Synthesis software are forward-annotated to the Quartus II software. For all devices, one Tcl file (**.tcl**) acts as a Quartus II Project Configuration file. Another **.tcl** file can be generated that contains timing constraints for the Quartus II Classic Timing Analyzer. The Assignment and Configuration File (**.acf**) stores the assignments and configuration settings for a MAX+PLUS II project.

(3) This file forward-annotates timing constraints in synopsys design constraint (**.sdc**) format for the TimeQuest Timing Analyzer.

If your area or timing requirements are not met, you can change the constraints and resynthesize the design in the Precision Synthesis software, or you can change constraints to optimize the design during place-and-route in the Quartus II software. Repeat the process until the area and timing requirements are met (Table 11–1).

You can use other options and techniques in the Quartus II software to meet area and timing requirements. One such option is the **WYSIWYG Primitive Resynthesis** option, which can perform optimizations on your EDIF netlist in the Quartus II software.

For information about netlist optimizations, refer to the *Netlist Optimizations and Physical Synthesis* chapter in volume 2 of the *Quartus II Handbook*. For more recommendations about how to optimize your design, refer to the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook.*

While simulation and analysis can be performed at various points in the design process, final timing analysis should be performed after placement and routing is complete.

During the synthesis process, the Precision Synthesis software produces several intermediate and output files. Table 11–1 lists these files and provides a brief description of each file type.

Table 11–1. Precision Synthesis Software Intermediate and Output Files

File Extension	File Description
.psp	Precision Synthesis Project File
.xdb	Mentor Graphics Design Database File
.rep *(1)*	Synthesis Area and Timing Report File
.edf	Technology-specific netlist in electronic design interchange format (EDIF)
.acf	Assignment and Configurations file for backward compatibility with the MAX+PLUS II software. An **.acf** file is created only for ACEX 1K, FLEX 10K, FLEX 10KA, FLEX 6000, FLEX 8000, MAX 7000, MAX 9000, and MAX 3000 devices.
.tcl	Forward-annotated Tcl assignments and constraints file. The <*project name*>**.tcl** file is generated for all devices. It acts as the Quartus II Project Configuration file and is used to make basic project and placement assignments, and to create and compile a Quartus II project for your EDIF netlist. If the project is set up to use the TimeQuest Timing Analyzer, this file contains the command required to use the TimeQuest Timing Analyzer instead of the Classic Timing Analyzer. The <*project name*>**_pnr_constraints.tcl** file is generated automatically for devices that use the Classic Timing Analyzer by default in the Quartus II software, and contains timing constraints for the Classic Timing Analyzer.
.sdc	Quartus II timing constraints file in Synopsys Design Constraints format This file is generated automatically if the device uses the TimeQuest Timing Analyzer by default in the Quartus II software, and has the naming convention <*project name*>**_pnr_constraints.sdc**. For more information about generating a TimeQuest constraint file, refer to "Exporting Designs to the Quartus II Software Using NativeLink Integration" on page 11–11.

Note to Table 11–1:

(1) The timing report file includes performance estimates that are based on pre-place-and-route information. Use the f_{MAX} reported by the Quartus II software after place-and-route for accurate post-place-and-route timing information. The area report file includes post-synthesis device resource utilization statistics that can differ from the resource usage after place-and-route due to black boxes or further optimizations performed during placement and routing. Use the device utilization reported by the Quartus II software after place-and-route for final resource utilization results. See "Synthesizing the Design and Evaluating the Results" on page 11–11 for details.

Creating and Compiling a Project in the Precision Synthesis Software

After creating your design files, create a project in the Precision Synthesis software that contains the basic settings for compiling the design.

Creating a Project

Set up your design files as follows:

1. In the Precision Synthesis software, click the **New Project** icon in the **Design Bar** on the left side of the GUI.
2. Set the **Project Name** and the **Project Folder**. The implementation name of the design corresponds to this project name.
3. Add input files to the project with the **Add Input Files** icon in the **Design Bar**. Precision Synthesis software automatically detects the top-level module/entity of the design. It uses the top-level module/entity to name the current implementation directory, logs, reports, and netlist files.
4. In the **Design Bar**, click the **Setup Design** icon.
5. To specify a target device family, expand the Altera entry and choose the target device and speed grade.
6. If desired, set a global design frequency and/or default input and output delays. This constrains all clock paths and all I/O pins in your design. Modify the settings for individual paths or pins that do not require such a setting.

To generate additional netlist files (for example, an HDL netlist for simulation), on the Tools menu, point to **Set Options** and **Output** and select the desired output format. The Precision Synthesis software generates a separate file for each selected type of file: EDIF, Verilog HDL, and VHDL.

Compiling the Design

To compile the design into a technology-independent implementation, in the **Design Bar**, click the **Compile** icon.

Mapping the Precision Synthesis Design

In the next steps, you set constraints and map the design to technology-specific cells. The Precision Synthesis software maps the design by default to the fastest possible implementation that meets your timing constraints. To accomplish this, you must specify timing requirements for the automatically determined clock sources. With this information, the Precision Synthesis software performs static timing analysis to determine the location of the critical timing paths. The Precision Synthesis software achieves the best results for your design when you set as many realistic constraints as possible. Be sure to set constraints for timing, mapping, false paths, multicycle paths, and other factors that control the structure of the implemented design.

Mentor Graphics recommends creating an **.sdc** file and adding this file to the **Constraint Files** section of the **Project Files** list. You can create this file with a text editor, by issuing command line constraint parameters, or using the Precision Synthesis software to generate one automatically for you on the first synthesis run. To create a constraint file with the user interface, set constraints on design objects (such

as clocks, design blocks, or pins) in the Design Hierarchy browser. By default, the Precision Synthesis software saves all timing constraints and attributes in two files: **precision_rtl.sdc** and **precision_tech.sdc**. The **precision_rtl.sdc** file contains constraints set on the RTL-level database (after compilation) and the **precision_tech.sdc** file contains constraints set on the gate-level database (after synthesis) located in the current implementation directory.

You can also enter constraints at the command line. After adding constraints at the command line, update the **.sdc** file with the **update constraint file** command. You can add constraints that change infrequently directly to the HDL source files with HDL attributes or pragmas.

The Precision SDC constraints file contains all the constraints for the Precision Synthesis project. For the Quartus II software, placement constraints are written in a **.tcl** file along with timing constraints for the Classic Timing Analyzer. The Quartus II **.sdc** file contains only timing constraints for the TimeQuest Timing Analyzer.

For details about the syntax of Synopsys Design Constraint commands, refer to the *Precision RTL Synthesis User's Manual* and the *Precision Synthesis Reference Manual*. For more details and examples of attributes, refer to the *Attributes* chapter in the *Precision Synthesis Reference Manual.* To access these manuals, in the Precision Synthesis software, click **Help** and select **Open Manuals Bookcase**.

Setting Timing Constraints

Timing constraints, based on the industry-standard **.sdc** file format, help the Precision Synthesis software to deliver optimal results. Missing timing constraints can result in incomplete timing analysis and might prevent timing errors from being detected. Precision Synthesis software provides constraint analysis prior to synthesis to ensure that designs are fully and accurately constrained. If the selected device uses the Classic Timing Analyzer by default in the Quartus II software, all timing constraints are forward-annotated to the Quartus II software using Tcl scripts for the Quartus II Classic Timing Analyzer. If the selected device uses the TimeQuest Timing Analyzer by default in the Quartus II software, <*project name*>**_pnr_constraints.sdc** is generated that contains timing constraints in SDC format.

Because the **.sdc** file format requires that timing constraints must be set relative to defined clocks, you must specify your clock constraints before applying any other timing constraints.

You also can use multicycle path and false path assignments to relax requirements or exclude nodes from timing requirements. Doing so can improve area utilization and allow the software optimizations to focus on the most critical parts of the design.

For details about the syntax of Synopsys Design Constraint commands, refer to the *Precision RTL Synthesis User's Manual* and the *Precision Synthesis Reference Manual*. To access these manuals, in the Precision Synthesis software, click **Help** and select **Open Manuals Bookcase**.

Setting Mapping Constraints

Mapping constraints affect how your design is mapped into the target Altera device. You can set mapping constraints in the user interface, in HDL code, or with the **set_attribute** command in the constraint file.

Assigning Pin Numbers and I/O Settings

The Precision Synthesis software supports assigning device pin numbers, I/O standards, drive strengths, and slew-rate settings to top-level ports of the design. You can set these timing constraints with the **set_attribute** command, the GUI, or by specifying synthesis attributes in your HDL code. These constraints are forward-annotated in the <*project name*>**.tcl** file that is read by the Quartus II software during place-and-route and do not affect synthesis.

You can use the **set_attribute** command in Precision's **.sdc** file format to specify pin number constraints, I/O standards, drive strengths, and slow slew-rate settings. Table 11–2 outlines the format to use for entries in the Precision constraint file.

Table 11–2. Constraint File Settings

Constraint	Entry Format for Precision Constraint File
Pin number	`set_attribute -name PIN_NUMBER -value "<pin number>" -port <port name>`
I/O standard	`set_attribute -name IOSTANDARD -value "<I/O Standard>" -port <port name>`
Drive strength	`set_attribute -name DRIVE -value "<drive strength in mA>" -port <port name>`
Slew rate	`set_attribute -name SLEW -value "TRUE | FALSE" -port <port name>`

You can also specify these options in the GUI. To specify a pin number or other I/O setting in the Precision Synthesis GUI, follow these steps:

1. After compiling the design, expand the **Ports** entry in the Design Hierarchy Browser.
2. Under **Ports**, expand the **Inputs** or **Outputs** entry.

You also can assign I/O settings by right-clicking the pin in the Schematic Viewer.

3. Right-click the desired pin name and select the **Set Input Constraints** option under **Inputs** or **Set Output Constraints** option under **Outputs**.
4. Enter the desired pin number on the Altera device in the **Pin Number** box (**Port Constraints** dialog box).
5. Select the I/O standard from the **IO_STANDARD** list.
6. For output pins, you can also select a drive strength setting and slew rate setting using the **DRIVE** and **SLOW SLEW** lists.

You also can use synthesis attributes or pragmas in your HDL code to make these assignments. Example 11–1 and Example 11–2 show code samples that make a pin assignment in your HDL code.

Example 11–1. Verilog HDL Pin Assignment

```
//pragma attribute clk pin_number P10;
```

Example 11–2. VHDL Pin Assignment

```
attribute pin_number : string
attribute pin_number of clk : signal is “P10”;
```

You can use the same syntax to assign the I/O standard using the attribute `IOSTANDARD`, drive strength using the attribute `DRIVE`, and slew rate using the attribute `SLEW`.

For more details about attributes and how to set these attributes in your HDL code, refer to the *Precision Synthesis Reference Manual.* To access this manual, in the Precision Synthesis software, click **Help** and select **Open Manuals Bookcase**.

Assigning I/O Registers

The Precision Synthesis software performs timing-driven I/O register mapping by default. It moves registers into an I/O element (IOE) when doing so does not negatively impact the register-to-register performance of your design, based on the timing constraints.

You can force a register to the device's IOE using the Complex I/O constraint. This option does not apply if you turn off **I/O pad insertion.** Refer to "Disabling I/O Pad Insertion" for more information.

To force an I/O register into the device's IOE using the GUI, follow these steps:

1. After compiling the design, expand the **Ports** entry in the Design Hierarchy browser.
2. Under **Ports**, expand the **Inputs** or **Outputs** entry, as desired.
3. Under **Inputs** or **Outputs**, right-click the desired pin name, point to **Map Input Register to IO** or **Map Output Register to IO** for input or output respectively, and click **True**.

You also can make the assignment by right-clicking on the pin in the Schematic Viewer.

For the Stratix and Cyclone series, and MAX II device families, the Precision Synthesis software can move an internal register to an I/O register without any restrictions on design hierarchy.

For more mature devices, the Precision Synthesis software can move an internal register to an I/O register only when the register exists in the top level of the hierarchy. If the register is buried in the hierarchy, you must flatten the hierarchy so that the buried registers are moved to the top level of the design.

Disabling I/O Pad Insertion

The Precision Synthesis software assigns I/O pad atoms (device primitives used to represent the I/O pins and I/O registers) to all ports in the top level of a design by default. In certain situations, you might not want the software to add I/O pads to all I/O pins in the design. The Quartus II software can compile a design without I/O pads; however, including I/O pads provides the Precision Synthesis software with the most information about the top-level pins in the design.

Preventing the Precision Synthesis Software from Adding I/O Pads

If you are compiling a subdesign as a separate project, I/O pins cannot be primary inputs or outputs of the device and therefore should not have an I/O pad associated with them. To prevent the Precision Synthesis software from adding I/O pads, perform the following steps:

1. On the Tools menu, click **Set Options**. The **Options** dialog box appears.
2. On the **Optimization** page, turn off **Add IO Pads**.
3. Click **Apply**.

These steps add the following command to the project file:

```
setup_design -addio=false
```

Preventing the Precision Synthesis Software from Adding an I/O Pad on an Individual Pin

To prevent I/O pad insertion on an individual pin when you are using a black box, such as DDR or a phase-locked loop (PLL), at the external ports of the design, follow these steps:

1. After compiling the design, in the Design Hierarchy browser, expand the **Ports** entry by clicking the "+" icon.
2. Under **Ports**, expand the **Inputs** or **Outputs** entry.
3. Under **Inputs** or **Outputs**, right-click the desired pin name and click **Set Input Constraints**.
4. In the **Port Constraints** dialog box for the selected pin name, turn off **Insert Pad**.

You also can make the assignment by right-clicking on the pin in the Schematic Viewer or by attaching the `nopad` attribute to the port in the HDL source code.

Controlling Fan-Out on Data Nets

Fan-out is defined as the number of nodes driven by an instance or top-level port. High fan-out nets can have significant delays that result in an unroutable net. On a critical path, high fan-out nets can cause larger delays in a single net segment that result in the timing constraints not being met. To prevent this behavior, each device family has a global fan-out value set in the Precision Synthesis software library. In addition, the Quartus II software automatically routes high fan-out signals on global routing lines in the Altera device whenever possible.

To eliminate routability and timing issues associated with high fan-out nets, the Precision Synthesis software also allows you to override the library default value on a global or individual net basis. You can override the library value by setting a `max_fanout` attribute on the net.

Synthesizing the Design and Evaluating the Results

To synthesize the design for the target device, click on the **Synthesize** icon in the **Precision Synthesis Design Bar**. During synthesis, the Precision Synthesis software optimizes the compiled design, then writes out netlists and reports to the implementation subdirectory of your working directory after the implementation is saved, using the naming convention:

<*project name*>`_impl_`<*number*>

After synthesis is complete, you can evaluate the results in terms of area and timing. The *Precision RTL Synthesis User's Manual* on the Mentor Graphics website describes different results that can be evaluated in the software.

There are several schematic viewers available in the Precision Synthesis software: RTL schematic, Technology-mapped schematic, and Critical Path schematic. These analysis tools allow you to quickly and easily isolate the source of timing or area issues, and to make additional constraint or code changes to optimize the design.

Obtaining Accurate Logic Utilization and Timing Analysis Reports

Historically, designers have relied on post-synthesis logic utilization and timing reports to determine how much logic their design requires, how big a device they require, and how fast the design runs. However, today's FPGA devices provide a wide variety of advanced features in addition to basic registers and look-up tables (LUTs). The Quartus II software has advanced algorithms to take advantage of these features, as well as optimization techniques to increase performance and reduce the amount of logic required for a given design. In addition, designs can contain black boxes and functions that take advantage of specific device features. Because of these advances, synthesis tool reports provide post-synthesis area and timing estimates, but the place-and-route software should be used to obtain final logic utilization and timing reports.

Exporting Designs to the Quartus II Software Using NativeLink Integration

The NativeLink feature in the Quartus II software facilitates the seamless transfer of information between the Quartus II software and EDA tools, which allows you to run other EDA design entry/synthesis, simulation, and timing analysis tools automatically from within the Quartus II software.

After a design is synthesized in the Precision Synthesis software, the technology-mapped design is written to the current implementation directory as an EDIF netlist file, along with a Quartus II Project Configuration File and a place-and-route constraints file. You can use the Project Configuration script, <*project name*>**.tcl**, to create and compile a Quartus II project for your EDIF netlist. This script makes basic project assignments, such as assigning the target device

specified in the Precision Synthesis software. For the Quartus II Classic Timing Analyzer, the Project Configuration script calls the place-and-route constraints script, <*project name*>**_pnr_constraints.tcl**, to make your timing constraints. If you select an Arria GX, Stratix III, Cyclone III, or newer device, the constraints are written in SDC format to the <*project name*>**_pnr_constraints.sdc** file by default and is used by the Fitter and the TimeQuest Timing Analyzer in the Quartus II software.

If you want to use the Quartus II TimeQuest Timing Analyzer, use the following Precision command before compilation:

```
setup_design -timequest_sdc
```

With this command, a file named <*project name*>**_pnr_constraints.sdc** is generated after the synthesize command.

Running the Quartus II Software from within the Precision Synthesis Software

Precision Synthesis software also has a built-in place-and-route environment that allows you to run the Quartus II Fitter and view the results in the Precision Synthesis GUI. This feature is useful when performing an initial compilation of your design to view post-place-and-route timing and device utilization results, but not all the advanced Quartus II options that control the compilation process are available.

After you specify an Altera device as the target, set the options for the Quartus II software. On the Tools menu, click **Set Options**. On the **Integrated Place and Route** page (under **Quartus II Modular**), specify the path to the Quartus II executables in the **Path to Quartus II installation tree** box.

To automate the place-and-route process, click the **Run Quartus II** icon in the **Quartus II Modular** window of the Precision Synthesis toolbar. The Quartus II software uses the current implementation directory as the Quartus II project directory and runs a full compilation in the background (that is, the user interface does not appear).

Two primary Precision Synthesis software commands control the place-and-route process. Use the `setup_place_and_route` command to set the place-and-route options. The process is started with the `place_and_route` command.

Precision Synthesis software versions 2004a and later support using individual Quartus II executables, such as analysis and synthesis (`quartus_map`), Fitter (`quartus_fit`), and the Classic Timing Analyzer (`quartus_tan`) or the TimeQuest Timing Analyzer (`quartus_sta`) (only for software version 2006a and later), for improved runtime and memory utilization during place and route. This flow is referred to as the **Quartus II Modular** flow option in Precision Synthesis software and is compatible with Quartus II software versions beginning with version 4.0. By default, the Precision Synthesis software generates a Quartus II Project Configuration File (**.tcl** file) for Arria GX, Stratix series, MAX II, and Cyclone series device families. When you use this flow, all timing constraints that you set during synthesis are exported to the Quartus II place-and-route constraints file <*project name*>**_pnr_constraints.tcl**, or <*project name*>**_pnr_constraints.sdc**, depending on which Quartus II timing analyzer the Precision Synthesis software is targeting.

For other device families, the Precision Synthesis software uses the **Quartus II** flow option, which enables the Quartus II compilation flow that existed in Precision Synthesis software versions earlier than 2004a. The Quartus II Project Configuration File (**.tcl** file) is written when using the **Quartus II** flow option that includes supported timing constraints that you specified during synthesis. This **.tcl** file is compatible with all versions of the Quartus II software; however, the format and timing constraints do not take full advantage of the features in the Quartus II software introduced with version 4.0.

To force the use of a particular flow when it is not the default for a certain device family, use the following command to set up the integrated place-and-route flow:

```
setup_place_and_route -flow "<Altera Place-and-Route flow>"
```

Depending on the device family, you can use one of the following flow options in the preceding command:

- `Quartus II Modular`
- `Quartus II`
- `MAX+PLUS II`

For example, for the Stratix II or MAX II device families (which were not supported in Quartus II software versions earlier than 4.0), you can use only the **Quartus II Modular** flow. For the Stratix device family, you can use either the **Quartus II Modular** or **Quartus II** flows. The FLEX 8000 device family, which is not supported in the Quartus II software, is supported only by the **MAX+PLUS II** flow.

After the design is compiled in the Quartus II software from within the Precision Synthesis software, you can invoke the Quartus II GUI manually and then open the project using the generated Quartus II project file. You can view reports, run analysis tools, specify options, and run the various processing flows available in the Quartus II software.

Running the Quartus II Software Manually Using the Precision Synthesis-Generated Tcl Script

You can use the Quartus II software separately from the Precision Synthesis software. To run the Tcl script generated by the Precision Synthesis software to set up your project and start a full compilation, perform the following steps:

1. Ensure the **.edf**, **.tcl** files, and **.sdc** file (if using the TimeQuest Timing Analyzer) are located in the same directory (by default, the files should be located in the implementation directory).
2. In the Quartus II software, on the View menu, point to **Utility Windows** and click **Tcl Console**.
3. At the Tcl Console command prompt, type the command:

   ```
   source <path>/<project name>.tcl ↵
   ```
4. On the File menu, click **Open Project**. Browse to the project name, and click **Open**.
5. Compile the project in the Quartus II software.

Using Quartus II Software to Launch the Precision Synthesis Software

With NativeLink integration, you can set up the Quartus II software to run the Precision Synthesis software. This feature allows you to use the Precision Synthesis software to synthesize a design as part of a normal compilation.

For detailed information about using NativeLink integration with the Precision Synthesis software, go to *Specifying EDA Tool Settings* in the Quartus II Help index.

Passing Constraints to the Quartus II Software

The place-and-route constraints script forward-annotates timing constraints that you made in the Precision Synthesis software. This integration allows you to enter these constraints once in the Precision Synthesis software, and then pass them automatically to the Quartus II software.

All of the constraints you set in the Precision Synthesis software are mapped to the Quartus II software. For some constraints you set in the Precision Synthesis software, there might be a different command mapped to the Quartus II software, depending on whether you are using the TimeQuest Timing Analyzer or the Classic Timing Analyzer.

Refer to the introductory text in the section "Exporting Designs to the Quartus II Software Using NativeLink Integration" on page 11–11 for information on how to ensure the Precision Synthesis software targets the TimeQuest Timing Analyzer.

The following constraints are translated by the Precision Synthesis software and are applicable to the Classic Timing Analyzer and the TimeQuest Timing Analyzer:

- create_clock
- set_input_delay
- set_output_delay
- set_max_delay
- set_min_delay
- set_false_path
- set_multicycle_path

create_clock

You can specify a clock in the Precision Synthesis software, as shown in Example 11–3.

Example 11–3. Specifying a Clock using create_clock

```
create_clock -name <clock_name> -period <period in ns> -waveform {<edge_list>} -domain \
<ClockDomain> <pin>
```

The period is specified in units of nanoseconds (ns). If no clock domain is specified, the clock belongs to a default clock domain `main`. All clocks in the same clock domain are treated as synchronous (related) clocks. If no <*clock_name*> is provided, the default name `virtual_default` is used. The <*edge_list*> sets the rise and fall edges of the clock signal over an entire clock period. The first value in the list is a rising transition, typically the first rising transition after time zero. The waveform can contain any even number of alternating edges, and the edges listed should alternate between rising and falling. The position of any edge can be equal to or greater than zero but must be equal to or less than the clock period.

If `-waveform` <*edge_list*> is not specified, and `-period` <*period in ns*> is specified, the default waveform has a rising edge of 0.0 and a falling edge of <*period_value*>/2.

The Precision Synthesis software passes the clock definitions to the Quartus II software with the `create_base_clock` command in the place-and-route constraints file for the Classic Timing Analyzer. For the TimeQuest Timing Analyzer, the clock constraint is mapped to the TimeQuest `create_clock` setting in the Quartus II software.

The following list describes some differences in the clock properties supported by the Precision Synthesis software and the Quartus II software:

- The Quartus II software supports only clock waveforms with two edges in a clock cycle. If the Precision Synthesis software finds a multi-edge clock, it issues an error message when you synthesize your design in the Precision Synthesis software. This applies to both the Quartus II TimeQuest Timing Analyzer and the Quartus II Classic Timing Analyzer.
- Clocks in the same clock domain are annotated with the `create_relative_clock` command to create related clocks for the Quartus II Classic Timing Analyzer.
- The Quartus II Classic Timing Analyzer assumes the first clock edge to be at time zero (0.0). If the Precision Synthesis software waveform has a first transition at a time different than time zero, the Precision Synthesis software creates a base clock without any target, then uses this to create a relative clock with an offset set to the first clock edge.

set_input_delay

This port-specific input delay constraint is specified in the Precision Synthesis software, as shown in Example 11–4.

Example 11–4. Specifying set_input_delay

```
set_input_delay {<delay_value> <port_pin_list>} -clock <clock_name> -rise -fall -add_delay
```

This constraint is mapped to the `set_input_delay` setting in the Quartus II software.

When the reference clock <*clock_name*> is not specified, all clocks are assumed to be the reference clocks for this assignment. The input pin name for the assignment can be an input pin name of a time group. The software can use the option `clock_fall` to specify delay relative to the falling edge of the clock.

Although the Precision Synthesis software allows you to set input delays on pins inside the design, these constraints are not sent to the Quartus II software, and a message is displayed.

set_output_delay

This port-specific output delay constraint is specified in the Precision Synthesis software, as shown in Example 11–5.

Example 11–5. Using the set_output_delay Constraint

```
set_output_delay {<delay_value> <port_pin_list>} -clock <clock_name> -rise -fall -add_delay
```

This constraint is mapped to the `set_output_delay` setting in the Quartus II software.

When the reference clock <*clock_name*> is not specified, all clocks are assumed to be the reference clocks for this assignment. The output pin name for the assignment can be an output pin name of a time group.

Although the Precision Synthesis software allows you to set output delays on pins inside the design, these constraints are not sent to the Quartus II software.

set_max_delay

The total delay for a point-to-point timing path constraint is specified in the Precision Synthesis software, as shown in Example 11–6.

Example 11–6. Using the set_max_delay Constraint

```
set_max_delay -from {<from_node_list>} -to {<to_node_list>} <delay_value>
```

This command specifies that the maximum required delay for any start point in <*from_node_list*> to any endpoint in <*to_node_list*> must be less than <*delay_value*>. Typically, this command is used to override the default setup constraint for any path with a specific maximum time value for the path.

The node lists can contain a collection of clocks, registers, ports, pins, or cells. The `-from` and `-to` parameters specify the source (start point) and the destination (endpoint) of the timing path, respectively. The source list (<*from_node_list*>) cannot include output ports, and the destination list (<*to_node_list*>) cannot include input ports. If you include more than one node on a list, you must enclose the nodes in quotes or in '{ }' braces.

If you specify a clock in the source list, you must specify a clock in the destination list. Applying `set_max_delay` between clocks applies the exception from all registers or ports driven by the source clock to all registers or ports driven by the destination clock. Applying exceptions between clocks is more efficient than applying them for specific node to node, or node to clock paths. If you want to specify pin names in the list, the source must be a clock pin, and the destination must be any non-clock input pin to a register. Assignments from clock pins, or to and from cells, apply to all registers in the cell or for those driven by the clock pin.

set_min_delay

The minimum delay for a point-to-point timing path constraint is specified in the Precision Synthesis software, as shown in Example 11–7.

Example 11–7. Using the set_min_delay Constraint

```
set_min_delay -from {<from_node_list>} -to {<to_node_list>} <delay_value>
```

This command specifies that the minimum required delay for any start point in *<from_node_list>* to any endpoint in *<to_node_list>* must be greater than *<delay_value>*. Typically, you use this command to override the default setup constraint for any path with a specific minimum time value for the path.

The node lists can contain a collection of clocks, registers, ports, pins, or cells. The `-from` and `-to` parameters specify the source (start point) and the destination (endpoint) of the timing path, respectively. The source list (*<from_node_list>*) cannot include output ports, and the destination list (*<to_node_list>*) cannot include input ports. If you include more than one node to a list, you must enclose the nodes in quotes or in '{ }' braces.

If you specify a clock in the source list, you must specify a clock in the destination list. Applying `set_min_delay` between clocks applies the exception from all registers or ports driven by the source clock to all registers or ports driven by the destination clock. Applying exceptions between clocks is more efficient than applying them for specific node to node, or node to clock paths. If you want to specify pin names in the list, the source must be a clock pin, and the destination must be any non-clock input pin to a register. Assignments from clock pins, or to and from cells, apply to all registers in the cell or for those driven by the clock pin.

set_false_path

The false path constraint is specified in the Precision Synthesis software, as shown in Example 11–8.

Example 11–8. Using the set_false_path Constraint

```
set_false_path -to <to_node_list> -from <from_node_list> -reset_path
```

The node lists can be a list of clocks, ports, instances, and pins. Multiple elements in the list can be represented using wildcards such as "*" and "?".

In place-and-route Tcl constraints file, this setting in the Precision Synthesis software is mapped to a `set_timing_cut_assignment` setting for the Classic Timing Analyzer. For the TimeQuest Timing Analyzer, this constraint is mapped to the `set_false_path` setting.

The node lists for this assignment represents top-level ports and/or nets connected to instances (end points of timing assignments).

The Quartus II software supports `setup`, `hold`, `rise`, or `fall` options for this assignment only if you are using the TimeQuest Timing Analyzer.

The Quartus II Classic Timing Analyzer does not support false paths with the `through` path specification. Any setting in the Precision Synthesis software with a `through` specification can be mapped to a setting in the Quartus II software only if you use the TimeQuest Timing Analyzer.

For the Classic Timing Analyzer, if you use the `-from` or `-to` option without using both options, the Precision Synthesis command is converted to a Quartus II command using wildcards. Table 11–3 lists these `set_false_path` constraints in the Precision Synthesis software and the Quartus II software equivalent when the Classic Timing Analyzer is used.

Table 11–3. set_false_path Constraints with the Classic Timing Analyzer

Precision Synthesis Assignment	Quartus II Equivalent
set_false_path -from <*from_node_list*>	set_timing_cut_assignment -to {*} -from \ <*node_list*>
set_false_path -to <*to_node_list*>	set_timing_cut_assignmet -to <*node_list*> \ -from {*}

set_multicycle_path

This multi-cycle path constraint is specified in the Precision Synthesis software, as shown in Example 11–9.

Example 11–9. Using the set_multicycle_path Constraint

```
set_multicycle_path <multiplier_value> [-start] [-end] -to <to_node_list> -from <from_node_list> \
-reset_path
```

The node list can contain clocks, ports, instances, and pins. Multiple elements in the list can be represented using wildcards such as "*" and "?". Paths without multicycle path definitions are identical to paths with multipliers of 1. To add one additional cycle to the datapath, use a multiplier value of 2. The option `start` indicates that source clock cycles should be considered for the multiplier. The option `end` indicates that destination clock cycles should be considered for the multiplier. The default is to reference the end clock.

In the place-and-route Tcl constraints file, this setting in the Precision Synthesis software is mapped to a `set_multicycle_assignment` setting for the Classic Timing Analyzer. For TimeQuest Timing Analyzer, this constraint is mapped to the `set_multicycle_path` setting.

The node lists represent top-level ports and/or nets connected to instances (end points of timing assignments). The node lists can contain wildcards (such as "*"); the Quartus II software automatically expands all wildcards.

For the Classic Timing Analyzer, if you use the `-from` or `-to` option without using both options, the Precision Synthesis command is converted to a Quartus II command using wildcards. Table 11–4 lists the `set_multicycle_path` constraints in the Precision Synthesis software and the Quartus II software equivalent, when the Classic Timing Analyzer is used.

Table 11–4. set_multicycle_path Constraints for the Classic Timing Analyzer

Precision Synthesis Assignment	Quartus II Equivalent
set_multicycle_path -from \ <*from_node_list*> <*value*>	set_multicycle_assignment -to {*} \ -from <*node_list*> <*value*>
set_multicycle_path -to \ <*to_node_list*> <*value*>	set_multicycle_assignmet -to \ <*node_list*> -from {*} <*value*>

The Quartus II software supports the `rise` or `fall` options on this assignment only if you use the TimeQuest Timing Analyzer.

The Quartus II Classic Timing Analyzer does not support multicycle path with a `through` path specification. Any setting in Precision Synthesis software with a `-through` specification can be mapped to a setting in the Quartus II software only if you use the TimeQuest Timing Analyzer.

Guidelines for Altera Megafunctions and Architecture-Specific Features

Altera provides parameterizable megafunctions, including the LPMs, device-specific Altera megafunctions, IP available as Altera MegaCore functions, and IP available through the Altera Megafunction Partners Program (AMPP℠). You can use megafunctions and IP functions by instantiating them in your HDL code or you can infer certain megafunctions from generic HDL code.

If you want to instantiate a megafunction such as a PLL in your HDL code, you can do so with the MegaWizard™ Plug-In Manager to parameterize the function or instantiating the function using the port and parameter definition. The MegaWizard Plug-In Manager provides a graphical interface within the Quartus II software for customizing and parameterizing any available megafunction for the design. "Instantiating Altera Megafunctions Using the MegaWizard Plug-In Manager" and "Instantiating Intellectual Property Using the MegaWizard Plug-In Manager and IP Toolbench" on page 11–20 describe the MegaWizard Plug-In Manager flow with the Precision Synthesis software.

For more information about specific Altera megafunctions, refer to the Quartus II Help. For more information about IP functions, refer to the appropriate IP documentation.

The Precision software automatically recognizes certain types of HDL code and infers the appropriate megafunction. The Precision Synthesis software provides options to control inference of certain types of megafunctions, as described in "Inferring Altera Megafunctions from HDL Code" on page 11–22.

For a detailed discussion about instantiating versus inferring megafunctions, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*. This chapter also provides details on using the MegaWizard Plug-In Manager in the Quartus II software and explains the files generated by the wizard, as well as providing coding style recommendations and HDL examples for inferring megafunctions in Altera devices.

Instantiating Altera Megafunctions Using the MegaWizard Plug-In Manager

This section describes how to instantiate Altera megafunctions using the MegaWizard Plug-In Manager, and how to generate the files that are included in the Precision Synthesis project for synthesis.

You can run the stand-alone version of the MegaWizard Plug-In Manager by typing the following command at a command prompt:

```
qmegawiz ↵
```

Using MegaWizard Plug-In Manager-Generated Verilog HDL Files for Megafunction Instantiation

The MegaWizard Plug-In Manager generates a Verilog HDL instantiation template file <*output file*>**_inst.v** and a hollow-body black box module declaration <*output file*>**_bb.v** for use in your Precision Synthesis design. Incorporate the instantiation template file, <*output file*>**_inst.v**, into your top-level design to instantiate the megafunction wrapper file, <*output file*>**.v**.

Include the hollow-body black box module declaration <*output file*>**_bb.v** in your Precision Synthesis project to describe the port connections of the black box. Adding the megafunction wrapper file <*output file*>**.v** in your Precision Synthesis project is optional, but you must add it to your Quartus II project along with the Precision Synthesis-generated EDIF netlist.

Alternatively, you can include the megafunction wrapper file <*output file*>**.v** in your Precision Synthesis project and then right-click on the file in the input file list, and select **Properties**. In the **Input file properties** dialog box, turn on **Exclude file from Compile Phase** and click **OK**. When this option is on, the Precision Synthesis software excludes the file from compilation and makes a copy of the file in the appropriate directory so that the Quartus II software can use it during place and route.

Using MegaWizard Plug-In Manager-Generated VHDL Files for Megafunction Instantiation

The MegaWizard Plug-In Manager generates a VHDL component declaration file <*output file*>**.cmp** and a VHDL instantiation template file <*output file*>**_inst.vhd** for use in your Precision Synthesis design. Incorporate the component declaration and instantiation template into your top-level design to instantiate the megafunction wrapper file, <*output file*>**.vhd**.

Adding the megafunction wrapper file <*output file*>**.vhd** in your Precision Synthesis project is optional, but you must add it to your Quartus II project along with the Precision Synthesis-generated EDIF netlist.

Alternatively, you can include the megafunction wrapper file <*output file*>**.vhd** in your Precision Synthesis project and then right-click on the file in the input file list, and select **Properties**. In the **Input file properties** dialog box, turn on **Exclude file from Compile Phase** and click **OK**. When this option is on, the Precision Synthesis software excludes the file from compilation and makes a copy of the file in the appropriate directory so that the Quartus II software can use it during place and route.

Instantiating Intellectual Property Using the MegaWizard Plug-In Manager and IP Toolbench

Many Altera IP functions include a resource and timing estimation netlist that the Precision Synthesis software can use to synthesize and optimize logic around the IP efficiently. As a result, the Precision Synthesis software provides better timing correlation, area estimates, and Quality of Results (QoR) than a black-box approach.

To create this netlist file, perform the following steps:

1. Select the IP function in the MegaWizard Plug-In Manager and click **Next** to open the IP Toolbench.
2. Click **Set Up Simulation**, which sets up all the EDA options.

3. Enable the **Generate netlist** option to generate a netlist for resource and timing estimation and click **OK**.
4. Click **Generate** to generate the netlist file.

The Quartus II software generates a file <*output file*>**_syn.v**. This netlist contains the "grey box" information for resource and timing estimation, but does not contain the actual implementation. Include this netlist file into your Precision Synthesis project as an input file. Then include the megafunction wrapper file <*output file*>**.v | vhd** into the Quartus II project along with your EDIF output netlist.

The generated "grey box" netlist file, <*output file*>**_syn.v**, is always in Verilog HDL format, even if you select VHDL as the output file format.

There is currently no grey box support for SOPC Builder systems in the MegaWizard Plug-In Manager. For information about creating a grey box netlist file from the command line, search Altera's Knowledge Database. Alternatively, you can use a black box approach as described in "Using Generated Verilog HDL Files for Black Box IP Function Instantiation".

Using Generated Verilog HDL Files for Black Box IP Function Instantiation

You can use the `syn_black_box` or `black_box` compiler directive to declare a module as a black box. The top-level design files must contain the IP port mapping and a hollow-body module declaration. You can apply the directive to the module declaration in the top-level file or a separate file included in the project to instruct the Precision Synthesis software that this is a black box.

The `syn_black_box` and `black_box` directives are supported only on module or entity definition.

Example 11–10 shows a sample top-level file that instantiates **my_verilogIP.v**, which is a simplified customized variation generated by the MegaWizard Plug-In Manager and IP Toolbench.

Example 11–10. Top-Level Verilog HDL Code with Black Box Instantiation of IP

```
module top (clk, count);
   input clk;
   output[7:0] count;

   my_verilogIP verilogIP_inst (.clock (clk), .q (count));
endmodule

// Module declaration
// The following attribute is added to create a
// black box for this module.
module my_verilogIP (clock, q) /* synthesis syn_black_box */;
   input clock;
   output[7:0] q;
endmodule
```

Using Generated VHDL Files for Black Box IP Function Instantiation

You can use the `syn_black_box` or `black_box` compiler directive to declare a component as a black box. The top-level design files must contain the megafunction variation component declaration and port mapping. Apply the directive to the component declaration in the top-level file.

The `syn_black_box` and `black_box` directives are supported only on module or entity definition.

Example 11–11 shows a sample top-level file that instantiates **my_vhdlIP.vhd**, which is a simplified customized variation generated by the MegaWizard Plug-In Manager and IP Toolbench.

Example 11–11. Top-Level VHDL Code with Black Box Instantiation of IP

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
ENTITY top IS
  PORT (
    clk: IN STD_LOGIC ;
    count: OUT STD_LOGIC_VECTOR (7 DOWNTO 0)
  );
END top;

ARCHITECTURE rtl OF top IS
  COMPONENT my_vhdlIP
  PORT (
    clock: IN STD_LOGIC ;
    q: OUT STD_LOGIC_VECTOR (7 DOWNTO 0)
  );
  end COMPONENT;
  attribute syn_black_box : boolean;
  attribute syn_black_box of my_vhdlIP: component is true;
  BEGIN
    vhdlIP_inst : my_vhdlIP PORT MAP (
       clock => clk,
       q => count
    );
END rtl;
```

Inferring Altera Megafunctions from HDL Code

The Precision Synthesis software automatically recognizes certain types of HDL code and maps arithmetic and relational operators, and memory (RAM and ROM), to efficient technology-specific implementations. This allows for the use of technology-specific resources to implement these structures by inferring the appropriate Altera megafunction to provide optimal results. In some cases, the Precision Synthesis software has options that you can use to disable or control inference.

For coding style recommendations and examples for inferring megafunctions in Altera devices, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*, and the *Precision Synthesis Style Guide* in the Precision Manuals Bookcase. To access these manuals, in the Precision Synthesis software, click **Help** and select **Open Manuals Bookcase**.

Multipliers

The Precision Synthesis software detects multipliers in HDL code and maps them directly to device atoms to implement the multiplier in the appropriate type of logic. The Precision Synthesis software also allows you to control the device resources that are used to implement individual multipliers, as described in the following section.

Controlling DSP Block Inference for Multipliers

By default, the Precision Synthesis software uses DSP blocks available in the Stratix series of devices to implement multipliers. The default setting is **AUTO**, to allow Precision Synthesis software the flexibility to choose between logic look-up tables (LUTs) and DSP blocks, depending on the size of the multiplier. You can use the Precision Synthesis GUI or HDL attributes to direct the mapping to only logic elements or to only DSP blocks. The options for multiplier mapping in the Precision Synthesis software are shown in Table 11–5.

Table 11–5. Options for dedicated_mult Parameter to Control Multiplier Implementation in Precision Synthesis

Value	Description
ON	Use only DSP blocks to implement multipliers, regardless of the size of the multiplier.
OFF	Use only logic (LUTs) to implement multipliers.
AUTO	Use logic (LUTs) and DSP blocks to implement multipliers depending on the size of the multipliers.

Using the GUI

To set the `Use Dedicated Multiplier` option in the Precision Synthesis GUI, perform the following steps:

1. Compile the design.
2. In the Design Hierarchy browser, right-click the operator for the desired multiplier and click **Use Dedicated Multiplier**.

Using Attributes

To control the implementation of a multiplier in your HDL code, use the `dedicated_mult` attribute with the appropriate value from Table 11–5, as shown in Example 11–12 and Example 11–13.

Example 11–12. Setting the dedicated_mult Attribute in Verilog HDL

```
//synthesis attribute <signal name> dedicated_mult <value>
```

Example 11–13. Setting the dedicated_mult Attribute in VHDL

```
ATTRIBUTE dedicated_mult: STRING;
ATTRIBUTE dedicated_mult OF <signal name>: SIGNAL IS <value>;
```

The `dedicated_mult` attribute can be applied to signals and wires; it does not work when applied to a register. This attribute can be applied only to simple multiplier code, such as `a = b * c`.

Some signals for which the `dedicated_mult` attribute is set can be synthesized away by the Precision Synthesis software because of design optimization. In such cases, if you want to force the implementation, you should preserve the signal by setting the `preserve_signal` attribute to `TRUE`, as shown in Example 11–14 and Example 11–15.

Example 11–14. Setting the preserve_signal Attribute in Verilog HDL

```
//synthesis attribute <signal name> preserve_signal TRUE
```

Example 11–15. Setting the preserve_signal Attribute in VHDL

```
ATTRIBUTE preserve_signal: BOOLEAN;
ATTRIBUTE preserve_signal OF <signal name>: SIGNAL IS TRUE;
```

Example 11–16 and Example 11–17 are examples in Verilog HDL and VHDL of using the `dedicated_mult` attribute to implement the given multiplier in regular logic in the Quartus II software.

Example 11–16. Verilog HDL Multiplier Implemented in Logic

```
module unsigned_mult (result, a, b);
   output [15:0] result;
   input [7:0] a;
   input [7:0] b;
   assign result = a * b;
   //synthesis attribute result dedicated_mult OFF
endmodule
```

Example 11–17. VHDL Multiplier Implemented in Logic

```
LIBRARY ieee;
USE ieee.std_logic_1164.ALL;
USE ieee.std_logic_arith.ALL;
USE ieee.std_logic_unsigned.ALL;

ENTITY unsigned_mult IS
   PORT(
      a: IN std_logic_vector (7 DOWNTO 0);
      b: IN std_logic_vector (7 DOWNTO 0);
      result: OUT std_logic_vector (15 DOWNTO 0));
ATTRIBUTE dedicated_mult: STRING;
END unsigned_mult;

ARCHITECTURE rtl OF unsigned_mult IS
   SIGNAL a_int, b_int: UNSIGNED (7 downto 0);
   SIGNAL pdt_int:  UNSIGNED (15 downto 0);
ATTRIBUTE dedicated_mult OF pdt_int: SIGNAL IS "OFF";
BEGIN
   a_int <= UNSIGNED (a);
   b_int <= UNSIGNED (b);
   pdt_int <= a_int * b_int;
   result <= std_logic_vector(pdt_int);
END rtl;
```

Multiplier-Accumulators and Multiplier-Adders

The Precision Synthesis software detects multiply-accumulators or multiply-adders in HDL code and infers an ALTMULT_ACCUM or ALTMULT_ADD megafunction so that the logic can be placed in DSP blocks, or maps directly to device atoms to implement the multiplier in the appropriate type of logic.

The Precision Synthesis software supports inference for these functions only if the target device family has dedicated DSP blocks.

The Precision Synthesis software also allows you to control the device resources used to implement multiply-accumulators or multiply-adders in your project or in a particular module. Refer to "Controlling DSP Block Inference" for more information.

For more information about DSP blocks in Altera devices, refer to the appropriate Altera device family handbook and device-specific documentation. For details about which functions a given DSP block can implement, refer to the DSP Solutions Center on the Altera website at www.altera.com.

For more information about inferring Multiply-Accumulator and Multiply-Adder megafunctions in HDL code, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*, and the *Precision Synthesis Style Guide* in the Precision Synthesis Manuals Bookcase.

Controlling DSP Block Inference

By default, the Precision Synthesis software infers the ALTMULT_ADD or ALTMULT_ACCUM megafunction as appropriate for your design. These megafunctions allow the Quartus II software the flexibility to choose regular logic or DSP blocks depending on the device utilization and the size of the function.

You can use the `extract_mac` attribute to prevent the inference of an ALTMULT_ADD or ALTMULT_ACCUM megafunction in a certain module or entity. The options for this attribute are shown in Table 11–6.

Table 11–6. Options for extract_mac Attribute Controlling DSP Implementation

Value	Description
TRUE	The ALTMULT_ADD or ALTMULT_ACCUM megafunction is inferred
FALSE	The ALTMULT_ADD or ALTMULT_ACCUM megafunction is not inferred

To control inference, use the `extract_mac` attribute with the appropriate value from Table 11–6 in your HDL code, as shown in Example 11–18 and Example 11–19.

Example 11–18. Setting the extract_mac Attribute in Verilog HDL

```
//synthesis attribute <module name> extract_mac <value>
```

Example 11–19. Setting the extract_mac Attribute in VHDL

```
ATTRIBUTE extract_mac: BOOLEAN;
ATTRIBUTE extract_mac OF <entity name>: ENTITY IS <value>;
```

To control the implementation of the multiplier portion of a multiply-accumulator or multiply-adder, you must use the `dedicated_mult` attribute.

Example 11–20 and Example 11–21 use the `extract_mac`, `dedicated_mult`, and `preserve_signal` attributes (in Verilog HDL and VHDL) to implement the given DSP function in logic in the Quartus II software.

Example 11–20. Using extract_mac, dedicated_mult and preserve_signal in Verilog HDL

```
module unsig_altmult_accum1 (dataout, dataa, datab, clk, aclr, clken);
   input [7:0] dataa, datab;
   input clk, aclr, clken;
   output    [31:0] dataout;

   reg       [31:0] dataout;
   wire      [15:0] multa;
   wire      [31:0] adder_out;

   assign multa = dataa * datab;

   //synthesis attribute multa preserve_signal TRUE
   //synthesis attribute multa dedicated_mult OFF
   assign adder_out = multa + dataout;

   always @ (posedge clk or posedge aclr)
   begin
      if (aclr)
      dataout <= 0;
      else if (clken)
      dataout <= adder_out;
   end

   //synthesis attribute unsig_altmult_accum1 extract_mac FALSE
endmodule
```

Example 11–21. Using extract_mac, dedicated_mult, and preserve_signal in VHDL

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
USE ieee.std_logic_arith.all;
USE ieee.std_logic_signed.all;
ENTITY signedmult_add IS
   PORT(
      a, b, c, d: IN STD_LOGIC_VECTOR (7 DOWNTO 0);
      result: OUT STD_LOGIC_VECTOR (15 DOWNTO 0));
   ATTRIBUTE preserve_signal: BOOLEAN;
   ATTRIBUTE dedicated_mult: STRING;
   ATTRIBUTE extract_mac: BOOLEAN;
   ATTRIBUTE extract_mac OF signedmult_add: ENTITY IS FALSE;
END signedmult_add;
ARCHITECTURE rtl OF signedmult_add IS
   SIGNAL a_int, b_int, c_int, d_int : signed (7 DOWNTO 0);
   SIGNAL pdt_int, pdt2_int : signed (15 DOWNTO 0);
   SIGNAL result_int: signed (15 DOWNTO 0);
   ATTRIBUTE preserve_signal OF pdt_int: SIGNAL IS TRUE;
   ATTRIBUTE dedicated_mult OF pdt_int: SIGNAL IS "OFF";
   ATTRIBUTE preserve_signal OF pdt2_int: SIGNAL IS TRUE;
   ATTRIBUTE dedicated_mult OF pdt2_int: SIGNAL IS "OFF";
BEGIN
   a_int <= signed (a);
   b_int <= signed (b);
   c_int <= signed (c);
   d_int <= signed (d);
   pdt_int <= a_int * b_int;
   pdt2_int <= c_int * d_int;
   result_int <= pdt_int + pdt2_int;
   result <= STD_LOGIC_VECTOR(result_int);
END rtl;
```

RAM and ROM

The Precision Synthesis software detects memory structures in HDL code and converts them to an operator that infers an ALTSYNCRAM or LPM_RAM_DP megafunction, depending on the device family. The software then places these functions in memory blocks.

The software supports inference for these functions only if the target device family has dedicated memory blocks.

For more information about inferring RAM and ROM megafunctions in HDL code, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*, and the *Precision Synthesis Style Guide* in the Precision Synthesis Manuals Bookcase. To access these manuals, in the Precision Synthesis software, click **Help** and select **Open Manuals Bookcase**.

Incremental Compilation and Block-Based Design

As designs become more complex and designers work in teams, a block-based hierarchical or incremental design flow is often an effective design approach. In an incremental compilation flow, you can make changes to a part of the design while maintaining the placement and performance of unchanged parts of the design. Design iterations can be made dramatically faster by focusing new compilations on particular design partitions and merging results with the results of previous compilations of other partitions. In a bottom-up or team-based approach, you can perform optimization on individual blocks and then integrate them into a final design and optimize it at the top level.

The first step in a hierarchical or incremental design flow is to make sure that different parts of your design do not affect each other. Ensure that you have separate netlists for each partition in your design so that you can take advantage of the incremental compilation design flow in the Quartus II software. If the whole design is in one netlist file, changes in one partition affect other partitions because of possible node name changes when you resynthesize the design.

You can create different implementations for each partition in your Precision Synthesis project, which allows you to switch between partitions without leaving the current project file. You can also create a separate project for each partition if you require separate projects for a bottom-up or team-based design flow. Alternatively, you can use the incremental synthesis capability in the Precision RTL Plus software.

For more information about creating partitions and using incremental compilation in the Quartus II software, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Creating a Design with Precision RTL Plus Incremental Synthesis

The Precision RTL Plus incremental synthesis flow for Quartus II incremental compilation uses a partition-based approach to achieve faster design iterations cycle time in one Precision implementation without sacrificing design performance.

Using the incremental synthesis feature, you can create different netlist files for different partitions of a design hierarchy within one partition implementation. This makes each partition independent of the others in either a top-down or a bottom-up incremental compilation flow. In either case, only the portions of a design that have been updated must be recompiled during design iterations. You can make changes and resynthesize one partition in a design to create a new netlist without affecting the synthesis results or fitting of other partitions.

The following steps show a general flow for partition-based incremental synthesis with Quartus II incremental compilation.

1. Create Verilog HDL or VHDL design files as you do in the regular design flow.
2. Determine which hierarchical blocks you want to treat as separate partitions in your design and indicate the partitions using the `incr_partition` attribute. For the syntax to create partitions, refer to “Creating Partitions with the incr_partition Attribute” on page 11–29.
3. Create a project in the Precision RTL Plus Synthesis software and add the HDL design files to the project.

4. Enable incremental synthesis in the Precision RTL Plus Synthesis software using one of these methods:
   - On the Tools menu, click **Set Options**. On the **Optimization** page, turn on **Enable Incremental Synthesis**.
   - Run the following command in the Transcript Window:

     ```
     setup_design -enable_incr_synth ↵
     ```
5. Run the basic Precision Synthesis flow of compile, synthesis, and place-and-route on your design. In subsequent runs, the Precision RTL Plus Synthesis software processes only the parts of the design that have changed, resulting in a shorter iteration than the initial run. The performance of the unchanged partitions is preserved.

   The Precision RTL Plus Synthesis software sets the netlist types of the unchanged partitions to **Post-Fit**, and the changed partitions to **Post-Synthesis**. You can change the netlist type during timing closure in the Quartus II software to get the best QoR.
6. Import the EDIF netlist for each partition and the top-level **.tcl** file into the Quartus II software and set up the Quartus II project to use incremental compilation.
7. Compile your Quartus II project.

   To change the Quartus II incremental compilation netlist type for a partition, on the Assignments menu, click **Design Partitions Window**.

   - To preserve the previous post-fit placement results, change the **Netlist Type** of the partition to **Post-Fit**.
   - To preserve the previous routing results, set the **Fitter Preservation Level** of the partition to **Placement and Routing**.

Creating Partitions with the incr_partition Attribute

Partitions are set using the HDL `incr_partition` attribute. The Precision Synthesis software creates or deletes partitions by looking at this attribute during compile iterations. The attribute can be attached to either the design unit definition, or an instance. Example 11–22 and Example 11–23 show how to use the attribute to create partitions. Simply remove the attribute or set the attribute value to false to delete the partitions.

The Precision Synthesis software ignores partitions set in a black box.

Example 11–22. Using incr_partition Attribute to Create Partition in Verilog HDL

Design unit partition:

```
module my_block(
  input clk;
  output reg [31:0] data_out) /* synthesis incr_partition */ ;
```

Instance partition:

```
my_block my_block_inst(.clk(clk), .data_out(data_out));
// synthesis attribute my_block_inst incr_partition true
```

Example 11–23. Using incr_partition Attribute to Create Partition in VHDL

Design unit partition:

```
entity my_block is
  port(
    clk : in std_logic;
    data_out : out std_logic_vector(31 downto 0)
  );
  attribute incr_partition : boolean;
  attribute incr_partition of my_block : entity is true;
end entity my_block;
```

Instance partition:

```
component my_block is
  port(
    clk : in std_logic;
    data_out : out std_logic_vector(31 downto 0)
  );
end component;

attribute incr_partition : boolean;
attribute incr_partition of my_block_inst : label is true;

my_block_inst my_block
  port map(clk, data_out);
```

Creating Multiple EDIF Netlist Files Using Separate Precision Projects or Implementations

This section describes how to manually generate multiple EDIF netlist files for incremental compilation using black boxes and separate Precision projects or implementations for each design partition. This manual flow is supported in versions of the Precision software that do not include the incremental synthesis feature. You might also use this feature if you perform synthesis in a team-based environment where there is no one top-level synthesis project that includes all of the lower-level design blocks.

In the Precision Synthesis software, create a separate implementation or a separate project for each lower-level module and for the top-level design that you want to maintain as a separate EDIF netlist file. Implement black box instantiations of lower-level modules in your top-level implementation or project.

For more information about managing implementations and projects, refer to the *Precision RTL Synthesis User's Manual*. To access this manual, in the Precision Synthesis software, click **Help** and select **Open Manuals Bookcase**.

When synthesizing the implementations for lower-level modules, perform these steps in the Precision Synthesis software:

1. On the Tools menu, turn off **Add IO Pads** on the **Optimization** page under **Set Options**.

You must turn off the **Add IO Pads** option while synthesizing the lower-level modules individually. Enable the **Add IO Pads** option only while synthesizing the top-level module.

2. Read the HDL files for the modules.

Modules can include black box instantiations of lower-level modules that are also maintained as separate EDIF files.

3. Add constraints for all partitions in the design.

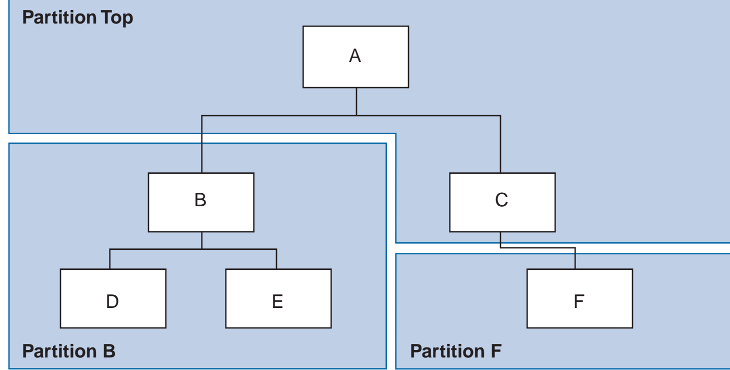
When synthesizing the top-level design implementation, perform these steps:

1. Read the HDL files for top-level designs.
2. On the Tools menu, click **Set Options**. On the **Optimization** page, turn on **Add IO Pads**.
3. Create black boxes for lower-level modules in the top-level design.
4. Add constraints.

In a top-down Quartus II incremental compilation flow, Precision constraints made on lower-level modules are not passed to the Quartus II software. Ensure that appropriate constraints are made in the top-level Precision Synthesis project, or in the Quartus II project.

The following sections describe an example of implementing black boxes to create separate EDIF netlists. Figure 11–2 shows an example of a design hierarchy separated into various partitions.

Figure 11–2. Partitions in a Hierarchical Design



In Figure 11–2, the top-level partition contains the top-level block in the design (block A) and the logic that is not defined as part of another partition. In this example, the partition for top-level block A also includes the logic in the C sub-block. Because block F is contained in its own partition, it is not treated as part of the top-level partition A. Another separate partition, B, contains the logic in blocks B, D, and E. In a team-based design, different engineers may work on the logic in different partitions. One netlist is created for the top-level module A and its submodule C, another netlist is created for module B and its submodules D and E, while a third netlist is created for module F. To create multiple EDIF netlist files for this design, follow these steps:

1. Generate an EDIF file for module B. Use **B.v/.vhd**, **D.v/.vhd**, and **E.v/.vhd** as the source files.
2. Generate an EDIF file for module F. Use **F.v/.vhd** as the source file.
3. Generate a top-level EDIF file for module A. Use **A.v/.vhd** and **C.v/.vhd** as the source files. Ensure that you create black boxes for modules B and F, which were optimized separately in the previous steps.

The goal is to individually synthesize and generate an EDIF netlist file for each lower-level module and then instantiate these modules as black boxes in the top-level file. You can then synthesize the top-level file to generate the EDIF netlist file for the top-level design. Finally, both the lower-level and top-level EDIF netlist files are provided to your Quartus II project.

When you make design or synthesis optimization changes to part of your design, resynthesize only the changed partition to generate the new EDIF netlist file. Do not resynthesize the implementations or projects for the unchanged partitions.

Creating Black Boxes in Verilog HDL

Any design block that is not defined in the project or included in the list of files to be read for a project is treated as a black box by the software. In Verilog HDL, you must provide an empty module declaration for any module that is treated as a black box.

A black box for the top-level file **A.v** is shown in the following example. Use this same procedure for any lower-level files, which also contain a black box for any module beneath the current level of hierarchy.

Example 11–24. Verilog HDL Black Box for Top-Level File A.v

```
module A (data_in, clk, e, ld, data_out);
   input data_in, clk, e, ld;
   output [15:0] data_out;
   wire [15:0] cnt_out;
   B U1 (.data_in (data_in),.clk(clk), .ld (ld),.data_out(cnt_out));
   F U2 (.d(cnt_out), .clk(clk), .e(e), .q(data_out));
   // Any other code in A.v goes here.
endmodule
// Empty Module Declarations of Sub-Blocks B and F follow here.
// These module declarations (including ports) are required for black
// boxes.
module B (data_in, clk, ld, data_out);
   input data_in, clk, ld;
   output [15:0] data_out;
endmodule
module F (d, clk, e, q);
   input [15:0] d;
   input clk, e;
   output [15:0] q;
endmodule
```

Creating Black Boxes in VHDL

Any design block that is not defined in the project or included in the list of files to be read for a project is treated as a black box by the software. In VHDL, you must have a component declaration for the black box just like any other block in the design.

A black box for the top-level file **A.vhd** is shown in Example 11–25. Follow this same procedure for any lower-level files that also contain a black box or for any block beneath the current level of hierarchy.

Example 11–25. VHDL Black Box for Top-Level File A.vhd

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
ENTITY A IS
   PORT ( data_in : IN INTEGER RANGE 0 TO 15;
      clk, e, ld : IN STD_LOGIC;
      data_out : OUT INTEGER RANGE 0 TO 15);
END A;
ARCHITECTURE a_arch OF A IS
COMPONENT B PORT(
   data_in : IN INTEGER RANGE 0 TO 15;
   clk, ld : IN STD_LOGIC;
   d_out : OUT INTEGER RANGE 0 TO 15);
END COMPONENT;
COMPONENT F PORT(
   d : IN INTEGER RANGE 0 TO 15;
   clk, e: IN STD_LOGIC;
   q : OUT INTEGER RANGE 0 TO 15);
END COMPONENT;
-- Other component declarations in A.vhd go here
signal cnt_out : INTEGER RANGE 0 TO 15;
BEGIN
   U1 : B
   PORT MAP (
      data_in => data_in,
      clk => clk,
      ld => ld,
      d_out => cnt_out);
   U2 : F
   PORT MAP (
      d => cnt_out,
      clk => clk,
      e => e,
      q => data_out);
   -- Any other code in A.vhd goes here
END a_arch;
```

After you complete the steps outlined in this section, you have different EDIF netlist files for each partition of the design. These files are ready for use with incremental compilation in the Quartus II software.

Creating Quartus II Projects for Multiple EDIF Files

The Precision Synthesis software creates a **.tcl** file for each implementation, and provides the Quartus II software with the appropriate constraints and information to set up a project. When using incremental synthesis, the Precision RTL Plus Synthesis software creates only a single **.tcl** file, <*project name*>**_incr_partitions.tcl**, to pass the partition information to the Quartus II software. For details about using the **.tcl** script generated by the Precision Synthesis software to set up your Quartus II project and to pass your top-level constraints, refer to "Running the Quartus II Software Manually Using the Precision Synthesis-Generated Tcl Script" on page 11–13.

 © March 2009 Altera Corporation

Depending on your design methodology, you can create one Quartus II project for all EDIF netlists (a top-down flow), or a separate Quartus II project for each EDIF netlist (a bottom-up flow). In a top-down compilation design flow, you create design partition assignments for each partition in the design within a single Quartus II project. This methodology provides the best QoR and performance preservation during incremental changes to your design. You might have to use a bottom-up design flow when each partition must be optimized separately, such as in certain team-based design flows.

To perform a bottom-up compilation in the Quartus II software, create separate Quartus II projects and import each design partition into a top-level design using the incremental compilation export and import features to maintain placement results.

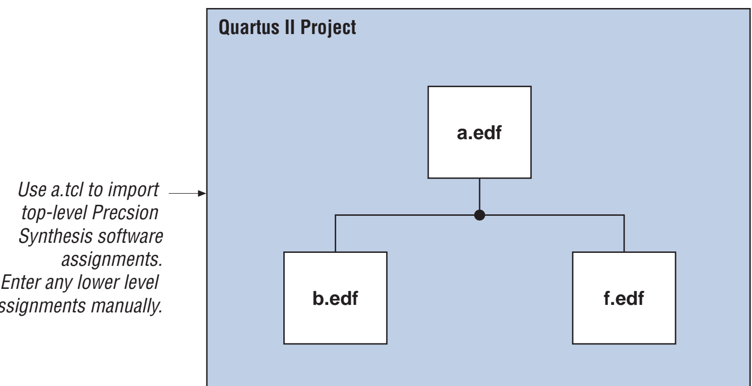
The following sections describe how to create the Quartus II projects for these two design flows.

Creating a Single Quartus II Project for a Top-Down Incremental Compilation Flow

Use the <*top-level project*>**.tcl** file generated for the top-level partition to create your Quartus II project and import all the netlists into this one Quartus II project for an incremental compilation flow. You can optimize all partitions within the single Quartus II project and take advantage of the performance preservation and compilation time reduction that incremental compilation provides. Figure 11–3 shows the design flow for the example design in Figure 11–2 on page 11–31.

All the constraints from the top-level implementation are passed to the Quartus II software in the top-level **.tcl** file, but any constraints made only in the lower-level implementations within the Precision Synthesis software are not forward-annotated. Enter these constraints manually in your Quartus II project.

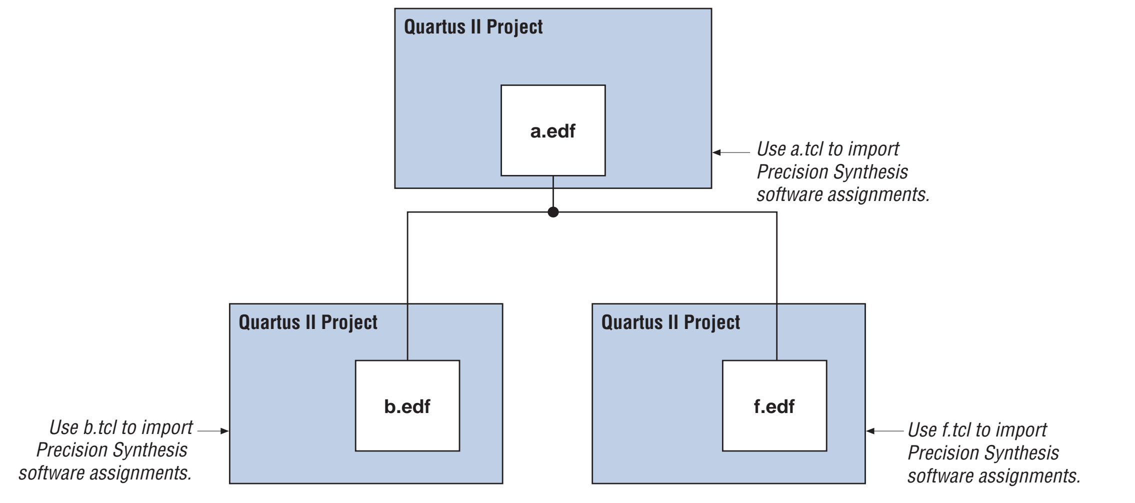
Figure 11–3. Design Flow Using Multiple EDIF Files with One Quartus II Project



Creating Multiple Quartus II Projects for a Bottom-Up Flow

Use the **.tcl** files generated by the Precision Synthesis software for each Precision Synthesis software implementation or project to generate multiple Quartus II projects, one for each partition in the design. Each designer in the project can optimize their block separately in the Quartus II software and export the placement of their blocks using incremental compilation. Designers should create a LogicLock region to provide a floorplan location assignment for each block; the top-level designer should then import all the blocks and assignments into the top-level project. Figure 11–4 shows the design flow for the example design in Figure 11–2 on page 11–31.

Figure 11–4. Design Flow: Using Multiple EDIF Files with Multiple Quartus II Projects



Hierarchy and Design Considerations

To ensure the proper functioning of the synthesis flow, you can create separate partitions only for modules, entities, or existing netlist files. In addition, each module or entity must have its own design file. If two different modules are in the same design file but are defined as being part of different partitions, you cannot maintain incremental synthesis because both regions must be recompiled when you change one of the modules.

Altera recommends that you register all inputs and outputs of each partition. This makes logic synchronous and avoids any delay penalty on signals that cross partition boundaries.

If you use boundary tri-states in a lower-level block, the Precision Synthesis software pushes the tri-states through the hierarchy to the top level to make use of the tri-state drivers on output pins of Altera devices. Because pushing tri-states requires optimizing through hierarchies, lower-level tri-states are not supported with a block-based compilation methodology. You should use tri-state drivers only at the external output pins of the device and in the top-level block in the hierarchy.

For more tips on design partitioning, refer to the *Best Practices for Incremental Compilation Partitions and Floorplan Assignments* chapter in volume 1 of the *Quartus II Handbook*.

Conclusion

Advanced synthesis is an important part of the design flow. The Mentor Graphics Precision Synthesis software and Quartus II design flow allow you to control how to prepare your design files for the Quartus II place-and-route process. This allows you to improve performance and optimize your design for use with Altera devices. Several of the methodologies outlined in this chapter can help you optimize your design to achieve performance goals and decrease design time.

Document Revision History

Table 11–7 shows the revision history for this chapter.

Table 11–7. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Updated list of supported devices for the Quartus II software version 9.0 release ■ Chapter 11 was previously Chapter 10 in software version 8.1	Updated chapter for the Quartus II software version 9.0 release.
November 2008 v8.1.0	■ Changed to 8-1/2 x 11 page size ■ Title changed to *Mentor Graphics Precision Synthesis Support* ■ Updated list of supported devices ■ Added information about the Precision RTL Plus incremental synthesis flow ■ Updated Figure 10-1 to include SystemVerilog ■ Updated "Guidelines for Altera Megafunctions and Architecture-Specific Features" on page 10–19 ■ Updated "Incremental Compilation and Block-Based Design" on page 10–28 ■ Added section "Creating Partitions with the incr_partition Attribute" on page 10–29	Updated chapter for the Quartus II software version 8.1 release.
May 2008 v8.0.0	■ Removed Mercury from the list of supported devices ■ Changed Precision version to 2007a update 3 ■ Added note for Stratix IV support ■ Renamed "Creating a Project and Compiling the Design" section to "Creating and Compiling a Project in the Precision RTL Synthesis Software" ■ Added information about constraints in the Tcl file ■ Updated document based on the Quartus II software version 8.0	Updated chapter based on the Quartus II software version 8.0

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

12. Mentor Graphics LeonardoSpectrum Support

QII51010-9.0.0

Introduction

This chapter documents key design methodologies and techniques for Altera® devices using the LeonardoSpectrum and Quartus II design flow. Combining HDL coding techniques, Mentor Graphics LeonardoSpectrum™ software constraints, and Quartus® II options provide the performance increase required for today's system-on-a-programmable-chip (SOPC) designs.

The LeonardoSpectrum software is a mature synthesis tool supporting legacy devices and many current devices. The LeonardoSpectrum software version 2008b supports the Arria® GX, Stratix® IV, Stratix III, Stratix II, Stratix, Stratix GX, Cyclone® III, Cyclone II, Cyclone, MAX® II, MAX series, APEX™ series, FLEX® series, and ACEX® series device families. Altera recommends using the advanced Precision Synthesis software for new designs in new device families.

For more information about Precision RTL Synthesis, refer to the *Mentor Graphics Precision RTL Synthesis Support* chapter in volume 1 of the *Quartus II Handbook*.

This chapter assumes that you have set up, licensed, and are familiar with the LeonardoSpectrum software.

To obtain and license the LeonardoSpectrum software, refer to the Mentor Graphics website at www.mentor.com. For information about installing the LeonardoSpectrum software and setting up your working environment, refer to the *LeonardoSpectrum Installation Guide* and the *LeonardoSpectrum User's Manual*.

Design Flow

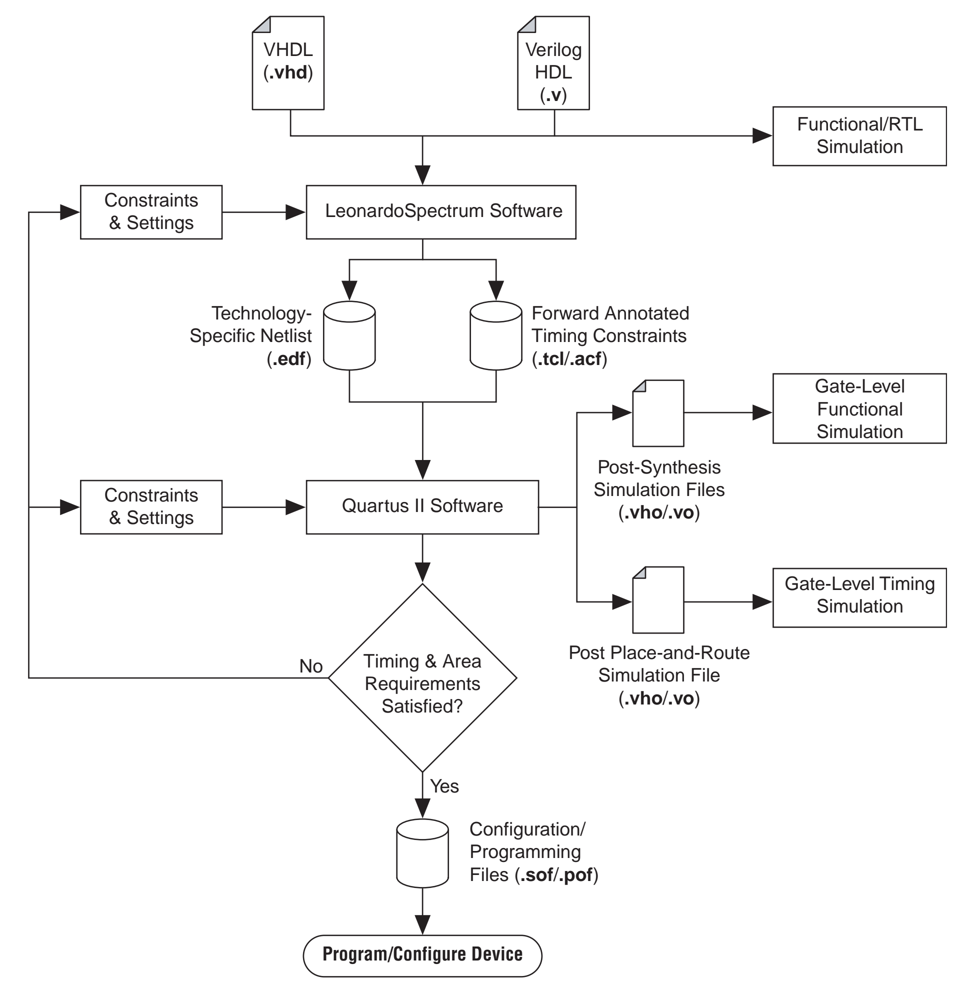
The following are basic steps in a LeonardoSpectrum-Quartus II design flow:

1. Create Verilog HDL or VHDL design files in the LeonardoSpectrum software or a text editor.
2. Import the Verilog HDL or VHDL design files into the LeonardoSpectrum software for synthesis.
3. Select a target device and add timing constraints and compiler directives to help optimize the design during synthesis.
4. Synthesize the project in the LeonardoSpectrum software.
5. Create a Quartus II project and import the technology-specific EDIF Input File (**.edf**) netlist and the Tcl Script File (**.tcl**) generated by the LeonardoSpectrum software into the Quartus II software for placement and routing, and for performance evaluation.
6. After obtaining place-and-route results that meet your requirements, configure or program the Altera device.

Figure 12–1 shows the recommended design flow using the LeonardoSpectrum and Quartus II software.

If your area and timing requirements are satisfied, use the programming files generated by the Quartus II software to program or configure the Altera device. As shown in Figure 12–1, if the area or timing requirements are not met, change the constraints in the LeonardoSpectrum software and re-run the synthesis. Repeat the process until the area and timing requirements are met. You can also use other Quartus II software options and techniques to meet the area and timing requirements.

Figure 12–1. Recommended Design Flow Using LeonardoSpectrum and Quartus II Software



The LeonardoSpectrum software supports both VHDL and Verilog HDL source files. With the appropriate license, it also supports mixed synthesis, allowing a combination of VHDL and Verilog HDL source files. After synthesis, the LeonardoSpectrum software produces several intermediate and output files. Table 12–1 lists these file extensions with a short description of each file.

Table 12–1. LeonardoSpectrum Intermediate and Output Files

File Extension(s)	File Description
.xdb	Technology-independent register transfer level (RTL) netlist file that can only be read by the LeonardoSpectrum software.
.edf	Technology-specific output netlist in electronic design interchange format (EDIF).

Table 12–1. LeonardoSpectrum Intermediate and Output Files

File Extension(s)	File Description
.acf/**.tcl** *(1)*	Forward-annotated constraint file containing constraints and assignments.

Note to Table 12–1:

(1) An assignment and configuration (**.acf**) file is created only for ACEX 1K, FLEX series, and MAX series devices. The assignment and configuration file is generated for backward compatibility with the MAX+PLUS® II software. A **.tcl** file is generated for the Quartus II software that also contains Tcl commands to create a Quartus II project.

Altera recommends that you do not use project directory names that include spaces. Some file operations in the LeonardoSpectrum software do not work correctly if the path name contains spaces.

Specify timing constraints and compiler directives for the design in the LeonardoSpectrum software, or in a constraint file (**.ctr**). Many of these constraints are forward-annotated in the **.tcl** file for use by the Quartus II software.

The LeonardoInsight™ Schematic Viewer is an add-on graphical tool for schematic views of the technology-independent RTL netlist (**.xdb**) and the technology-specific gate-level results. You can use the Schematic Viewer to visually analyze and debug the design. It also supports cross-probing between the RTL and gate-level schematics, the design browser, and the source code in the HDLInventor™ text editor.

Optimization Strategies

You can configure most general settings in the **Quick Setup** tab in the LeonardoSpectrum user interface. Other Flow tabs provide additional options, and some Flow tabs include multiple Power tabs (at the bottom of the screen) with more options. Advanced optimization options in the LeonardoSpectrum software include timing-driven synthesis, encoding style, resource sharing, and mapping I/O registers.

Timing-Driven Synthesis

The LeonardoSpectrum software supports timing-driven synthesis through user-assigned timing constraints to optimize the performance of the design. The process for setting constraints in the LeonardoSpectrum software is straightforward. Constraints such as clock frequency can be specified globally or for individual clock signals. The following sections describe how to set the various types of timing constraints in the LeonardoSpectrum software.

The timing constraints described in "Global Power Tab" are set in the **Constraints** Flow tab. In this tab, there are Power tabs at the bottom, such as **Global** and **Clock**, for setting various constraints.

Global Power Tab

The **Global** tab is the default Power tab in the **Constraints** Flow tab where you can specify the global clock frequency. The **Clock Frequency** on the **Quick Setup** tab is equivalent to the **Registers to Registers** delay setting. You can also specify the **Input Ports to Registers**, **Registers to Output Ports**, and **Inputs to Outputs** delays that correspond to global t_{SU}, t_{CO}, and t_{PD} requirements, respectively, in the Quartus II software. The timing diagram on this tab reflects the settings you have made.

Clock Power Tab

You can set various constraints for each clock in your design. First, select the clock name in the Clock(s) window. The clock names appear after the design is read from the **Input** Flow tab. Configure settings for that particular clock and click **Apply**. If necessary, you can also set the **Duty Cycle** to a value other than the default 50%. The timing diagram shows these settings.

If a clock has an **Offset** from the main clock, which is considered to be time "0", this constraint corresponds to the `OFFSET_FROM_BASE_CLOCK` setting in the Quartus II software.

You can specify the pin number for the clock input pin in the **Pin Location** field. This pin number is passed to the Quartus II software for place-and-route, but does not affect synthesis in the LeonardoSpectrum software.

Input and Output Power Tabs

Configure settings for individual input or output pins in the **Input** and **Output** tabs. First, select a name in the Input Ports or Output Ports window. The names appear after the design is read from the **Input** Flow tab. Then make the setting for that pin as described below.

The **Arrival Time** setting indicates that the input signal arrives a specified time after the rising clock edge (time "0"). This setting constrains the path from the pin to the first register by including the arrival time in the total delay, and corresponds to the `EXTERNAL_INPUT_DELAY` assignment in the Quartus II software.

The **Required Time** setting indicates the maximum delay after time "0" that the output signal should arrive at the output pin. This setting directly constrains the register to output delay, and corresponds with the `EXTERNAL_OUTPUT_DELAY` assignment in the Quartus II software.

Specify the pin number for the I/O pin in the **Pin Location** field. This pin number is passed to the Quartus II software for place-and-route, but does not affect synthesis in the LeonardoSpectrum software.

Other Constraints

The following sections describe other constraints that can be set with the LeonardoSpectrum user interface and contain these topics:

- "Encoding Style"
- "Resource Sharing"
- "Mapping I/O Registers"

Encoding Style

The LeonardoSpectrum software encodes state machines during the synthesis process. To improve performance when coding state machines, separate state machine logic from all arithmetic functions and data paths. When encoded, a design cannot be re-encoded later in the optimization process. You must follow a particular VHDL or Verilog HDL coding style for the LeonardoSpectrum software to identify the state machine.

Table 12–2 shows the state machine encoding styles supported by the LeonardoSpectrum software.

Table 12–2. State Machine Encoding Styles in the LeonardoSpectrum Software

Style	Description
Binary	Generates state machines with the fewest possible flipflops. Binary state machines are useful for area-critical designs when timing is not the primary concern.
Gray	Generates state machines where only one flipflop changes during each transition. Gray-encoded state machines tend to be glitchless.
One-hot	Generates state machines containing one flipflop for each state. One-hot state machines provide the best performance and shortest clock-to-output delays. However, one-hot implementations are usually larger than binary implementations.
Random	Generates state machines using random state machine encoding. Only use random state machine encoding when no other implementation achieves the desired results.
Auto (Default)	Implements binary or one-hot encoding, depending on the size of enumerated types in the state machine.

The **Encoding Style** setting is created in the **Input** Flow tab. It instructs the software to use a particular state machine encoding style for all state machines. The default **Auto** selection implements binary or one-hot encoding, depending on the size of enumerated types in the state machine.

To ensure proper recognition and improve performance when coding state machines, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook* for design guidelines.

Resource Sharing

You can also enable the **Resource Sharing** setting in the **Input** Flow tab. This setting allows optimization to reduce device resources. You should generally leave this setting turned on.

Mapping I/O Registers

The **Map I/O Registers** option is located in the **Technology** Flow tab. The **Map I/O Registers** option applies to Altera FPGAs containing I/O cells (IOCs) or I/O elements (IOEs). If the option is turned on, input or output registers are moved into the device's I/O cells for faster setup or clock-to-output times.

Timing Analysis with the Leonardo-Spectrum Software

The LeonardoSpectrum software reports successful synthesis with an information message in the Transcript or Information window. Estimated device usage and timing results are reported in the Device Utilization section of this window. Figure 12–2 shows an example of a LeonardoSpectrum compilation report.

Figure 12–2. LeonardoSpectrum Compilation Report

```
*************************************************
Device Utilization for EP20K200EQC208
*************************************************
Resource                  Used    Avail   Utilization
-------------------------------------------------
IOs                       22      136      16.18%
LCs                       114     8320      1.37%
Memory Bits               0       106496    0.00%

-------------------------------------------------
                          Clock Frequency Report

        Clock                   : Frequency
      ------------------------------------

        clk                     : 52.2 MHz
        clk2                    : 149.5 MHz

                          Critical Path Report
```

The LeonardoSpectrum software estimates the timing results based on timing models. The LeonardoSpectrum software has no information about how the design is placed and routed in the Quartus II software, so it cannot report accurate routing delays. Additionally, if the design includes any black boxed Altera-specific functions, the LeonardoSpectrum software does not report timing information for these functions.

Final timing results are generated by the Quartus II software and are reported separately in the Transcript or Information window if the **Run Integrated Place and Route** option is turned on. Refer to "Integration with the Quartus II Software" for more information.

Exporting Designs Using NativeLink Integration

You can use NativeLink® integration to integrate the LeonardoSpectrum software and the Quartus II software with a single GUI for both the synthesis and place-and-route operations. You can run the Quartus II software from within the LeonardoSpectrum software GUI with NativeLink integration or you can run the LeonardoSpectrum software from within the Quartus II software GUI for device families supported in the Quartus II software.

Generating Netlist Files

The LeonardoSpectrum software generates an **.edif** netlist file readable as an input file in the Quartus II software for place-and-route. Select the **.edif** file option name in the **Output** Flow tab. The **.edif** netlist file is also generated if the **Auto** option is turned on in the **Output** Flow tab.

Including Design Files for Black Boxed Modules

If the design has black boxed megafunctions, be sure to include the MegaWizard™ Plug-In Manager-generated custom megafunction variation design file in the Quartus II project directory, or add it to the list of project files for place-and-route.

Passing Constraints with Scripts

The LeonardoSpectrum software can write out a **.tcl** file called <*project name*>**.tcl**. This file contains commands to create a Quartus II project along with constraints and other assignments. To output a Tcl script, turn on the **Write Vendor Constraint Files** option in the **Output** Flow tab.

To create and compile a Quartus II project using the **.tcl** file generated from the LeonardoSpectrum software, perform the following steps in the Quartus II software:

1. Place the **.edif** netlist files and Tcl scripts in the same directory.
2. On the View menu, point to **Utility**, and click **Tcl Console** to open the Quartus II Tcl Console.
3. Type `source <path>/<project name>.tcl` at a Tcl Console command prompt.
4. On the File menu, click **Open Project** to open the new project. On the Processing menu, click **Start Compilation**.

Integration with the Quartus II Software

You can launch the Quartus II software from within the LeonardoSpectrum software with the **Place And Route** section in the **Quick Setup** tab. Turn on the **Run Integrated Place and Route** option to start the compilation using the Quartus II software to show the fitting and performance results. You can also run the place-and-route software by turning on the **Run Quartus** option on the **Physical** Flow tab and clicking **Run PR**.

To use integrated place-and-route software, on the Options menu, point to **Place and Route Path** and click **Tools**. Specify the location of the Quartus II software executable file (browse to <*Quartus II software installation directory*>**/bin**).

Guidelines for Altera Megafunctions and LPM Functions

Altera provides parameterizable megafunctions ranging from simple arithmetic units, such as adders and counters, to advanced phase-locked loop (PLL) blocks, multipliers, and memory structures. These functions are performance-optimized for Altera devices. Megafunctions include the library of parameterized modules (LPM), device-specific megafunctions such as PLLs, LVDS, and digital signal processing (DSP) blocks, intellectual property (IP) available as Altera MegaCore® functions, and IP available through the Altera Megafunction Partners Program (AMPP℠).

Some IP cores require that you synthesize them in the LeonardoSpectrum software. Refer to the user guide for the specific IP.

There are two methods for handling megafunctions in the LeonardoSpectrum software: inference and instantiation.

The LeonardoSpectrum software supports inferring some of the Altera megafunctions, such as multipliers, DSP functions, and RAM and ROM blocks. The LeonardoSpectrum software supports all Altera megafunctions through instantiation.

Instantiating Altera Megafunctions

There are two methods of instantiating Altera megafunctions in the LeonardoSpectrum software. The first and least common method is to directly instantiate the megafunction in the Verilog HDL or VHDL code. The second method, to maintain target technology awareness, is to use the MegaWizard Plug-In Manager in the Quartus II software to set up and parameterize a megafunction variation. The megafunction wizard creates a wrapper file that instantiates the megafunction. The advantage of using the megafunction wizard in place of the instantiation method is the megafunction wizard properly sets all the parameters and you do not need the library support required in the direct instantiation method. This is referred to as black box methodology.

Altera recommends using the MegaWizard Plug-In Manager to ensure that the ports and parameters are set correctly.

When directly instantiating megafunctions, see the Quartus II Help for a list of the ports and parameters.

Inferring Altera Memory Elements

The LeonardoSpectrum software can infer memory blocks from Verilog HDL or VHDL code. When the LeonardoSpectrum software detects a RAM or ROM from the style of the RTL code at a technology-independent level, it then maps the element to a generic module in the RTL database. During the technology-mapping phase of synthesis, the LeonardoSpectrum software maps the generic module to the most optimal primitive memory cells, or Altera megafunction, for the target Altera technology.

For more information about inferring RAM and ROM megafunctions, including examples of VHDL and Verilog HDL code, see the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

Inferring RAM

The LeonardoSpectrum software supports RAM inference for various device families. The following are the restrictions for the LeonardoSpectrum software to successfully infer RAM in a design:

- The write process must be synchronous
- The read process can be asynchronous or synchronous depending on the target Altera architecture
- Resets on the memory are not supported

Table 12–3 shows a summary of the minimum memory sizes and minimum address widths for inferring RAM in various device families.

Table 12–3. Inferring RAM Summary

Devices	RAM Primitive	Minimum RAM Size	Minimum Address Width
Stratix Series and Cyclone Series	`altsyncram`	2 bits	1 bit
APEX Series, Excalibur and Mercury	`altdpram`	64 bits	4 bits
FLEX 10KE and ACEX 1K	`altdpram`	128 bits	5 bits

To disable RAM inference, set the `extract_ram` and `infer_ram` variables to “false.” On the Tools menu, click **Variable Editor** to enter the value “false” when synthesizing in the user interface with the **Advanced** Flow tabs, or add the commands `set extract_ram false` and `set infer_ram false` to your synthesis script.

Inferring ROM

You can implement ROM behavior in HDL source code with CASE statements or specify the ROM as a table. The LeonardoSpectrum software infers both synchronous and asynchronous ROM depending on the target Altera device. For example, memory for the Stratix series devices must be synchronous to be inferred.

To disable ROM inference, set the `extract_rom` variable to “false.” To enter the value “false” when synthesizing in the user interface with the **Advanced Flow** tabs, on the Tools menu, click **Variable Editor**, or add the commands set `extract_rom` false to your synthesis script.

Inferring Multipliers and DSP Functions

Some Altera devices include dedicated DSP blocks optimized for DSP applications. The following Altera megafunctions are used with DSP block modes:

- LPM_MULT
- ALTMULT_ACCUM
- ALTMULT_ADD

You can instantiate these megafunctions in the design or have the LeonardoSpectrum software infer the appropriate megafunction by recognizing a multiplier, multiplier-accumulator (MAC), or multiplier-adder in the design. The Quartus II software maps the functions to the DSP blocks in the device during place-and-route.

For more information about inferring multipliers and DSP functions, including examples of VHDL and Verilog HDL code, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

Simple Multipliers

The LPM_MULT megafunction implements the DSP block in the simple multiplier mode. The following functionality is supported in this mode:

- The DSP block includes registers for the input and output stages, and an intermediate pipeline stage
- Signed and unsigned arithmetic is supported

Multiplier Accumulators

The ALTMULT_ACCUM megafunction implements the DSP block in the multiply-accumulator mode. The following functionality is supported in this mode:

- The DSP block includes registers for the input and output stages, and an intermediate pipeline stage
- The output registers are required for the accumulator
- The input and pipeline registers are optional

- Signed and unsigned arithmetic is supported

If the design requires input registers to be used as shift registers, use the black box method to instantiate the ALTMULT_ACCUM megafunction.

Multiplier Adders

The LeonardoSpectrum software can infer multiplier adders and map them to either the two-multiplier adder mode or the four-multiplier adder mode of the DSP blocks. The LeonardoSpectrum software maps the HDL code to the correct ALTMULT_ADD function.

The following functionality is supported in these modes:

- The DSP block includes registers for the input and output stages, and an intermediate pipeline stage
- Signed and unsigned arithmetic is supported, but support for the Verilog HDL "signed" construct is limited

Controlling DSP Block Inference

Device features, such as dedicated DSP blocks, multipliers, multiply-accumulators, and multiply-adders can be implemented in DSP blocks or in logic. You can control this implementation through attribute settings in the LeonardoSpectrum software.

As shown in Table 12–4, attribute settings in the LeonardoSpectrum software control the implementation of the multipliers in DSP blocks or logic at the signal block (or module), and project level.

Table 12–4. Attribute Settings for DSP Blocks in the LeonardoSpectrum Software *(Note 1)*

Level	Attribute Name	Value	Description
Global	`extract_mac` *(2)*	TRUE	All multipliers in the project mapped to DSP blocks.
		FALSE	All multipliers in the project mapped to logic.
Module	`extract_mac` *(3)*	TRUE	Multipliers inside the specified module mapped to DSP blocks.
		FALSE	Multipliers inside the specified module mapped to logic.
Signal	`dedicated_mult`	ON	LPM inferred and multipliers implemented in DSP block.
		OFF	LPM inferred, but multipliers implemented in logic by the Quartus II software.
		LCELL	LPM not inferred, and multipliers implemented in logic by the LeonardoSpectrum software.
		AUTO	LPM inferred, but the Quartus II software automatically maps the multipliers to either logic or DSP blocks based on the Quartus II software place-and-route.

Notes to Table 12–4:

(1) The `extract_mac` attribute takes precedence over the `dedicated_mult` attribute.
(2) For devices with DSP blocks, the `extract_mac` attribute is set to "true" by default for the entire project.
(3) For devices with DSP blocks, the `extract_mac` attribute is set to "true" by default for all modules.

Global Attribute

You can set the global attribute `extract_mac` to control the implementation of multipliers in DSP blocks for the entire project. You can set this attribute using the script interface. The script command is:

`set extract_mac` *<value>*

Module Level Attributes

You can control the implementation of multipliers inside a module or component by setting attributes in the Verilog HDL source code. The attribute used is `extract_mac`. Setting this attribute for a module affects only the multipliers inside that module. The command is:

`//synthesis attribute` *<module name>* `extract_mac` *<value>*

The Verilog HDL and VHDL code samples in Example 12–1 and Example 12–2 show how to use the `extract_mac` attribute.

Example 12–1. Using Module Level Attributes in Verilog HDL Code

```
module mult_add ( dataa, datab, datac, datad, result);
//synthesis attribute mult_add extract_mac FALSE
// Port Declaration
input [15:0] dataa;
input [15:0] datab;
input [15:0] datac;
input [15:0] datad;

output [32:0] result;

// Wire Declaration
wire [31:0] mult0_result;
wire [31:0] mult1_result;

// Implementation
// Each of these can go into one of the 4 mults in a
// DSP block
assign mult0_result = dataa * `signed datab;
//synthesis attribute mult0_result preserve_signal TRUE

assign mult1_result = datac * datad;

// This adder can go into the one-level adder in a DSP
// block
assign result = (mult0_result + mult1_result);

endmodule
```

Example 12–2. Using Module Level Attributes in VHDL Code

```
library ieee ;
USE ieee.std_logic_1164.all;

USE ieee.std_logic_arith.all;

entity mult_acc is
   generic (size : integer := 4) ;
   port (
      a: in std_logic_vector (size-1 downto 0) ;
      b: in std_logic_vector (size-1 downto 0) ;
      clk : in std_logic;
       accum_out: inout std_logic_vector (2*size downto 0)
   ) ;
   attribute extract_mac : boolean;
   attribute extract_mac of mult_acc : entity is FALSE;
end mult_acc;

architecture synthesis of mult_acc is
    signal a_int, b_int : signed (size-1 downto 0);
    signal pdt_int : signed (2*size-1 downto 0);
    signal adder_out : signed (2*size downto 0);

begin
    a_int <= signed (a);
    b_int <= signed (b);
    pdt_int <= a_int * b_int;
    adder_out <= pdt_int + signed(accum_out);
    process (clk)
    begin
       if (clk'event and clk = '1') then
          accum_out <= std_logic_vector (adder_out);
       end if;
    end process;
end synthesis ;
```

Signal Level Attributes

You can control the implementation of individual LPM_MULT multipliers by using the `dedicated_mult` attribute, as shown below:

`//synthesis attribute` <*signal_name*> `dedicated_mult` <*value*>

The `dedicated_mult` attribute is only applicable to signals or wires; it is not applicable to registers.

Table 12–5 shows the supported values for the `dedicated_mult` attribute.

Table 12–5. Values for the dedicated_mult Attribute (Part 1 of 2)

Value	Description
ON	LPM inferred and multipliers implemented in DSP block.
OFF	LPM inferred and multipliers synthesized, implemented in logic, and optimized by the Quartus II software. *(1)*
LCELL	LPM not inferred and multipliers synthesized, implemented in logic, and optimized by the LeonardoSpectrum software. *(1)*

Table 12–5. Values for the dedicated_mult Attribute (Part 2 of 2)

Value	Description
AUTO	LPM inferred but the Quartus II software maps the multipliers automatically to either the DSP block or logic based on resource availability.

Note to Table 12–5:

(1) Although both dedicated_mult=OFF and dedicated_mult=LCELLS result in logic implementations, the optimized results in these two cases may differ.

Some signals for which the `dedicated_mult` attribute is set might get synthesized away by the LeonardoSpectrum software due to design optimization. In such cases, if you want to force the implementation, the signal is preserved from being synthesized away by setting the `preserve_signal` attribute to "true."

The `extract_mac` attribute must be set to "false" for the module or project level when using the `dedicated_mult` attribute.

Example 12–3 and Example 12–4 are samples of Verilog HDL and VHDL codes, respectively, using the `dedicated_mult` attribute.

Example 12–3. Signal Attributes for Controlling DSP Block Inference in Verilog HDL Code

```
module mult (AX, AY, BX, BY, m, n, o, p);
input [7:0] AX, AY, BX, BY;
output [15:0] m, n, o, p;
wire [15:0] m_i = AX * AY; // synthesis attribute m_i dedicated_mult ON
// synthesis attribute m_i preserve_signal TRUE
//Note that the preserve_signal attribute prevents
// signal m_i from getting synthesized away
wire [15:0] n_i = BX * BY; // synthesis attribute n_i dedicated_mult OFF
wire [15:0] o_i = AX * BY; // synthesis attribute o_i dedicated_mult AUTO
wire [15:0] p_i = BX * AY; // synthesis attribute p_i dedicated_mult
LCELL
// since n_i , o_i , p_i signals are not preserved,
// they may be synthesized away based on the design
assign m = m_i;
assign n = n_i;
assign o = o_i;
assign p = p_i;
endmodule
```

Example 12–4. Signal Attributes for Controlling DSP Block Inference in VHDL Code

```
library ieee ;
USE ieee.std_logic_1164.all;
USE ieee.std_logic_arith.all;
USE ieee.std_logic_unsigned.all;
USE ieee.std_logic_signed.all;
ENTITY mult is

PORT( AX,AY,BX,BY: IN
std_logic_vector (17 DOWNTO 0);
m,n,o,p: OUT
std_logic_vector (35 DOWNTO 0));
attribute dedicated_mult: string;
attribute preserve_signal : boolean
END mult;
ARCHITECTURE struct of mult is

signal m_i, n_i, o_i, p_i : unsigned (35 downto 0);
attribute dedicated_mult of m_i:signal is "ON";
attribute dedicated_mult of n_i:signal is "OFF";
attribute dedicated_mult of o_i:signal is "AUTO";
attribute dedicated_mult of p_i:signal is "LCELL";

begin

m_i <= unsigned (AX) * unsigned (AY);
n_i <= unsigned (BX) * unsigned (BY);
o_i <= unsigned (AX) * unsigned (BY);
p_i <= unsigned (BX) * unsigned (AY);

m <= std_logic_vector(m_i);
n <= std_logic_vector(n_i);
o <= std_logic_vector(o_i);
p <= std_logic_vector(p_i);
end struct;
```

Guidelines for Using DSP Blocks

In addition to the guidelines mentioned earlier in this section, use the following guidelines while designing with DSP blocks in the LeonardoSpectrum software:

- To access all the control signals for the DSP block, such as `sign A`, `sign B`, and `dynamic addnsub`, use the black box technique.
- While performing signed operations, ensure that the specified data width of the output port matches the data width of the expected result. Otherwise, the sign bit might be lost or data might be incorrect because the sign is not extended. For example, if the data widths of input `A` and `B` are `width_a` and `width_b`, respectively, the maximum data width of the result can be (`width_a + width_b +2`) for the four-multipliers adder mode. Thus, the data width of the output port should be less than or equal to (`width_a + width_b +2`).
- While using the accumulator, the data width of the output port should be equal to or greater than (`width_a + width_b`). The maximum width of the accumulator can be (`width_a + width_b + 16`). Accumulators wider than this are implemented in logic.

- If the design uses more multipliers than are available in a particular device, you might get a no fit error in the Quartus II software. In such cases, use the attribute settings in the LeonardoSpectrum software to control the mapping of multipliers in your design to DSP blocks or logic.

Block-Based Design with the Quartus II Software

The incremental compilation and LogicLock™ block-based design flows enable users to design, optimize, and lock down a design one section at a time. You can independently create and implement each logic module into a hierarchical or team-based design. With this method, you can preserve the performance of each module during system integration and have more control over placement of your design. To maximize the benefits of the incremental compilation or LogicLock design methodology in the Quartus II software, you can partition a new design into a hierarchy of netlist files during synthesis in the LeonardoSpectrum software.

You can create different netlist files with the LeonardoSpectrum software for different sections of a design hierarchy. When you have different netlist files, it means that each section is independent of the others. When synthesizing the entire project, only portions of a design that have been updated have to be re-synthesized when you compile the design. You can make changes, optimize, and re-synthesize your section of a design without affecting other sections.

For more information about incremental compilation, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*. For more information about the LogicLock feature, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

Hierarchy and Design Considerations

You must plan your design's structure and partitioning carefully to use incremental compilation and LogicLock features effectively. Optimal hierarchical design practices include partitioning the blocks at functional boundaries, registering the boundaries of each block, minimizing the I/O between each block, separating timing-critical blocks, and keeping the critical path within one hierarchical block.

For more recommendations for hierarchical design partitioning, refer to the *Design Recommendations for Altera Devices and the Quartus II Design Assistant* chapter in volume 1 of the *Quartus II Handbook*.

To ensure the proper functioning of the synthesis tool, you can apply the LogicLock option in the LeonardoSpectrum software only to modules, entities, or netlist files. In addition, each module or entity should have its own design file. It is difficult to maintain incremental synthesis if two different modules are in the same design file (but are defined as being part of different regions), because both regions have to be recompiled when you change one of the modules or entities.

If you use boundary tri-states in a lower-level block, the LeonardoSpectrum software pushes (or "bubbles") the tri-states through the hierarchy to the top-level to take advantage of the tri-state drivers on the output pins of the Altera device. Because bubbling tri-states require optimizing through hierarchies, lower-level tri-states are not supported with a block-level design methodology. You should use tri-state drivers only at the external output pins of the device and in the top-level block in the hierarchy.

If the hierarchy is flattened during synthesis, logic is optimized across boundaries, preventing you from making LogicLock assignments to the flattened blocks. Altera recommends preserving the hierarchy when compiling the design. In the **Optimize** command of your script, use the **Hierarchy Preserve** command, or in the user interface, select **Preserve** in the **Hierarchy** section on the **Optimize** Flow tab.

If you are compiling your design with a script, you can use an alternative method for preventing optimization across boundaries. In this case, use the **Auto** hierarchy setting and set the `auto_dissolve` attribute to false on the instances or views that you want to preserve (that is, the modules with LogicLock assignments) using the following syntax:

```
set_attribute -name auto_dissolve -value false \
     .work.<block1>.INTERFACE
```

This alternative method flattens your design according to the `auto_dissolve` limits, but does not optimize across boundaries where you apply the attribute as described.

For more details about LeonardoSpectrum attributes and hierarchy levels, refer to the LeonardoSpectrum documentation in the Help menu.

Creating a Design with Multiple .edif Files

The first stage of a hierarchical design flow is to generate multiple **.edif** files, so that you can take advantage of the incremental compilation flows in the Quartus II software. If the whole design is in one **.edif** file, changes in one block affect other blocks because of possible node name changes. You can generate multiple **.edif** files either by using the LogicLock option in the LeonardoSpectrum software, or by manually using a black box methodology on each block that you want to be part of a LogicLock region.

After you have created multiple **.edif** files with one of these methods, you must create the appropriate Quartus II project(s) to place-and-route the design.

Generating Multiple .edif Files Using the LogicLock Option

This section describes how to generate multiple **.edif** files using the LogicLock option in the LeonardoSpectrum software.

When synthesizing a top-level design that includes LogicLock regions, perform the following general steps:

1. Read in the Verilog HDL or VHDL source files.
2. Add LogicLock constraints.
3. Optimize and write output netlist files, or choose **Run Flow**.

To set the correct constraints and compile the design, perform the following steps in the LeonardoSpectrum software:

1. On the Tools menu, switch to the **Advanced Flow** tab instead of the **Quick Setup** tab.
2. Set the target technology and speed grade for the device on the **Technology Flow** tab.
3. Open the input source files on the **Input Flow** tab.
4. Click **Read** on the **Input Flow** tab to read the source files but not begin optimization.
5. Select the **Module Power** tab located at the bottom of the **Constraints** Flow tab.
6. Click on a module to be placed in a LogicLock region in the **Modules** section.
7. Turn on the **LogicLock** option.
8. Type the desired LogicLock region name in the text field under the **LogicLock** option.
9. Click **Apply**.
10. Repeat steps 6-9 for any other modules that you want to place in LogicLock regions.

In some cases, you are prompted to save your LogicLock and other non-global constraints in a Constraints File (**.ctr**) when you click anywhere off the **Constraints Flow** tab. The default name is <*project name*>**.ctr**. This file is added to your **Input** file list, and must be manually included later if you recreate the project.

The command written into the LeonardoSpectrum Information or Transcript Window is the Tcl command that gets written into the **.ctr** file. The format of the "path" for the module specified in the command should be work.<*module*>**.INTERFACE**. To ensure that you don't see an optimized version of the module, do not perform a **Run Flow** on the **Quick Setup** tab prior to setting LogicLock constraints. Always use the **Read** command, as described in step 4.

11. Continue making any other settings as required on the **Constraints** tab.
12. Select **Preserve** in the **Hierarchy** section on the **Optimize** tab to ensure that the hierarchy names are not flattened during optimization.
13. Continue making any other settings as required on the **Optimize** tab.
14. Run your synthesis flow with each Flow tab, or click **Run Flow**.

Synthesis creates an **.edif** file for each module that has a LogicLock assignment in the **Constraints** Flow tab. You can now use these files with the incremental compilation flows in the Quartus II software.

You might occasionally see multiple **.edif** files and LogicLock commands for the same module. An “unfolded” version of a module is created when you instantiate a module more than once and the boundary conditions of the instances are different. For example, if you apply a constant to one instance of the block, it might be optimized to eliminate unneeded logic. In this case, the LeonardoSpectrum software must create a separate module for each instantiation (unfolding). If this unfolding occurs, you see more than one **.edif** file, and each EDIF file has a LogicLock assignment to the same LogicLock region. When you import the **.edif** files to the Quartus II software, the **.edif** files created from the module are placed in different LogicLock regions. Any optimizations performed in the Quartus II software using the LogicLock methodology must be performed separately for each **.edif** netlist file.

Creating a Quartus II Project for Multiple .edif Files Including LogicLock Regions

The LeonardoSpectrum software creates **.tcl** files that provide the Quartus II software with the appropriate LogicLock assignments, creating a region for each **.edif** file along with the information to set up a Quartus II project.

The **.tcl** file contains the commands shown in Example 12–5 for each LogicLock region. This example is for module taps where the name `taps_region` was typed as the LogicLock region name in the **Constraints** Flow tab in the LeonardoSpectrum software.

Example 12–5. Tcl File for Module Taps with taps_region as LogicLock Region Name

```
project add_assignment {taps} {taps_region} {} {}
    {LL_AUTO_SIZE} {ON}
project add_assignment {taps} {taps_region} {} {}
    {LL_STATE} {FLOATING}
project add_assignment {taps} {taps_region} {} {}
    {LL_MEMBER_OF} {taps_region}
```

These commands create a LogicLock region with Auto-Size and Floating-Origin properties. This flexible LogicLock region allows the Quartus II Compiler to select the size and location of the region.

For more information about Tcl commands, refer to the *TCL Scripting* chapter in volume 2 of the *Quartus II Handbook*.

You can use the following methods to import the **.edif** file and corresponding **.tcl** file into the Quartus II software:

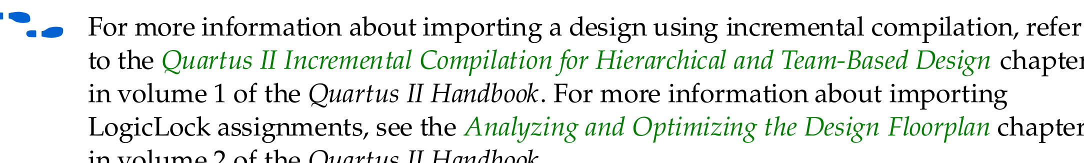
- Use the **.tcl** file that is created for each **.edif** file by the LeonardoSpectrum software. This method allows you to generate multiple Quartus II projects, one for each block in the design. Each designer in the project can optimize their block separately in the Quartus II software and preserve their results. Altera recommends this method for bottom-up incremental and hierarchical design methodologies because it allows each block in the design to be treated separately. Each block can be brought into one top-level project with the import function.

  or

- Use the <*top-level project*>**.tcl** file that contains the assignments for all blocks in the project. This method allows the top-level designer to import all the blocks into one Quartus II project. You can optimize all modules in the project at once in a top-down design flow. If additional optimization is required for individual blocks, each designer can use their **.edif** file to create a separate project at that time. You would then have to add new assignments to the top-level project using the import function.

In both methods, use the following steps to create the Quartus II project, import the appropriate LogicLock assignments, and compile the design:

1. Place the **.edif** and **.tcl** files in the same directory.
2. On the View menu, point to **Utility Windows** and click **Tcl Console** to open the **Quartus II Tcl Console**.
3. Type `source <path>/<project name>.tcl` ↵.
4. To open the new completed project, on the File menu, click **Open Project**. Browse to and select the project name, and click **Open**.



For more information about importing a design using incremental compilation, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*. For more information about importing LogicLock assignments, see the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

Generating Multiple .edif Files Using Black Boxes

This section describes how to manually generate multiple **.edif** files using the black box technique. The manual flow was supported in older versions of the LeonardoSpectrum software. The manual flow is discussed here because some designers want more control over the project for each submodule.

To create multiple **.edif** files in the LeonardoSpectrum software, create a separate project for each module and top-level design that you want to maintain as a separate **.edif** file. Implement black box instantiations of lower-level modules in your top-level project.

When synthesizing the projects for the lower-level modules and the top-level design, use the following general guidelines.

For lower-level modules:

- Turn off **Map IO Registers** for the target technology on the **Technology** Flow tab.
- Read the HDL files for the modules. Modules may include black box instantiations of lower-level modules that are also maintained as separate **.edif** files.
- Add constraints.
- Turn off **Add I/O Pads** on the **Optimize** Flow tab.

For the top-level design:

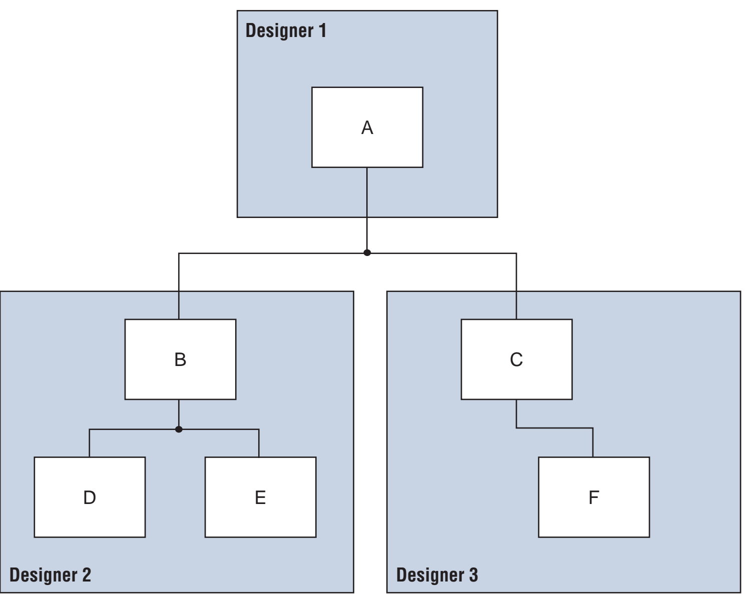
- Turn on **Map IO Registers** if you want to implement input and/or output registers in the IOEs for the target technology on the **Technology** Flow tab.

- Read the HDL files for the top-level design.
  - Black box lower-level modules in the top-level design.
- Add constraints (clock settings should be made at this time).

The following sections describe examples of black box modules in a block-based and team-based design flow.

In Figure 12–3, the top-level design A is assigned to one engineer (designer 1), while two-engineers work on the lower levels of the design. Designer 2 works on B and its submodules D and E, while designer 3 works on C and its submodule F.

Figure 12–3. Block-Based and Team-Based Design Example



One netlist is created for the top-level module A, another netlist is created for B and its submodules D and E, and another netlist is created for C and its submodule F. To create multiple **.edif** files, perform the following steps:

1. Generate an **.edif** file for module C. Use **C.v** and **F.v** as the source files.
2. Generate an **.edif** file for module B. Use **B.v**, **D.v**, and **E.v** as the source files.
3. Generate a top-level **.edif** file **A.v** for module A. Ensure that your black box modules B and C were optimized separately in steps 1 and 2.

Black Box Methodology in Verilog HDL

Any design block that is not defined in the project, or included in the list of files to be read for a project, is treated as a black box by the software. In Verilog HDL, you must also provide an empty module declaration for the module that you plan to treat as a black box.

Example 12–6 shows an example of the **A.v** top-level file. If any of your lower-level files also contain a black-boxed lower-level file in the next level of hierarchy, follow the same procedure.

Example 12–6. Verilog HDL Top-Level File Black Boxing Example

```
module A (data_in,clk,e,ld,data_out);
    input data_in, clk, e, ld;
    output [15:0] data_out;

    reg [15:0] cnt_out;
    reg [15:0] reg_a_out;

    B U1 ( .data_in (data_in),.clk (clk), .e(e), .ld (ld),
           .data_out(cnt_out) );

    C U2 ( .d(cnt_out), .clk (clk), .e(e), .q (reg_out));
    // Any other code in A.v goes here.

endmodule

// Empty Module Declarations of Sub-Blocks B and C follow here.
// These module declarations (including ports) are required for
blackboxing.

module B (data_in,e,ld,data_out );
    input data_in, clk, e, ld;
    output [15:0] data_out;
endmodule

module C (d,clk,e,q );
    input d, clk, e;
    output [15:0] q;
endmodule
```

Previous versions of the LeonardoSpectrum software required an attribute statement `//exemplar attribute U1 NOOPT TRUE`, which instructed the software to treat the instance `U1` as a black box. This attribute is no longer required, although it is still supported in the software.

Black Boxing in VHDL

Any design block that is not defined in the project, or included in the list of files to be read for a project, is treated as a black box by the software. In VHDL, a component declaration is required for the black box which is normal for any other block in the design.

Example 12–7 shows an example of the **A.vhd** top-level file. If any of your lower-level files also contain a black boxed lower-level file in the next level of hierarchy, follow the same procedure.

Example 12–7. VHDL Top-Level File Black Boxing Example

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
ENTITY A IS
PORT ( data_in : IN INTEGER RANGE 0 TO 15;
    clk : IN STD_LOGIC;
    e : IN STD_LOGIC;
    ld : IN STD_LOGIC;
    data_out : OUT INTEGER RANGE 0 TO 15
);
END A;

ARCHITECTURE a_arch OF A IS

COMPONENT B PORT(
    data_in : IN INTEGER RANGE 0 TO 15;
    clk : IN STD_LOGIC;
    e : IN STD_LOGIC;
    ld : IN STD_LOGIC;
    data_out : OUT INTEGER RANGE 0 TO 15
);
END COMPONENT;

COMPONENT C PORT(
    d : IN INTEGER RANGE 0 TO 15;
    clk : IN STD_LOGIC;
    e : IN STD_LOGIC;
    q : OUT INTEGER RANGE 0 TO 15
);
END COMPONENT;

-- Other component declarations in A.vhd go here

signal cnt_out : INTEGER RANGE 0 TO 15;
signal reg_a_out : INTEGER RANGE 0 TO 15;
BEGIN
CNT : C
PORT MAP (
    data_in => data_in,
    clk => clk,
    e => e,
    ld => ld,
    data_out => cnt_out
);

REG_A : D
PORT MAP (
    d => cnt_out,
    clk => clk,
    e => e,
    q => reg_a_out
);

-- Any other code in A.vhd goes here

END a_arch;
```

Previous versions of the LeonardoSpectrum software required the attribute statement `noopt of C: component is TRUE`, which instructed the software to treat the component C as a black box. This attribute is no longer required, although it is still supported in the software.

After you have completed the steps outlined in this section, you have a different **.edif** netlist file for each block of code. You can now use these files for incremental compilation flows in the Quartus II software.

Creating a Quartus II Project for Multiple .edif Files

The LeonardoSpectrum software creates a **.tcl** file for each **.edif** file, which provides the Quartus II software with the information to set up a project.

As in the previous section, there are two different methods for bringing each **.edif** file and corresponding **.tcl** file into the Quartus II software:

- Use the **.tcl** file that is created for each **.edif** file by the LeonardoSpectrum software. This method generates multiple Quartus II projects, one for each block in the design. Each designer in the project can optimize their block separately in the Quartus II software and preserve their results. Designers should create a LogicLock region for each block; the top-level designer should then import all the blocks and assignments into the top-level project. Altera recommends this method for bottom-up incremental and hierarchical design methodology because it allows each block in the design to be treated separately; each block can be imported into one top-level project.

  or

- Use the <*top-level project*>**.tcl** file that contains the information to set up the top-level project. This method allows the top-level designer to create LogicLock regions for each block and bring all the blocks into one Quartus II project. Designers can optimize all modules in the project at once in a top-down design flow. If additional optimization is required for individual blocks, each designer can take their **.edif** file and create a separate Quartus II project at that time. New assignments would then have to be added to the top-level project manually or through the import function.

For more information about importing designs using incremental compilation, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*. For more information about importing LogicLock regions, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

In both methods, use the following steps to create the Quartus II project and compile the design:

1. Place the **.edif** and **.tcl** files in the same directory.
2. On the View menu, point to **Utility Windows** and click **Tcl Console**. The Quartus II Tcl Console appears.
3. At a Tcl prompt, type `source <path>/<project name>.tcl` ↵.
4. On the File menu, click **Open Project**. In the New Project window, browse to and select the project name. Click **Open**.
5. To create LogicLock assignments, on the Assignments menu, click **LogicLock Regions Window**.
6. On the Processing menu, click **Start Compilation**.

Incremental Synthesis Flow

If you make changes to one or more submodules, you can manually create new projects in the LeonardoSpectrum software to generate a new **.edif** netlist file when there are changes to the source files. Alternatively, you can use incremental synthesis to generate a new netlist for the changed submodule(s). To perform incremental synthesis in the LeonardoSpectrum software, use the script described in this section to reoptimize and generate a new **.edif** netlist file for only the affected modules using the LeonardoSpectrum top-level project. This method applies only when you are using the **LogicLock** option in the LeonardoSpectrum software.

Modifications Required for the LogicLock_Incremental.tcl Script File

There are three sets of entries in the file that must be modified before beginning incremental synthesis. The variables in the **.tcl** file are surrounded by angle brackets (< >).

1. Add the list of source files that are included in the project. You can enter the full path to the file or just the file name if the files are located in the working directory.
2. Indicate which modules in the design have changed. These modules are the **.edif** files that are regenerated by the LeonardoSpectrum software. These modules contain a LogicLock assignment in the original compilation.

   ☞ Obtain the LeonardoSpectrum software path for each module by looking at the **.ctr** file that contains the LogicLock assignments from the original project. Each LogicLock assignment is applied to a particular module in the design.

3. Enter the target device family using the appropriate device keyword. The device keyword is written into the Transcript or Information window when you select a target Technology and click **Load Library** or **Apply** on the **Technology** Flow tab in the graphical user interface.

Example 12–8 shows the **LogicLock_Incremental.tcl** file for the incremental synthesis flow. You must modify the **.tcl** file before you can use it for your project.

Example 12–8. LogicLock_Interface.tcl Script File for Incremental Synthesis

```
##############################################
#### LogicLock Incremental Synthesis Flow ####
##############################################

## You must indicate which modules have changed (based on the source files
## that have changed) and provide the complete path to each module

## You must also specify the list of design files and the target Altera
## technology being used

# Read the design source files.
read <list of design files separated by spaces (such as block1.v block2.v)>

# Get the list of modified modules in bottom-up "depth first search" order
# where the lower-level blocks are listed first (these should be modules
# that had LogicLock assignments and separate EDIF netlist files in the
# first pass and had their source code modified)

set list_of_modified_modules {.work.<block2>.INTERFACE .work.<block1>.INTERFACE}

foreach module $list_of_modified_modules {
   set err_rc [regexp {\.(.*)\.(.*)\.(.*)} $module unused lib module_name arch]
   present_design $module

   # Run optimization, preserving hierarchy. You must specify a technology.
   optimize -ta <technology> -hierarchy preserve

   # Ensure that the lower-level module is not optimized again when
   # optimizing higher-level modules.
   dont_touch $module
}

foreach module $list_of_modified_modules {
   set err_rc [regexp {\.(.*)\.(.*)\.(.*)} $module unused lib module_name arch]
   present_design $module
   undont_touch $module
   auto_write $module_name.edf
   # Ensure that the lower-level module is not written out in the EDIF file
   # of the higher-level module.
   noopt $module
}
```

Running the Tcl Script File in LeonardoSpectrum

When you have modified the Tcl script, as described in "Modifications Required for the LogicLock_Incremental.tcl Script File" on page 12–24, you can compile your design using the script.

You can run the script in batch mode at the command line prompt using the following command:

spectrum -file <*Tcl_file*> ↵

To run the script from the interface, on the File menu, click **Run Script**, then browse to your **.tcl** file and click **Open**.

The LogicLock incremental design flow uses module-based design to help you preserve performance of modules and have control over placement. By tagging the modules that require separate **.edif** files, you can make multiple **.edif** files for use with the Quartus II software from a single LeonardoSpectrum software project.

Conclusion

Advanced synthesis is an important part of the design flow. Taking advantage of the Mentor Graphics LeonardoSpectrum software and the Quartus II design flow allows you to control how your design files are prepared for the Quartus II place-and-route process, as well as to improve performance and optimize a design for use with Altera devices. The methodologies outlined in this chapter can help optimize a design to achieve performance goals and save design time.

13. Analyzing Designs with Quartus II Netlist Viewers

QII51013-9.0.0

Introduction

As FPGA designs grow in size and complexity, the ability to analyze how your synthesis tool interprets your design becomes critical. Often, with today's advanced designs, several design engineers are involved in coding and synthesizing different design blocks, making it difficult to analyze and debug the design. The Quartus® II RTL Viewer, State Machine Viewer, and Technology Map Viewer provide powerful ways to view your initial and fully mapped synthesis results during the debugging, optimization, or constraint entry process.

The first section in this chapter, "When to Use Viewers: Analyzing Design Problems", describes examples of using the viewers to analyze your design at various stages of the design cycle. The sections following this provide an introduction to the Quartus II design flow using netlist viewers, an overview of each viewer, and an explanation of the user interface. These sections describe the following tasks:

- How to navigate and filter schematics
- How to probe to and from other windows within the Quartus II software
- How to view a timing path from the Timing Analyzer report

This chapter contains the following sections regarding netlist viewers:

- "Introduction to the User Interface" on page 13–6
- "Navigating the Schematic View" on page 13–18
- "Customizing the Schematic Display in the RTL Viewer" on page 13–29
- "Filtering in the Schematic View" on page 13–29
- "Probing to Source Design File and Other Quartus II Windows" on page 13–35
- "Probing to the Viewers from Other Quartus II Windows" on page 13–37
- "Viewing a Timing Path" on page 13–38
- "Other Features in the Schematic Viewer" on page 13–39
- "Debugging HDL Code with the State Machine Viewer" on page 13–46

The final section provides a detailed example that uses the viewer to analyze a design and quickly resolve a design problem.

When to Use Viewers: Analyzing Design Problems

You can use netlist viewers to analyze your design to determine how it was interpreted by the Quartus II software. This section provides simple examples of how to use the RTL Viewer, State Machine Viewer, and Technology Map Viewer to analyze problems encountered in the design process.

The following sections contain information about how netlist viewers display your design:

- "Quartus II Design Flow with Netlist Viewers" on page 13–3
- "RTL Viewer Overview" on page 13–4
- "State Machine Viewer Overview" on page 13–5
- "Technology Map Viewer Overview" on page 13–5

Using the RTL Viewer is a good way to view your initial synthesis results to determine whether you have created the desired logic, and that the logic and connections have been interpreted correctly by the software. You can use the RTL Viewer and State Machine Viewer to check your design visually before simulation or other verification processes. Catching design errors at this early stage of the design process can save you valuable time.

If you see unexpected behavior during verification, use the RTL Viewer to trace through the netlist and ensure that the connections and logic in your design are as expected. You can also use the State Machine Viewer to view state machine transitions and transition equations. Viewing the design can help you find and analyze the source of design problems. If your design looks correct in the RTL Viewer, you know to focus your analysis on later stages of the design process and investigate potential timing violations or issues in the verification flow itself.

You can use the Technology Map Viewer to look at the results at the end of synthesis and technology mapping by running the viewer after performing Analysis and Synthesis. If you have compiled your design through the Fitter stage, you can view your post-mapping netlist in the Technology Map Viewer (Post-Mapping) and your post-fitting netlist in the Technology Map Viewer. If you perform only Analysis and Synthesis, both viewers display the same post-mapping netlist.

In addition, you can use the RTL Viewer or Technology Map Viewer to locate the source of a particular signal, which can help you debug your design. Use the navigation techniques described in this chapter to search easily through the design. You can trace back from a point of interest to find the source of the signal and ensure the connections are as expected.

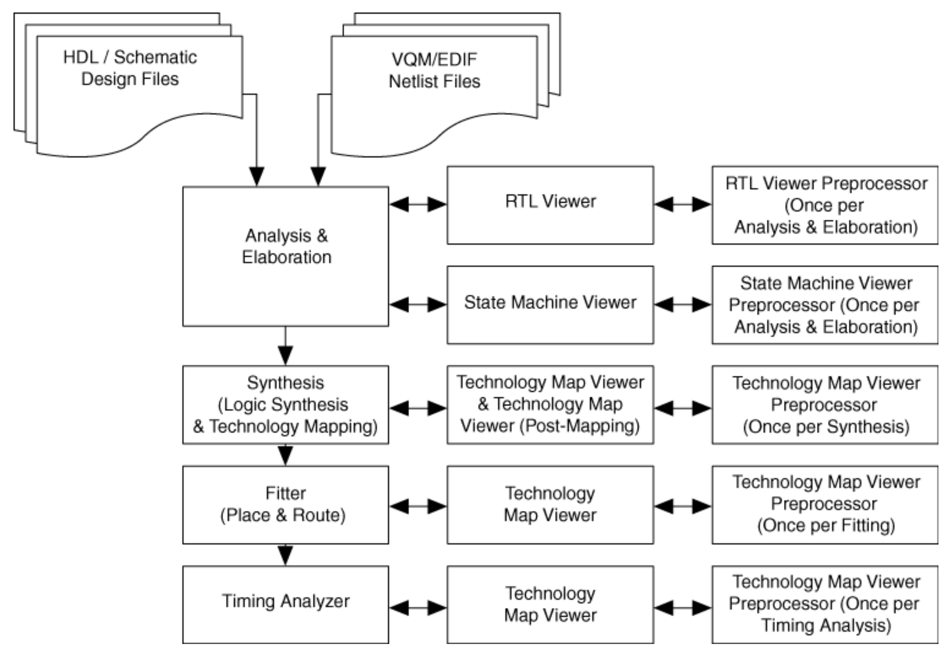
You can also use the Technology Map Viewer to help you locate post-synthesis nodes in your netlist and make assignments when optimizing your design. This functionality is useful, for example, when making a multicycle clock timing assignment between two registers in your design. Start at an I/O port and trace forward or backward through the design and through levels of hierarchy to find nodes that interest you, or locate a specific register by visually inspecting the schematic.

You can use the RTL Viewer, State Machine Viewer, and Technology Map Viewer in many other ways throughout the design, debugging, and optimization stages. Viewing the design netlist is a powerful way to analyze design problems. This chapter shows you how to use the various features of the netlist viewers to increase your productivity when analyzing a design.

Quartus II Design Flow with Netlist Viewers

The first time you open one of the netlist viewers after compiling the design, a preprocessor stage runs automatically before the viewer opens. If you close the viewer and open it again later without recompiling the design, the viewer opens immediately without performing the preprocessing stage. Figure 13–1 shows how the netlist viewers fit into the basic Quartus II design flow.

Figure 13–1. Quartus II Design Flow Including the RTL Viewer and Technology Map Viewer



To use a viewer, and before the viewer can run the preprocessor and open the design, compile your design with the following minimum compilation:

- To open the RTL Viewer or State Machine Viewer, first perform Analysis and Elaboration.
- To open the Technology Map Viewer or the Technology Map Viewer (Post-Mapping), first perform Analysis and Synthesis.

If you open one of the viewers without first compiling the design with the appropriate minimum compilation stage, the viewer does not appear. Instead, the Quartus II software issues an error message instructing you to run the necessary compilation stage and restart the viewer.

Both viewers display the results of the last successful compilation. Therefore, if you make a design change that causes an error during Analysis and Elaboration, you cannot view the netlist for the new design files, but you can still see the results from the last successfully compiled version of the design files. If you receive an error during compilation and you have not yet successfully run the appropriate compilation stage for your project, the viewer cannot be displayed; in this case, the Quartus II software issues an error message when you try to open the viewer.

If the viewer window is open when you start a new compilation, the viewer closes automatically. You must open the viewer again to view the new design netlist after compilation completes successfully.

RTL Viewer Overview

The Quartus II RTL Viewer allows you to view a register transfer level (RTL) graphical representation of your Quartus II integrated synthesis results or your third-party netlist file within the Quartus II software.

You can view results after Analysis and Elaboration when your design uses any supported Quartus II design entry method, including Verilog HDL Design Files (**.v**), SystemVerilog Design Files (**.sv**), VHDL Design Files (**.vhd**), AHDL Text Design Files (**.tdf**), schematic Block Design Files (**.bdf),** or schematic Graphic Design Files (**.gdf)** imported from the MAX+PLUS® II software. You can also view the hierarchy of atom primitives (such as device logic cells and I/O ports) when your design uses a synthesis tool to generate a Verilog Quartus Mapping File (**.vqm**) or Electronic Design Interchange Format (.**edf**) netlist file. Refer to Figure 13–1 for a flow diagram.

The Quartus II RTL Viewer displays a schematic view of the design netlist after Analysis and Elaboration or netlist extraction is performed by the Quartus II software, but before technology mapping and any synthesis or fitter optimization algorithms occur. This view is not the final design structure because optimizations have not yet occurred. This view most closely represents your original source design. If you synthesized your design using the Quartus II integrated synthesis, this view shows how the Quartus II software interpreted your design files. If you are using a third-party synthesis tool, this view shows the netlist written by your synthesis tool.

When displaying your design, the RTL Viewer optimizes the netlist to maximize readability in the following ways:

- Logic with no fan-out (its outputs are unconnected) and logic with no fan-in (its inputs are unconnected) are removed from the display.
- Default connections such as V_{CC} and GND are not shown.
- Pins, nets, wires, module ports, and certain logic are grouped into buses where appropriate.
- Constant bus connections are grouped.
- Values are displayed in hexadecimal format.
- NOT gates are converted to bubble inversion symbols in the schematic.
- Chains of equivalent combinational gates are merged into a single gate. For example, a 2-input AND gate feeding a 2-input AND gate is converted to a single 3-input AND gate.
- State machine logic is converted into a state diagram, state transition table, and state encoding table, which are displayed in the State Machine Viewer.

To run the RTL Viewer for a Quartus II project, first analyze the design to generate an RTL netlist. To analyze the design and generate an RTL netlist, on the Processing menu, point to **Start** and click **Start Analysis & Elaboration**. You can also perform a full compilation on any process that includes the initial Analysis and Elaboration stage of the Quartus II compilation flow.

To run the RTL Viewer, on the Tools menu, point to **Netlist Viewers** and click **RTL Viewer**.

You can set the RTL Viewer preprocessing to run during a full compilation, which allows you to launch the RTL Viewer after Analysis and Synthesis has completed, but while the Fitter is still running. In this case, you do not have to wait for the Fitter to finish before viewing the schematic. This technique is useful for a large design that requires a substantial amount of time in the place-and-route stage.

To set the RTL Viewer preprocessing to run during compilation, on the Assignments menu, click **Settings**. In the **Category** list, select **Compilation Process Settings** and turn on **Run RTL Viewer preprocessing during compilation**. By default, this option is turned off.

State Machine Viewer Overview

The State Machine Viewer presents a high-level view of finite state machines in your design. The State Machine Viewer provides a graphical representation of the states and their related transitions, as well as a state transition table that displays the condition equation for each of the state transitions, and encoding information for each state.

To run the State Machine Viewer, on the Tools menu, point to **Netlist Viewers** and click **State Machine Viewer**. To open the State Machine Viewer for a particular state machine, double-click the state machine instance in the RTL Viewer or right-click the state machine instance and click **Hierarchy Down**.

Technology Map Viewer Overview

The Quartus II Technology Map Viewer provides a technology-specific, graphical representation of your design after Analysis and Synthesis or after the Fitter has mapped your design into the target device. The Technology Map Viewer shows the hierarchy of atom primitives (such as device logic cells and I/O ports) in your design. For supported families, you can also view internal registers and look-up tables (LUTs) inside logic cells (LCELLs) and registers in I/O atom primitives. Refer to "Viewing Contents of Atom Primitives" on page 13–19 for details.

Where possible, the port names of each hierarchy are maintained throughout synthesis. However, port names might change or be removed from the design. For example, if a port is unconnected or driven by GND or V_{CC}, it is removed during synthesis. When a port name is changed, the port is assigned a related user logic name in the design or a generic port name such as `IN1` or `OUT1`.

You can view your Quartus II technology-mapped results after synthesis, fitting, or timing analysis. To run the Technology Map Viewer for a Quartus II project, on the Processing menu, point to **Start** and click **Start Analysis & Synthesis** to synthesize and map the design to the target technology. At this stage, the Technology Map Viewer shows the same post-mapping netlist as does the Technology Map Viewer (Post-Mapping). You can also perform a full compilation, or any process that includes the synthesis stage in the compilation flow.

If you have completed the Fitter stage, the Technology Map Viewer shows the changes made to your netlist by the Fitter, such as physical synthesis optimizations, while the Technology Map Viewer (Post-Mapping) shows the post-mapping netlist. If you have completed the Timing Analysis stage, you can locate timing paths from the Timing Analyzer report in the Technology Map Viewer (refer to "Viewing a Timing Path" on page 13–38 for details). Refer to Figure 13–1 on page 13–3 for a flow diagram.

To run the Technology Map Viewer, on the Tools menu, point to **Netlist Viewers** and click **Technology Map Viewer**, or select **Technology Map Viewer** from the Applications toolbar.

To run the Technology Map Viewer (Post-Mapping), on the Tools menu, point to **Netlist Viewers** and click **Technology Map Viewer (Post-Mapping)**.

Introduction to the User Interface

The RTL Viewer window and Technology Map Viewer window each consist of two main parts: the schematic view and the hierarchy list. Figure 13–2 shows the RTL Viewer window and indicates these two parts. Both viewers also contain a toolbar that provides tools to use in the schematic view. In the Quartus II software version 9.0, the toolbar contains a **Hierarchy List** button. This tool enables you to refine your searches. For more information, refer to "Find Command" on page 13–44.

You can have only one RTL Viewer, one Technology Map Viewer, one Technology Map Viewer (Post-Mapping), and one State Machine Viewer window open at the same time, although each window can show multiple pages. For example, you cannot have two RTL Viewer windows open at the same time. The viewer window has characteristics similar to other "child" windows in the Quartus II software; it can be resized and moved, minimized or maximized, tiled or cascaded, and moved in front of or behind other windows.

You can detach the window and move it outside the Quartus II main interface. To detach a window, click the **Detach Window** icon on the toolbar, or, on the Window menu, click **Detach Window**. To attach the detached window back to the Quartus II main interface, click the **Attach Window** icon on the toolbar, or, on the Window menu, click **Attach Window**.

Figure 13–2. RTL Viewer Window and RTL Toolbar

Schematic View

The schematic view is shown on the right side of the RTL Viewer and Technology Map Viewer. It contains a schematic representing the design logic in the netlist. This view is the main screen for viewing your gate-level netlist in the RTL Viewer and your technology-mapped netlist in the Technology Map Viewer.

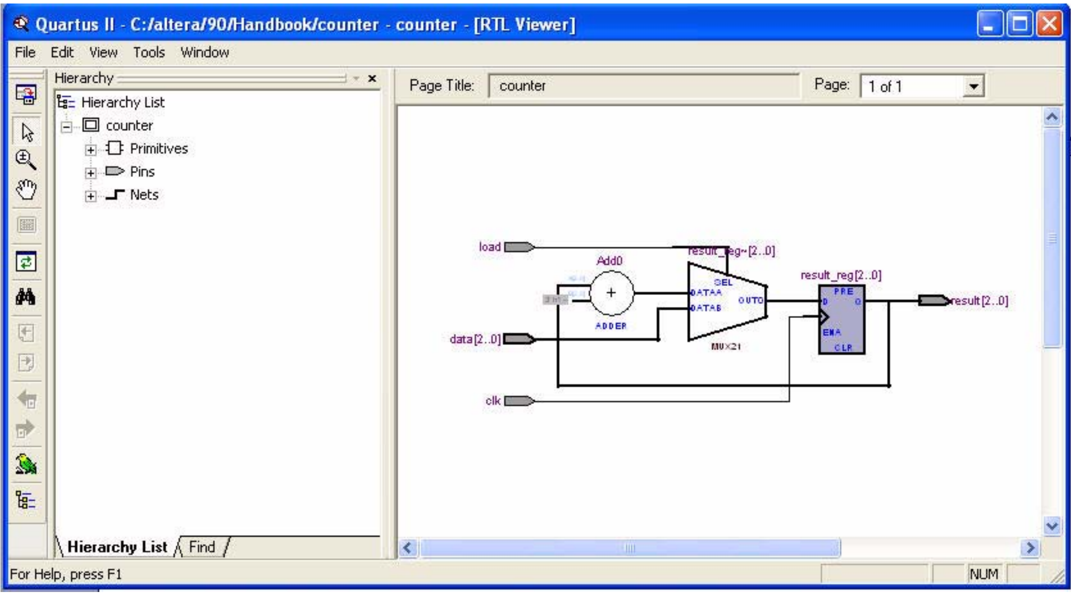
Schematic Symbols

The symbols for nodes in the schematic represent elements of your design netlist. These elements include input and output ports, registers, logic gates, Altera® primitives, high-level operators, and hierarchical instances.

Figure 13–3 shows an example of an RTL Viewer schematic for a 3-bit synchronous loadable counter. Example 13–1 shows the Verilog HDL code that produced this schematic. This example includes multiplexers and a group of registers (Table 13–1) in a bus along with an ADDER operator (Table 13–3 on page 13–12) inferred by the counting function in the HDL code.

The schematic in Figure 13–3 displays wire connections between nodes with a thin black line and bus connections with a thick black line.

Figure 13–3. Example Schematic Diagram in the RTL Viewer



Example 13–1. Code Sample for Counter Schematic Shown in Figure 13–3

```
module counter (input [2:0] data, input clk, input load, output [2:0]
result);
   reg [2:0] result_reg;
   always @ (posedge clk)
      if (load)
         result_reg <= data;
      else
         result_reg <= result_reg + 1;
   assign result = result_reg;
endmodule
```

Figure 13–4 shows a portion of the corresponding Technology Map Viewer schematic with a compiled design that targets a Stratix® device. In this schematic, you can see the LCELL (logic cell) device-specific primitives that represent the counter function, labeled with their post-synthesis node names. The `REGOUT` port represents the output of the register in the LCELL; the `COMBOUT` port represents the output of the combinational logic in the LUT of the LCELL. The hexadecimal number in parentheses below each LCELL primitive represents the LUT mask, which is a hexadecimal representation of the logic function of the LCELL.

Figure 13–4. Example Schematic Diagram in the Technology Map Viewer

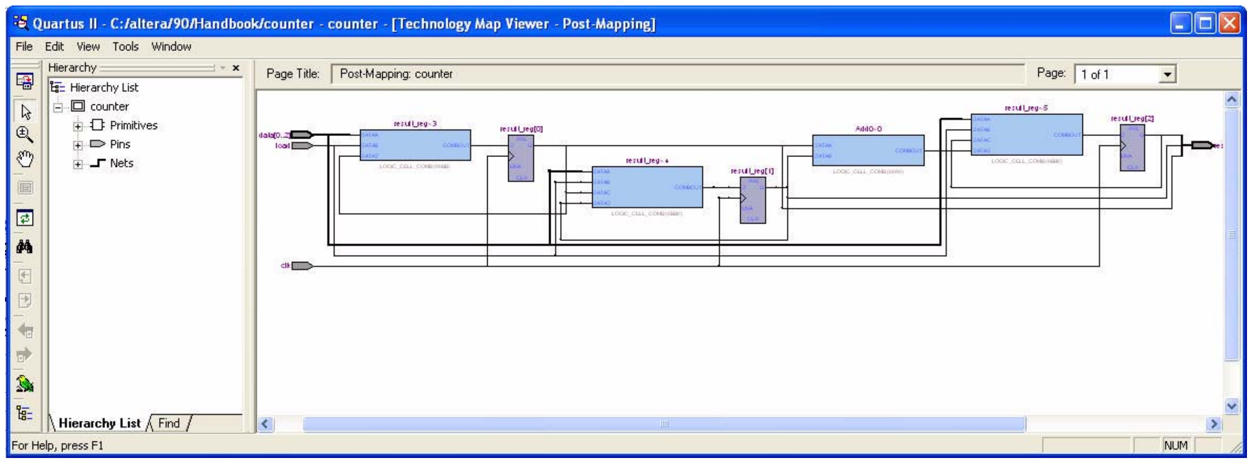


Table 13–1 lists and describes the primitives and basic symbols that you can display in the schematic view of the RTL Viewer and Technology Map Viewer. Table 13–3 on page 13–12 lists and describes the additional higher-level operator symbols used in the RTL Viewer schematic view.

The logic gates and operator primitives appear only in the RTL Viewer. Logic in the Technology Map Viewer is represented by atom primitives, such as registers and LCELLs.

Table 13–1. Symbols in the Schematic View (Part 1 of 3)

Symbol	Description
I/O Ports	An input, output, or bidirectional port in the current level of hierarchy. A device input, output, or bidirectional pin when viewing the top-level hierarchy. The symbol can also represent a bus. Only one wire is shown connected to the bidirectional symbol, representing both the input and output paths. Input symbols appear on the left-most side of the schematic. Output and bidirectional symbols appear on the right-most side of the schematic.
I/O Connectors	An input or output connector, representing a net that comes from another page of the same hierarchy (refer to "Partitioning the Schematic into Pages" on page 13–26). To go to the page that contains the source or the destination, right-click on the net and choose the page from the menu (refer to "Following Nets Across Schematic Pages" on page 13–27).
Hierarchy Port Connector	A connector representing a port relationship between two different hierarchies. A connector indicates that a path passes through a port connector in a different level of hierarchy.
OR, AND, XOR Gates	An OR, AND, or XOR gate primitive (the number of ports can vary). A small circle (bubble symbol) on an input or output port indicates the port is inverted.

Table 13–1. Symbols in the Schematic View (Part 2 of 3)

Symbol	Description
MUX	A multiplexer (MUX) primitive with a selector port that selects between port 0 and port 1. A MUX with more than two inputs is displayed as an operator (refer to "Operator Symbols in the RTL Viewer Schematic View" on page 13–12).
BUFFER	A buffer primitive. The figure shows the tri-state buffer, with an inverted output enable port. Other buffers without an enable port include LCELL, SOFT, CARRY, and GLOBAL. The NOT gate and EXP expander buffers use this symbol without an enable port and with an inverted output port.
CARRY_SUM	A CARRY_SUM buffer primitive with the following ports: ■ SI – SUM IN ■ SO – SUM OUT ■ CI – CARRY IN ■ CO – CARRY OUT
LATCH	A latch primitive with the following ports: ■ D – data input ■ ENA – enable input ■ Q – data output ■ PRE – preset ■ CLR – clear
DFFE/DFFEA/DFFAE	A DFFE (data flipflop with enable) primitive, with the same ports as a latch and a clock trigger. The other flipflop primitives are similar: ■ DFFEA (data flipflop with enable and asynchronous load) primitive with additional ALOAD asynchronous load and ADATA data signals ■ DFFEAS (data flipflop with enable and both synchronous and asynchronous load), which has ASDATA as the secondary data port
Atom Primitive	Primitives are low-level nodes that cannot be expanded to any lower hierarchy. The symbol displays the port names, the primitive type, and its name. The blue shading indicates an atom primitive in the Technology Map Viewer that allows you to view the internal details of the primitive. Refer to "Viewing Contents of Atom Primitives" on page 13–19 for details.
Other Primitive	Any primitive that does not fall into the categories above. Primitives are low-level nodes that cannot be expanded to any lower hierarchy. The symbol displays the port names, the primitive or operator type, and its name. The figure shows an LCELL WYSIWYG primitive, with DATAA to DATAD and COMBOUT port connections. This type of LCELL primitive is found in the Technology Map Viewer for technology-specific atom primitives when the contents of the atom primitive cannot be viewed. The RTL Viewer contains similar primitives if the source design is a VQM or EDIF netlist.

Table 13–1. Symbols in the Schematic View (Part 3 of 3)

Symbol	Description
Instance	An instance in the design that does not correspond to a primitive or operator (generally a user-defined hierarchy block), indicated by the double outline and green shading. The symbol displays the instance name. To open the schematic for the lower-level hierarchy, right-click and choose the appropriate command (refer to "Traversing and Viewing the Design Hierarchy" on page 13–18).
Encrypted Instance	A user-defined encrypted instance in the design, indicated by the double outline and gray shading. The symbol displays the instance name. You cannot open the schematic for the lower level hierarchy, because the source design is encrypted.
State Machine Instance	A finite state machine instance in the design, indicated by the double outline and yellow shading. Double-clicking this instance opens the State Machine Viewer. Refer to "State Machine Viewer" on page 13–16 for more details.
RAM	A synchronous memory instance with registered inputs and optionally registered outputs, indicated by purple shading. The symbol shows the device family and the type of TriMatrix memory block. This figure shows a true dual-port memory block in a Stratix M-RAM block.
Logic Cloud	A logic cloud is a group of combinational logic, indicated by a cloud symbol. Refer to "Grouping Combinational Logic into Logic Clouds" on page 13–22 for more details.
Constant 16' d129 -- 16' h0081 -- 16' b10000001 --	A constant signal value that is highlighted in gray and displayed in hexadecimal format by default throughout the schematic. To change the format, refer to "Changing the Constant Signal Value Formatting" on page 13–24.

Table 13–2 lists and describes the symbol used only in the State Machine Viewer.

Table 13–2. Symbol Available Only in the State Machine Viewer

Symbol	Description
State Node tap1	The node representing a state in a finite state machine. State transitions are indicated with arcs between state nodes. The double circle border indicates the state connects to logic outside the state machine, while a single circle border indicates the state node does not feed outside logic.

Table 13–3 lists and describes the additional higher level operator symbols used in the RTL Viewer schematic view.

Table 13–3. Operator Symbols in the RTL Viewer Schematic View (Part 1 of 2)

Symbol	Description
Add0 A[7..0] B[7..0] + ADDER	An adder operator: `OUT = A + B`
Mult0 A[7..0] B[7..0] X MULTIPLIER	A multiplier operator: `OUT = A ¥ B`
Div0 A[7..0] B[7..0] / DIVIDER	A divider operator: `OUT = A / B`
Equal0 A[7..0] B[7..0] = EQUAL	Equals
ShiftLeft0 A[7..0] COUNT[7..0] << LEFT_SHIFT	A left shift operator: `OUT = (A << COUNT)`
ShiftRight0 A[7..0] COUNT[7..0] >> RIGHT_SHIFT	A right shift operator: `OUT = (A >> COUNT)`

Table 13–3. Operator Symbols in the RTL Viewer Schematic View (Part 2 of 2)

Symbol	Description
Mod0 A[7..0] B[7..0] % MODULO	A modulo operator: `OUT = (A % B)`
LessThan0 A[7..0] B[7..0] < LESS_THAN	A less than comparator: `OUT = (A < B : A > B)`
Mux~0 SEL[2..0] DATA[7..0] OUT MUX	A multiplexer: `OUT = DATA [SEL]` The data range size is $2^{\text{sel range size}}$
Select~0 SEL[3..0] DATA[3..0] OUT SELECTOR	A selector: A multiplexer with one-hot select input and more than two input signals
Decoder~1 IN[1..0] OUT[3..0] DECODER	A binary number decoder: `OUT` = (binary_number (`IN`) == x) for x = 0 to x = $2^{(n+1)} - 1$

Selecting an Item in the Schematic View

To select an item in the schematic view, ensure that the Selection Tool is enabled in the viewer toolbar (this tool is enabled by default). Click on an item in the schematic view to highlight it in red.

Select multiple items by pressing the **Shift** or **Ctrl** key while selecting with your mouse. You can also select all nodes in a region by selecting a rectangular box area with your mouse cursor when the Selection Tool is enabled. To select nodes in a box, move your mouse to one corner of the area you want to select, click the mouse button, and drag the mouse to the opposite corner of the box, then release the mouse button. By default, creating a box like this highlights and selects all nodes in the selected area (instances, primitives, and pins), but not the nets. The **Viewer Options** dialog box provides an option to select nets. To include nets, right-click in the schematic and click **Viewer Options**. In the **Net Selection** section, turn on the **Select entire net when segment is selected** option.

Items selected in the schematic view are automatically selected in the hierarchy list (refer to the "Hierarchy List" on page 13–14). The list expands automatically if required to show the selected entry. However, the list does not collapse automatically when entries are not being used or are deselected.

When you select a hierarchy box, node, or port in the schematic view, the item is highlighted in red but none of the connecting nets are highlighted. When you select a net (wire or bus) in the schematic view, all connected nets are highlighted in red. The selected nets are highlighted across all hierarchy levels and pages. Net selection can be useful when navigating a netlist because you see the net highlighted when you traverse between hierarchy levels or pages.

In some cases, when you select a net that connects to nets in other levels of the hierarchy, these connected nets also are highlighted in the current hierarchy. If you prefer that these nets not be highlighted, use the **Viewer Options** dialog box option to highlight a net only if the net is in the current hierarchy. Right-click in the schematic and click **Viewer Options**. In the **Net Selection** section, turn on the **Limit selections to current hierarchy** option.

Moving and Panning in the Schematic View

When the schematic view page is larger than the portion currently displayed, you can use the scroll bars at the bottom and right side of the schematic view to see other areas of the page.

You can also use the Hand Tool to "grab" the schematic page and drag it in any direction. Enable the Hand Tool with the toolbar button. Click and drag to move around the schematic view without using the scroll bars.

In addition to the scroll bars and Hand Tool, you can use the middle-mouse/wheel button to move and pan in the schematic view. Click the middle-mouse/wheel button once to enable the feature. Move the mouse or scroll the wheel to move around the schematic view. Click the middle-mouse/wheel button again to turn the feature off.

Hierarchy List

The hierarchy list is displayed on the left side of the viewer window. The hierarchy list displays the entire netlist in a tree format based on the hierarchical levels of the design. Within each level, similar elements are grouped into sub-categories. Using the hierarchy list, traverse through the design hierarchy to view the logic schematic for each level. You can also select an element in the hierarchy list to be highlighted in the schematic view.

Nodes inside atom primitives are not listed in the hierarchy list.

For each module in the design hierarchy, the hierarchy list displays the applicable elements listed in Table 13–4. Click the "+" icon to expand an element.

Table 13–4. Hierarchy List Elements (Part 1 of 2)

Elements	Description
Instances	Modules or instances in the design that can be expanded to lower hierarchy levels.
State Machines	State machine instances in the design that can be viewed in the State Machine Viewer.

Table 13–4. Hierarchy List Elements (Part 2 of 2)

Elements	Description
Primitives	Low-level nodes that cannot be expanded to any lower hierarchy level. These include: ■ Registers and gates that you can view in the RTL Viewer when using Quartus II integrated synthesis ■ Logic cell atoms in the Technology Map Viewer or in the RTL Viewer when using a VQM or EDIF from third-party synthesis software In the Technology Map Viewer, you can view the internal implementation of certain atom primitives, but you cannot traverse into a lower level of hierarchy.
Pins	The I/O ports in the current level of hierarchy. ■ Pins are device I/O pins when viewing the top hierarchy level and are I/O ports of the design when viewing the lower levels. ■ When a pin represents a bus or an array of pins, expand the pin entry in the list view to see individual pin names.
Nets	Nets or wires connecting the nodes. When a net represents a bus or array of nets, expand the net entry in the tree to see individual net names.
Logic Clouds	A group of related combinational logics of a particular source. You can automatically or manually group combinational logics or ungroup logic clouds in your design.

Selecting an Item in the Hierarchy List

When you click any item in the hierarchy list, the viewer performs the following actions:

- Searches for the item in the currently viewed pages and displays the page containing the selected item in the schematic view if it is not currently displayed. (If you are currently viewing a filtered netlist, for example, the relevant page within the filtered netlist is displayed.)
- If the selected item is not found in the currently viewed pages, the entire design netlist is searched and the item is displayed in a default view.
- Highlights the selected item in red in the schematic view.

When you double-click an instance in the hierarchy list, the viewer displays the underlying implementation of the instance.

You can select multiple items by pressing the **Shift** or **Ctrl** key while selecting with your mouse. When you right-click an item in the hierarchy list, you can navigate in the schematic view using the **Filter** and **Locate** commands. Refer to "Filtering in the Schematic View" on page 13–29 and "Probing to Source Design File and Other Quartus II Windows" on page 13–35 for more information.

Enable or Disable the Auto Hierarchy List

When you select any node or net in a schematic, the hierarchy list is expanded automatically to show the selected node or net in the list. This allows you to easily identify the node or net when you have a complex schematic. By default, this option is disabled.

To enable the auto hierarchy list option, perform the following steps:

1. On the Tools menu, click **Options**.
2. In the **Options** dialog box, click **Netlist Viewers** under **Category**.

3. Turn on the **Enable Auto Hierarchy Expansion** option.
4. Click **OK**.

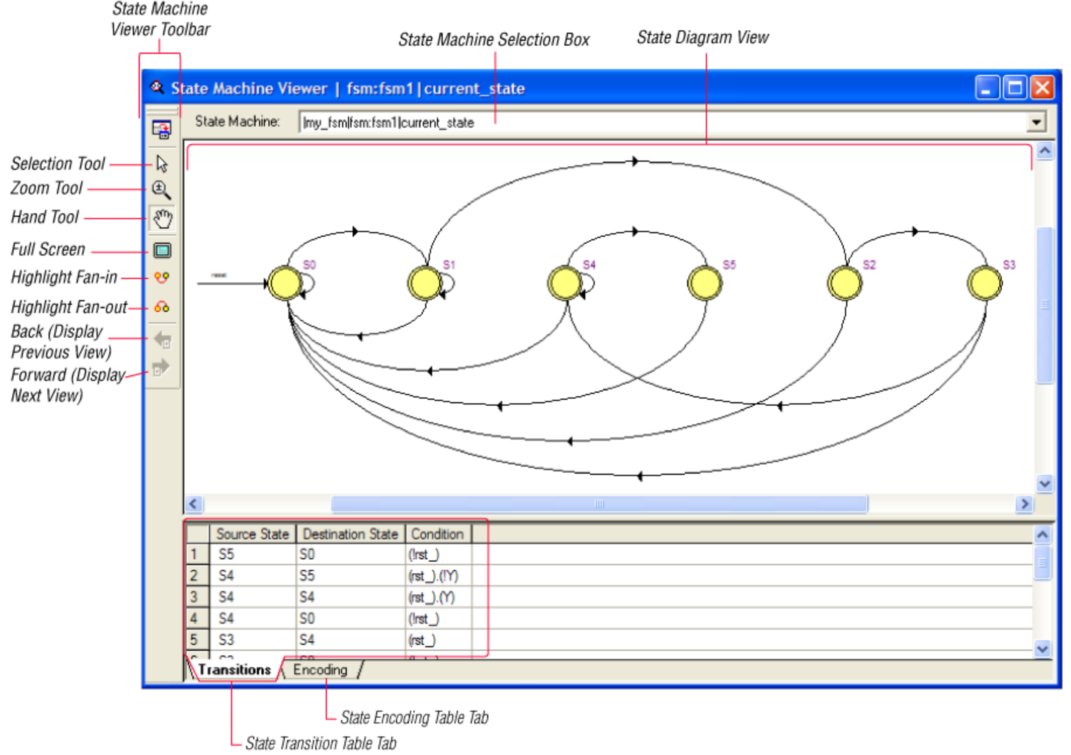
State Machine Viewer

The State Machine Viewer displays a graphical representation of the state machines in your design. You can open the State Machine Viewer in any of the following ways:

- On the Tools menu, point to **Netlist Viewers** and click **State Machine Viewer**
- Double-click on a state machine instance in the RTL Viewer
- Right-click on a state machine instance in the RTL Viewer and click **Hierarchy Down**
- Select a state machine instance in the RTL Viewer, and on the Project menu, point to **Hierarchy** and click **Down**

Figure 13–5 shows an example of the State Machine Viewer for a simple state machine. The State Machine toolbar on the left side of the viewer provides tools you can use in the state diagram view.

Figure 13–5. State Machine in the State Machine Viewer



State Diagram View

The state diagram view is shown at the top of the State Machine Viewer window. It contains a diagram of the states and state transitions.

The nodes that represent each state are arranged horizontally in the state diagram view with the initial state (the state node that receives the reset signal) in the left-most position. Nodes that connect to logic outside of the state machine instance are represented by a double circle. The state transition is represented by an arc with an arrow pointing in the direction of the transition.

When you select a node in the state diagram view, if you turn on the **Highlight Fan-in** or **Highlight Fan-out** command from the View menu or the State Machine Viewer toolbar, the respective fan-in or fan-out transitions from the node are highlighted in red.

An encrypted block with a state machine displays encoding information in the state encoding table, but does not display a state transition diagram or table.

State Transition Table

The state transition table on the Transitions tab at the bottom of the State Machine Viewer window displays the condition equation for each state transition. Each transition (each arc in the state diagram view) is represented by a row in the table. The table has the following three columns:

- **Source State**—the name of the source state for the transition
- **Destination State**—the name of the destination state for the transition
- **Condition**—the condition equation that causes the transition from source state to destination state

To see all of the transitions to and from each state name, click the appropriate column heading to sort on that column.

The text in each column is left-aligned by default; to change the alignment and more easily see the relevant part of the text, right-click in the column and click **Align Right**. To change back to left alignment, click **Align Left**.

Click in any cell in the table to select it. To select all cells, right-click in the cell and click **Select All**; or, on the Edit menu, click **Select All**. To copy selected cells to the clipboard, right-click the cells and click **Copy Table**; or, on the Edit menu, point to **Copy** and click **Copy Table**. You can paste the table into any text editor as tab-separated columns.

State Encoding Table

The state encoding table on the **Encoding** tab at the bottom of the State Machine Viewer window displays encoding information for each state transition.

To view state encoding information in the State Machine Viewer, you must have synthesized your design using Start Analysis & Synthesis. If you have only elaborated your design using Start Analysis & Elaboration, the encoding information is not displayed.

Selecting an Item in the State Machine Viewer

You can select and highlight each state node and transition in the State Machine Viewer. To select a state transition, click the arc that represents the transition.

When you select a state node, transition arc, or both in the state diagram view, the matching state node and equation conditions in the state transition table are highlighted. Conversely, when you select a state node, equation condition, or both in the state transition table, the corresponding state node and transition arc are highlighted in the state diagram view.

Switching Between State Machines

A design may contain multiple state machines. To choose which state machine to view, use the **State Machine** selection box located at the top of the State Machine Viewer. Click in the drop-down box and select the desired state machine.

Navigating the Schematic View

The previous sections provided an overview of the user interface for each netlist viewer, and how to select an item in each viewer. This section describes methods to navigate through the pages and hierarchy levels in the schematic view of the RTL Viewer and Technology Map Viewer.

Traversing and Viewing the Design Hierarchy

You can open different hierarchy levels in the schematic view using the hierarchy list (refer to "Hierarchy List" on page 13–14), or the **Hierarchy Up** and **Hierarchy Down** commands (right-click menu) in the schematic view.

Use the **Hierarchy Down** command to go down into, or expand an instance's hierarchy, and open a lower level schematic showing the internal logic of the instance. Use the **Hierarchy Up** command to go up in hierarchy, or collapse a lower level hierarchy, and open the parent higher level hierarchy. When the Selection Tool is selected, the appropriate option is available when your mouse pointer is located over an area of the schematic view that has a corresponding lower or higher level hierarchy.

The mouse pointer changes as it moves over different areas of the schematic to indicate whether you can move up, down, or both up and down in the hierarchy (Figure 13–6). To open the next hierarchy level, right-click in that area of the schematic and click **Hierarchy Down** or **Hierarchy Up**, as appropriate, or double-click in that area of the schematic.

Figure 13–6. Mouse Pointers Indicate How to Traverse Hierarchy

Flattening the Design Hierarchy

You can flatten the design hierarchy to view the design without hierarchical boundaries. To flatten the hierarchy from the current level and all the lower level hierarchies of the current design hierarchy, right-click in the schematic and click **Flatten Netlist**. To flatten the entire design, choose **Flatten Netlist** from the top-level schematic of the design.

Viewing the Contents of a Design Hierarchy within the Current Schematic

You can use the **Display Content** and **Hide Content** (right-click menu) commands to show or hide a lower hierarchy level for a specific instance within the schematic for the current hierarchy level.

To display the lower hierarchy netlist of an instance on the same schematic as the remaining logic in the currently viewed netlist, right-click the selected instance and click **Display Content**.

To hide all of the lower hierarchy logic of a hierarchy box into a closed instance, right-click the selected instance and click **Hide Content**.

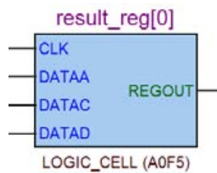
Viewing Contents of Atom Primitives

In the Technology Map Viewer, you can view the contents of certain device atom primitives to see their underlying implementation details. For logic cell (LCELL) atoms in the Stratix and Cyclone® series of devices, in Arria® GX devices, and in MAX® II devices, you can view LUTs, registers, and logic gates. For I/O atoms in the Stratix and Cyclone series of devices, in Arria GX devices, and HardCopy® II devices, you can view registers and logic gates.

In addition, you can view the implementation of RAM and DSP blocks in certain devices in the RTL Viewer or Technology Map Viewer. You can view the implementation of RAM blocks in the Stratix and Cyclone series of devices, and in Arria GX devices. You can view the implementation of DSP blocks only in the Stratix series of devices and Arria GX devices.

If you can view the contents of an atom instance, it is blue in the schematic view (Figure 13–7).

Figure 13–7. Instance That Can Be Expanded to View Internal Contents



To view the contents of one or more atom primitive instances, select the desired atom instances. Right-click a selected instance and click **Display Content**. You can also double-click on the desired atom instance to view the contents. Figure 13–8 shows an expanded version of the instance in Figure 13–7.

Figure 13–8. Internal Contents of the Atom Instance in Figure 13–7.

To hide the contents (and revert to the compact format), select and right-click the atom instance(s), and click **Hide Content**.

In the schematic view, the internal details within an atom instance cannot be selected as individual nodes. Any mouse action on any of the internal details is treated as a mouse action on the atom instance.

Viewing the Properties of Instances and Primitives

You can view the properties of an instance or primitive using the **Properties** dialog box. To view the properties of an instance or a primitive in the RTL Viewer or Technology Map Viewer, right-click the node and click **Properties**.

The **Properties** dialog box contains the following information about the selected node:

- The parameter values of an instance.
- The active level of the port (for example, active high or active low). An active low port is denoted with an exclamation mark "!".
- The port's constant value (for example, V_{CC} or GND). Table 13–5 describes the possible value of a port.

Table 13–5. Possible Port Values

Value	Description
V_{CC}	The port is not connected and has V_{CC} value (tied to V_{CC})
GND	The port is not connected and has GND value (tied to GND)
--	The port is connected and has value (other than V_{CC} or GND)
Unconnected	The port is not connected and has no value (hanging)

In the LUT of a logic cell (LCELL), the **Properties** dialog box contains the following additional information:

- The schematic of the LCELL.
- The Truth Table representation of the LCELL.

- The Karnaugh map representation of the LCELL.

Viewing LUT Representations in the Technology Map Viewer

You can view different representations of an LUT by right-clicking on the selected LUT and selecting **Properties**. This feature is supported for the Stratix and Cyclone series of devices, Arria GX devices, and MAX II devices only. There are three tabs in the **Properties** dialog box, which you can choose from to view the LUT representations:

- The **Schematic** tab (see Figure 13–9) shows you the equivalent gate representations of the LUT.
- The **Truth Table** tab (see Figure 13–10) shows the truth table representations.
- The **Karnaugh Map** tab (see Figure 13–11) shows the Karnaugh map representations of the LUT. The Karnaugh map supports up to 6 input LUTs.

For details about the **Ports** tab, refer to "Viewing the Properties of Instances and Primitives".

Figure 13–9. Schematic Tab

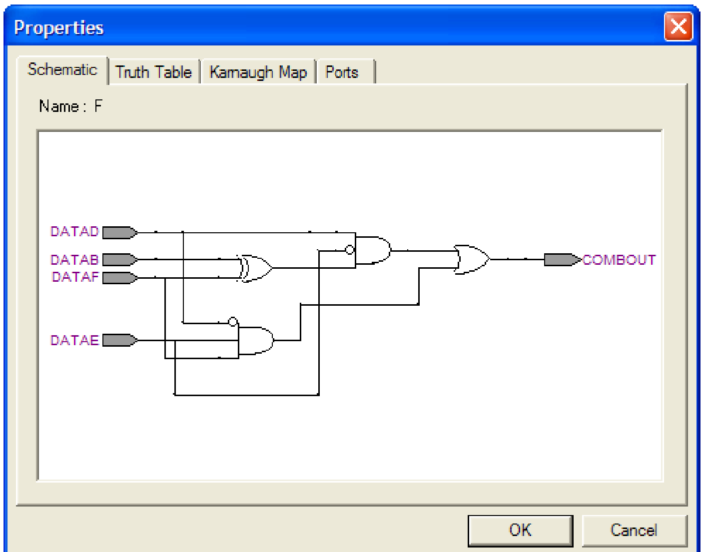


Figure 13–10. Truth Table Tab

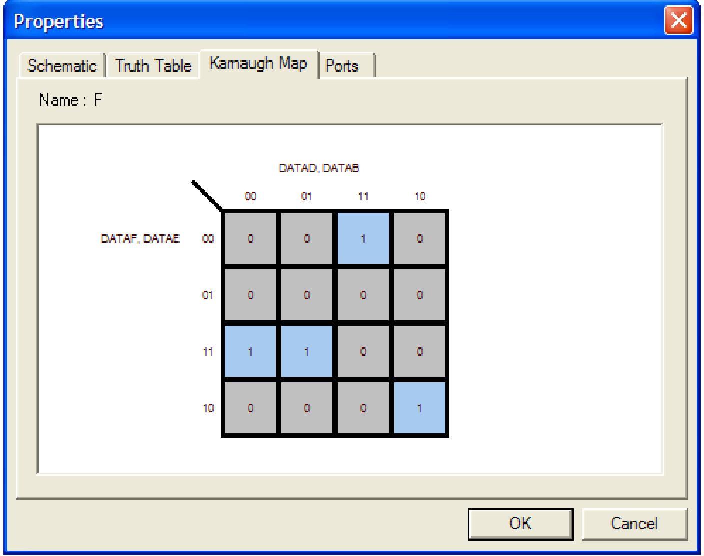
	DATAF	DATAE	DATAD	DATAB	OUT
1	0	0	0	0	0
2	0	0	0	1	0
3	0	0	1	0	0
4	0	0	1	1	1
5	0	1	0	0	0
6	0	1	0	1	0
7	0	1	1	0	0
8	0	1	1	1	0
9	1	0	0	0	0
10	1	0	0	1	0
11	1	0	1	0	1
12	1	0	1	1	0
13	1	1	0	0	1
14	1	1	0	1	1

Figure 13–11. Karnaugh Map Tab



Grouping Combinational Logic into Logic Clouds

The following sections describes how to group combinational logic into logic clouds.

☞ For the definition of a logic cloud, refer to Table 13–1 on page 13–9.

Logic Clouds in the RTL Viewer

You can automatically group all combinational logic nodes in your design into logic clouds. On the Tools menu, click **Options**, and in the **Category** list, click the "+" to expand **Netlist Viewers** and select **RTL Viewer**. On the **RTL Viewer** page, turn on **Group combinational logic into logic cloud**. You can also turn on this option by right-clicking in the schematic and clicking **Viewer Options**. In the **RTL/Technology Map Viewer Options** dialog box, click the **Customize View** tab. Under **Customize Groups** section, turn on **Group combinational logic into logic cloud**. Figure 13–12 and Figure 13–13 show the schematic before and after the combinational logic grouping operation in the RTL Viewer.

Logic Clouds in the Technology Map Viewer

In the Technology Map Viewer, the **Group combinational logic into logic clouds** option is supported for Stratix II, Cyclone II, and HardCopy families of devices only. To set this option, right-click in the schematic and click **Viewer Options**. In the **RTL/Technology Map Viewer Options** dialog box, click on the **Customize View** tab. Turn on the **Group combinational logic into logic cloud** option.

Figure 13–12. Schematic Before Combinational Logic Grouping

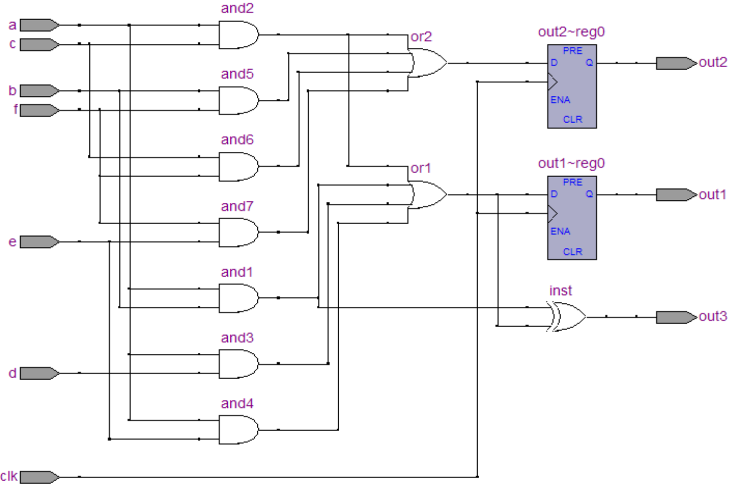


Figure 13–13. Schematic After Combinational Logic Grouping

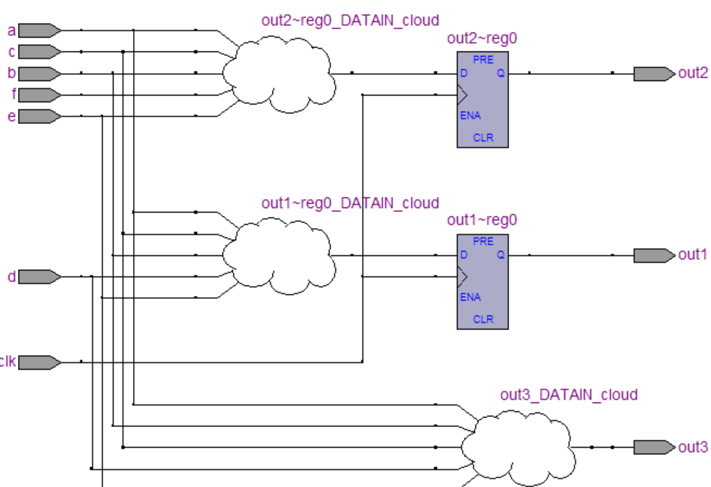


Manually Group and Ungroup Logic Clouds

To group logic nodes into a logic cloud manually, right-click the selected node or input port and select **Group source logic into logic cloud**. To ungroup a logic cloud manually, right-click on the selected logic cloud and select **Ungroup source logic from logic cloud**. You can also ungroup a logic cloud manually by double-clicking on the selected logic cloud. These options are not available if the nodes cannot be grouped.

Changing the Constant Signal Value Formatting

The constant signal value is highlighted in gray in the schematic view. By default, the value is displayed in hexadecimal format, but you can also choose binary or decimal format. To change the value formatting, on the Tools menu, click **Options**. In the **Category** list, select **Netlist Viewers** and select the desired format from the **Constant Signal Format** list.

Changing the format affects all constant signal values throughout the schematic. Refer to Table 13–3 on page 13–12 to see what constant signal values look like in the schematic.

Zooming and Magnification

You can control the magnification of your schematic on the View menu, with the Zoom Tool in the toolbar, or the **Ctrl** key and mouse wheel button, as described in this section.

The **Fit in Window**, **Fit Selection in Window**, **Zoom In**, **Zoom Out**, and **Zoom** commands are available on the View menu, by right-clicking in the schematic view and selecting **Zoom**, or from the Zoom toolbar. To enable the Zoom toolbar, on the Tools menu, click **Customize**. Click the **Toolbars** tab and click **Zoom** to enable the toolbar.

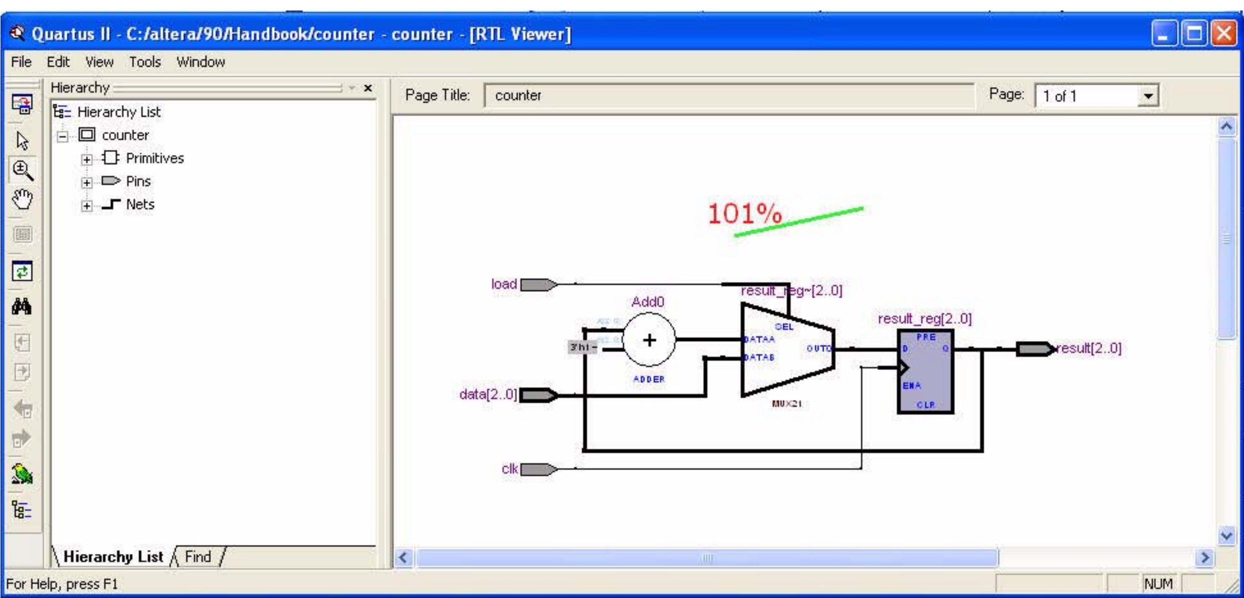
By default, the viewer displays most pages sized to fit in the window. If the schematic page is very large, the schematic is displayed at the minimum zoom level, and the view is centered on the first node. Click **Zoom In** to view the image at a larger size, and click **Zoom Out** to view the image (when the entire image is not displayed) at a smaller size. The **Zoom** command allows you to specify a magnification percentage (100% is considered the normal size for the schematic symbols). To change the minimum and maximum zoom level, on the Tools menu, click **Options**. In the **Options** dialog box, in the **Category** list, select **Netlist Viewers** and set the desired minimum and maximum zoom level.

The **Fit Selection in Window** command zooms in on the selected nodes in a schematic to fit within the window. Use the Selection Tool to select one or more nodes (instances, primitives, pins, and nets), then select **Fit Selection in Window** to enlarge the area covered by the selection. This feature is helpful when you want to see a particular element in a large schematic. After you select a node, you can easily zoom in to view the particular node.

You can also use the Zoom Tool on the viewer toolbar to control magnification in the schematic view. When you select the Zoom Tool in the toolbar, clicking in the schematic zooms in and centers the view on the location you clicked. Right-click on the schematic to zoom out and center the view on the location you clicked. When you select the Zoom Tool, you can also zoom in to a certain portion of the schematic by selecting a rectangular box area with your mouse cursor. The schematic is enlarged to show the selected area.

Alternatively, you can specify the magnification percentage by right-clicking on the desired area and dragging the mouse toward your right to zoom in or toward your left to zoom out with the Zoom Tool. You will see a green line with the zoom percentage above it. The zoom percentage is proportional to the length of the green line (Figure 13–14). Release the mouse button at the desired zoom percentage.

Figure 13–14. Dragging the Mouse Pointer to Change Zoom Percentage



By default, the viewers maintain the zoom level when filtering on the schematic (refer to "Filtering in the Schematic View" on page 13–29). To change the behavior so that the zoom level is always reset to "Fit in Window," on the Tools menu, click **Options**. In the **Category** list, select **Netlist Viewers**, and turn off **Maintain zoom level**.

Schematic Debugging and Tracing Using the Bird's Eye View

Viewing the entire schematic can be useful when debugging and tracing through a large netlist. The Quartus II software allows you to view the entire schematic in a single window. The bird's eye view is displayed in a separate window that is linked directly to the netlist viewers. This feature is available in the RTL, Technology Map, and Technology Map (Post-Mapping) viewers.

The bird's eye view shows the current area of interest. Select the desired area by clicking and dragging the indicator or using the right-mouse button to form a rectangular box around the desired area. You can also click and drag the rectangular box to move around the schematic. To open the bird's eye view, on the View menu, click **Bird's Eye View**, or click on the **Bird's Eye View** icon in the Viewer toolbar (Figure 13–15).

Figure 13–15. Bird's Eye View and Full Screen Icon

Full Screen View

To set the viewer window to fill the whole screen, on the View menu, click **Full Screen**, or click the **Full Screen** icon in the viewer toolbar (Figure 13–15), or press **Ctrl+Alt+Space**. The keyboard shortcut toggles between the full screen and standard screen views.

Partitioning the Schematic into Pages

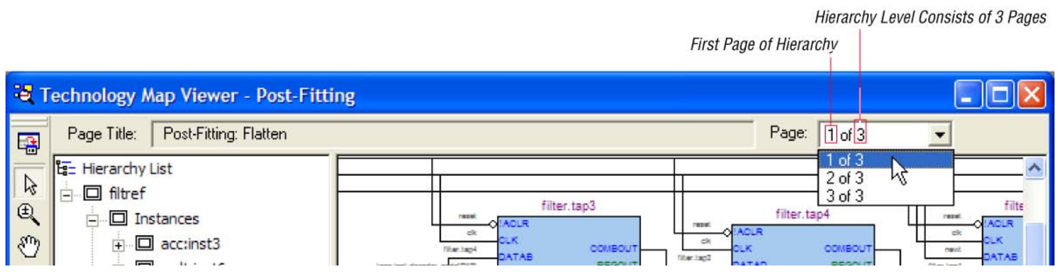
For large design hierarchies, the RTL Viewer and Technology Map Viewer partition your netlist into multiple pages in the schematic view. To control how much of the design is visible on each page, on the Tools menu, click **Options**. In the **Category** list, select **Netlist Viewers** and set the desired options under **Display Settings**.

The **Nodes per page** option specifies the number of nodes per partitioned page. The default value is 50 nodes; the range is 1 to 1,000 nodes. The **Ports per page** option specifies the number of ports (or pins) per partitioned page. The default value is 1,000 ports (or pins); the range is 1 to 2,000 ports (or pins). The viewers partition your design into a new page if either the node number or the port number exceeds the limit you have specified. You might occasionally see the number of ports exceed the limit, depending on the configuration of nodes on the page.

If the **Display boundary around hierarchy levels** option is turned on and the total number of nodes or ports within the hierarchy exceeds the value of **Nodes per page** or **Ports per page**, the boundary is displayed as a hierarchy port connector (refer to Table 13–1 on page 13–9). For more information about the **Display boundary around hierarchy levels** option, refer to "Filtering Across Hierarchies" on page 13–33.

When a hierarchy level is partitioned into multiple pages, the title bar for the schematic window indicates which page is displayed and how many total pages exist for this level of hierarchy (shown in the format:
Page <*current page number*> **of** <*total number of pages*>), as shown in Figure 13–16.

Figure 13–16. RTL Viewer Title Bars Indicating Page Number Information



When you change the number of nodes or ports per page, the change applies only to new pages that are shown or opened in the viewer. To refresh the current page so that it displays the changed number of nodes or ports, click the **Refresh** button in the toolbar.

Moving between Schematic Pages

To move to another schematic page, on the View menu, click **Previous Page** or **Next Page**, or click the **Previous Page** icon or the **Next Page** icon in the viewer toolbar.

To go to a particular page of the schematic, on the Edit menu, click **Go To**, or right-click in the schematic view and click **Go To**. In the **Page** list, select the desired page number. You can also go to a particular page by selecting the desired page number from the pull-down list on the top right of the viewer window.

Moving Back and Forward Through Schematic Pages

To return to the previous view after changing the page view, click **Back** on the View menu, or click the **Back** icon on the viewer toolbar. To go to the next view, click **Forward** on the View menu, or click the **Forward** icon on the viewer toolbar.

You can go forward only if you have not made any changes to the view since going back. Use the **Back** and **Forward** commands to switch between page views. These commands do not undo an action, such as selecting a node.

Following Nets Across Schematic Pages

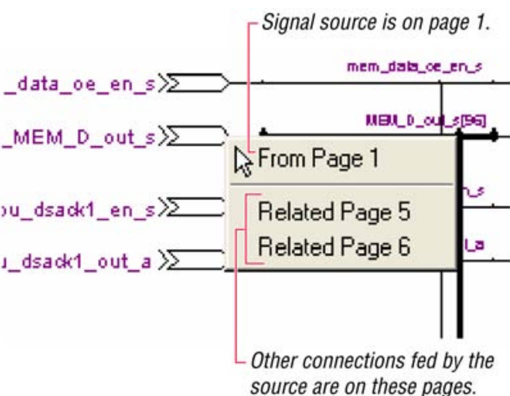
Input and output connectors indicate nodes that connect across pages of the same hierarchy. Right-click on a connector to display a menu of commands that trace the net through the pages of the hierarchy.

After you right-click to follow a connector port, the viewer opens a new page, which centers the view on the particular source or destination net using the same zoom factor used by the previous page. To trace a specific net to the new page of the hierarchy, Altera recommends that you first select the desired net, which highlights it in red, before you right-click to traverse pages.

Input Connectors

Figure 13–17 shows an example of the menu that appears when you right-click an input connector. The **From** command opens the page containing the source of the signal. The **Related** commands, if applicable, open the specified page containing another connection fed by the same source.

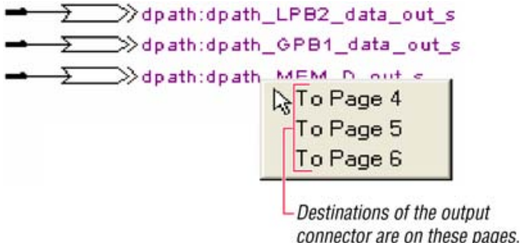
Figure 13–17. Input Connector Right Button Pop-Up Menu



Output Connectors

Figure 13–18 shows an example of the menu that appears when you right-click an output connector. The **To** command opens the specified page that contains a destination of the signal.

Figure 13–18. Output Connector Right Button Pop-Up Menu



Go to Net Driver

To locate the source of a particular net in the schematic view, select the net to highlight it, right-click the selected net, point to **Go to Net Driver** and click **Current page**, **Current hierarchy**, or **Across hierarchies**. Refer to Table 13–6 for details.

Table 13–6. Go to Net Driver Commands

Command	Action
Current page	Locates the source or driver on the current page of the schematic only.
Current hierarchy	Locates the source within the current level of hierarchy, even if the source is located on another page of the netlist schematic.
Across hierarchies	Locates the source across hierarchies until the software reaches the source at the top hierarchy level.

The schematic view opens the correct page of the schematic if required, and adjusts the centering of the page so that you can see the net source. The schematic shows the default page for the net driver. The view is an unfiltered view, so no filtering results are kept.

Customizing the Schematic Display in the RTL Viewer

You can customize the schematic display for better viewing and to speed up your debugging process. The options that control the schematic display are available in the **Customize View** tab of the **RTL/Technology Map Viewer Options** dialog box. To open the dialog box, right-click in the schematic and click **Viewer Options**. You can turn on the options to remove fan-out free nodes, simplify logic, group or ungroup related nodes, and group combinational logic into a logic cloud.

You can also customize the schematic view in the RTL Viewer by clicking **Options** on the Tools menu. In the **Category** list, click the "+" icon to expand **Netlist Viewers** and select **RTL Viewer**. Set the desired customization for your schematic display.

When the settings are changed, the list of previously viewed pages is cleared. The settings are revision-specific, so different revisions can have different settings.

To remove fan-out free registers from your schematic display, turn on **Remove registers without fan-out**. By default, this option is turned on.

To remove all single-input nodes and merge a chain of equivalent combinational gates that have direct connections (without inversion in between) into a single multiple-input gate, turn on **Show simplified logic.** By default, this option is turned on.

To group all related nodes into a single node, turn on **Group all related nodes**. This option is turned on by default. You can manually group or ungroup any nodes by right-clicking the selected nodes in the schematic and selecting **Group Related Nodes** to group or **Ungroup Selected Nodes** to ungroup.

Filtering in the Schematic View

Filtering allows you to filter out nodes and nets in your netlist to view only the logic that interests you.

Filter your netlist by selecting hierarchy boxes, nodes, ports of a node, nets, or states in a state machine that are part of the path you want to see. The following filter commands are available:

- **Sources—**Displays the sources of the selection
- **Destinations—**Displays the destinations of the selection
- **Sources & Destinations—**Displays both the sources and destinations of the selection
- **Selected Nodes and Nets—**Displays only the selected nodes and nets with the connections between them
- **Between Selected Nodes—**Displays nodes and connections in the path between the selected nodes

- **Bus Index**—Displays the sources or destinations for one or more indices of an output or input bus port

Select a hierarchy box, node, port, net, or state node, right-click in the window, point to **Filter** and click the appropriate filter command. The viewer generates a new page showing the netlist that remains after filtering.

When filtering in a state diagram in the State Machine Viewer, sources and destinations refer to the previous and next transition states or paths between transition states in the state diagram. The transition table and encoding table also reflect the filtering.

You can go back to the netlist page before it was filtered using the **Back** command, described in "Moving Back and Forward Through Schematic Pages" on page 13–27.

When viewing a filtered netlist, clicking an item in the hierarchy list causes the schematic view to display an unfiltered view of the appropriate hierarchy level. You cannot use the hierarchy list to select items or navigate in a filtered netlist.

Filter Sources Command

To filter out all but the source of the selected item, right click the item, point to **Filter** and click Sources. The selected object type determines what is displayed, as outlined in Table 13–7 and shown in Figure 13–19.

Table 13–7. Selected Objects Determine Filter Sources Display

Selected Object	Result Shown in Filtered Page
Node or hierarchy box	Shows all the sources of the node's input ports. For an example, refer to Figure 13–19.
Net	Shows the sources that feed the net.
Input port of a node	Shows only the input source nodes that feed this port.
Output port of a node	Shows only the selected node.
State node in a state machine	Shows the states that feed the selected state (previous transition states).

Filter Destinations Command

To filter out all but the destinations of the selected node or port as outlined in Table 13–8 and shown in Figure 13–19, right-click the node or port, point to **Filter** and click **Destinations**.

Table 13–8. Selected Objects Determine Filter Destinations Display

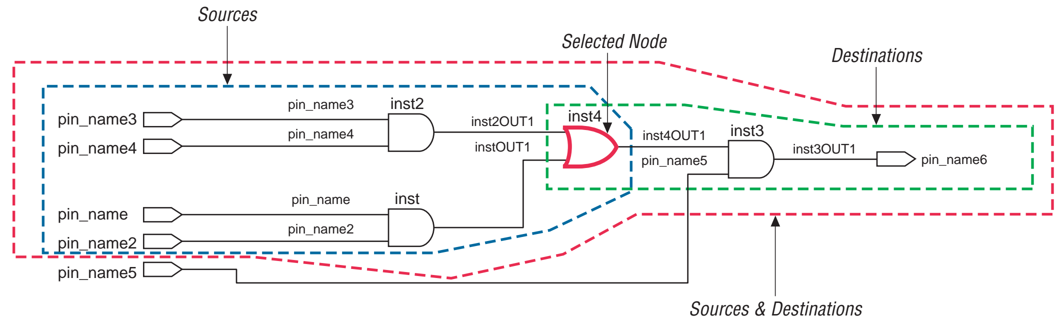
Selected Object	Result Shown in Filtered Page
Node or hierarchy box	Shows all the destinations of the node's output ports. For an example, refer to Figure 13–19.
Net	Shows the destinations fed by the net.
Input port of a node	Shows only the selected node.
Output port of a node	Shows only the fan-out destination nodes fed by this port.
State node in a state machine	Shows the states that are fed by the selected states (next transition states).

 © March 2009 Altera Corporation

Filter Sources and Destinations Command

The **Sources & Destinations** command is a combination of the **Sources** and **Destinations** filtering commands, in which the filtered page shows both the sources and the destinations of the selected item. To select this option, right-click on the desired object, point to **Filter** and click **Sources & Destinations**. Refer to the example in Figure 13–19.

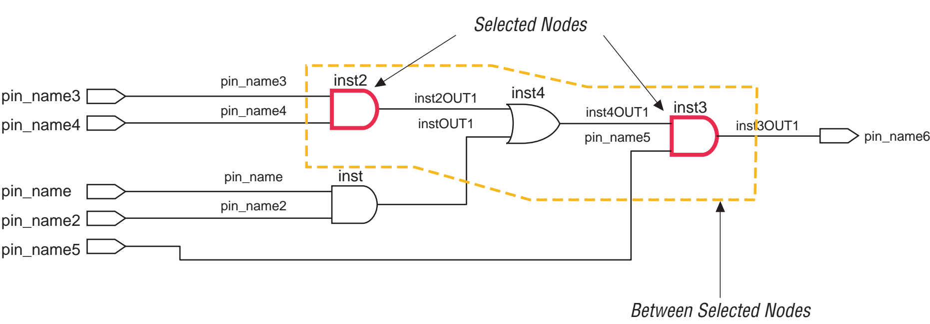
Figure 13–19. Sources, Destinations, and Sources and Destinations Filtering for inst4



Filter Between Selected Nodes Command

To show the nodes in the path between two or more selected nodes or hierarchy boxes, right-click, point to **Filter** and click **Between Selected Nodes**. For this option, selecting a port of a node is the same as selecting the node. For an example, refer to Figure 13–20.

Figure 13–20. Between Selected Nodes Filtering Between inst2 and inst3



Filter Selected Nodes and Nets Command

To create a filtered page that shows only the selected nodes, nets, or both, and, if applicable, the connections between the selected nodes, nets, or both, right-click, point to **Filter**, and click **Selected Nodes & Nets**. Figure 13–21 shows a schematic with several nodes selected.

Figure 13–21. Using Selected Nodes and Nets to Select Nodes

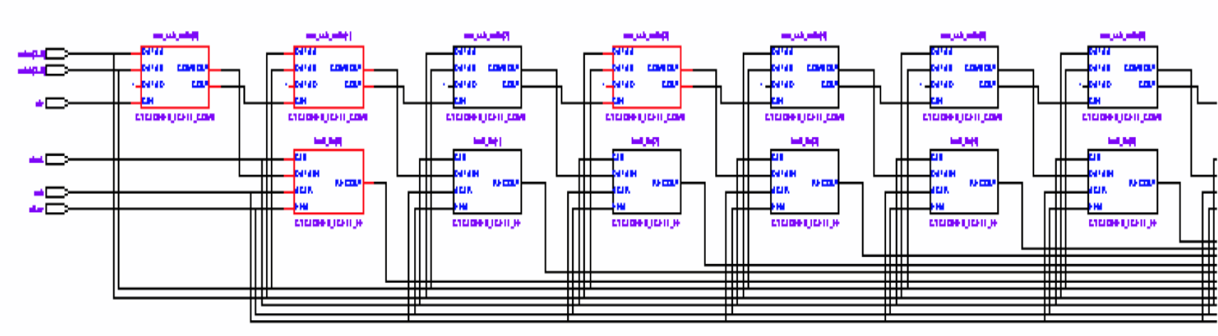


Figure 13–22 shows the schematic after filtering has been performed. If you select a net, the filtered page shows the immediate sources and destinations of the selected net.

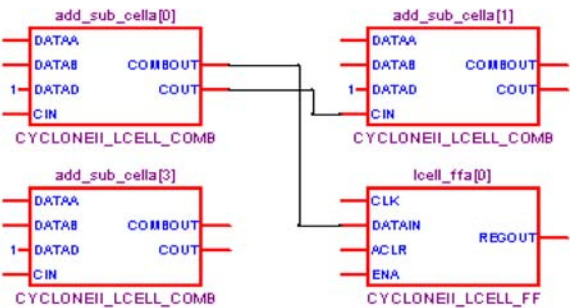
Figure 13–22. Selected Nodes and Nets Filtering on Figure 13–21 Schematic



Filter Bus Index Command

To show the path related to a specific index of a bus input or output port in the RTL Viewer, right-click the port, point to **Filter**, and click **Bus Index**. The **Select Bus Index** dialog box allows you to select the indices of interest.

Filter Command Processing

The options to control filtering are available in the **Tracing** section of the **RTL/Technology Map Viewer Options** dialog box. Right-click in the schematic and click **Viewer Options** to open the dialog box.

For all the filtering commands, the viewer stops tracing through the netlist to obtain the filtered netlist when it reaches one of the following objects:

- A pin
- A specified number of filtering levels, counting from the selected node or port; the default value is 3

Specify the number of filtering levels in the **Tracing** section of the **RTL/Technology Map Viewer Options** dialog box. The default value is 3, which ensures optimal processing time when performing filtering, but you can specify a value from 1 to 15. To see more than 15 levels, set the **Expanding** option. For more information, refer to "Expanding a Filtered Netlist".

- A register (optional; turned on by default)

Turn the **Stop filtering at register** option on or off in the **Tracing** section of the **RTL/Technology Map Viewer Options** dialog box. Right-click in the schematic and click **Viewer Options** to open the dialog box.

By default, the filtered schematic shows all possible connections between the nodes shown in the schematic. To remove the connections that are not directly part of the path that was traced to generate a filtered netlist, turn off the **Shows all connections between nodes** option in the **Tracing** section of the **RTL/Technology Map Viewer Options** dialog box.

Filtering Across Hierarchies

The filtering commands display nodes in all hierarchies by default. When the filtered path passes through levels of hierarchy on the same schematic page, green hierarchy boxes group the logic and show the hierarchy boundaries. A green rectangular symbol appears on the border that represents the port relationship between two different hierarchies (Figure 13–23 and Figure 13–24).

The **RTL/Technology Map Viewer Options** dialog box provides an option to control filtering if you prefer to filter only within the current hierarchy. Right-click in the schematic and click **Viewer Options**. In the **Tracing** section, turn off the **Filter across hierarchy** option.

To disable the box hierarchy display, on the Tools menu, click **Options**. In the **Category** list, select **Netlist Viewers** and turn off **Display boundary around hierarchy levels**.

Netlists of the same hierarchy that are displayed over more than one page are not grouped with a box. Filtering and expanding on a blue atom primitive does not trace the underlying netlist even when **Filter across hierarchy** is enabled.

Figure 13–23 and 13–34 show examples of filtering across hierarchical boundaries. Figure 13–23 shows an example after the **Sources** filter has been applied to an input port of the `taps` instance, where the input port of the lower level hierarchical block connects directly to an input pin of the design. The name of the instance is indicated within the green border and appears as a tooltip when you move your mouse pointer over the instance.

Figure 13–23. Filtering Across Hierarchical Boundaries, Small Example

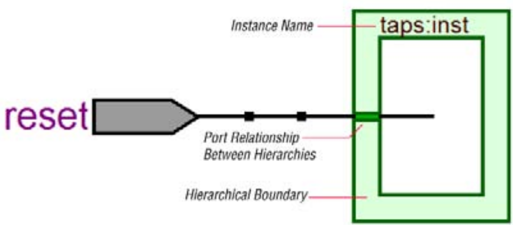


Figure 13–24 shows a larger example after the **Sources** filter has been applied to an input port of an instance, in which the source comes from input pins that are fed through another level of hierarchy.

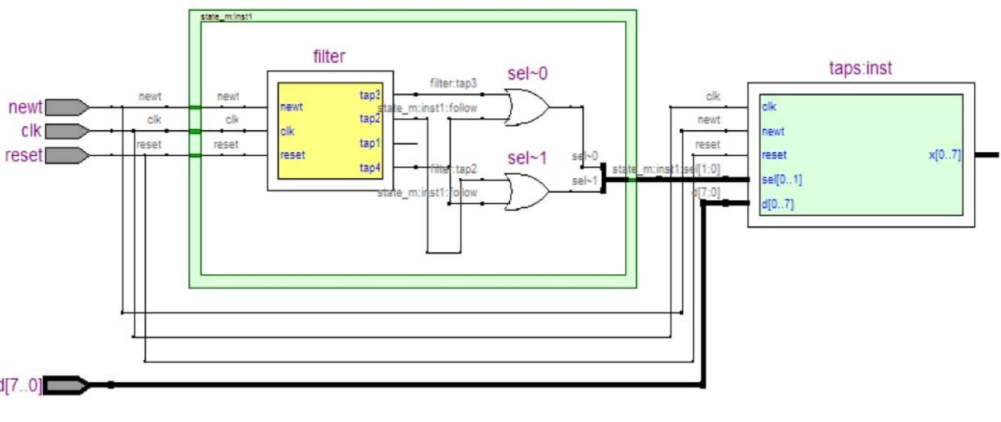
Figure 13–24. Filtering Across Hierarchical Boundaries, Large Example



Sources command applied to an input port of an instance in which the source comes from input pins that are fed through another level of hierarchy.

Expanding a Filtered Netlist

After a netlist is filtered, some ports might not have connections displayed because their connections are not part of the main path through the netlist. Two expansion features, immediate expansion and the **Expand** command, allow you to add the fan-in or fan-out signals of these ports to the schematic display of a filtered netlist.

You can immediately expand any port whose connections are not displayed. When you double-click that port in the filtered schematic, one level of logic is expanded.

To expand more than one level of logic, right-click the port and click the **Expand** command. This command expands logic from the selected port by the amount specified in **Viewer Options**. To set these options, right-click in the schematic view and click **Viewer Options**. In the **Expansion** section, set the **Number of expansion levels** option to specify the number of levels to expand (the default value is 3 and the range is 1 to 15 levels). You can also set the **Stop expanding at register** option (which is turned on by default) to specify whether netlist expansion should stop when a register is reached.

You can select multiple nodes to expand when you use the **Expand** command. If you select ports that are located on multiple schematic pages, only the ports on the currently viewed page appear in the expanded schematic.

In the State Machine Viewer, the **Expand** command has the following three options:

- **Sources**—Displays the states that feed the selected states (previous transition states)
- **Destinations**—Displays the states that are fed by the selected states (next transition states)
- **Sources & Destinations**—Displays both the previous and next transition states

The state transition table and state encoding table also reflect the changes to the filter.

The expansion feature works across hierarchical boundaries if the filtered page containing the port to be expanded was generated with the **Filter across hierarchy** option turned on (refer to "Filtering in the Schematic View" on page 13–29 for details about this option). When viewing timing paths in the Technology Map Viewer, the **Expand** command always works across hierarchical boundaries because filtering across hierarchy is always turned on for these schematics (refer to "Viewing a Timing Path" on page 13–38 for details about these schematics).

Reducing a Filtered Netlist

In some cases, removing logic from a filtered schematic or state diagram makes the schematic view easier to read or minimizes distracting logic that you do not require to view in the schematic.

To reduce elements in the filtered schematic or state diagram view, right-click the node or nodes you want to remove and click **Reduce**.

Probing to Source Design File and Other Quartus II Windows

The RTL Viewer, Technology Map Viewer, and State Machine Viewer let you cross-probe from the viewer to the source design file and to various other windows within the Quartus II software. You can select one or more hierarchy boxes, nodes, nets, state nodes, or state transition arcs that interest you in the viewer and locate the corresponding items in another applicable Quartus II software window. You can then view and make changes or assignments in the appropriate editor or floorplan.

To locate an item from the viewer in another window, right-click the items of interest in the schematic or state diagram view, point to **Locate**, and click the appropriate command. The following commands are available:

- **Locate in Assignment Editor**
- **Locate in Pin Planner**
- **Locate in Timing Closure Floorplan**
- **Locate in Chip Planner**
- **Locate in Resource Property Editor**
- **Locate in RTL Viewer**
- **Locate in Technology Map Viewer**

- **Locate in Design File**

The options available for locating depend on the type of node and whether it exists after placement and routing. If a command is enabled in the menu, it is available for the selected node. You can use the **Locate in Assignment Editor** command for all nodes, but assignments might be ignored during placement and routing if they are applied to nodes that do not exist after synthesis.

The viewer automatically opens another window for the appropriate editor or floorplan and highlights the selected node or net in the newly opened window. You can switch back to the viewer by selecting it in the Window menu or by closing, minimizing, or moving the new window.

When probing to a logic cloud in the RTL Viewer, a message box appears that prompts you to ungroup the logic cloud or allow it to remain grouped.

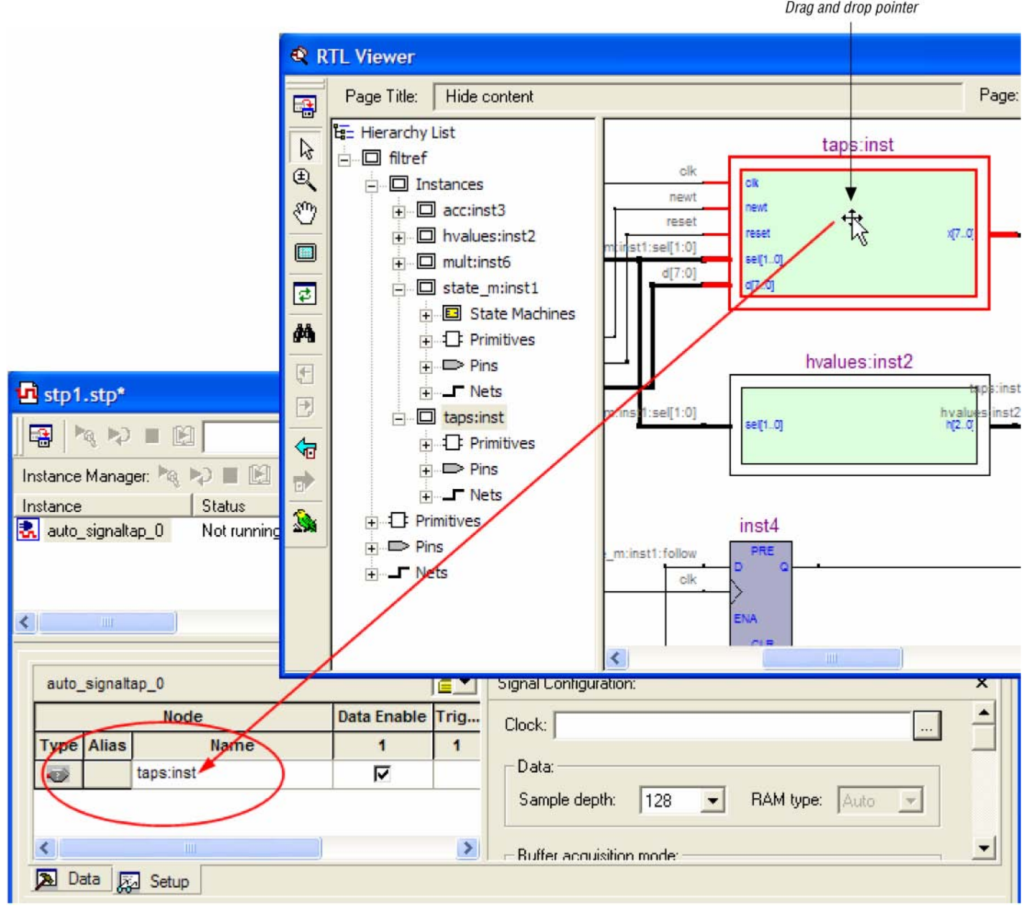
Moving Selected Nodes to Other Quartus II Windows

You can drag selected nodes from the netlist viewers to the Text Editor, Block Editor, Pin Planner, SignalTap® II Embedded Logic Analyzer, and Waveform Editor windows within the Quartus II software. Whenever you see the drag-and-drop pointer on the selected node in the netlist viewers, it means that the node can be dragged to other child windows within the Quartus II software.

To tap a node from the schematic in the Technology Map Viewer to an open SignalTap II Embedded Logic Analyzer window or to a new SignalTap II file (**.stf**), right-click on the selected node in the schematic diagram or in the hierarchy list and then click **Add Node to SignalTap II Logic Analyzer**. If the node cannot be tapped, the option is unavailable.

Figure 13–25 shows the drag-and-drop pointer and an example of dragging a node from the RTL Viewer to the SignalTap II Logic Analyzer.

Figure 13–25. Dragging a Node to the SignalTap II Logic Analyzer



Probing to the Viewers from Other Quartus II Windows

You can cross-probe to the RTL Viewer and Technology Map Viewer from other windows within the Quartus II software. You can select one or more nodes or nets in another window and locate them in one of the viewers.

You can locate nodes between the RTL Viewer, State Machine Viewer, and Technology Map Viewer and you can locate nodes in the RTL Viewer or Technology Map Viewer from the following Quartus II software windows:

- Project Navigator
- Timing Closure Floorplan
- Chip Planner
- Resource Property Editor
- Node Finder
- Assignment Editor
- Messages Window
- Compilation Report

- TimeQuest Timing Analyzer (supports the Technology Map Viewer only)

To locate elements in the viewer from another Quartus II window, select the node or nodes in the appropriate window; for example, select an entity in the **Entity** list on the **Hierarchy** tab in the Project Navigator, or select nodes in the Timing Closure Floorplan, or select node names in the **From** or **To** column in the Assignment Editor. Next, right-click the selected object, point to **Locate**, and click **Locate in RTL Viewer** or **Locate in Technology Map Viewer**. After you choose this command, the viewer window opens, or is brought to the foreground if the viewer window is already open.

☞ The first time the window opens after a compilation, the preprocessor stage runs before the viewer window opens.

The viewer shows the selected nodes and, if applicable, the connections between the nodes. The display is similar to what you see if you right-click the object, point to **Filter,** and click **Selected Nodes & Nets using Filter Across Hierarchy**. If the nodes cannot be found in the viewer, a message box displays the message: **Can't find requested location**.

Viewing a Timing Path

To see a visual representation of a timing path, cross-probe from the Timing Analysis section of the Compilation Report with the Classic Timing Analyzer, or from a report panel in the TimeQuest Timing Analyzer.

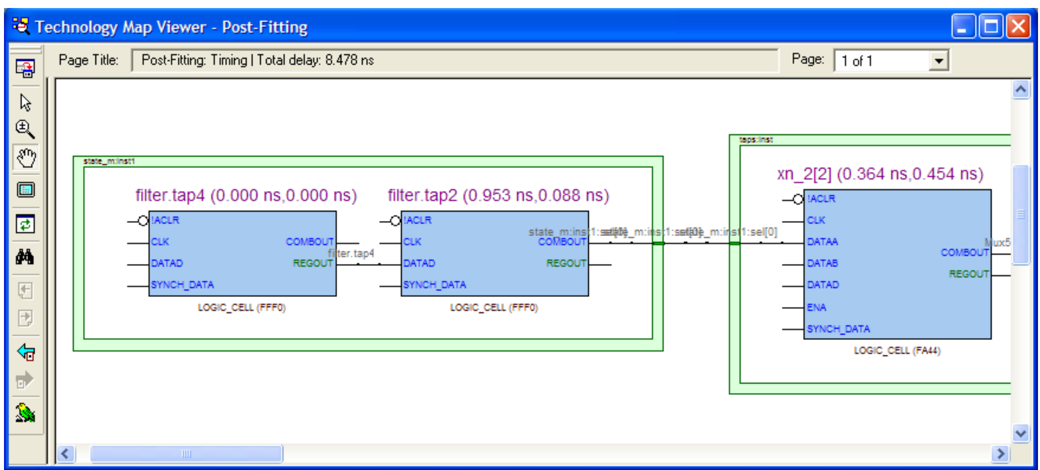
To take advantage of this feature, you must first successfully complete a full compilation of your design, including the timing analyzer stage. To access the timing analyzer report that contains the timing results for your design, on the Processing menu, click **Compilation Report**. On the left side of the Compilation Report, select **Timing Analyzer** or **TimeQuest Timing Analyzer**. When you select a detailed report, the timing information is listed in a table format on the right side of the Compilation Report; each row of the table represents a timing path in the design. You can also view timing paths in TimeQuest report panels. To view a particular timing path in the Technology Map Viewer or RTL Viewer, highlight the appropriate row in the table, right-click, point to **Locate**, and click **Locate in Technology Map Viewer** or **Locate in RTL Viewer**.

In the Technology Map Viewer, the schematic page displays the nodes along the timing path with a summary of the total delay. If you locate from the Classic Timing Analyzer, the timing path also includes timing data representing the interconnect (IC) and cell delays associated with each node. The delay for each node is shown in the following format: *<post-synthesis node name>* (*<IC delay>* ns, *<cell delay>* ns).

When you locate the timing path from the TimeQuest Timing Analyzer to the Technology Map Viewer, the interconnect and cell delay associated with each node is displayed on top of the schematic symbols. The total slack of the selected timing path is displayed in the **Page Title** section of the schematic. If the nodes are grouped in a logic cloud, the delay information displayed with the logic cloud is the total sum delay of the grouped nodes. The delay information for each node in the logic cloud is displayed in a tooltip. Move the mouse pointer over the logic cloud to see the tooltip. For more information about tooltips, refer to "Tooltips" on page 13–39.

Figure 13–26 shows a portion of a Classic Timing Analyzer timing path represented in the Technology Map Viewer. The total delay for the entire path through several levels of logic (only three levels are shown in Figure 13–26) is 7.159 ns. The delays are indicated for each level of logic. For example, the IC delay to the first LCELL primitive is 0.383 ns and the cell delay through the LCELL is 0.075 ns. When the timing path passes through a level of hierarchy, green hierarchy boxes group the logic and show the hierarchical boundaries. A green rectangular symbol on the border indicates the path passes between two different hierarchies.

Figure 13–26. Timing Path Schematic in the Technology Map Viewer



In the RTL Viewer, the schematic page displays the nodes in the paths between the source and destination registers with a summary of the total delay.

The RTL Viewer netlist is based on an initial stage of synthesis, so the post-fitting nodes might not exist in the RTL Viewer netlist. Therefore, the internal delay numbers are not displayed in the RTL Viewer as they are in the Technology Map Viewer, and the timing path might not be displayed exactly as it appears in the timing analysis report. If multiple paths exist between the source and destination registers, the RTL Viewer might display more than just the timing path. There are also some cases in which the path cannot be displayed, such as paths through state machines, encrypted intellectual property (IP), or registers that are created during the fitter process. In cases where the timing path displayed in the RTL Viewer might not be the correct path, the compiler issues messages.

Other Features in the Schematic Viewer

This section describes other features in the schematic view that enhance usability and help you analyze your design.

Tooltips

A tooltip is displayed whenever the mouse pointer is held over an element in the schematic. The tooltip contains useful information about a node, net, logic cloud, input port, and output port. Table 13–9 lists the information contained in the tooltip for each type of node.

The tooltip information for an instance (the first row in Table 13–9) includes a list of the primitives found within that level of hierarchy and the number of each primitive contained in the current instance. The number includes all hierarchical blocks below the current instance in the hierarchy. This information lets you estimate the size and complexity of a hierarchical block without navigating into the block.

The tooltip information for atom primitives in the Technology Map Viewer (the second row of Table 13–9) shows the equation for the design atom. The equations are an expanded version of the equations you can view in the Equations window in the Timing Closure Floorplan. Advanced users can use these equations to analyze the design implementation in detail.

For details about understanding equations, refer to the Quartus II Help.

To copy tooltips into the clipboard for use in other applications, right-click the desired node or netlist and click **Copy Tooltip**.

To turn off tooltips or change the duration of time that a tooltip is displayed in the view, on the Tools menu, click **Options**. In the **Category** list, select **Netlist Viewers** and set the desired options under **Tooltip settings**.

The **Show names in tooltip for** option specifies the number of seconds to display the names of assigned nodes and pins in a tooltip when the pointer is over the assigned nodes and pins. Selecting **Unlimited** displays the tooltip as long as the pointer remains over the node or pin. Selecting **0** turns off tooltips. The default value is 5 seconds.

The **Delay showing tooltip for** option specifies the number of seconds you must hold the mouse pointer over assigned nodes and pins before the tooltip displays the names of the assigned nodes and pins. Selecting **0** displays the tooltip immediately when the pointer is over an assigned node or pin. Selecting **Unlimited** prevents tooltips from being displayed. The default value is 1 second.

Table 13–9. Tooltip Information (Part 1 of 2)

<table>

Table 13–9. Tooltip Information (Part 2 of 2)

Tooltip Format	Description	Example Tooltips
Pin	Format: <*pin name*>, <*pin type*>	pc_clock, INPUT Test_probe, OUTPUT
Connector	Format: <*connector name*>	inst4_CLK
Net	Format: <*net name*>, `fan-out` = <*number of fan-out signals*>	state_m:inst1:decoder_node[2][0], fan-out = 1
Output Port	Format: `fan-out` = <*number of fan-out signals*>	fan-out = 9
Input Port	The information displayed depends on the type of source net. The examples of the tooltips shown represent the following types of source nets: *(1)* Single net *(2)* Individual nets, part of the same bus net *(3)* Combination of different bus nets *(4)* Constant inputs *(5)* Combination of single net and constant input *(6)* Bus net **Source from**—refers to the source net name that connects to the input port. **Destination Index**—refers to the bit(s) at the destination input port to which the source net is connected (not applicable for single nets).	Source from: reset:reset_i:rst *(1)* < Destination Index > | Source from: *(2)* < [11] > | sample~0:OUT1 < [10] > | sample~1:OUT1 < [9] > | sample~2:OUT1 < [8] > | sample~3:OUT1 < [7] > | sample~4:OUT1 < [6] > | sample~5:OUT1 < [5] > | sample~6:OUT1 < [4] > | sample~7:OUT1 < [3] > | sample~8:OUT1 < [2] > | sample~9:OUT1 < [1] > | sample~10:OUT1 < [0] > | sample~11:OUT1 < Destination Index > | Source from: *(3)* < [7..6] > | node2:OUT1 < [5] > | ct[3]:OUT1 < [4] > | node2:OUT1 < [3..2] > | ct[3]:OUT1 < [1] > | node2:OUT1 < [0] > | ct[3]:OUT1 < Destination Index > | Source from: *(4)* < [11..0] > | 12' h000 < Destination Index > | Source from: *(5)* < [2..1] > | 2' h1 < [0] > | always7~2:OUT1 < Destination Index > | Source from: *(6)* < [15..0] > | md_me:inst18:dout[15:0]
State Machine Node	Format: <*node name*>	state_m:inst1|filter.tap1
State Machine Transition Arc	This information is displayed when you hold your mouse over the arrow on the arc representing the transition between two states. Format: (<*equation for transition between states*>)	(!newt)

Radial Menu

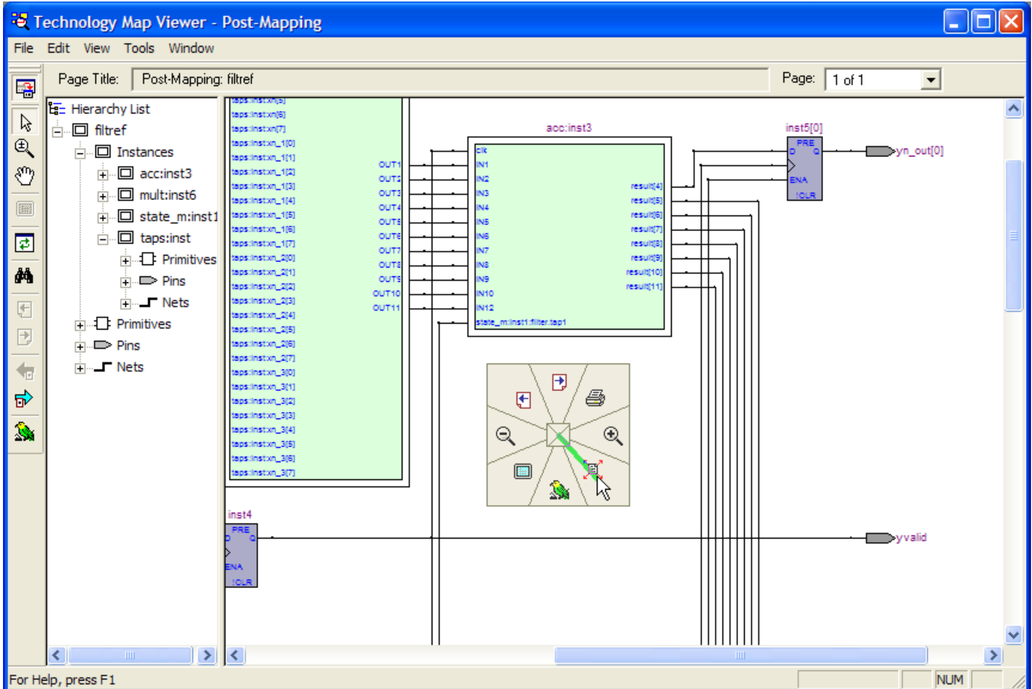
The radial menu is a rectangle-shaped menu with eight commands you can choose from. The menu provides a quick way to perform any of the commands with a single click whenever you are in the schematic view. The radial menu feature is enabled by default.

To open the radial menu, right-click and hold anywhere in the schematic view and wait for the menu to appear. By default, the menu appears after 0.2 seconds. The radial menu appears with the mouse pointer always at the center point. The small rectangle at the center of the menu indicates a non-trigger boundary where no command is started when you click within the rectangle.

To start the desired command, hold down the right mouse button, drag the mouse onto the command, and then release the mouse button. If you decide not to trigger any command after the radial menu appears, press the ESC key or drag the pointer back into the small rectangle and release the mouse button.

Figure 13–27 shows the radial menu.

Figure 13–27. Radial Menu



Enabling and Disabling the Radial Menu

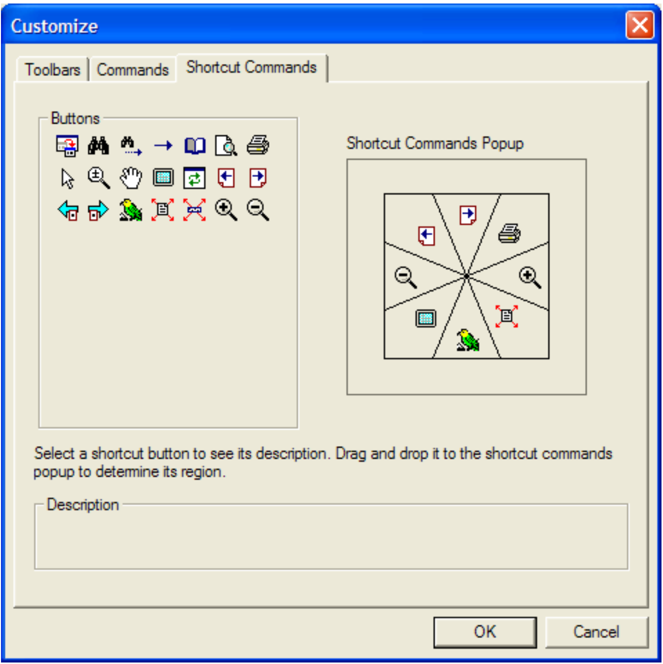
To enable the radial menu feature, on the Tools menu, click **Options**. In the **Options** dialog box, click **Netlist Viewers** and turn on the **Enable Radial Menu** option under **Radial Menu settings**. Turn off the **Enable Radial Menu option** to disable the feature.

Customizing the Shortcut Commands

The radial menu consists of eight commands that are separated into eight different regions. There are 8 out of 24 commands to choose from, and the command can appear more than once. To customize the command list on the menu, first launch the RTL Viewer, the Technology Map Viewer, or the Technology Map Viewer (Post-Mapping). On the Tools menu, click **Customize RTL Viewer**, **Customize Technology Map Viewer**, or **Customize Technology Map Viewer (Post-Mapping)**. On the **Shortcut Commands** tab, drag and drop the icon under **Buttons** into any region under **Shortcut Commands Popup**. You can click on the icon under **Buttons** to see its description.

Figure 13–28 shows the **Shortcut Commands** tab for customizing the radial menu.

Figure 13–28. Shortcut Commands Tab



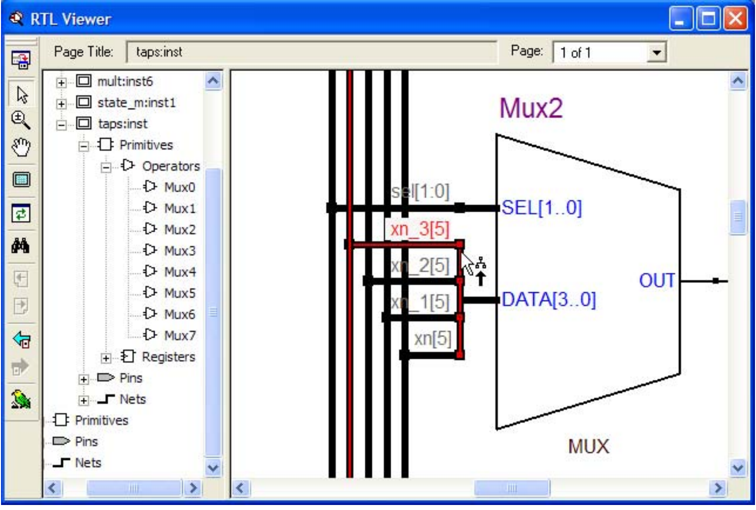
Changing the Time Interval

To change the amount of time you have to wait before the Radial menu appears, on the Tools menu, click **Options**. In the **Options** dialog box, select **Netlist Viewers**. Select the desired time interval in the pull-down list for **Delay showing radial menu for**. The default delay is 0.2 seconds. The Radial menu feature must be enabled before you can change this setting. Refer to "Enabling and Disabling the Radial Menu" on page 13–42 for details about how to enable the Radial menu feature.

Rollover

You can highlight an element and view its name in your schematic using the Rollover feature. When you place your mouse pointer over an object, the object is highlighted and the name is displayed (Figure 13–29). This feature is enabled by default in the netlist viewers. To turn off the Rollover feature, on the Tools menu, click **Options**. In the **Options** dialog box, in the **Category** list, select **Netlist Viewers** and turn off **Enable Rollover**.

Figure 13–29. Rollover in the RTL Viewer and Technology Map Viewer



Displaying Net Names in the Schematic

To see the names of all the nets displayed in your schematic, on the Tools menu, click **Options**. In the **Category** list, select **Netlist Viewers** and under **Display Settings**, turn on **Show Net Name**. This option is disabled by default. If you turn on this option, the schematic view refreshes automatically to display the net names.

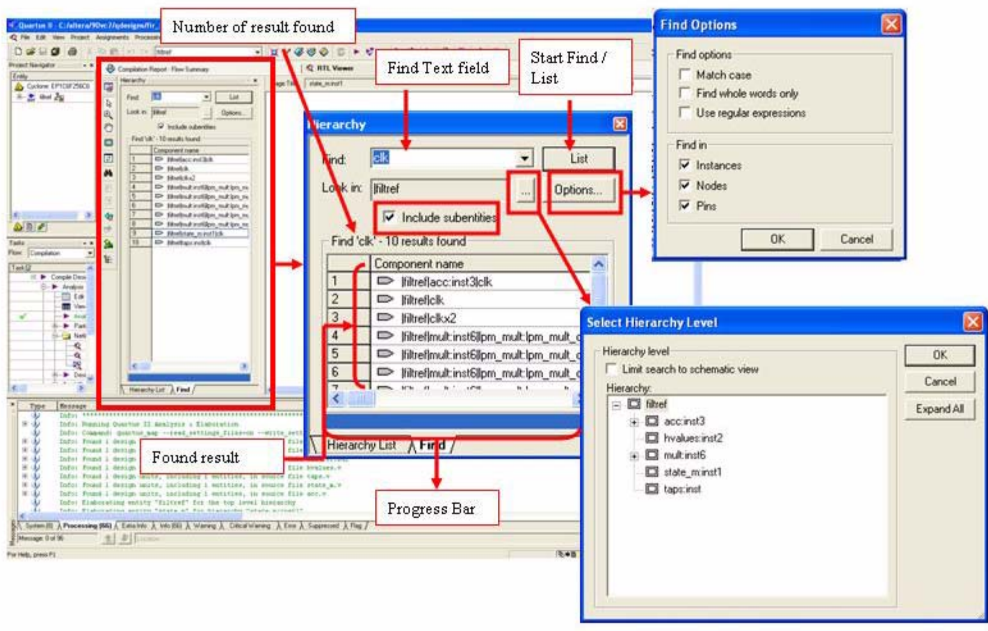
Displaying Node Names in the Schematic

In some designs, nodes have long names that overlap the ports of other symbols in the schematic. To remove the node names from the schematic, on the Tools menu, click **Options**. In the **Category** list, select **Netlist Viewers** and under **Display Settings**, turn off **Show node name**. This option is turned on by default.

Find Command

To open the **Hierarchy** dialog box shown in Figure 13–30, on the Edit menu, click **Find**, or click the **Find** icon in the viewer toolbar, or right-click in the schematic view and click **Find**. There is also a **Hierarchy List** button at the bottom of the toolbar in the viewer window. You can use the **Tab** button to switch between the Find and Hierarchy lists.

Figure 13–30. Hierarchy Dialog Box



You can narrow the range of the search process by setting the following options in the **Hierarchy** dialog box:

- Click on the **Select Hierarchy Level** button to specify the level of the search. In the **Select Hierarchy Level** dialog box, choose the particular instance that you want to search.
- Turn on the **Include subentities** option to include child hierarchies of the parent instance during the search.
- Click **Options** to open the **Find Options** dialog box. Turn on **Instances**, **Nodes**, **Pins**, or any combination of the three to further refine the parameters of the search.

When you click **List**, a progress bar appears below the **Find** box. When the bar is full, the search process is finished.

All results that match the criteria you set are listed in a table. The number of results is shown. When you double-click on an item in the table, the related node is highlighted in red in the schematic view.

For more details about using the **Hierarchy** dialog box, refer to “Finding Nodes in the RTL Viewer and Technology Map Viewer” in the Quartus II Help.

Exporting and Copying a Schematic Image

You can export the schematic view of the RTL Viewer or Technology Map Viewer into various types of image formats. This allows you to include the schematic in project documentation or share it with other project members. The currently supported formats are JPEG File Interchange Format (**.jpg**), Portable Network Graphics (**.png**), Graphics Interchange Format (**.gif**), or Windows Bitmap (**.bmp**). To export the

schematic view, on the File menu, click **Export**. In the **Export** dialog box, type a file name and location and select the desired file type. The default file name is based on the current instance name; the default file type is **.jpg**. However, for pages that use filtering, expanding, or reducing operations, the default name is **Filter**<*number of export operation*>**.jpg**.

Nodes grouped as logic clouds are not shown in the exported or copied schematic image; the logic clouds are shown instead.

You can copy the whole image or only a portion of the image. To copy the full image, on the Edit menu, point to **Copy** and click **Full Image**. To copy a portion of the image, on the Edit menu, point to **Copy** and click **Partial Image**. The cursor changes to a plus sign to indicate that you can draw a box shape. Drag the mouse pointer around the portion of the schematic you want to copy. When you release the mouse button, the partial image is copied to the clipboard.

Occasionally, due to the design size and objects selected, an image is too large to copy to the clipboard. In this case, the Quartus II software displays an error message.

To export or copy a schematic that is too large to copy in one piece, first split the design into multiple pages to export or to copy smaller portions of the design. For information about how to control how much of your design is shown on each schematic page, refer to "Partitioning the Schematic into Pages" on page 13–26. As an alterative, use the Partial Image feature to copy a portion of the image.

The Copy feature is not available on UNIX platforms.

Printing

To print your schematic page, on the File menu, click **Print**. You can print each schematic page onto one full page, or you can print the selected parts of your schematic onto one page with the **Selection** option. Refer to "Partitioning the Schematic into Pages" on page 13–26 to control how much of your design is shown on each schematic page.

Before printing, you can modify the page orientation. On the File menu, click **Page Setup**. Change the page orientation from **Portrait** to **Landscape**, or to the setting that best fits your design. You can also adjust the page margins in the **Page Setup** dialog box.

The hierarchy list in the viewers and the table view of the State Machine Viewer cannot be printed. You can use the State Machine Viewer **Copy** command to copy the table to a text editor and print from the text editor.

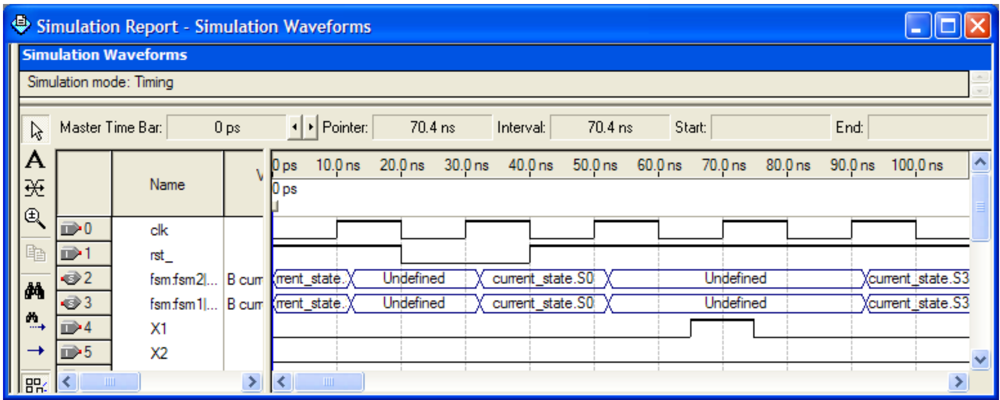
Debugging HDL Code with the State Machine Viewer

This section provides an example of using the State Machine Viewer to help debug HDL code. This example shows how you can use the various features in the netlist viewers to help solve design problems.

Simulation of State Machine Gives Unexpected Results

This section presents a design scenario in which you compiled your design and performed a simulation in the Quartus II Simulator. The simulation result is shown in Figure 13–31 and has unexpected undefined states.

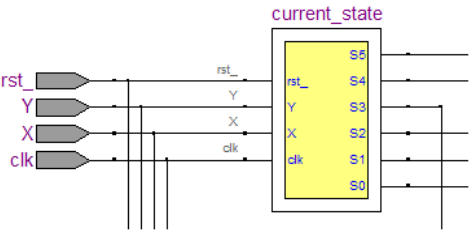
Figure 13–31. Simulation Result Showing Undefined States



To analyze the state machine design in the State Machine Viewer, follow these steps:

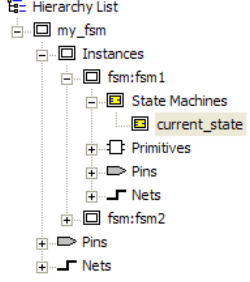
1. Open the State Machine Viewer for the state machine of interest. You can do this in any of the following ways:
   - On the Tools menu, point to **Netlist Viewers** and click **State Machine Viewer**. In the **State Machine** selection box, choose the state machine that you want to view.
   - On the Tools menu, point to **Netlist Viewers** and click **RTL Viewer**. Browse to the hierarchy block that contains the state machine definition and double-click the yellow state machine instance to open the State Machine Viewer (Figure 13–32).You can open the State Machine Viewer using either of two methods:
   - In the schematic view, double-click an instance in the hierarchy to open the lower hierarchy level. You can traverse through the schematic hierarchy in this way to open the schematic page that contains the state machine (Figure 13–32).

Figure 13–32. State Machine Instance in RTL Viewer Schematic View



- In the hierarchy list, click the "**+** " symbol next to **Instances** to open a list of the instances in that hierarchy level of the design. You can traverse down the hierarchy tree in this way to find the instance that contains the state machine. Click on the name of the state machine in the **State Machines** folder (Figure 13–33) to open the appropriate schematic in the schematic view (Figure 13–32).

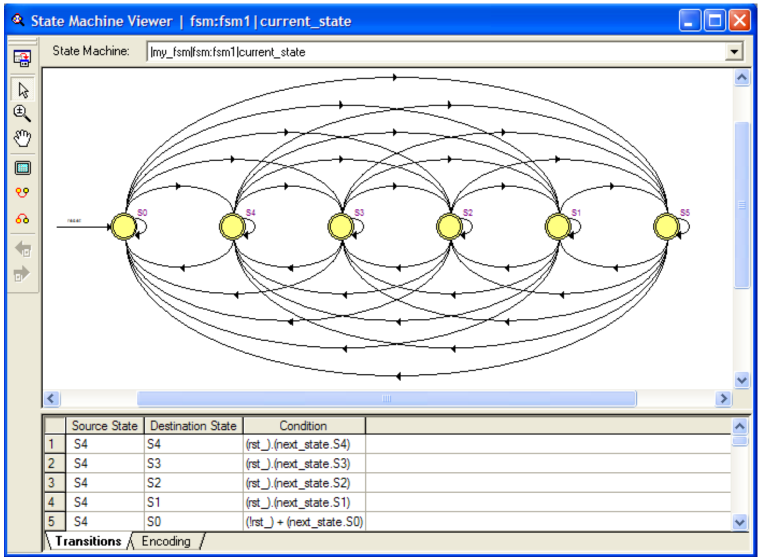
Figure 13–33. State Machine Instance in RTL Viewer Hierarchy List



Double-click the state machine instance (Figure 13–32) to see its state transition diagram in the State Machine Viewer (Figure 13–34).

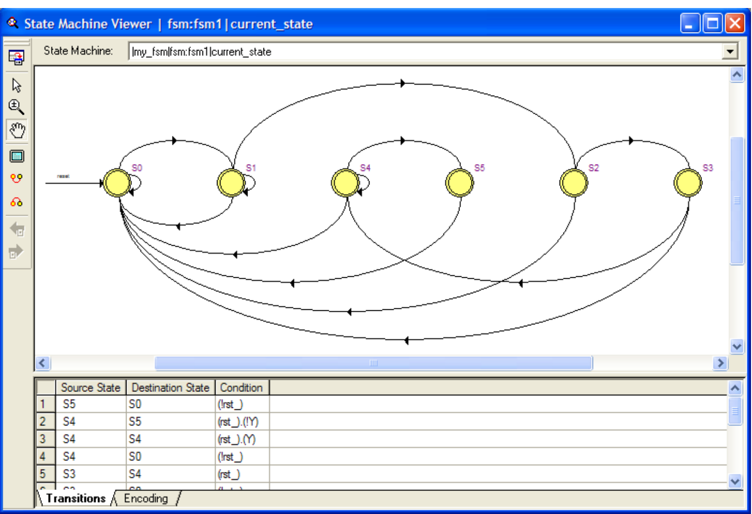
2. You can analyze this state machine instance using the state machine diagram, transition table, and encoding table. Clearly something is wrong with the state machine because every state has a transition to every other state (Figure 13–34). After inspecting the state machine behavior, you determine that in this scenario, the designer forgot to create default assignments for the next state (that is, `next_state = current_state` if the conditions are not met).

Figure 13–34. State Machine Viewer Showing Incorrect Transitions



3. After fixing the error in the HDL code, recompile the design and repeat steps 1-2 to view the new state machine diagram and transition table (shown in Figure 13–35), and check that the state transitions now occur correctly.

Figure 13–35. State Machine Viewer Showing Correct Transitions



4. Perform a new simulation, as shown in Figure 13–36, and verify that the state machine performs as expected.

Figure 13–36. Simulation Result Showing Correct States

Conclusion

The Quartus II RTL Viewer, State Machine Viewer, and Technology Map Viewer allow you to explore and analyze your initial synthesis netlist, post-synthesis netlist, or post-fitting and physical synthesis netlist. The viewers provide a number of features in the hierarchy list and schematic view to help you quickly trace through your netlist and find specific hierarchies or nodes of interest. These capabilities can help you debug, optimize, or constrain your design more efficiently to increase your productivity.

Document Revision History

Table 13–10 shows the revision history for this chapter.

Table 13–10. Document Revision History (Part 1 of 2)

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Chapter 13 was formerly Chapter 12 in version 8.1.0 ■ Updated Figure 13–2, Figure 13–3, Figure 13–4, Figure 13–14, and Figure 13–30 ■ Added "Enable or Disable the Auto Hierarchy List" on page 13–15 ■ Updated "Find Command" on page 13–44	Updated for the Quartus II software version 9.0 release.

Table 13–10. Document Revision History (Part 2 of 2)

Date and Document Version	Changes Made	Summary of Changes
November 2008 v8.1.0	Changed page size to 8.5” × 11”	—
May 2008 v8.0.0	■ Added Arria GX support ■ Updated operator symbols ■ Updated information about the radial menu feature ■ Updated zooming feature ■ Updated information about probing from schematic to SignalTap II Analyzer ■ Updated constant signal information ■ Added .png and .gif to the list of supported image file formats ■ Updated several figures and tables ■ Added new sections “Enabling and Disabling the Radial Menu”, “Changing the Time Interval”, “Changing the Constant Signal Value Formatting”, “Logic Clouds in the RTL Viewer”, “Logic Clouds in the Technology Map Viewer”, “Manually Group and Ungroup Logic Clouds”, “Customizing the Shortcut Commands” ■ Renamed several sections ■ Removed section “Customizing the Radial Menu” ■ Moved section “Grouping Combinational Logic into Logic Clouds” ■ Updated document content based on the Quartus II software version 8.0	Updated for Quartus II software version 8.0.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

About this Handbook

This handbook provides comprehensive information about the Altera® Quartus® II design software, version 9.0.

How to Contact Altera

For the most up-to-date information about Altera products, see the following table.

Contact *(Note 1)*	Contact Method	Address
Technical support	Website	www.altera.com/support
Technical training	Website	www.altera.com/training
	Email	custrain@altera.com
Altera literature services	Email	literature@altera.com
Non-technical support (General)	Email	nacomp@altera.com
(Software Licensing)	Email	authorization@altera.com

Note:

(1) You can also contact your local Altera sales office or sales representative.

Third-Party Software Product Information

Third-party software products described in this handbook are not Altera products, are licensed by Altera from third parties, and are subject to change without notice. Updates to these third-party software products may not be concurrent with Quartus II software releases. Altera has assumed responsibility for the selection of such third-party software products and its use in the Quartus II 9.0 software release. To the extent that the software products described in this handbook are derived from third-party software, no third party warrants the software, assumes any liability regarding use of the software, or undertakes to furnish you any support or information relating to the software. EXCEPT AS EXPRESSLY SET FORTH IN THE APPLICABLE ALTERA PROGRAM LICENSE SUBSCRIPTION AGREEMENT UNDER WHICH THIS SOFTWARE WAS PROVDED TO YOU, ALTERA AND THIRD-PARTY LICENSORS DISCLAIM ALL WARRANTIES WITH RESPECT TO THE USE OF SUCH THIRD-PARTY SOFTWARE CODE OR DOCUMENTATION IN THE SOFTWARE, INCLUDING, WITHOUT LIMITATION, ANY WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, TITLE, AND NONINFRINGEMENT. For more information, including the latest available version of specific third-party software products, refer to the documentation for the software in question.

Typographic Conventions

The following table shows the typographic conventions that this document uses.

Visual Cue	Meaning
Bold Type with Initial Capital Letters	Command names, dialog box titles, checkbox options, and dialog box options are shown in bold, initial capital letters. Example: **Save As** dialog box.
bold type	External timing parameters, directory names, project names, disk drive names, file names, file name extensions, and software utility names are shown in bold type. Examples: $\mathbf{f_{MAX}}$, **\qdesigns** directory, **d:** drive, **chiptrip.gdf** file.
Italic Type with Initial Capital Letters	Document titles are shown in italic type with initial capital letters. Example: *AN 75: High-Speed Board Design.*
Italic type	Internal timing parameters and variables are shown in italic type. Examples: t_{PIA}, $n + 1$. Variable names are enclosed in angle brackets (< >) and shown in italic type. Example: *<file name>*, *<project name>*.**pof** file.
Initial Capital Letters	Keyboard keys and menu names are shown with initial capital letters. Examples: Delete key, the Options menu.
"Subheading Title"	References to sections within a document and titles of on-line help topics are shown in quotation marks. Example: "Typographic Conventions."
`Courier type`	Signal and port names are shown in lowercase Courier type. Examples: `data1`, `tdi`, `input`. Active-low signals are denoted by suffix `n`, e.g., `resetn`. Anything that must be typed exactly as it appears is shown in Courier type. For example: `c:\qdesigns\tutorial\chiptrip.gdf`. Also, sections of an actual file, such as a Report File, references to parts of files (e.g., the AHDL keyword `SUBDESIGN`), as well as logic function names (e.g., `TRI`) are shown in Courier.
1., 2., 3., and a., b., c., etc.	Numbered steps are used in a list of items when the sequence of the items is important, such as the steps listed in a procedure.
■ ■	Bullets are used in a list of items when the sequence of the items is not important.
✓	The checkmark indicates a procedure that consists of one step only.
☞	The hand points to information that requires special attention.
CAUTION	A caution calls attention to a condition or possible situation that can damage or destroy the product or the user's work.
WARNING	A warning calls attention to a condition or possible situation that can cause injury to the user.
↵	The angled arrow indicates you should press the Enter key.
(feet)	The feet direct you to more information on a particular topic.

Section II. I/O and PCB Tools

Chapter 5. I/O Management

Introduction 5-1
Understanding Altera FPGA Pin Terminology 5-2
Package Pins 5-2
Pads 5-3
I/O Banks 5-3
VREF Groups 5-4
I/O Planning Overview 5-5
Device Selection 5-7
Early I/O Planning Using the Pin Planner 5-8
Create or Import a Megafunction or IP MegaCore Variation from the Pin Planner 5-9
Configure Nodes 5-10
Configure Megafunction Nodes 5-10
Configure User Nodes 5-12
I/O Analysis for Designs with Pins Only 5-14
Importing and Exporting Pin Assignments 5-16
Spreadsheets and .csv Files 5-16
Quartus II Settings Files 5-16
Tcl Script 5-17
FPGA Xchange File 5-17
.pin File 5-18
Creating Pin-Related Assignments 5-19
Using the Pin Planner 5-20
Groups List 5-21
All Pins List 5-24
Pad View Window 5-26

Package View 5-28
Pin Migration View 5-30
Using the Pin Finder to Find Compatible Pin Locations 5-33
SSN Visualization View 5-34
Creating Reserved Pin Assignments 5-34
Creating Pin Location Assignments 5-35
Changing Pin Locations 5-42
Swapping Pin Locations 5-43
Show I/O Banks 5-44
Show VREF Groups 5-45
Show Edges 5-47
Show DQ/DQS Pins 5-48
Displaying and Accepting Fitter Placements 5-49
Assignment Editor 5-50
Setting Pin Locations from the Device Pin Number List 5-50
Setting Pin Locations from the Design Signal Name List 5-51
Tcl Scripts 5-53
Chip Planner or Timing Closure Floorplan 5-53
Using HDL 5-54
Synthesis Attributes 5-55
Using Low-Level I/O Primitives 5-56
Validating Pin Assignments 5-56
Using the Live I/O Check Feature to Validate Pin Assignments 5-57
Using I/O Assignment Analysis to Validate Pin Assignments 5-59
I/O Assignment Analysis Design Flows 5-59
Inputs for I/O Assignment Analysis 5-65
Understanding the I/O Assignment Analysis Report and Messages 5-67
Scripting Support 5-72
Validating Pin Assignments after Full Compilation 5-74
Accepting Fitter Placements—Back-Annotating Assignments 5-74
I/O Timing Analysis 5-75
I/O Timing and Power with Capacitive Loading 5-77
Advanced I/O Timing in the Quartus II Software 5-78
Enabling and Configuring Advanced I/O Timing 5-78
Define Overall Board Trace Models 5-78
Customize the Board Trace Model in the Pin Planner 5-80
Create Signal Integrity Result Reports 5-82
Incorporating PCB Design Tools 5-83
Conclusion 5-84
Referenced Documents 5-84
Document Revision History 5-85

Chapter 6. Simultaneous Switching Noise (SSN) Analysis and Optimizations

Introduction 6-1
Definitions 6-1
Understanding SSN and Its Effects 6-2
SSN Estimation Tools from Altera 6-5
Design Factors Affecting SSN Results 6-5
Using the SSN Analyzer in the Quartus II Software 6-5
Tools Overview 6-6
I/O Standards Supported in the Quartus II SSN Analyzer 6-6
Tool Inputs 6-7
Board Trace Models 6-7
PCB Layers and PCB Layer Thickness 6-8

Signal Breakout Layers 6-9
I/O Assignments 6-10
Automatic Aggressor Identification 6-10
Group Assignments 6-10
Running the SSN Analyzer 6-11
Understanding the SSN Reports 6-12
Settings Report 6-12
Summary Report 6-12
Input Pins Report 6-12
Output Pins Report 6-12
Confidence Metric Details Report 6-13
Unanalyzed Pins Report 6-13
Visualizing SSN in the Pin Planner 6-13
Invoking the SSN Map 6-13
SSN Analyzer Usage Models 6-14
Early Pin-Out SSN Analysis 6-15
Early Pin-Out SSN Analysis Using the Early SSN Estimator Spreadsheet 6-15
Early Pin-Out SSN Analysis Using the Quartus II SSN Analyzer 6-15
SSN Aware Fitter 6-17
Default Assignments Used in Early SSN Analysis 6-17
Final Pin-Out Analysis: Fully Constrained Design SSN Analysis 6-18
Scripting Support 6-18
Run Time Considerations in SSN Analysis 6-18
Running SSN Analyzer with Multi-CPU machines 6-19
Running the Complete Design for SSN Analysis after I/O Assignment Analysis 6-19
Running the Complete Design for SSN Analysis after a Full Fit 6-19
Making ECO Changes and Rerunning SSN Analysis 6-19
Running SSN Analysis for One I/O Bank 6-19
SSN Optimization 6-20
Back-Annotating the Fitter Results 6-22
SSN Optimization in Your System 6-22
Conclusion 6-22
Referenced Documents 6-23
Document Revision History 6-23

Chapter 7. Signal Integrity Analysis with Third-Party Tools

Introduction 7-1
I/O Model Selection: IBIS or HSPICE 7-3
FPGA to Board Signal Integrity Analysis Flow 7-3
Create I/O and Board Trace Model Assignments 7-5
Output File Generation 7-6
Customize the Output Files 7-6
Set Up and Run Simulations in Third-Party Tools 7-7
Interpret Simulation Results 7-7
Simulation with IBIS Models 7-7
Elements of an IBIS Model 7-7
Creating Accurate IBIS Models 7-8
Download IBIS Models 7-8
Generate Custom IBIS Models with the IBIS Writer 7-9
Design Simulation Using the Mentor Graphics HyperLynx Software 7-10
Configuring LineSim to Use Altera IBIS Models 7-12
Integrating Altera IBIS Models into LineSim Simulations 7-14
Running and Interpreting LineSim Simulations 7-15
Simulation with HSPICE Models 7-17

Supported Devices and Signaling . . . 7-17
Accessing HSPICE Simulation Kits . . . 7-18
The Double Counting Problem in HSPICE Simulations . . . 7-18
Defining the Double Counting Problem . . . 7-18
The Solution to Double Counting . . . 7-19
HSPICE Writer Tool Flow . . . 7-20
Applying I/O Assignments . . . 7-20
Enabling HSPICE Writer . . . 7-20
Enabling HSPICE Writer Using Assignments . . . 7-21

Chapter 8. Mentor Graphics PCB Design Tools Support
Introduction . . . 8-1
FPGA-to-PCB Design Flow . . . 8-2

Setting Up the Quartus II Software 8-4
Generating Pin-Out Files 8-6
Generating FPGA Xchange Files 8-6
Creating a Backup Quartus II Settings File 8-6
FPGA-to-Board Integration with the I/O Designer Software 8-7
I/O Designer Database Wizard 8-9
Updating Pin Assignments from the Quartus II Software 8-13
Sending Pin Assignment Changes to the Quartus II Software 8-16
Protecting Assignments in the Quartus II Software 8-18
Generating Symbols for the DxDesigner Software 8-18
Setting Up the I/O Designer Software to Work with the DxDesigner Software 8-19
Create Symbols with the Symbol Wizard 8-20
Export Symbols to the DxDesigner Software 8-22
Scripting Support 8-22
FPGA-to-Board Integration with the DxDesigner Software 8-23
DxDesigner Project Settings 8-24
DxDesigner Symbol Wizard 8-25
Conclusion 8-28
Referenced Documents 8-28
Document Revision History 8-29

Chapter 9. Cadence PCB Design Tools Support

Introduction 9-1
Product Comparison 9-2
FPGA-to-PCB Design Flow 9-2
Setting Up the Quartus II Software 9-4
Generating .pin Files 9-5
FPGA-to-Board Integration with the Cadence Allegro Design Entry HDL Software 9-5
Symbol Creation 9-5
Allegro PCB Librarian Part Developer 9-6
Instantiating the Symbol in the Cadence Allegro Design Entry HDL Software 9-14
FPGA-to-Board Integration with Allegro Design Entry CIS 9-14
Allegro Design Entry CIS Project Creation 9-15
Generate Part 9-16
Split Part 9-17
Instantiate Symbol in Design Entry CIS Schematic 9-19
Altera Libraries for Design Entry CIS 9-20
Conclusion 9-22
Referenced Document 9-22
Document Revision History 9-22

Section III. Area, Timing and Power Optimization

Introduction III-1
Physical Implementation III-1
Trade Offs and Limitations III-1
Preserving Results and Enabling Teamwork III-2
Reducing Area III-2
Reducing Critical Path Delay III-2
Reduce Power Consumption III-3
Reducing Runtime III-3
Using Quartus II Tools III-3
Design Analysis III-3
Advisors III-4
Design Space Explorer III-4

Further Reading III-4

Chapter 10. Area and Timing Optimization

Introduction 10-1
Optimizing Your Design 10-2
Initial Compilation: Required Settings 10-3
Device Settings 10-3
I/O Assignments 10-3
Timing Requirement Settings 10-4
Timing Constraint Check—Report Unconstrained Paths 10-5
Device Migration Settings 10-5
Partitions and Floorplan Assignments for Incremental Compilation 10-6
Initial Compilation: Optional Settings 10-6
Design Assistant 10-7
Smart Compilation Setting 10-7
Early Timing Estimation 10-7
Optimize Hold Timing 10-8
Asynchronous Control Signal Recovery/Removal Analysis 10-9
Limit to One Fitting Attempt 10-9
Optimize Multi-Corner Timing 10-10
Fitter Effort Setting 10-10
Auto Fit 10-10
Standard Fit 10-11
Fast Fit 10-11
Design Analysis 10-11
Error and Warning Messages 10-12
Ignored Timing Assignments 10-12
Resource Utilization 10-12
I/O Timing (Including t_{PD}) 10-13
Register-to-Register Timing 10-14
Timing Analysis with the TimeQuest Timing Analyzer 10-14
Timing Analysis with the Classic Timing Analyzer 10-15
Tips for Analyzing Failing Paths 10-17
Tips for Analyzing Failing Clock Paths that Cross Clock Domains 10-17
Global Routing Resources 10-18
Compilation Time 10-19
Resource Utilization Optimization Techniques (LUT-Based Devices) 10-19
Using the Resource Optimization Advisor 10-19
Resolving Resource Utilization Issues Summary 10-20
I/O Pin Utilization or Placement 10-20
Use I/O Assignment Analysis 10-20
Modify Pin Assignments or Choose a Larger Package 10-20
Logic Utilization or Placement 10-21
Optimize Synthesis for Area, Not Speed 10-21
Restructure Multiplexers 10-21
Perform WYSIWYG Resynthesis with Balanced or Area Setting 10-22
Use Register Packing 10-22
Remove Fitter Constraints 10-24
Change State Machine Encoding 10-25
Flatten the Hierarchy During Synthesis 10-25
Retarget Memory Blocks 10-25
Use Physical Synthesis Options to Reduce Area 10-26
Retarget or Balance DSP Blocks 10-27
Optimize Source Code 10-28

Use a Larger Device 10-28
Routing 10-29
Set Auto Register Packing to Sparse or Sparse Auto 10-29
Set Fitter Aggressive Routability Optimizations to Always 10-29
Increase Placement Effort Multiplier 10-30
Increase Router Effort Multiplier 10-30
Remove Fitter Constraints 10-30
Optimize Synthesis for Area, Not Speed 10-31
Optimize Source Code 10-32
Use a Larger Device 10-32
Timing Optimization Techniques (LUT-Based Devices) 10-32
Timing Optimization Advisor 10-32
Metastability Analysis and Optimization Techniques 10-32
I/O Timing Optimization 10-33
Improving Setup and Clock-to-Output Times Summary 10-34
Timing-Driven Compilation 10-35
Fast Input, Output, and Output Enable Registers 10-36
Programmable Delays 10-36
Use PLLs to Shift Clock Edges 10-39
Use Fast Regional Clock Networks and Regional Clocks Networks 10-39
Change How Hold Times are Optimized for MAX II Devices 10-40
Register-to-Register Timing Optimization Techniques (LUT-Based Devices) 10-40
Improving Register-to-Register Timing Summary 10-40
Physical Synthesis Optimizations 10-41
Turn Off Extra-Effort Power Optimization Settings 10-44
Optimize Synthesis for Speed, Not Area 10-44
Flatten the Hierarchy During Synthesis 10-45
Set the Synthesis Effort to High 10-45
Change State Machine Encoding 10-45
Duplicate Logic for Fan-Out Control 10-45
Prevent Shift Register Inference 10-46
Use Other Synthesis Options Available in Your Synthesis Tool 10-46
Fitter Seed 10-47
Set Maximum Router Timing Optimization Level 10-47
Enable Beneficial Skew Optimization 10-48
Optimize Source Code 10-48
LogicLock Assignments 10-49
Hierarchy Assignments 10-50
Path Assignments 10-50
Location Assignments and Back-Annotation 10-51
Custom Regions 10-52
Back-Annotation and Manual Placement 10-52
Optimizing Placement for Stratix, Stratix II, Arria GX, and Cyclone II Devices 10-54
Optimizing Placement for Cyclone Devices 10-54
Optimizing Placement for APEX II and APEX 20KE/C Devices 10-54
Resource Utilization Optimization Techniques (Macrocell-Based CPLDs) 10-55
Use Dedicated Inputs for Global Control Signals 10-55
Reserve Device Resources 10-56
Pin Assignment Guidelines and Procedures 10-56
Control Signal Pin Assignments 10-56
Output Enable Pin Assignments 10-56
Estimate Fan-In When Assigning Output Pins 10-57
Outputs Using Parallel Expander Pin Assignments 10-57
Resolving Resource Utilization Problems 10-58

Resolving Macrocell Usage Issues 10-58
Resolving Routing Issues 10-58
Using LCELL Buffers to Reduce Required Resources 10-59
Timing Optimization Techniques (Macrocell-Based CPLDs) 10-60
Improving Setup Time 10-61
Improving Clock-to-Output Time 10-61
Improving Propagation Delay (t_{PD}) 10-62
Improving Maximum Frequency (f_{MAX}) 10-63
Optimizing Source Code—Pipelining for Complex Register Logic 10-64
Compilation-Time Optimization Techniques 10-64
Incremental Compilation 10-64
Use Multiple Processors for Parallel Compilation 10-65
Reduce Synthesis Time and Synthesis Netlist Optimization Time 10-66
Synthesis Netlist Optimizations 10-67
Check Early Timing Estimation before Fitting 10-67
Reduce Placement Time 10-67
Fitter Effort Setting 10-67
Placement Effort Multiplier Settings 10-68
Final Placement Optimization Levels 10-68
Physical Synthesis Effort Settings 10-68
Limit to One Fitting Attempt 10-68
Preserving Placement, Incremental Compilation, and LogicLock Regions 10-69
Reduce Routing Time 10-69
Identify Routing Congestion in the Chip Planner 10-69
Identify Routing Congestion in the Timing Closure Floorplan for Legacy Devices 10-69
Placement Effort Multiplier Setting 10-70
Preserve Routing Incremental Compilation and LogicLock Regions 10-70
Setting Process Priority 10-70
Other Optimization Resources 10-70
Design Space Explorer 10-70
Other Optimization Advisors 10-71
Scripting Support 10-71
Initial Compilation Settings 10-71
Resource Utilization Optimization Techniques (LUT-Based Devices) 10-72
I/O Timing Optimization Techniques (LUT-Based Devices) 10-73
Register-to-Register Timing Optimization Techniques (LUT-Based Devices) 10-74
Duplicate Logic for Fan-Out Control 10-74
Conclusion 10-74
Referenced Documents 10-75
Document Revision History 10-76

Chapter 11. Power Optimization

Introduction 11-1
Power Dissipation 11-2
Design Space Explorer 11-3
Power-Driven Compilation 11-4
Power-Driven Synthesis 11-4
Power-Driven Fitter 11-8
Recommended Flow for Power-Driven Compilation 11-10
Area-Driven Synthesis 11-10
Gate-Level Register Retiming 11-11
Design Guidelines 11-12
Clock Power Management 11-12
LAB-Wide Clock Enable Example 11-13

Reducing Memory Power Consumption . . . 11-14
Memory Power Reduction Example . . . 11-16
Pipelining and Retiming . . . 11-17
Architectural Optimization . . . 11-18
I/O Power Guidelines . . . 11-19
Dynamically-Controlled On-Chip Terminations . . . 11-20
Power Optimization Advisor . . . 11-21
Power Optimization Advisor Example . . . 11-21
Conclusion . . . 11-24
Referenced Documents . . . 11-24
Document Revision History . . . 11-25

Chapter 12. Analyzing and Optimizing the Design Floorplan
Introduction . . . 12-1
Chip Planner Overview . . . 12-2
Starting the Chip Planner . . . 12-3
The Chip Planner Toolbar . . . 12-3
Chip Planner Tasks and Layers . . . 12-4
LogicLock Regions . . . 12-6
Creating LogicLock Regions . . . 12-7
Placing LogicLock Regions . . . 12-7
Placing Device Features into LogicLock Regions . . . 12-8
LogicLock Regions Window . . . 12-8
Hierarchical (Parent and Child) LogicLock Regions . . . 12-9
Reserved LogicLock Region . . . 12-10
Creating Non-Rectangular LogicLock Regions . . . 12-10
Examples of Non-Rectangular LogicLock Regions Using Reserved Property . . . 12-11
Example 1: Creating an L-Shaped Region . . . 12-11
Example 2: Region with Disjoint Areas . . . 12-13
Excluded Resources . . . 12-14
Additional Quartus II LogicLock Design Features . . . 12-15
Tooltips . . . 12-15
Show Critical Paths . . . 12-15
Analysis and Synthesis Resource Utilization by Entity . . . 12-15
Path-Based Assignments . . . 12-15
Quartus II Revisions Feature . . . 12-16
LogicLock Assignment Precedence . . . 12-16
Virtual Pins . . . 12-17
Using LogicLock Regions in the Chip Planner . . . 12-18
Assigning LogicLock Region Content . . . 12-18
Creating LogicLock Regions with the Chip Planner . . . 12-19
Viewing Connections Between LogicLock Regions in the Chip Planner . . . 12-19
Design Floorplan Analysis Using the Chip Planner . . . 12-19
Chip Planner Floorplan Views . . . 12-20
First-Level View . . . 12-20
Second-Level View . . . 12-21
Third-Level View . . . 12-21
Bird's Eye View . . . 12-22
Viewing Architecture-Specific Design Information . . . 12-24
Viewing Available Clock Networks in the Device . . . 12-24
Viewing Critical Paths . . . 12-26
Viewing Physical Timing Estimates . . . 12-27
Viewing Routing Congestion . . . 12-29
Viewing I/O Banks . . . 12-30

Generating Fan-In and Fan-Out Connections 12-31
Generating Immediate Fan-In and Fan-Out Connections 12-32
Highlight Routing 12-33
Show Delays 12-34
Exploring Paths in the Chip Planner 12-35
Locate Path from the Timing Analysis Report to the Chip Planner 12-35
Analyzing Connections for a Path 12-36
Viewing Assignments in the Chip Planner 12-37
Viewing Routing Channels for a Path in the Chip Planner 12-37
Cell Delay Table 12-38
Viewing High-Speed and Low Power Tiles in Stratix III Devices in the Chip Planner 12-39
Design Analysis Using the Timing Closure Floorplan 12-40
Timing Closure Floorplan Views 12-41
Field View 12-42
Other Views 12-42
Viewing Assignments 12-42
Viewing Critical Paths 12-43
Physical Timing Estimates 12-46
Viewing Routing Congestion 12-47
Timing Closure Floorplan View 12-48
LogicLock Regions in the Timing Closure Floorplan 12-49
Creating LogicLock Regions in the Timing Closure Floorplan Editor 12-49
Using Drag and Drop to Place Logic 12-50
Rubber Banding 12-50
Show Connection Count 12-50
Analyzing LogicLock Region Connectivity Using the Timing Closure Floorplan 12-50
Using LogicLock Methodology for Older Device Families 12-52
The Quartus II LogicLock Methodology 12-52
Improving Design Performance 12-53
LogicLock Restrictions 12-53
Preserving Timing Results Using the LogicLock Flow 12-54
Back-Annotating Routing Information 12-55
Back-Annotating LogicLock Regions 12-56
Scripting Support 12-57
Initializing and Uninitializing a LogicLock Region 12-57
Creating or Modifying LogicLock Regions 12-57
Obtaining LogicLock Region Properties 12-58
Assigning LogicLock Region Content 12-58
Prevent Further Netlist Optimization 12-58
Save a Node-Level Netlist for the Entire Design into a Persistent Source File 12-58
Setting LogicLock Assignment Priority 12-59
Assigning Virtual Pins 12-59
Back-Annotating LogicLock Regions 12-59
Conclusion 12-59
Referenced Documents 12-60
Document Revision History 12-60

Chapter 13. Netlist Optimizations and Physical Synthesis

Introduction 13-1
WYSIWYG Primitive Resynthesis 13-1
Performing Physical Synthesis Optimizations 13-3
Automatic Asynchronous Signal Pipelining 13-5
Physical Synthesis for Combinational Logic 13-6
Physical Synthesis for Registers—Register Duplication 13-7

Physical Synthesis for Registers—Register Retiming 13-8
Preserving Your Physical Synthesis Results 13-10
Physical Synthesis Options for Fitting 13-11
Applying Netlist Optimization Options 13-12
Scripting Support 13-12
Synthesis Netlist Optimizations 13-13
Physical Synthesis Optimizations 13-13
Incremental Compilation 13-14
Back-Annotating Assignments 13-14
Conclusion 13-14
Referenced Documents 13-15
Document Revision History 13-15

Chapter 14. Design Space Explorer

Introduction 14-1
DSE Concepts 14-1
Exploration Space and Exploration Point 14-1
Seed and Seed Sweeping 14-1
DSE Exploration 14-2
General Description 14-2
Timing Analyzer Support 14-3
DSE Flow 14-3
DSE Support for Altera Device Families 14-4
DSE Project Settings 14-4
Setting Up the DSE Work Environment 14-5
Specifying the Revision 14-5
Setting the Initial Seed 14-5
Project Uses Quartus II Integrated Synthesis 14-5
Restructuring LogicLock Regions 14-5
Exploration Settings 14-5
Using DSE to Search for the Best Performance 14-6
Effort Level 14-6
Seed Sweep 14-6
Extra Effort Space 14-7
Physical Synthesis Space 14-7
Physical Synthesis with Retiming Space 14-7
Selective Performance Optimization 14-7
DSE Flow Options 14-8
Create a Revision from the DSE Point 14-8
Stop Flow When Zero Failing Paths are Achieved 14-8
Continue Exploration Even If Base Compilation Fails 14-8
Run Quartus II PowerPlay Power Analyzer During Exploration 14-9
Archive All Compilations 14-9
Stop Flow After Time 14-9
Skip Base Analysis and Compilation If Possible 14-9
DSE Configuration File 14-9
Parallel DSE Information 14-10
Computer Load Sharing Using Parallel DSE 14-10
Parallel DSE Using LSF Resources 14-10
Parallel DSE Using a Quartus II Master Process 14-10
Concurrent Local Compilations 14-11
Referenced Documents 14-12
Document Revision History 14-12

Section IV. Engineering Change Management

Chapter 15. Engineering Change Management with the Chip Planner

Introduction . . . 15-1
Engineering Change Orders . . . 15-2
Performance . . . 15-2

Chapter Revision Dates

The chapters in this book, *Quartus II Handbook Version 9.0 Volume 2: Design Implementation and Optimization*, were revised on the following dates. Where chapters or groups of chapters are available separately, part numbers are listed.

Chapter 1 Assignment Editor
Revised: *March 2009*
Part Number: *QII52001-9.0.0*

Chapter 2 Command-Line Scripting
Revised: *March 2009*
Part Number: *QII52002-9.0.0*

Chapter 3 Tcl Scripting
Revised: *March 2009*
Part Number: *QII52003-9.0.0*

Chapter 4 Managing Quartus II Projects
Revised: *March 2009*
Part Number: *QII52012-9.0.0*

Chapter 5 I/O Management
Revised: *March 2009*
Part Number: *QII52013-9.0.0*

Chapter 6 Simultaneous Switching Noise (SSN) Analysis and Optimizations
Revised: *March 2009*
Part Number: *QII52018-9.0.0*

Chapter 7 Signal Integrity Analysis with Third-Party Tools
Revised: *March 2009*
Part Number: *QII53020-9.0.0*

Chapter 8 Mentor Graphics PCB Design Tools Support
Revised: *March 2009*
Part Number: *QII52015-9.0.0*

Chapter 9 Cadence PCB Design Tools Support
Revised: *March 2009*
Part Number: *QII52014-9.0.0*

Chapter 10 Area and Timing Optimization
Revised: *March 2009*
Part Number: *QII52005-9.0.0*

Chapter 11 Power Optimization
Revised: *March 2009*
Part Number: *QII52016-9.0.0*

Chapter 12 Analyzing and Optimizing the Design Floorplan
Revised: *March 2009*
Part Number: *QII52006-9.0.0*

Chapter 13 Netlist Optimizations and Physical Synthesis
Revised: *March 2009*
Part Number: *QII52007-9.0.0*

Chapter 14 Design Space Explorer
Revised: *March 2009*
Part Number: *QII52008-9.0.0*

Chapter 15 Engineering Change Management with the Chip Planner
Revised: *March 2009*
Part Number: *QII52017-9.0.0*

Section I. Scripting and Constraint Entry

As a result of the increasing complexity of today's FPGA designs and the demand for higher performance, designers must make a large number of complex timing and logic constraints to meet their performance requirements. Once you have created a project and your design, you can use the Quartus® II software Assignment Editor and other GUI features to specify your initial design constraints, such as pin assignments, device options, logic options, and timing constraints.

This section describes how to enter constraints in the Quartus II software, how to take advantage of Quartus II modular executables, how to develop and run Tcl scripts to perform a wide range of functions, and how to manage the Quartus II project for your design.

This section includes the following chapters:

- Chapter 1, Assignment Editor
- Chapter 2, Command-Line Scripting
- Chapter 3, Tcl Scripting
- Chapter 4, Managing Quartus II Projects

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

1. Assignment Editor

QII52001-9.0.0

Introduction

The complexity of today's FPGA designs is compounded by the increasing density and associated pin counts of current FPGAs. It requires you to make a large number of pin assignments that include the pin locations and I/O standards to successfully implement a complex design in the latest generation of FPGAs.

To facilitate the process of entering these assignments, Altera has developed an intuitive, spreadsheet interface called the Assignment Editor (sometimes referred to as the editor in this chapter). The Assignment Editor is designed to make the process of creating, changing, and managing a large number of assignments as easy as possible.

This chapter discusses the following topics:

- "Overview of the Assignment Editor"
- "User Interface" on page 1–3
- "Navigating the Assignment Editor Spreadsheet" on page 1–5
- "Exporting and Importing Assignments" on page 1–7
- "Creating Timing Constraints Using the Assignment Editor" on page 1–9
- "Tcl Interface" on page 1–10
- "Probing to Source Design Files and Other Quartus II Windows" on page 1–10

Overview of the Assignment Editor

You can use the Assignment Editor throughout the design cycle, for making either timing or logic assignments. Altera recommends making assignments using the Assignment Editor to help reduce mistakes while making assignments throughout the design cycle. With the editor's dynamic syntax-checking capability, illegal assignments or incorrect settings can be avoided. You can also use the Assignment Editor to view, filter, and sort assignments based on node name or assignment type.

Even though the Assignment Editor allows you to make pin assignments, Altera recommends using the Pin Planner instead. You can use the Assignment Editor to view and verify the pin assignments that you have made.

The Assignment Editor is a resizable window. This scalability makes it easy to view or edit your assignments right next to your design files. To open the Assignment Editor, click the Assignment Editor icon in the toolbar, or on the Assignments menu, click **Assignment Editor**.

You can also launch the Assignment Editor by pressing **Ctrl**+**Shift**+**A** in the Quartus® II software.

The assignments made in the Assignment Editor are saved in the Quartus II Settings File (**.qsf**), which is located in the project directory. A separate **.qsf** file exists for each individual revision. Every new assignment is placed on a new line at the end of the **.qsf** file. Refer to the Quartus II Help for the syntax of the **.qsf** file. Refer to the "Viewing and Saving Assignments in the Assignment Editor" section for more details about how Assignment Editor handles your assignments.

Every time an assignment is created or updated, the Quartus II software displays the equivalent Tcl command in the **System** tab of the Messages window. You can use the displayed messages as references when making assignments using Tcl commands.

For information about exporting your assignments to a Tcl file, refer to "Tcl Interface" on page 1–10.

Dynamic Syntax Checking

As you enter assignments, the Assignment Editor checks for basic legality and syntax. This checking is not as thorough as the checks performed during compilation, but it rejects incorrect settings.

If there are incomplete assignments when you click **Save** on the File menu, a prompt gives you the choice to either save the file and lose incomplete assignments or cancel the save operation.

The legality status of the assignments is color coded. The color of the text in each row indicates if the assignment is incomplete, disabled, non-editable, or contains errors or warnings (Table 1–1). To customize the colors used in the Assignment Editor, on the Tools menu, click **Options**.

Table 1–1. Description of the Color Codes in the Spreadsheet

Text Color	Description
Green	A new assignment can be created
Dark Yellow	The assignment contains warnings, such as unknown node name
Dark Red	The assignment is incomplete
Red	The assignment has an error, such as an illegal value
Light Gray	The assignment is disabled or turned off
Gray	The assignment is non-editable or read-only

Viewing and Saving Assignments in the Assignment Editor

Although the Assignment Editor is the most common method of entering and modifying assignments, there are other methods you can use to make and edit assignments. For this reason, you can refresh the Assignment Editor after you add, remove, or change an assignment outside the Assignment Editor.

By default, all assignments made in the Quartus II software are first stored in memory, then to the **.qsf** file on the disk after you start a processing task, or if you save or close your project. Saving assignments to memory avoids reading and writing to your disk drive and improves the performance of the software.

After making assignments in the Assignment Editor, on the File menu, click **Save** to save your assignments and update the **.qsf** file.

© March 2009 Altera Corporation

Starting with the Quartus II software version 5.1, you can force all assignments to be written to a disk drive. On the Tools menu, click **Options**. In the **Options** dialog box, open the **Processing** page and turn off **Update assignments to disk during design processing only**.

For more information about how the Quartus II software writes to the **.qsf** file, refer to the *Managing Quartus II Projects* chapter in volume 2 of the *Quartus II Handbook*.

You can refresh the Assignment Editor window by clicking **Refresh** on the View menu. If you make an assignment using the Tcl console, Pin Planner, or directly modifying the **.qsf** file outside the Assignment Editor, you must click **Refresh** to update the Assignment Editor spreadsheet.

If the **.qsf** file is edited while the project is open, on the File menu, click **Save Project** to ensure that you are editing the latest **.qsf** file.

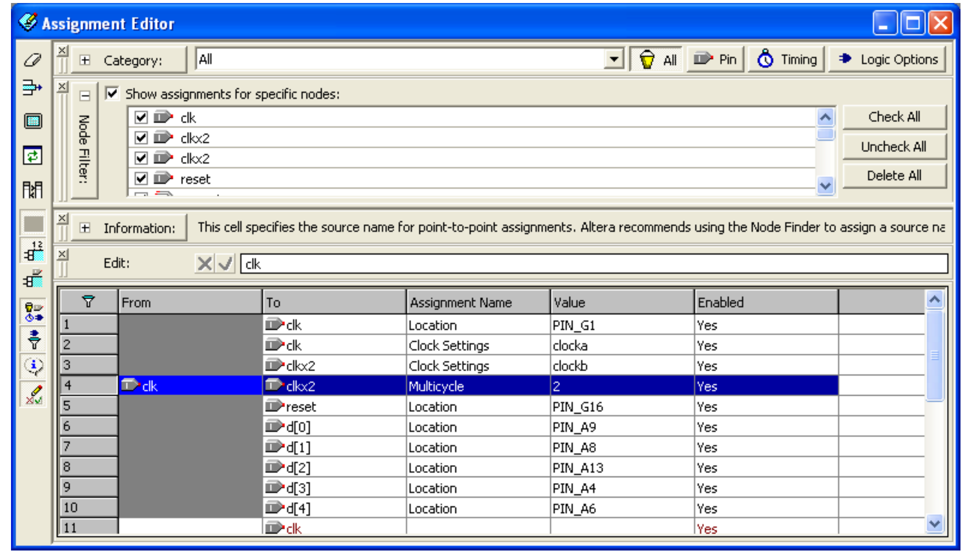
Each time the Assignment Editor is refreshed, the following message is displayed in the **System** tab of the Messages window:

```
Info: Assignments reloaded -- assignments updated outside Assignment
Editor
```

User Interface

The Assignment Editor window consists of four bars and a spreadsheet (Figure 1–1). The spreadsheet is where you view and edit the assignments. You can use the bars to filter, edit, or get detailed information about the assignments.

Figure 1–1. The Assignment Editor Window



You can hide all four bars in the View menu if desired, or you can collapse all the bars for a better view of the spreadsheet. Table 1–2 provides a brief description of each bar.

Table 1–2. Assignment Editor Bar Descriptions

Bar Name	Description
Category	Lists the types of available assignments
Node Filter	Lists a selection of design nodes to be viewed or assigned
Information	Displays a description of the selected assignment
Edit	Allows you to edit the text in the selected cell(s)

Category Bar

The **Category** bar lists all assignment categories available for the selected device. You can use the **Category** bar to select a particular type of assignment and filter out all other assignments, making the spreadsheet show only the applicable assignments. For example, to view all t_{SU} (setup time) assignments in your project, select **tsu** in the **Category** list. If you select **All** in the **Category** list, the Assignment Editor displays all assignments.

When you collapse the **Category** bar, three buttons are displayed that allow you to select from various preset categories (Figure 1–2). For example, clicking the **Timing** button changes the spreadsheet to show only the timing-related assignments of your project.

Figure 1–2. Collapsed Category Bar

Node Filter Bar

The **Node Filter** bar is used when you want the spreadsheet to show only assignments for specific nodes based on the list of selected node filters. The bar provides flexibility in how you view and make your settings.

For example, when **Show assignments for specific nodes** is turned on, the spreadsheet shows only assignments for nodes that match the selected node filter. You can create a new node filter by using the Node Finder to select a node name or by typing the node name. The node name filter can be a node name or assignment group, and can include wildcard symbols (* and ?). The wildcards symbols are used to filter for a selection of nodes with only one entry in the Node Filter. For more information about wildcard symbols and assignment groups, refer to "Navigating the Assignment Editor Spreadsheet" on page 1–5.

Information Bar

The **Information** bar provides a brief description of the currently selected cell and what information you should enter into the cell. For example, the **Information** bar describes whether a cell should contain a node name or a number value.

Edit Bar

The **Edit** bar is an efficient way to enter a value into one or more spreadsheet cells. To change the contents of multiple cells at the same time, select the cells in the spreadsheet, then type or choose the new value in the **Edit** field in the **Edit** bar.

© March 2009 Altera Corporation

Assignment Spreadsheet

The spreadsheet displays the assignments of your project. You can sort columns, use pull-down list boxes to view available options, and copy and paste multiple cells into the Assignment Editor. Refer to "Entering Values into the Spreadsheet" for details about ways to make assignments in the spreadsheet.

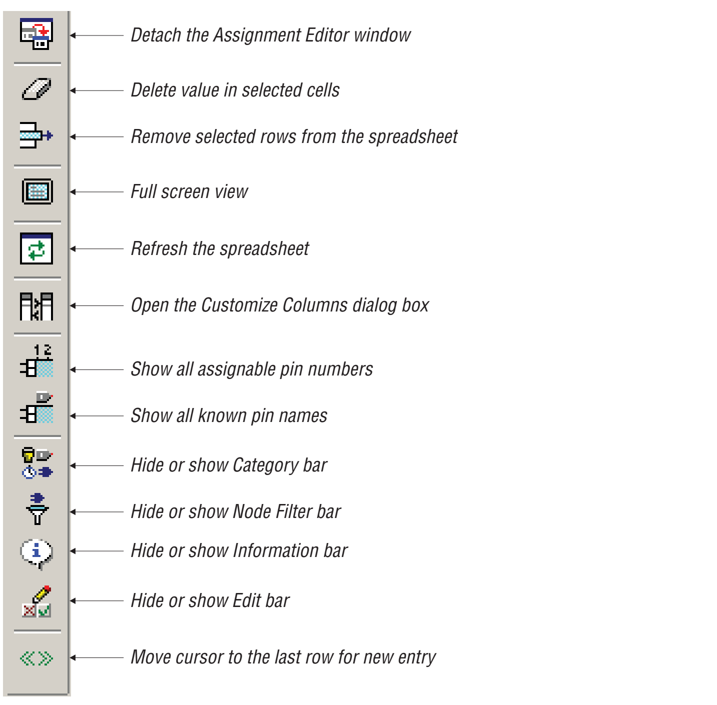
When you enter an assignment, the font color of the row changes to indicate the status of the assignment. For more information, refer to "Dynamic Syntax Checking" on page 1–2.

The spreadsheet also supports customizable columns that allow you to show, hide, and arrange columns. For more information, refer to "Customizing the Spreadsheet Columns" on page 1–7.

Toolbar

The Assignment Editor's toolbar contains shortcut buttons for easy access to the editor's features. Figure 1–3 describes the buttons in the toolbar.

Figure 1–3. Description of Icons in the Toolbar



Navigating the Assignment Editor Spreadsheet

This section describes methods for navigating through the spreadsheet.

Entering Values into the Spreadsheet

There are many ways to select or enter nodes into the spreadsheet, including the Node Finder, the Node Filter bar, the Edit bar, or by directly typing the node name into a cell in the spreadsheet.

To open the Node Finder, click **Node Finder** in the Edit menu, or right-click any cell in the spreadsheet or the Node Filter bar and click **Node Finder**. Alternatively, you can click **Node Finder** in the pull-down menu of the **To** and **From** columns in the spreadsheet.

A node type icon is shown beside each node name and filter to identify its type. Table 1–3 lists the different ions and describes its type.

Table 1–3. Node Type Icons

Node Type Icon	Description
a[0] a	Input pin
result[0] result	Output pin
taps_bidir taps_bidir	Bidirectional pin
taps:inst|xn[0] taps:inst|xn	Register
taps:inst|xn[1] taps:inst|xn	Combinational logic
Asg_1	Assignment group
d*	Node name or filter that contains wildcard symbols
taps:inst	Instance
ae	Missing information—probably caused by incorrect node name, or Analysis and Synthesis has not been performed

Wildcards

To simplify the tasks of making many node assignments, the Quartus II software accepts the `*` and `?` wildcard characters. Use these wildcard characters to reduce the number of individual assignments you need to make for your design.

The `*` wildcard character matches any string. For example, given an assignment made to a node specified as `reg*`, the Assignment Editor applies the assignment to all design nodes that match the prefix `reg` with none, one, or several characters following the prefix, such as `reg`, `reg1`, `reg[2]`, `regbank`, and `reg12bank`.

The `?` wildcard character matches any single character. For example, given an assignment made to a node specified as `reg?`, the Assignment Editor applies the assignment to all design nodes that match the prefix `reg` and any single character following, such as `reg1`, `rega`, and `reg4`.

All assignments that support wildcards are shown in the pull-down list under the **Assignment Name** column of the Assignment Editor with "(Accepts wildcards/groups)" displayed beside it.

Assignment Groups

An assignment group, also known as a time group, is a collection of design nodes grouped together and represented as a single unit for the purpose of making assignments to the collection. Using assignment groups with the Assignment Editor provides the flexibility required for making complex assignments to a large number of nodes. You can also exclude specific nodes, wildcards, and assignments from an assignment group.

To create an assignment group, on the Assignments menu, click **Assignment (Time) Groups**. The **Assignment Groups** dialog box appears. You can add or delete members of each assignment group using wildcards in the Node Finder.

For more information about using Assignment Groups for timing analysis, refer to the *Quartus II Classic Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Customizing the Spreadsheet Columns

To provide more control over the display of information in the spreadsheet, the Assignment Editor supports customizable columns.

You can move columns, sort them in ascending or descending order, show or hide individual columns, and align the content of the column left, center, or right for improved readability.

When the Quartus II software starts for the first time, you see a pre-selected set of columns. For example, when the Quartus II software is first started, the Comment column is hidden. To show or hide any of the available columns, on the View menu, click **Customize Columns**. When you restart the Quartus II software, your column settings are maintained.

You can use the **Comments** column to document the purpose of an assignment, or to explain why you applied a timing or logic constraint. You can use the **Enabled** column to disable any assignment without deleting it. This feature is useful when performing multiple compilations with different timing constraints or logic optimizations.

Exporting and Importing Assignments

Designs that use the LogicLock™ hierarchical design methodology use the **Import Assignments** command to import assignments into the current project. You can also use the **Export Assignments** command to save all the assignments in your project to a file to be used for archiving or to transfer assignments from one project to another.

On the Assignments menu, click **Export Assignments** or **Import Assignments** to do the following:

- Export your Quartus II assignments to a **.qsf** file.

- Import assignments from a Quartus II Entity Settings File (**.esf**), a MAX+PLUS® II Assignment and Configuration File (**.acf**), a Synopsys Design Constraint (**.sdc**) file, a text file (**.txt**), or a Comma Separated Value (**.csv**) file.

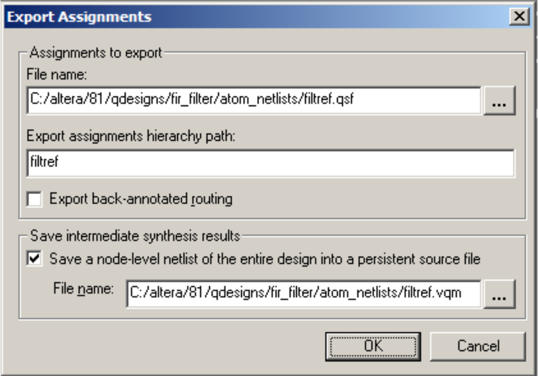
In addition to the **Export Assignments** and **Import Assignments** dialog boxes, the **Export** command on the File menu allows you to export your assignments to a **.tcl** file or a **.csv** file.

You can use these file formats for many different aspects of your project. For example, you can use a **.csv** file for documentation purposes or to transfer pin-related information to board layout tools. The **.tcl** file makes it easy to apply assignments in a scripted design flow. The LogicLock design flow uses the **.qsf** file to transfer your LogicLock region settings.

Exporting Assignments

You can use the **Export Assignments** dialog box to export your Quartus II software assignments into a **.qsf** file, generate a node-level netlist file, and export back-annotated routing information as a Routing Constraints File (**.rcf**). See Figure 1–4.

Figure 1–4. Export Assignments Dialog Box



On the Assignments menu, click **Export Assignments** to open the **Export Assignments** dialog box. The LogicLock design flow also uses this dialog box to export LogicLock regions.

For more information about using the **Export Assignments** dialog box to export LogicLock regions, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

On the File menu, click **Export** to export all assignments to a **.tcl** file or export a set of assignments to a **.csv** file. When you export assignments to a **.tcl** file, only user-created assignments are written to the Tcl script file; default assignments are not exported.

When assignments are exported to a **.csv** file, only the assignments displayed in the current view of the Assignment Editor are exported.

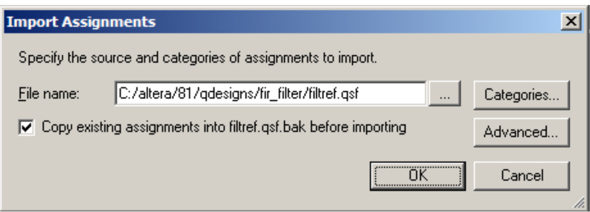
Importing Assignments

The **Import Assignments** dialog box allows you to import Quartus II assignments from a **.qsf** file, an **.esf** file, an **.acf** file, or a **.csv** file (Figure 1–5).

To import assignments from any of the supported assignment files, perform the following steps:

1. On the Assignments menu, click **Import Assignments**. The **Import Assignments** dialog box appears (Figure 1–5).

Figure 1–5. Import Assignments Dialog Box



2. In the **File name** text-entry box, type the file name or browse to the assignment file. The **Select File** dialog box appears.
3. In the **Select File** dialog box, select the file and click **Open**.
4. Click **OK**.

When you import a **.csv** file, the first uncommented row of the file must be in the exact format as it was when exported.

You can create a backup copy of your assignments before importing new assignments by turning on the **Copy existing assignments into <*revision name*>.qsf.bak before importing** option.

When importing assignments from a file, you can choose which assignment categories to import by following these steps:

1. Click **Categories** in the **Import Assignments** dialog box.
2. Turn on the categories you want to import from the **Assignment categories** list.

To select specific types of assignments to import, click **Advanced** in the **Import Assignments** dialog box. The **Advanced Import Settings** dialog box appears. You can choose to import instance, entity, or global assignments and select various assignment types to import.

For more information about these options, refer to the Quartus II Help.

Creating Timing Constraints Using the Assignment Editor

Accurate timing constraints guide the place-and-route engine in the Quartus II software to help optimize your design into the FPGA. After completing a place-and-route, perform a static timing analysis using the Quartus II Classic Timing Analyzer or the Quartus II TimeQuest Timing Analyzer to analyze slack and critical paths in your design.

If you are using the Quartus II Classic Timing Analyzer, create timing constraints using the Assignment Editor. In the Assignment Editor, select **Timing** in the **Category** list to show all timing-related settings and make the desired timing assignments in the editor's spreadsheet.

For more information about the Quartus II Classic Timing Analyzer, refer to the *Quartus II Classic Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

If you are using the Quartus II TimeQuest Timing Analyzer, the TimeQuest Timing Analyzer uses timing assignments from a Synopsys Design Constraint (**.sdc**) file. Therefore, you must convert assignments from the **.qsf** format to the **.sdc** format before you can proceed with the timing analysis.

For information about converting the timing assignments in your **.qsf** file to an **.sdc** file, refer to the *Switching to the Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Tcl Interface

Whether you use the Assignment Editor or another feature to create your design assignments, you can export them to a Tcl (**.tcl)** file. You can then use the **.tcl** file to reapply the settings or to archive your assignments. On the File menu, click **Export** to export your saved assignments to a **.tcl** file.

You can also generate a **.tcl** file that sets up your project and applies all the assignments to it. On the Project menu, click **Generate Tcl File for Project** to generate the file.

In addition, as you use the Assignment Editor to enter assignments, the equivalent Tcl commands are shown in the **System** tab of the Messages window. You can reference these Tcl commands to create a customized **.tcl** file. To copy a Tcl command from the **System** tab of the Messages window, right-click the message and click **Copy**.

For more information about Tcl scripting with the Quartus II software, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook.*

Probing to Source Design Files and Other Quartus II Windows

The Assignment Editor lets you cross-probe from the viewer to the source design file and to other windows within the Quartus II software. You can select a cell in the Assignment Editor spreadsheet and locate the corresponding item in another applicable Quartus II software window. To locate an item from the editor in another window, right-click the items of interest in the spreadsheet, point to **Locate**, and click the appropriate command. The following commands are available:

- Assignment Editor
- Pin Planner
- Timing Closure Floorplan
- Chip Planner (Floorplan & Chip Editor)
- Resource Property Editor

- Technology Map Viewer
- RTL Viewer
- Design File

Probing to the Assignment Editor from Other Quartus II Windows

You can cross-probe to the Assignment Editor from other windows within the Quartus II software. You can select one or more nodes or nets in another window and locate them in the Assignment Editor spreadsheet. This is useful when you want to see all assignments related to specific nodes.

You can locate nodes in the Assignment Editor from all windows within the Quartus II software. To locate assignments related to an element in the editor from other Quartus II windows, select the node or nodes in the appropriate window. For example, select an entity in the **Entity** list on the **Hierarchy** tab in the Project Navigator, or select nodes in the Timing Closure Floorplan. Next, right-click the selected object, point to **Locate**, and click **Locate in Assignment Editor**. The Assignment Editor opens, or it is brought to the foreground if it is already open.

Conclusion

As FPGAs continue to increase in density and pin count, it is essential to be able to quickly create and view design assignments. The Assignment Editor provides an intuitive and effective way of making assignments. With the spreadsheet interface and the **Category**, **Node Filter**, **Information**, and **Edit** bars, the Assignment Editor provides an efficient assignment entry solution for FPGA designers.

Document Revision History

Table 1–4 shows the revision history for this chapter.

Table 1–4. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0	■ Revised and reorganized the entire chapter. ■ Added section "Probing to Source Design Files and Other Quartus II Windows" on page 1–10. ■ Added description of node type icons (Table 1–3). ■ Added explanation of wildcard characters.	Updated for the Quartus II software version 9.0 release.
November 2008 v8.1	Changed to 8½" × 11" page size. No change to content.	Updated for the Quartus II software version 8.1.
May 2008 v8.0	Updated Quartus II software 8.0 revision and date.	Updated references.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

2. Command-Line Scripting

QII52002-9.0.0

Introduction

FPGA design software that easily integrates into your design flow saves time and improves productivity. The Altera® Quartus® II software provides you with a command-line executable for each step of the FPGA design flow to make the design process customizable and flexible.

The benefits provided by command-line executables include:

- Command-line control over each step of the design flow
- Easy integration with scripted design flows including makefiles
- Reduced memory requirements
- Improved performance

The command-line executables are also completely compatible with the Quartus II GUI, allowing you to use the exact combination of tools that you prefer.

This chapter describes how to take advantage of Quartus II command-line executables, and provides several examples of scripts that automate different segments of the FPGA design flow, including the following topics:

- "The Benefits of Command-Line Executables"
- "Introductory Example" on page 2–2
- "Command-Line Executables" on page 2–3
- "Design Flow" on page 2–9
- "The MegaWizard Plug-In Manager" on page 2–13
- "Command-Line Scripting Examples" on page 2–19

The Benefits of Command-Line Executables

The Quartus II command-line executables provide command-line control over each step of the design flow. Each executable includes options to control commonly used software settings. Each executable also provides detailed, built-in help describing its function, available options, and settings.

Command-line executables allow for easy integration with scripted design flows. You can easily create scripts in any language with a series of commands. These scripts can be batch-processed, allowing for integration with distributed computing in server farms. You can also integrate the Quartus II command-line executables in makefile-based design flows. All of these features enhance the ease of integration between the Quartus II software and other EDA synthesis, simulation, and verification software.

Command-line executables add integration and scripting flexibility without sacrificing the ease-of-use of the Quartus II GUI. You can use the Quartus II GUI and command-line executables at different stages in the design flow. For example, you might use the Quartus II GUI to edit the floorplan for the design, use the command-line executables to perform place-and-route, and return to the Quartus II GUI to perform debugging with the Chip Editor.

Command-line executables reduce the amount of memory required during each step in the design flow. Because each executable targets only one step in the design flow, it is relatively compact, both in file size and the amount of memory used when running. This memory reduction improves performance, and is particularly beneficial in design environments where computer networks or workstations are heavily used with reduced memory.

Introductory Example

The following introduction to design flow with command-line executables shows how to create a project, fit the design, perform timing analysis, and generate programming files.

The tutorial design included with the Quartus II software is used to demonstrate this functionality. If installed, the tutorial design is found in the <*Quartus II directory*>**/qdesigns/fir_filter** directory.

Before making changes, copy the tutorial directory and type the four commands shown in Example 2–1 at a command prompt in the new project directory:

The <*Quartus II directory*>**/quartus/bin** directory must be in your `PATH` environment variable.

Example 2–1. Introductory Example

```
quartus_map filtref --source=filtref.bdf --family=CYCLONE ↵
quartus_fit filtref --part=EP1C12F256C6 --fmax=80MHz --tsu=8ns ↵
quartus_asm filtref ↵
quartus_tan filtref ↵
```

The `quartus_map filtref --source=filtref.bdf --family=CYCLONE` command creates a new Quartus II project called **filtref** with the **filtref.bdf** file as the top-level file. It targets the Cyclone® device family and performs logic synthesis and technology mapping on the design files.

The `quartus_fit filtref --part=EP1C12Q240C6 --fmax=80MHz --tsu=8ns` command performs fitting on the **filtref** project. This command specifies an EP1C12Q240C6 device and the Fitter attempts to meet a global f_{MAX} requirement of 80 MHz and a global t_{SU} requirement of 8 ns.

The `quartus_asm filtref` command creates programming files for the **filtref** project.

The `quartus_tan filtref` command performs timing analysis on the **filtref** project to determine whether the design meets the timing requirements that were specified to the `quartus_fit` executable.

You can put the four commands from Example 2–1 into a batch file or script file, and run them. For example, you can create a simple UNIX shell script called **compile.sh**, which includes the code shown in Example 2–2.

Example 2–2. UNIX Shell Script: compile.sh

```
#!/bin/sh
PROJECT=filtref
TOP_LEVEL_FILE=filtref.bdf
FAMILY=Cyclone
PART=EP1C12F256C6
FMAX=80MHz
--TSU=8ns
quartus_map $PROJECT --source=$TOP_LEVEL_FILE --family=$FAMILY
quartus_fit $PROJECT --part=$PART --fmax=$FMAX --tsu=$TSU
quartus_asm $PROJECT
quartus_tan $PROJECT
```

Edit the script as necessary and compile your project.

Command-Line Executables

Table 2–1 lists the command-line executables and their respective descriptions.

Table 2–1. Quartus II Command-Line Executables and Descriptions (Part 1 of 3)

Executable	Description
Analysis and Synthesis `quartus_map`	Quartus II Analysis and Synthesis builds a single project database that integrates all the design files in a design entity or project hierarchy, performs logic synthesis to minimize the logic of the design, and performs technology mapping to implement the design logic using device resources such as logic elements.
Fitter `quartus_fit`	The Quartus II Fitter performs place-and-route by fitting the logic of a design into a device. The Fitter selects appropriate interconnection paths, pin assignments, and logic cell assignments. Quartus II Analysis and Synthesis must be run successfully before running the Fitter.
Assembler `quartus_asm`	The Quartus II Assembler generates a device programming image, in the form of one or more of the following from a successful fit (that is, place-and-route). ■ Programmer Object Files (**.pof**) ■ SRAM Object Files (**.sof**) ■ Hexadecimal (Intel-Format) Output Files (**.hexout**) ■ Tabular Text Files (**.ttf**) ■ Raw Binary Files (**.rbf**) The **.pof** and **.sof** files are then processed by the Quartus II Programmer and downloaded to the device with the MasterBlaster™ or the ByteBlaster™ II download cable, or the Altera Programming Unit (APU). The Hexadecimal (Intel-Format) Output Files, Tabular Text Files, and Raw Binary Files can be used by other programming hardware manufacturers that provide support for Altera devices. The Quartus II Fitter must be run successfully before running the Assembler.

Table 2–1. Quartus II Command-Line Executables and Descriptions (Part 2 of 3)

Executable	Description
Classic Timing Analyzer `quartus_tan`	The Quartus II Classic Timing Analyzer computes delays for the given design and device, and annotates them on the netlist. Then, the Classic Timing Analyzer performs timing analysis, allowing you to analyze the performance of all logic in your design. The `quartus_tan` executable includes Tcl support. Quartus II Analysis and Synthesis or the Fitter must be run successfully before running the Classic Timing Analyzer.
TimeQuest Timing Analyzer `quartus_sta`	The Quartus II TimeQuest Timing Analyzer computes delays for the given design and device, and annotates them on the netlist. Next, the TimeQuest Timing Analyzer performs timing analysis, allowing you to analyze the performance of all logic in your design. The `quartus_sta` executable includes Tcl support and SDC support. Quartus II Analysis and Synthesis or the Fitter must be run successfully before running the TimeQuest Timing Analyzer.
Design Assistant `quartus_drc`	The Quartus II Design Assistant checks the reliability of a design based on a set of design rules. The Design Assistant is especially useful for checking the reliability of a design before converting the design for HardCopy® devices. The Design Assistant supports designs that target any Altera device supported by the Quartus II software, except MAX® 3000 and MAX 7000 devices. Quartus II Analysis and Synthesis or the Fitter must be run successfully before running the Design Assistant.
Compiler Database Interface `quartus_cdb`	The Quartus II Compiler Database Interface generates incremental netlists for use with LogicLock™ back-annotation, or back-annotates device and resource assignments to preserve the fit for future compilations. The `quartus_cdb` executable includes Tcl support. Analysis and Synthesis must be run successfully before running the Compiler Database Interface.
EDA Netlist Writer `quartus_eda`	The Quartus II EDA Netlist Writer generates netlist and other output files for use with other EDA tools. Analysis and Synthesis, the Fitter, or Timing Analyzer must be run successfully before running the EDA Netlist Writer, depending on the arguments used.
Simulator `quartus_sim`	The Quartus II Simulator tests and debugs the logical operation and internal timing of the design entities in a project. The Simulator can perform two types of simulation: functional simulation and timing simulation. The `quartus_sim` executable includes Tcl support. Quartus II Analysis and Synthesis must be run successfully before running a functional simulation. The Timing Analyzer must be run successfully before running a timing simulation.
Power Analyzer `quartus_pow`	The Quartus II PowerPlay Power Analyzer estimates the thermal dynamic power and the thermal static power consumed by the design. For newer families such as Stratix® II and MAX II, the power drawn from each power supply is also estimated. Quartus II Analysis and Synthesis or the Fitter must be run successfully before running the PowerPlay Power Analyzer.

Table 2–1. Quartus II Command-Line Executables and Descriptions (Part 3 of 3)

Executable	Description
Programmer `quartus_pgm`	The Quartus II Programmer programs Altera devices. The Programmer uses one of the supported file formats: ■ **.pof** file ■ **.sof** file ■ Jam File (**.jam**) ■ Jam Byte-Code File (**.jbc**) Make sure you specify a valid programming mode, programming cable, and operation for a specified device.
Convert Programming File `quartus_cpf`	The Quartus II Convert Programming File module converts one programing file format to a different possible format. Make sure you specify valid options and an input programming file to generate the new requested programming file format.
Quartus Shell `quartus_sh`	The Quartus II Shell acts as a simple Quartus II Tcl interpreter. The Shell has a smaller memory footprint than the other command-line executables that support Tcl. The Shell may be started as an interactive Tcl interpreter (shell), used to run a Tcl script, or used as a quick Tcl command evaluator, evaluating the remaining command-line arguments as one or more Tcl commands.
TimeQuest Timing Analyzer GUI `quartus_staw`	This executable opens the Quartus II TimeQuest Timing Analyzer GUI. This is helpful because you don't have to open the entire Quartus II GUI for certain operations.
Programmer GUI `quartus_pgmw`	This executable opens up the programmer—a GUI to the `quartus_pgm` executable. This is helpful because users don't have to open the entire Quartus II GUI for certain operations

Command-Line Scripting Help

Help on command-line executables is available through different methods. You can access help built in to the executables with command-line options. You can use the Quartus II Command-Line and Tcl API Help browser for an easy graphical view of the help information. Additionally, you can refer to the *Quartus II Scripting Reference Manual* on the Quartus II literature page of Altera's website, which has the same information in PDF format.

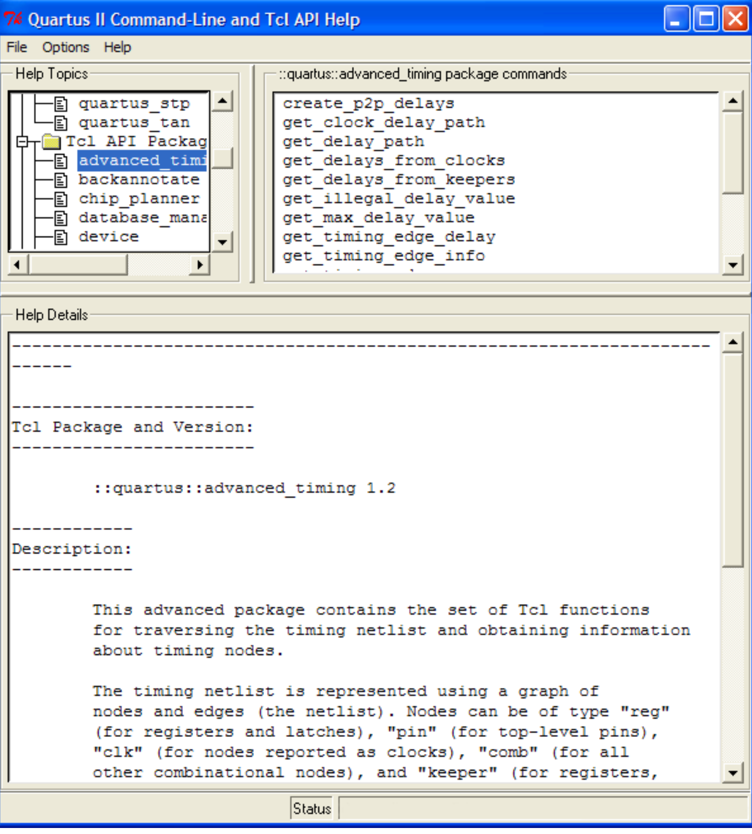
To use the Quartus II Command-Line and Tcl API Help browser, type the following:

```
quartus_sh --qhelp ↵
```

This command starts the Quartus II Command-Line and Tcl API Help browser, a viewer for information about the Quartus II Command-Line executables and Tcl API (Figure 2–1).

Use the `-h` option with any of the Quartus II Command-Line executables to get a description and list of supported options. Use the `--help=`*<option name>* option for detailed information about each option.

Figure 2–1. Quartus II Command-Line and Tcl API Help Browser



Command-Line Option Details

Command-line options are provided for many common global project settings and performing common tasks. You can use either of two methods to make assignments to an individual entity. If the project exists, open the project in the Quartus II GUI, change the assignment, and close the project. The changed assignment is updated in the Quartus II Settings File. Any command-line executables that are run after this update use the updated assignment. Refer to “Option Precedence” on page 2–7 for more information. You can also make assignments using the Quartus II Tcl scripting API. If you want to completely script the creation of a Quartus II project, choose this method.

Refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. Scripting information for all Quartus II project settings and assignments is located in the *QSF Reference Manual*.

© March 2009 Altera Corporation

Option Precedence

If you use command-line executables, you should be aware of the precedence of various project assignments and how to control the precedence. Assignments for a particular project exist in the Quartus II Settings File for the project. Assignments for a project can also be made with command-line options. Project assignments are reflected in compiler database files that hold intermediate compilation results and reflect assignments made in the previous project compilation.

All command-line options override any conflicting assignments found in the Quartus II Settings File or the compiler database files. There are two command-line options to specify whether Quartus II Settings File or compiler database files take precedence for any assignments not specified as command-line options.

Any assignment not specified as a command-line option or found in the Quartus II Settings File or compiler database file is set to its default value.

The file precedence command-line options are `--read_settings_files` and `--write_settings_files`.

By default, the `--read_settings_files` and `--write_settings_files` options are turned on. Turning on the `--read_settings_files` option causes a command-line executable to read assignments from the Quartus II Settings File instead of from the compiler database files. Turning on the `--write_settings_files` option causes a command-line executable to update the Quartus II Settings File to reflect any specified options, as happens when you close a project in the Quartus II GUI.

If you use command-line executables, you should be aware of the precedence of various project assignments and how to control the precedence. Assignments for a particular project can exist in three places:

- The Quartus II Settings File for the project
- The result of the last compilation, in the **\db** directory, reflects the assignments that existed when the project was compiled.
- Command-line options

Table 2–2 lists the precedence for reading assignments depending on the value of the `--read_settings_files` option.

Table 2–2. Precedence for Reading Assignments

Option Specified	Precedence for Reading Assignments
`--read_settings_files = on` (Default)	1. Command-line options 2. Quartus II Settings File 3. Project database (db directory, if it exists) 4. Quartus II software defaults
`--read_settings_files = off`	1. Command-line options 2. Project database (db directory, if it exists) 3. Quartus II software defaults

Table 2–3 lists the locations to which assignments are written, depending on the value of the `--write_settings_files` command-line option.

Table 2–3. Location for Writing Assignments

Option Specified	Location for Writing Assignments
`--write_settings_files = on` (Default)	Quartus II Settings File and compiler database
`--write_settings_files = off`	Compiler database

Example 2–3 assumes that a project named **fir_filter** exists, and that the analysis and synthesis step has been performed (using the `quartus_map` executable).

Example 2–3. Write Settings Files

```
quartus_fit fir_filter --fmax=80MHz ↵
quartus_tan fir_filter ↵
quartus_tan fir_filter --fmax=100MHz --tao=timing_result-100.tao
   --write_settings_files=off ↵
```

The first command, `quartus_fit fir_filter --fmax=80MHz`, runs the `quartus_fit` executable and specifies a global f_{MAX} requirement of 80 MHz.

The second command, `quartus_tan fir_filter`, runs Quartus II timing analysis for the results of the previous fit.

The third command reruns Quartus II timing analysis with a global f_{MAX} requirement of 100 MHz and saves the result in a file called **timing_result-100.tao**. By specifying the `--write_settings_files=off` option, the command-line executable does not update the Quartus II Settings File to reflect the changed f_{MAX} requirement. The compiler database files reflect the changed f_{MAX} requirement. If the `--write_settings_files=off` option is not specified, the command-line executable updates the Quartus II Settings File to reflect the 100-MHz global f_{MAX} requirement.

Use the options `--read_settings_files=off` and `--write_settings_files=off` (where appropriate) to optimize the way that the Quartus II software reads and updates settings files. Example 2–4 shows how to avoid unnecessary reading and writing.

Example 2–4. Avoiding Unnecessary Reading and Writing

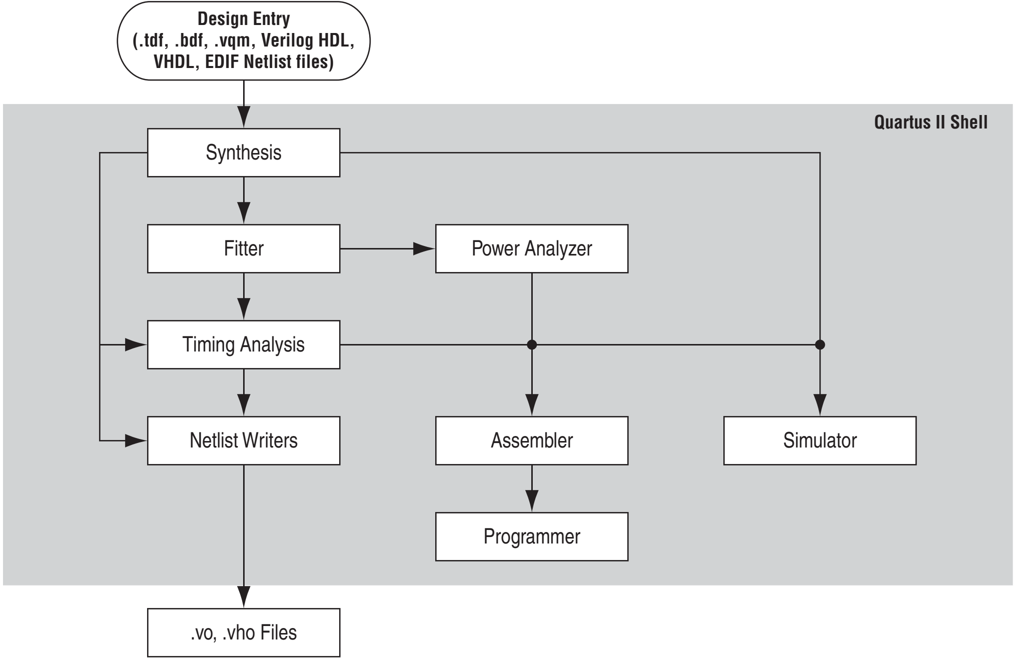
```
quartus_map filtref --source=filtref --part=EP1C12F256C6 ↵
quartus_fit filtref --fmax=100MHz --read_settings_files=off ↵
quartus_tan filtref --read_settings_files=off --write_settings_files=off ↵
quartus_asm filtref --read_settings_files=off --write_settings_files=off ↵
```

The `quartus_tan` and `quartus_asm` executables do not read or write settings files because they do not change any settings in the project.

Design Flow

Figure 2–2 shows a typical design flow.

Figure 2–2. Typical Design Flow



Compilation with quartus_sh --flow

Use the `quartus_sh` executable with the `--flow` option to perform a complete compilation flow with a single command. (For information about specialized flows, type `quartus_sh --help=flow` ↵ at a command prompt.) The `--flow` option supports the smart recompile feature and efficiently sets command-line arguments for each executable in the flow.

If you used the `quartus_cmd` executable to perform command-line compilations in earlier versions of the Quartus II software, you should use the `quartus_sh --flow` command beginning with the Quartus II software version 3.0.

The following example runs compilation, timing analysis, and programming file generation with a single command:

```
quartus_sh --flow compile filtref ↵
```

Text-Based Report Files

Each command-line executable creates a text report file when it is run. These files report success or failure, and contain information about the processing performed by the executable.

Report file names contain the revision name and the short-form name of the executable that generated the report file: <*revision*>.<*executable*>**.rpt**. For example, using the `quartus_fit` executable to place and route a project with the revision name **design_top** generates a report file named **design_top.fit.rpt**. Similarly, using the `quartus_tan` executable to perform timing analysis on a project with the revision name **fir_filter** generates a report file named **fir_filter.tan.rpt**.

As an alternative to parsing text-based report files, you can use the Tcl package called **::quartus::report**. For more information about this package, refer to "Command-Line Scripting Help" on page 2–5.

You can use Quartus II command-line executables in scripts that control a design flow that uses other software in addition to the Quartus II software. For example, if your design flow uses other synthesis or simulation software, and you can run the other software at a system command prompt, you can include it in a single script. The Quartus II command-line executables include options for common global project settings and operations, but you must use a Tcl script or the Quartus II GUI to set up a new project and apply individual constraints, such as pin location assignments and timing requirements. Command-line executables are very useful for working with existing projects, for making common global settings, and for performing common operations. For more flexibility in a flow, use a Tcl script, which makes it easier to pass data between different stages of the design flow and have more control during the flow.

For more information about Tcl scripts, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*, or the *Quartus II Scripting Reference Manual*.

For example, your script could run other synthesis software, then place-and-route the design in the Quartus II software, then generate output netlists for other simulation software. Example 2–5 shows how to do this with a UNIX shell script for a design that targets a Cyclone II device.

Example 2–5. Script for End-to-End Flow (Part 1 of 2)

```
#!/bin/sh
# Run synthesis first.
# This example assumes you use Synplify software
synplify -batch synthesize.tcl

# If your Quartus II project exists already, you can just
# recompile the design.
# You can also use the script described in a later example to
# create a new project from scratch
quartus_sh --flow compile myproject

# Use the quartus_tan executable to do best and worst case
# timing analysis
quartus_tan myproject --tao=worst_case
quartus_tan myproject --fast_model --tao=best_case

# Use the quartus_eda executable to write out a gate-level
# Verilog simulation netlist for ModelSim
quartus_eda my_project --simulation --tool=modelsim --format=verilog
```

Example 2–5. Script for End-to-End Flow (Part 2 of 2)

```
# Perform the simulation with the ModelSim software
vlib cycloneii_ver
vlog -work cycloneii_ver /opt/quartusii/eda/sim_lib/cycloneii_atoms.v
vlib work
vlog -work work my_project.vo
vsim -L cycloneii_ver -t 1ps work.my_project
```

Makefile Implementation

You can use the Quartus II command-line executables in conjunction with the `make` utility to automatically update files when other files they depend on change. The file dependencies and commands used to update files are specified in a text file called a makefile.

To facilitate easier development of efficient makefiles, the following “smart action” scripting command is provided with the Quartus II software:

`quartus_sh --determine_smart_action` ↵

Because assignments for a Quartus II project are stored in the Quartus II Settings File (**.qsf**), including it in every rule results in unnecessary processing steps. For example, updating a setting related to programming file generation (which requires re-running only `quartus_asm`) modifies the Quartus II Settings File, requiring a complete recompilation if the Quartus II Settings File is included in every rule.

The smart action command determines the earliest command-line executable in the compilation flow that must be run based on the current Quartus II Settings File, and generates a change file corresponding to that executable. For a given command-line executable named `quartus_`*<executable>*, the change file is named with the format *<executable>***.chg**. For example, if `quartus_map` must be re-run, the smart action command creates or updates a file named **map.chg**. Thus, rather than including the Quartus II Settings File in each makefile rule, include only the appropriate change file.

Example 2–6 uses change files and the smart action command. You can copy and modify it for your own use. A copy of this example is included in the help for the makefile option, which is available by typing:

`quartus_sh --help=makefiles` ↵

Example 2–6. Sample Makefile (Part 1 of 2)

```
###################################################################
# Project Configuration:
#
# Specify the name of the design (project), the Quartus II Settings
# File (.qsf), and the list of source files used.
###################################################################

PROJECT = chiptrip
SOURCE_FILES = auto_max.v chiptrip.v speed_ch.v tick_cnt.v time_cnt.v
ASSIGNMENT_FILES = chiptrip.qpf chiptrip.qsf

$(PROJECT).tan.rpt: tan.chg $(PROJECT).fit.rpt
	quartus_tan $(TAN_ARGS) $(PROJECT)
smart.log: $(ASSIGNMENT_FILES)
	quartus_sh --determine_smart_action $(PROJECT) > smart.log

###################################################################
# Project initialization
###################################################################

$(ASSIGNMENT_FILES):
	quartus_sh --prepare $(PROJECT)

map.chg:
	$(STAMP) map.chg
fit.chg:
	$(STAMP) fit.chg
tan.chg:
	$(STAMP) tan.chg
asm.chg:
	$(STAMP) asm.chg
```

A Tcl script is provided with the Quartus II software to create or modify files that can be specified as dependencies in the make rules, assisting you in makefile development. Complete information about this Tcl script and how to integrate it with makefiles is available by running the following command:

```
quartus_sh --help=determine_smart_action ↵
```

The MegaWizard Plug-In Manager

The MegaWizard™ Plug-In Manager and associated MegaWizard Plug-Ins provide a GUI-based flow to configure variation files. However, you can use command-line options to modify, update, or create variation files without using the GUI. This capability is useful in a fully scripted design flow, or in cases where you want to generate variation files without using the wizard GUI flow.

The MegaWizard Plug-In Manager has three functions:

- Providing an interface for you to select the output file or files
- Running a specific MegaWizard Plug-In
- Creating output files (such as variation files, symbol files, and simulation netlist files)

Each MegaWizard Plug-In provides a user interface you use to configure the Plug-In variation, and performs validation and error-checking of your selected ports and parameters.

When you create or update a Plug-In variation in the GUI, the parameters and values are entered through the GUI provided by the Plug-In. The he Plug-In Manager then generates the required files. When you create a Plug-In variation with the command line, you provide the parameters and values as command-line options.

The MegaWizard Plug-In Manager command-line executable is `qmegawiz`. Example 2–7 shows how to create a new variation file.

Example 2–7. MegaWizard Plug-In Manager Command-Line Executable

```
qmegawiz [options] [module=<module name>|wizard=<wizard name>] [<param>=<value> ...
    <port>=<used|unused> ...] [OPTIONAL_FILES=<optional files>] <variation file name>
```

When you use `qmegawiz` to update an existing variation file, the module or wizard name is not required.

If a megafunction changes between software version, the variation files must be updated. To do this, run `qmegawiz -silent` *<variation file name>*.

Table 2–4 describes the supported options.

Table 2–4. qmegawiz Options

Option	Description
`-silent`	Run the MegaWizard Plug-In Manager in command-line mode, without displaying the GUI.
`-f:`*<param file>*	A file that contains all options for the `qmegawiz` command. Refer to "Parameter File" on page 2–18.
`-p:`*<working directory>*	Sets the default working directory. Refer to"Working Directory" on page 2–18.

Refer to “Module and Wizard Names” on page 2–15 for information about specifying the module name or wizard name.

Refer to “Ports and Parameters” on page 2–15 for information about specifying ports and parameters.

Refer to “Optional Files” on page 2–16 for information about generating optional files.

Refer to “Variation File Name” on page 2–18 for information about specifying the variation file name.

Command-Line Support

Only the MegaWizard Plug-Ins listed in Table 2–5 support creation and update with the command-line mode. For Plug-Ins not listed in the table, you must use the MegaWizard Plug-In Manager GUI for creation and update.

Table 2–5. MegaWizard Plug-Ins with Command Line Support (Part 1 of 2)

MegaWizard Plug-In	Wizard Name	Module Name
alt2gxb	ALT2GXB	alt2gxb

	RAM: 1-PORT	
	ROM: 1-PORT	

Table 2–5. MegaWizard Plug-Ins with Command Line Support (Part 2 of 2)

MegaWizard Plug-In	Wizard Name	Module Name
dcfifo	FIFO	dcfifo
scfifo		scfifo

Module and Wizard Names

You must specify the wizard or module name, shown in Table 2–5, as a command-line option when you create a variation file. Use the option `module=<module name>` to specify the module, or use the option `wizard=<wizard name>` to specify the wizard. If there are spaces in the wizard or module name, enclose the name in double quotes, for example:

```
wizard="RAM: 2-PORT"
```

When there is a one-to-one mapping between the MegaWizard Plug-In and the wizard name and the module name, you can use either the wizard option or the module option.

When there are multiple wizard names that correspond to one module name, you should use the wizard option to specify one wizard.

When there are multiple module names that correspond to one wizard name, you should use the module option to specify one module. For example, use the module option if you create a FIFO because one wizard is common to both modules. However, you should use the wizard option if you create a RAM, because one module is common to three wizards.

If you edit or update an existing variation file, the wizard or module option is not necessary, because information about the wizard or module is already in the variation file.

Ports and Parameters

Ports and parameters for each MegaWizard Plug-In are described in Quartus II Help, and in the Megafunction User Guides on Altera's website. You should use these references to determine appropriate values for each port and parameter required for a particular variation configuration. Refer to "Strategies to Determine Port and Parameter Values" for more information. You do not have to specify every port and parameter supported by a Plug-In. The MegaWizard Plug-In Manager uses default values for any port or parameter you do not specify.

Specify ports as used or unused, for example:

```
<port>=used
<port>=unused
```

You can specify port names in any order. Grouping does not matter. Separate port configuration options from each other with spaces.

Specify a value for a parameter with the equal sign, for example:

```
<parameter>=<value>
```

You can specify parameters in any order. Grouping does not matter. Separate parameter configuration options from each other with spaces. You can specify port names and parameter names in upper or lower case; case does not matter.

All MegaWizard Plug-Ins allow you to specify the target device family with the INTENDED_DEVICE_FAMILY parameter as shown in the following example:

```
qmegawiz wizard=<wizard> INTENDED_DEVICE_FAMILY="Cyclone III" <file>
```

You must specify enough ports and parameters to create a legal configuration of the Plug-In. When you use the GUI flow, each MegaWizard Plug-In performs validation and error checking for the particular ports and parameters you choose. When you use command-line options to specify ports and parameters, you must ensure that the ports and parameters you use are complete and valid for your particular configuration.

For example, when you use a RAM Plug-In to configure a RAM to be 32 words deep, the Plug-In automatically configures an address port that is five bits wide. If you use the command-line flow to configure a RAM that is 32 words deep, you must use one option to specify the depth of the RAM, then calculate the width of the address port and specify that width with another option.

Invalid Configurations

If the combination of default and specified ports and parameters is not complete to create a legal configuration of the Plug-In, qmegawiz generates an error message that indicates what is missing and what values are supported. If the combination of default and specified ports and parameters results in an illegal configuration of the Plug-In, qmegawiz generates an error message that indicates what is illegal, and displays the legal values.

Strategies to Determine Port and Parameter Values

For simple Plug-In variations, it is often easy to determine appropriate port and parameter values with the information in Help and the Megafunction User Guides. Determining that a 32-word-deep RAM requires an address port that is five bits wide is straightforward. For complex Plug-In variations, an option in the GUI may affect multiple port and parameter settings, so it can be difficult to determine a complete set of ports and parameters. In this case, you should use the GUI to generate a variation file which includes the ports and parameters for your desired configuration. Open the variation file in a text editor and use the port and parameter values in the variation file as command-line options.

Optional Files

In addition to the variation file, the MegaWizard Plug-In Manager can generate other files, such as instantiation templates, simulation netlists, and symbols for graphic design entry. Use the OPTIONAL_FILES parameter to control whether the MegaWizard Plug-In Manager generates optional files. Table 2–6 lists valid arguments for the OPTIONAL_FILES parameter.

Table 2–6. Arguments for the OPTIONAL_FILES Parameter (Part 1 of 2)

Argument	Description
INST	Controls the generation of the <*variation*>**_inst.v** file.
INC	Controls the generation of the <*variation*>**.inc** file.
CMP	Controls the generation of the <*variation*>**.cmp** file.
BSF	Controls the generation of the <*variation*>**.bsf** file.

Table 2–6. Arguments for the OPTIONAL_FILES Parameter (Part 2 of 2)

Argument	Description
BB	Controls the generation of the <*variation*>**_bb.v** file.
SIM_NETLIST	Controls the generation of simulation netlist file, wherever there is wizard support.
SYNTH_NETLIST	Controls the generation of the synthesis netlist file, wherever there is wizard support.
ALL	Generates all applicable optional files.
NONE	Disables the generation of all optional files.

Specify a single optional file, for example:

OPTIONAL_FILES=<*argument*>

Specify multiple optional files separated by a vertical bar character, for example:

OPTIONAL_FILES=<*argument 1*>|...|<*argument n*>

If you prefix an argument with a dash (for example, -BB), it is excluded from the generated optional files. If any of the optional files exist when you run qmegawiz and they are excluded in the OPTIONAL_FILES parameter (with the NONE argument, or prefixed with a dash), they are deleted.

You can combine the ALL argument with other excluded arguments to generate "all files except <*excluded files*>." You can combine the NONE argument with other included arguments to generate "no files except <*files*>."

When you combine multiple arguments, they are processed from left to right, and arguments evaluated later have precedence over arguments evaluated earlier. Therefore, the ALL or NONE argument should be the first one in a combination of multiple arguments. When ALL is the first argument, all optional files are generated before exclusions are processed (deleted). When NONE is the first argument, none of the optional files are generated (in other words, any that exist are deleted), then any you specify are generated.

Table 2–7 shows examples for the OPTIONAL_FILES parameter and describes the result of each example.

Table 2–7. Examples of Different Optional File Arguments

Example Values for OPTIONAL_FILES	Description
BB	The optional file <*variation*>**_bb.v** is generated, and no optional files are deleted
BB|INST	The optional file <*variation*>**_bb.v** is generated, then the optional file <*variation*>**_inst.v** is generated, and no optional files are deleted.
NONE	No optional files are generated, and any existing optional files are deleted.
NONE|INC|BSF	Any existing optional files are deleted, then the optional file <*variation*>**.inc** is generated, then the optional file <*variation*>**.bsf** is generated.
ALL|-INST	All optional files are generated, then <*variation*>**_inst.v** is deleted if it exists.
-BB	The optional file <*variation*>**_bb.v** is deleted if it exists
-BB|INST	The optional file <*variation*>**_bb.v** is deleted if it exists, then the optional file <*variation*>**_inst.v** is generated.

The `qmegawiz` command accepts the `ALL` argument combined with other included file arguments, for example, `ALL|BB`, but that combination is equivalent to `ALL` because first all optional files are generated, then the file **<*variation*>_bb.v** is generated (again). Additionally, the software accepts the `NONE` argument combined with other excluded file arguments, for example, `NONE|-BB`, but that combination is equivalent to `NONE` because no optional files are generated (any that exist are deleted), then the file **<*variation*>_bb.v** is deleted if it exists.

Parameter File

You can put all the parameter values and port values in a file, and pass the file name as an argument to `qmegawiz` with the `-f:`<*parameter file*> option. For example, you could run the following command:

```
qmegawiz -silent module=altsyncram -f:rom_params.txt myrom.v ↵
```

The following options are in a file called **rom_params.txt**:

```
RAM_BLOCK_TYPE=M4K DEVICE_FAMILY=Stratix WIDTH_A=5 WIDTHAD_A=5
   NUMWORDS_A=32 INIT_FILE=rom.hex OPERATION_MODE=ROM
```

Working Directory

You can change the working directory that `qmegawiz` uses when it generates files. By default, the working directory is the current directory when you execute the `qmegawiz` command. Use the `-p` option to specify a different working directory, for example:

```
-p:<working directory>
```

You can specify the working directory with an absolute or relative path. Specify an alternative working directory any time you do not want files generated in the current directory. The alternative working directory can be useful if you generate multiple variations in a batch script, and keep generated files for the different Plug-In variations in separate directories.

Variation File Name

The language used for a variation file depends on the file extension of the variation file name. The MegaWizard Plug-In Manager creates HDL output files in a language based on the file name extension. Therefore, you must always specify a complete file name, including file extension, as the last argument to the `qmegawiz` command. Table 2–8 shows the file extension that corresponds to supported HDL types.

Table 2–8. Variation File Extensions

Variation File HDL Type	Required File Extension
Verilog HDL	**.v**
VHDL	**.vhd**
AHDL	**.tdf**

Command-Line Scripting Examples

This section of the chapter presents various examples of command-line executable use.

Create a Project and Apply Constraints

The command-line executables include options for common global project settings and commands. To apply constraints such as pin locations and timing assignments, run a Tcl script with the constraints in it. You can write a Tcl constraint file from scratch, or generate one for an existing project. From the Project menu, click **Generate Tcl File for Project**.

Example 2–8 creates a project with a Tcl script and applies project constraints using the tutorial design files in the <*Quartus II installation directory*>**/qdesigns/fir_filter/** directory.

Example 2–8. Tcl Script to Create Project and Apply Constraints

```
project_new filtref -overwrite
# Assign family, device, and top-level file
set_global_assignment -name FAMILY Cyclone
set_global_assignment -name DEVICE EP1C12F256C6
set_global_assignment -name BDF_FILE filtref.bdf
# Assign pins
set_location_assignment -to clk Pin_28
set_location_assignment -to clkx2 Pin_29
set_location_assignment -to d[0] Pin_139
set_location_assignment -to d[1] Pin_140
# Other pin assignments could follow
# Create timing assignments
create_base_clock -fmax "100 MHz" -target clk clocka
create_relative_clock -base_clock clocka -divide 2 -offset "500 ps" -target clkx2 clockb
set_multicycle_assignment -from clk -to clkx2 2
# Other timing assignments could follow
project_close
```

Save the script in a file called **setup_proj.tcl** and type the commands illustrated in Example 2–9 at a command prompt to create the design, apply constraints, compile the design, and perform fast-corner and slow-corner timing analysis. Timing analysis results are saved in two files.

Example 2–9. Script to Create and Compile a Project

```
quartus_sh -t setup_proj.tcl ↵
quartus_map filtref ↵
quartus_fit filtref ↵
quartus_asm filtref ↵
quartus_tan filtref --fast_model --tao=min.tao --export_settings=off ↵
quartus_tan filtref --tao=max.tao --export_settings=off ↵
```

You can use the following two commands to create the design, apply constraints, and compile the design:

```
quartus_sh -t setup_proj.tcl ↵
quartus_sh --flow compile filtref ↵
```

The `quartus_sh --flow compile` command performs a full compilation, and is equivalent to clicking the Start Compilation button in the toolbar.

Check Design File Syntax

The UNIX shell script example shown in Example 2–10 assumes that the Quartus II software **fir_filter** tutorial project exists in the current directory. (You can find the **fir_filter** project in the <*Quartus II directory*>**/qdesigns/fir_filter** directory unless the Quartus II software tutorial files are not installed.)

The `--analyze_file` option performs a syntax check on each file. The script checks the exit code of the `quartus_map` executable to determine whether there is an error during the syntax check. Files with syntax errors are added to the `FILES_WITH_ERRORS` variable, and when all files are checked, the script prints a message indicating syntax errors. When options are not specified, the executable uses the project database values. If not specified in the project database, the executable uses the Quartus II software default values. For example, the **fir_filter** project is set to target the Cyclone device family, so it is not necessary to specify the `--family` option.

Example 2–10. Shell Script to Check Design File Syntax

```
#!/bin/sh
FILES_WITH_ERRORS=""
# Iterate over each file with a .bdf or .v extension
for filename in `ls *.bdf *.v`
do
# Perform a syntax check on the specified file
    quartus_map fir_filter --analyze_file=$filename
  # If the exit code is non-zero, the file has a syntax error
    if [ $? -ne 0 ]
    then
       FILES_WITH_ERRORS="$FILES_WITH_ERRORS $filename"
    fi
done
if [ -z "$FILES_WITH_ERRORS" ]
then
    echo "All files passed the syntax check"
    exit 0
else
    echo "There were syntax errors in the following file(s)"
    echo $FILES_WITH_ERRORS
    exit 1
fi
```

Create a Project and Synthesize a Netlist Using Netlist Optimizations

This example creates a new Quartus II project with a file **top.edf** as the top-level entity. The `--enable_register_retiming=on` and `--enable_wysiwyg_resynthesis=on` options allow the technology mapper to optimize the design using gate-level register retiming and technology remapping.

For more details about register retiming, WYSIWYG primitive resynthesis, and other netlist optimization options, refer to the Quartus II Help.

The `--part` option tells the technology mapper to target an EP20K600EBC652-1X device. To create the project and synthesize it using the netlist optimizations described above, type the command shown in Example 2–11 at a command prompt.

© March 2009 Altera Corporation

Example 2–11. Creating a Project and Synthesizing a Netlist Using Netlist Optimizations

```
quartus_map top --source=top.edf --enable_register_retiming=on
   --enable_wysiwyg_resynthesis=on --part=EP20K600EBC652-1X ↵
```

Archive and Restore Projects

You can archive or restore a Quartus II project with a single command. This makes it easy to take snapshots of projects when you use batch files or shell scripts for compilation and project management. Use the `--archive` or `--restore` options for `quartus_sh` as appropriate. Type the command shown in Example 2–12 at a system command prompt to archive your project.

Example 2–12. Archiving a Project

```
quartus_sh --archive <project name> ↵
```

The archive file is automatically named <*project name*>**.qar.** If you want to use a different name, rename the archive after it has been created. This command overwrites any existing archive with the same name.

To restore a project archive, type the command shown in Example 2–13 at a system command prompt.

Example 2–13. Restoring a Project Archive

```
quartus_sh --restore <archive name> ↵
```

The command restores the project archive to the current directory and overwrites existing files.

Perform I/O Assignment Analysis

You can perform I/O assignment analysis with a single command. I/O assignment analysis checks pin assignments to ensure they do not violate board layout guidelines. I/O assignment analysis does not require a complete place and route, so it is a quick way to ensure your pin assignments are correct. The command shown in Example 2–14 performs I/O assignment analysis for the specified project and revision.

Example 2–14. Performing I/O Assignment Analysis

```
quartus_fit --check_ios <project name> --rev=<revision name> ↵
```

Update Memory Contents without Recompiling

You can use two simple commands to update the contents of memory blocks in your design without recompiling. Use the `quartus_cdb` executable with the `--update_mif` option to update memory contents from Memory Initialization Files or Hexadecimal (Intel-Format) Files. Then re-run the assembler with the `quartus_asm` executable to regenerate the SOF, POF, and any other programming files.

Example 2–15 shows these two commands.

Example 2–15. Commands to Update Memory Contents without Recompiling

```
quartus_cdb --update_mif <project name> [--rev=<revision name>]↵
quartus_asm <project name> [--rev=<revision name>]↵
```

Example 2–16 shows the commands for a DOS batch file for this example. You can paste the following lines into a DOS batch file called **update_memory.bat.**

Example 2–16. Batch file to Update Memory Contents without Recompiling

```
quartus_cdb --update_mif %1 --rev=%2
quartus_asm %1 --rev=%2
```

Type the following command at a system command prompt:

```
update_memory.bat <project name> <revision name> ↵
```

Create a Compressed Configuration File

You can create a compressed configuration file in two ways. The first way is to run `quartus_cpf` with an option file that turns on compression. The second way is to run `quartus_cpf` with a Conversion Setup File (**.cof**).

To create an option file that turns on compression, type

```
quartus_cpf -w <filename>.opt ↵
```

This interactive command walks you through some questions, including compression, then creates an option file based on your answers. Use the `--option` option to `quartus_cpf` to specify the option file you just created. For example, the following command creates a compressed Programming Object File (**.pof**) that targets an EPCS64 device:

```
quartus_cpf --convert --option=<filename>.opt --device=EPCS64 <file>.sof <file>.pof ↵
```

Alternatively, you can use the Convert Programming Files utility in the Quartus II software to create a conversion setup file. Configure any options you want, including compression, then save the conversion setup. Use the following command to run the conversion setup you specified:

```
quartus_cpf <file>.cof ↵
```

Fit a Design as Quickly as Possible

This example assumes that a project called **top** exists in the current directory, and that the name of the top-level entity is **top**. The `--effort=fast` option causes the Fitter to use the fast fit algorithm to increase compilation speed, possibly at the expense of reduced f_{MAX} performance. The `--one_fit_attempt=on` option restricts the Fitter to only one fitting attempt for the design.

To attempt to fit the project called **top** as quickly as possible, type the command shown in Example 2–17 at a command prompt.

Example 2–17. Fitting a Project Quickly

```
quartus_fit top --effort=fast --one_fit_attempt=on ↵
```

Fit a Design Using Multiple Seeds

This shell script example assumes that the Quartus II software tutorial project called **fir_filter** exists in the current directory (defined in the file **fir_filter.qpf**). If the tutorial files are installed on your system, this project exists in the <*Quartus II directory*>/qdesigns<*quartus_version_number*> /**fir_filter** directory. Because the top-level entity in the project does not have the same name as the project, you must specify the revision name for the top-level entity with the `--rev` option. The `--seed` option specifies the seeds to use for fitting.

A seed is a parameter that affects the random initial placement of the Quartus II Fitter. Varying the seed can result in better performance for some designs.

After each fitting attempt, the script creates new directories for the results of each fitting attempt and copies the complete project to the new directory so that the results are available for viewing and debugging after the script has completed.

Example 2–18 is designed for use on UNIX systems using **sh** (the shell).

Example 2–18. Shell Script to Fit a Design Using Multiple Seeds

```
#!/bin/sh
ERROR_SEEDS=""
quartus_map fir_filter --rev=filtref
# Iterate over a number of seeds
for seed in 1 2 3 4 5
do
echo "Starting fit with seed=$seed"
# Perform a fitting attempt with the specified seed
quartus_fit fir_filter --seed=$seed --rev=filtref
# If the exit-code is non-zero, the fitting attempt was
# successful, so copy the project to a new directory
if [ $? -eq 0 ]
then
          mkdir ../fir_filter-seed_$seed
          mkdir ../fir_filter-seed_$seed/db
          cp * ../fir_filter-seed_$seed
          cp db/* ../fir_filter-seed_$seed/db
else
          ERROR_SEEDS="$ERROR_SEEDS $seed"
fi
done
if [ -z "$ERROR_SEEDS" ]
then
echo "Seed sweeping was successful"
exit 0
else
echo "There were errors with the following seed(s)"
echo $ERROR_SEEDS
exit 1
fi
```

Use the Design Space Explorer (DSE) included with the Quartus II software script (by typing `quartus_sh --dse` ↵ at a command prompt) to improve design performance by performing automated seed sweeping.

For more information about the DSE, type `quartus_sh --help=dse` ↵ at the command prompt, or refer to the *Design Space Explorer* chapter in volume 2 of the *Quartus II Handbook*, or see the Quartus II Help.

The QFlow Script

A Tcl/Tk-based graphical interface called QFlow is included with the command-line executables. You can use the QFlow interface to open projects, launch some of the command-line executables, view report files, and make some global project assignments. The QFlow interface can run the following command-line executables:

- `quartus_map` (Analysis and Synthesis)
- `quartus_fit` (Fitter)
- `quartus_tan` (Timing Analysis)
- `quartus_asm` (Assembler)
- `quartus_eda` (EDA Netlist Writer)

To view floorplans or perform other GUI-intensive tasks, launch the Quartus II software.

Start QFlow by typing the following command at a command prompt:

```
quartus_sh -g ↵
```

Figure 2–3 shows the QFlow interface.

Figure 2–3. QFlow Interface

The QFlow script is located in the <*Quartus II directory*>**/common/tcl/apps/qflow/** directory.

Document Revision History

Table 2–9 shows the revision history for this chapter.

Table 2–9. Document Revision History

Date / Version	Changes Made	Summary of Changes
March 2009, v9.0.0	No change to content.	Updated for the Quartus II software version 9.0 release.

November 2008, v8.1.0	Added the following sections:
	■ "The MegaWizard Plug-In Manager" on page 2–13
	  ■ "Command-Line Support" on page 2–14
	  ■ "Module and Wizard Names" on page 2–15
	  ■ "Ports and Parameters" on page 2–15
	  ■ "Invalid Configurations" on page 2–16
	  ■ "Strategies to Determine Port and Parameter Values" on page 2–16
	  ■ "Optional Files" on page 2–16
	  ■ "Parameter File" on page 2–18
	  ■ "Working Directory" on page 2–18
	  ■ "Variation File Name" on page 2–18
	■ "Create a Compressed Configuration File" on page 2–22
	Updated "Option Precedence" on page 2–7 to clarify how to control precedence
	Corrected Example 2–5 on page 2–10
	Changed Example 2–1, Example 2–2, Example 2–4, and Example 2–7 to use the EP1C12F256C6 device
	Minor editorial updates
	Updated entire chapter using 8½" × 11" chapter template
		Updated for the Quartus II software version 8.1 release.

May 2008, v8.0.0	Updated "Referenced Documents" on page 2–20. Updated references in document.	Updated for the Quartus II software version 8.0.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

3. Tcl Scripting

QII52003-9.0.0

Introduction

Developing and running Tcl scripts to control the Altera® Quartus® II software allows you to perform a wide range of functions, such as compiling a design or writing procedures to automate common tasks.

You can use Tcl scripts to manage a Quartus II project, make assignments, define design constraints, make device assignments, run compilations, perform timing analysis, import LogicLock™ region assignments, use the Quartus II Chip Editor, and access reports. You can automate your Quartus II assignments using Tcl scripts so that you do not have to create them individually. Tcl scripts also facilitate project or assignment migration. For example, when using the same prototype or development board for different projects, you can automate reassignment of pin locations in each new project. The Quartus II software can also generate a Tcl script based on all the current assignments in the project, which aids in switching assignments to another project.

The Quartus II software Tcl commands follow the EDA industry Tcl application programming interface (API) standards for using command-line options to specify arguments. This simplifies learning and using Tcl commands. If you encounter an error using a command argument, the Tcl interpreter gives help information showing correct usage.

This chapter includes sample Tcl scripts for automating the Quartus II software. You can modify these example scripts for use with your own designs. You can find more Tcl scripts in the Design Examples section of the Support area of Altera's website.

This chapter includes the following topics:

- "Quartus II Tcl Packages" on page 3–2
- "Quartus II Tcl API Help" on page 3–4
- "Executables Supporting Tcl" on page 3–7
- "End-to-End Design Flows" on page 3–9
- "Creating Projects and Making Assignments" on page 3–10
- "Compiling Designs" on page 3–14
- "Reporting" on page 3–15
- "Timing Analysis" on page 3–18
- "Automating Script Execution" on page 3–22
- "Other Scripting Features" on page 3–25
- "Using the Quartus II Tcl Shell in Interactive Mode" on page 3–29
- "Quartus II Legacy Tcl Support" on page 3–32
- "Using the tclsh Shell" on page 3–32
- "Tcl Scripting Basics" on page 3–33

What is Tcl?

Tcl (pronounced "tickle") is a popular scripting language that is similar to many shell scripting and high-level programming languages. It provides support for control structures, variables, network socket access, and APIs. Tcl is the EDA industry-standard scripting language used by Synopsys, Mentor Graphics®, and Altera software. It allows you to create custom commands and works seamlessly across most development platforms. For a list of recommended literature on Tcl, refer to "External References" on page 3–39.

You can create your own procedures by writing scripts containing basic Tcl commands, user-defined procedures, and Quartus II API functions. You can then automate your design flow, run the Quartus II software in batch mode, or execute the individual Tcl commands interactively in the Quartus II Tcl interactive shell.

If you're unfamiliar with Tcl scripting, or are a Tcl beginner, refer to "Tcl Scripting Basics" on page 3–33 for an introduction to Tcl scripting.

The Quartus II software, beginning with version 4.1, supports Tcl/Tk version 8.4, supplied by the Tcl DeveloperXchange at tcl.activestate.com.

Quartus II Tcl Packages

The Quartus II Tcl commands are grouped in packages by function. Table 3–1 describes each Tcl package.

Table 3–1. Tcl Packages (Part 1 of 2)

Package Name	Package Description
advanced_timing	Traverse the timing netlist and get information about timing nodes
backannotate	Back annotate assignments
chip_planner	Identify and modify resource usage and routing with the Chip Editor
database_manager	Manage version-compatible database files
device	Get device and family information from the device database
flow	Compile a project, run command-line executables and other common flows
insystem_memory_edit	Read and edit memory contents in Altera devices
jtag	Control the JTAG chain
logic_analyzer_interface	Query and modify the logic analyzer interface output pin state
logiclock	Create and manage LogicLock regions
misc	Perform miscellaneous tasks
project	Create and manage projects and revisions, make any project assignments including timing assignments
report	Get information from report tables, create custom reports
sdc	Specifies constraints and exceptions to the TimeQuest Timing Analyzer
simulator	Configure and perform simulations
sta	Contains the set of Tcl functions for obtaining advanced information from the Quartus II TimeQuest Timing Analyzer
stp	Run the SignalTap® II Logic Analyzer
timing	Annotate timing netlist with delay information, compute and report timing paths

Table 3–1. Tcl Packages (Part 2 of 2)

Package Name	Package Description
timing_assignment	Contains the set of Tcl functions for making project-wide timing assignments, including clock assignments; all Tcl commands designed to process Quartus II Classic Timing Analyzer assignments have been moved to this package
timing_report	List timing paths
sdc_ext	Altera-specific SDC commands

By default, only the minimum number of packages is loaded automatically with each Quartus II executable. This keeps the memory requirement for each executable as low as possible. Because the minimum number of packages is automatically loaded, you must load other packages before you can run commands in those packages.

Table 3–2 lists the Quartus II Tcl packages available with Quartus II executables and indicates whether a package is loaded by default (●) or is available to be loaded as necessary (◓). A white circle (○) means that the package is not available in that executable.

Table 3–2. Tcl Package Availability by Quartus II Executable (Part 1 of 2)

	Quartus II Executable						
Packages	**Quartus_sh**	**Quartus_tan**	**Quartus_cdb**	**Quartus_sim**	**Quartus_stp**	**Quartus_sta Quartus_staw**	**Tcl Console**
advanced_timing	○	◓	○	○	○	○	○
backannotate	○	○	◓	○	○	○	◓
chip_planner	○	○	◓	○	○	○	○
device	●	◓	●	●	○	●	◓
flow	◓	◓	◓	◓	○	◓	◓
insystem_memory_edit	○	○	○	○	●	○	○
jtag	○	○	○	○	●	○	○
logic_analyzer_interface	○	○	○	○	●	○	○
logiclock	○	◓	◓	○	○	○	◓
misc	●	●	●	●	●	●	●
old_api	○	○	○	○	○	○	●
project	●	●	●	●	●	●	●
report	◓	◓	◓	●	○	●	◓
sdc	○	○	○	○	○	●	○
sdc_ext	○	○	○	○	○	●	○
simulator	○	○	○	●	○	○	○

Table 3–2. Tcl Package Availability by Quartus II Executable (Part 2 of 2)

Packages	Quartus II Executable						
	Quartus_sh	Quartus_tan	Quartus_cdb	Quartus_sim	Quartus_stp	Quartus_sta Quartus_staw	Tcl Console
sta	○	○	○	○	○	●	○
stp	○	○	○	○	●	○	○
timing	○	●	○	○	○	○	○
timing_assignmen t	●	●	●	●	●	○	○
timing_report	○	◓	○	○	●	○	●

Notes to Table 3–2:

(1) A dark circle (●) indicates that the package is loaded automatically.

(2) A half-circle (◓) means that the package is available but not loaded automatically.

(3) A white circle (○) means that the package is not available for that executable.

Because different packages are available in different executables, you must run your scripts with executables that include the packages you use in the scripts. For example, if you use commands in the **timing** package, you must use the `quartus_tan` executable to run the script because the `quartus_tan` executable is the only one with support for the **timing** package.

Loading Packages

To load a Quartus II Tcl package, use the `load_package` command as follows:

```
load_package [-version <version number>] <package name>
```

This command is similar to the `package require` Tcl command (described in Table 3–3 on page 3–5), but you can easily alternate between different versions of a Quartus II Tcl package with the `load_package` command.

For additional information about these and other Quartus II command-line executables, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook.*

Quartus II Tcl API Help

Access the Quartus II Tcl API Help reference by typing the following command at a system command prompt:

```
quartus_sh --qhelp ↵
```

This command runs the Quartus II Command-Line and Tcl API help browser, which documents all commands and options in the Quartus II Tcl API. It includes detailed descriptions and examples for each command.

In addition, the information in the Tcl API help is available in the *Quartus II Scripting Reference Manual*.

© March 2009 Altera Corporation

Quartus II Tcl help allows easy access to information about the Quartus II Tcl commands. To access the help information, type `help` at a Tcl prompt, as shown in Example 3–1.

Example 3–1. Help Output

```
tcl> help

* Type "help -tcl"
to get an overview on Quartus II Tcl usages.
```

Using the `-tcl` option with `help` displays an introduction to the Quartus II Tcl API that focuses on how to get help for Tcl commands (short help and long help) and Tcl packages.

The Tcl API help is also available in Quartus II online help. Search for the command or package name to find details about that command or package.

Table 3–3 summarizes the help options available in the Tcl environment.

Table 3–3. Help Options Available in the Quartus II Tcl Environment (Part 1 of 2)

Help Command	Description
`help`	To view a list of available Quartus II Tcl packages, loaded and not loaded.
`help -tcl`	To view a list of commands used to load Tcl packages and access command-line help.
`help -pkg` *`<package_name>`* `[-version` *`<version number>`*`]`	To view help for a specified Quartus II package that includes the list of available Tcl commands. For convenience, you can omit the `::quartus::` package prefix, and type `help -pkg` *<package name>* ↵. If you do not specify the `-version` option, help for the currently loaded package is displayed by default. If the package for which you want help is not loaded, help for the latest version of the package is displayed by default. Examples: `help -pkg ::quartus::project` ↵ `help -pkg project` ↵ `help -pkg project -version 1.0` ↵

Table 3–3. Help Options Available in the Quartus II Tcl Environment (Part 2 of 2)

Help Command	Description

`<command_name> -h`
or
`<command_name> -help`
	To view short help for a Quartus II Tcl command for which the package is loaded.
	Examples:
	`project_open -h` ↵
	`project_open -help` ↵

`package require ::quartus::<package name> [<version>]`	To load a Quartus II Tcl package with the specified version. If <version> is not specified, the latest version of the package is loaded by default. Example: `package require ::quartus::project 1.0` ↵ This command is similar to the **load_package** command. The advantage of using **load_package** is that you can alternate freely between different versions of the same package. Type `<`*package name*`> [-version <`*version number*`>]` ↵ to load a Quartus II Tcl package with the specified version. If the `-version` option is not specified, the latest version of the package is loaded by default. Example: `load_package ::quartus::project -version 1.0` ↵

`help -cmd <command name> [-version <version number>]`
or
`<command name> -long_help`
	To view long help for a Quartus II Tcl command. Only `<`*command name*`> -long_help` requires that the associated Tcl package is loaded.
	If you do not specify the `-version` option, help for the currently loaded package is displayed by default.
	If the package for which you want help is not loaded, help for the latest version of the package is displayed by default.
	Examples:
	`project_open -long_help` ↵
	`help -cmd project_open` ↵
	`help -cmd project_open -version 1.0` ↵

`help -examples`	To view examples of Quartus II Tcl usage.
`help -quartus`	To view help on the predefined global Tcl array that can be accessed to view information about the Quartus II executable that is currently running.
`quartus_sh --qhelp`	To launch the Tk viewer for Quartus II command-line help and display help for the command-line executables and Tcl API packages. For more information about this utility, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Executables Supporting Tcl

Some of the Quartus II command-line executables support Tcl scripting (refer to Table 3–4). Each executable supports different sets of Tcl packages. Refer to Table 3–4 to determine the appropriate executable to run your script.

Table 3–4. Command-Line Executables Supporting Tcl Scripting

Executable Name	Executable Description
`quartus_sh`	The Quartus II Shell is a simple Tcl scripting shell, useful for making assignments, general reporting, and compiling.
`quartus_tan`	Use the Quartus II Classic Timing Analyzer to perform simple timing reporting and advanced timing analysis.
`quartus_cdb`	The Quartus II Compiler Database supports back annotation, LogicLock region operations, and Chip Editor functions.
`quartus_sim`	The Quartus II Simulator supports the automation of design simulation.
`quartus_sta` `quartus_staw`	The Quartus II TimeQuest Timing Analyzer supports SDC terminology for constraint entry and reporting.
`quartus_stp`	The Quartus II SignalTap II executable supports in-system debugging tools.

The `quartus_tan` and `quartus_cdb` executables support supersets of the packages supported by the `quartus_sh` executable. Use the `quartus_sh` executable if you run Tcl scripts with only project management and assignment commands, or if you require a Quartus II command-line executable with a small memory footprint.

For more information about these command-line executables, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Command-Line Options: -t, -s, and --tcl_eval

Table 3–5 lists three command-line options you can use with executables that support Tcl.

Table 3–5. Command-Line Options Supporting Tcl Scripting

Command-Line Option	Description
`-t <script file> [<script args>]`	Run the specified Tcl script with optional arguments.
`-s`	Open the executable in the interactive Tcl shell mode.
`--tcl_eval <tcl command>`	Evaluate the remaining command-line arguments as Tcl commands. For example, the following command displays help for the project package: `quartus_sh --tcl_eval help -pkg project`

Run a Tcl Script

Running an executable with the `-t` option runs the specified Tcl script. You can also specify arguments to the script. Access the arguments through the `argv` variable, or use a package such as cmdline, which supports arguments of the following form:

```
-<argument name> <argument value>
```

The **cmdline** package is included in the <*Quartus II directory*>**/common/tcl/packages** directory.

For example, to run a script called **myscript.tcl** with one argument, `Stratix`, type the following command at a system command prompt:

```
quartus_sh -t myscript.tcl Stratix ↵
```

Beginning with version 4.1, the Quartus II software supports the `argv` variable. In previous software versions, script arguments are accessed in the `quartus(args)` global variable.

Refer to “Accessing Command-Line Arguments” on page 3–27 for more information.

Interactive Shell Mode

Running an executable with the `-s` option starts an interactive Tcl shell that displays a `tcl>` prompt. For example, type `quartus_tan -s` ↵ at a system command prompt to open the Quartus II Classic Timing Analyzer executable in interactive shell mode. Commands you type in the Tcl shell are interpreted when you click **Enter**. You can run a Tcl script in the interactive shell with the following command:

```
source <script name> ↵
```

If a command is not recognized by the shell, it is assumed to be an external command and executed with the `exec` command.

Evaluate as Tcl

Running an executable with the `--tcl_eval` option causes the executable to immediately evaluate the remaining command-line arguments as Tcl commands. This can be useful if you want to run simple Tcl commands from other scripting languages.

For example, the following command runs the Tcl command that prints out the commands available in the project package.

```
quartus_sh --tcl_eval help -pkg project ↵
```

Using the Quartus II Tcl Console Window

You can run Tcl commands directly in the Quartus II Tcl Console window. On the View menu, click **Utility Windows.** By default, the Tcl Console window is docked in the bottom-right corner of the Quartus II GUI. Everything typed in the Tcl Console is interpreted by the Quartus II Tcl shell.

The Quartus II Tcl Console window supports the Tcl API used in the Quartus II software version 3.0 and earlier for backward compatibility with older designs and EDA tools.

Tcl messages appear in the **System** tab (Messages window). Errors and messages written to `stdout` and `stderr` also are shown in the Quartus II Tcl Console window.

You can do limited timing analysis in the Tcl console in the Quartus II GUI. With the **timing_report** package, you can use the `list_path` command to get details on paths listed in the timing report. However, if you want to get information about timing paths that are not listed in the timing report, you must use the `quartus_tan` executable in shell mode or run a script that reports on the paths in which you are interested.

© March 2009 Altera Corporation

If your design uses the Quartus II TimeQuest Timing Analyzer, you should perform scripted timing analysis in the TimeQuest Tcl console.

As Table 3–2 shows, the Tcl console in the Quartus II GUI does not include support for every package, so you cannot run scripts that use commands in packages that are not supported.

End-to-End Design Flows

You can use Tcl scripts to control all aspects of the design flow, including controlling other software if it includes a scripting interface.

Typically, EDA tools include their own script interpreters that extend core language functionality with tool-specific commands. For example, the Quartus II Tcl interpreter supports all core Tcl commands, and adds numerous commands specific to the Quartus II software. You can include commands in one Tcl script to run another script, which allows you to combine or chain together scripts to control different tools. Because scripts for different tools must be executed with different Tcl interpreters, it is difficult to pass information between the scripts unless one script writes information into a file and another script reads it.

Within the Quartus II software, you can perform many different operations in a design flow (such as synthesis, fitting, and timing analysis) from a single script, making it easy to maintain global state information and pass data between the operations. However, there are some limitations on the operations you can perform in a single script due to the various packages supported by each executable. For example, you cannot write a single script that performs simulation with commands in the **simulator** package while using commands in the **advanced_timing** package; those two packages are not available in the same executable. In a case where you wanted to include Tcl simulation and advanced timing analysis commands, you must write two scripts.

There are no limitations on running flows from any executable. Flows include operations found in the Start section of the Processing menu in the Quartus II GUI, and are also documented with the `execute_flow` Tcl command. If you can make settings in the Quartus II software and run a flow to get your desired result, you can make the same settings and run the same flow in any command-line executable.

To revisit the example with simulation and timing analysis, you could write one script that includes settings that configure a simulation, with settings that configure timing analysis. Then, run the simulation and timing analysis flows with the `execute_flow` command.

Configuring a simulation includes specifying settings such as name and location of the stimulus file, the duration of the simulation, whether to perform glitch detection or not, and more. Configuring timing analysis includes specifying settings such as the required clock frequency, the number of paths to report, and which timing model to use. You can make the settings, then run the flows with the `execute_flow` command, in any Quartus II command-line executable.

Creating Projects and Making Assignments

A benefit of the Tcl scripting API is that you can easily create a script that makes all the assignments for an existing project. You can use the script at any time to restore your project settings to a known state. From the Project menu, click **Generate Tcl File for Project** to automatically generate a **.tcl** file with all of your assignments. You can source this file to recreate your project, and you can edit the file to add other commands, such as compiling the design. The file is a good starting point to learn about project management commands and assignment commands.

Refer to "Interactive Shell Mode" on page 3–8 for information about sourcing a script. Scripting information for all Quartus II project settings and assignments is located in the *QSF Reference Manual*.

Example 3–2 shows how to create a project, make assignments, and compile the project. It uses the **fir_filter** tutorial design files in the **qdesigns** installation directory. Use the `quartus_sh` executable to run this Tcl script.

Example 3–2. Create and Compile a Project

```
load_package flow

# Create the project and overwrite any settings
# files that exist
project_new fir_filter -revision filtref -overwrite
# Set the device, the name of the top-level BDF,
# and the name of the top level entity
set_global_assignment -name FAMILY Cyclone
set_global_assignment -name DEVICE EP1C6F256C6
set_global_assignment -name BDF_FILE filtref.bdf
set_global_assignment -name TOP_LEVEL_ENTITY filtref
# Add other pin assignments here
set_location_assignment -to clk Pin_G1
# Create a base clock and a derived clock
create_base_clock -fmax "100 MHz" -target clk clocka
create_relative_clock -base_clock clocka -divide 2 \
   -offset "500 ps" -target clkx2 clockb
# Create a multicycle assignment of 2 between
# the two clock domains in the design.
set_multicycle_assignment -from clk -to clkx2 2
execute_flow -compile
project_close
```

The assignments created or modified while a project is open are not committed to the Quartus II Settings Files (**.qsf**) unless you explicitly call `export_assignments` or `project_close` (unless `-dont_export_assignments` is specified). In some cases, such as when running `execute_flow`, the Quartus II software automatically commits the changes.

HardCopy Device Design

For information about using a scripted design flow for HardCopy II designs, refer to the *Script-Based Design for HardCopy II Devices* chapter of the *HardCopy Handbook*. It contains sample scripts and recommendations to make your HardCopy II design flow easy.

A separate chapter in the *HardCopy Handbook* called *Timing Constraints for HardCopy II Devices* also contains information about script-based design for HardCopy II devices, with an emphasis on timing constraints.

Using LogicLock Regions

You can use Tcl commands to work with LogicLock™ regions. The following examples show how to export and import LogicLock regions for use in other designs. The examples use the files in the LogicLock tutorial design.

For additional information about the LogicLock design methodology, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

To compile a design and export LogicLock regions, follow these steps:

1. Create a project and add assignments.
2. Assign virtual pins.
3. Create a LogicLock region.
4. Assign a design entity to the region.
5. Compile the project.
6. Back-annotate the region.
7. Export the region.

Example 3–3 shows a script that creates a project called **lockmult**, and makes all the required assignments to compile the project. Next, the script compiles the project, back-annotates the design, and exports the LogicLock region. The script uses a procedure called `assign_virtual_pins`, which is described after the example. The example assumes that a design file named **pipemult.bdf** exists, and that it is a low-level module that would be instantiated multiple times in a higher-level module. Use the `quartus_cdb` executable to run this script.

Example 3–3. LogicLock Export Script

```
load_package flow
load_package logiclock
load_package backannotate

project_new lockmult -overwrite
set_global_assignment -name BDF_FILE pipemult.bdf
set_global_assignment -name FAMILY Cyclone
set_global_assignment -name DEVICE EP1C6F256C6
set_global_assignment -name TOP_LEVEL_ENTITY pipemult

# These two assignments cause the Quartus II software
# to generate a VQM file for the logic in the LogicLock
# region. The VQM file is imported into the top-level
# design.
set_global_assignment -name \
   LOGICLOCK_INCREMENTAL_COMPILE_FILE pipemult.vqm
set_global_assignment -name \
   LOGICLOCK_INCREMENTAL_COMPILE_ASSIGNMENT ON

create_base_clock -fmax 200MHz -target clk clk_200
assign_virtual_pins { clk }
#Prepare LogicLock data structures before
#LogicLock-related commands.
initialize_logiclock

# Create a region named lockmult and assign pipemult
# to it.
# The region is auto-sized and floating.
set_logiclock -region lockmult -auto_size true \
-floating true
set_logiclock_contents -region lockmult -to pipemult
execute_flow -compile

# Back annotate the LogicLock Region and export a QSF
logiclock_back_annotate -region lockmult -lock
logiclock_export -file_name pipemult.qsf

uninitialize_logiclock
project_close
```

The `assign_virtual_pins` command is a procedure that makes virtual pin assignments to all bottom-level design pins, except for signals specified as arguments to the procedure. The procedure is defined in Example 3–4.

Example 3–4. assign_virtual_pins Procedure

```
proc assign_virtual_pins { skips } {

    # Analysis and elaboration must be run first to get the pin names
    execute_flow -analysis_and_elaboration

    # Get all pin names as a collection.

    set name_ids [get_names -filter * -node_type pin]
    foreach_in_collection name_id $name_ids {
        # Get the hierarchical path name of the pin.
        set hname [get_name_info -info full_path $name_id]
        #Skip the virtual pin assignment if the
        #pin is in the list of signals to be skipped.
        if {[lsearch -exact $skips $hname] == -1} {
            post_message "Setting VIRTUAL_PIN on $hname"
            set_instance_assignment -to $hname -name VIRTUAL_PIN ON
        } else {
            post_message "Skipping VIRTUAL_PIN for $hname"
        }
    }
}
```

When the script runs, it generates a netlist file named **pipemult.vqm** and a **.qsf** file named **pipemult.qsf,** which contains the back-annotated assignments. You can then import the LogicLock region in another design. This example uses the top-level design in the **topmult** directory.

To import it four times in the top-level LogicLock tutorial design, follow these steps:

1. Create the top-level project.
2. Add assignments.
3. Elaborate the design.
4. Import the LogicLock constraints.
5. Compile the project.

Example 3–5 shows a script that demonstrates these steps. The example assumes that a top-level file named **topmult.bdf** exists, and that it instantiates the **pipemult** entity. Use the `quartus_cdb` executable to run this script example.

Example 3–5. LogicLock Import Script

```
load_package flow
load_package logiclock

project_new topmult -overwrite
set_global_assignment -name BDF_FILE topmult.bdf
set_global_assignment -name VQM_FILE pipemult.vqm
set_global_assignment -name FAMILY Cyclone
set_global_assignment -name DEVICE EP1C6F256C6
create_base_clock -fmax 200MHz -target clk clk_200

# The LogicLock region will be used four times
# in the top-level design. These assignments
# specify that the back-annotated assignments in
# the QSF will be applied to the four entities
# in the top-level design.
set_instance_assignment -name LL_IMPORT_FILE pipemult.qsf \
    -to pipemult:inst
set_instance_assignment -name LL_IMPORT_FILE pipemult.qsf \
    -to pipemult:inst1
set_instance_assignment -name LL_IMPORT_FILE pipemult.qsf \
    -to pipemult:inst2
set_instance_assignment -name LL_IMPORT_FILE pipemult.qsf \
    -to pipemult:inst3

execute_flow -analysis_and_elaboration
initialize_logiclock
logiclock_import
uninitialize_logiclock
execute_flow -compile
project_close
```

For additional information about the LogicLock design methodology, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

Compiling Designs

You can run the Quartus II command-line executables from Tcl scripts. Use the included **flow** package to run various Quartus II compilation flows, or run each executable directly.

The flow Package

The **flow** package includes two commands for running Quartus II command-line executables, either individually or together in standard compilation sequence. The `execute_module` command allows you to run an individual Quartus II command-line executable. The `execute_flow` command allows you to run some or all of the modules in commonly-used combinations.

Altera recommends using the **flow** package instead of using system calls to run compiler executables.

© March 2009 Altera Corporation

Another way to run a Quartus II command-line executable from the Tcl environment is by using the `qexec` Tcl command, a Quartus II implementation of the Tcl `exec` command. For example, to run the Quartus II technology mapper on a given project, type:

```
qexec "quartus_map <project_name>" ↵
```

When you use the `qexec` command to compile a design, assignments made in the Tcl script (or from the Tcl shell) are not exported to the project database and settings file before compilation. Use the `export_assignments` command or compile the project with commands in the **flow** package to ensure assignments are exported to the project database and settings file.

You should use the `qexec` command to make system calls.

You can also run executables directly in a Tcl shell, using the same syntax as at the system command prompt. For example, to run the Quartus II technology mapper on a given project, type the following at the Tcl shell prompt:

```
quartus_map <project_name> ↵
```

Compile All Revisions

You can use a simple Tcl script to compile all revisions in your project. Save the script shown in Example 3–6 in a file called **compile_revisions.tcl** and type the following to run it:

```
quartus_sh -t compile_revisions.tcl <project name> ↵
```

Example 3–6. Compile All Revisions

```
load_package flow
project_open [lindex $quartus(args) 0]
set original_revision [get_current_revision]
foreach revision [get_project_revisions] {
    set_current_revision $revision
    execute flow -compile
}
set_current_revision $original_revision
project_close
```

Reporting

It is sometimes necessary to extract information from the report to evaluate the results when compilation is complete. For example, you might have to know how many device resources the design uses, or whether it meets your performance requirements. The Quartus II Tcl API provides easy access to report data so you do not have to write scripts to parse the text report files.

Use the commands that access report data one row at a time, or one cell at a time. If you know the exact cell or cells you want to access, use the `get_report_panel_data` command and specify the row and column names (or x and y coordinates) and the name of the appropriate report panel. You can often search for data in a report panel. To do this, use a loop that reads the report one row at a time with the `get_report_panel_row` command.

Column headings in report panels are in row 0. If you use a loop that reads the report one row at a time, you can start with row 1 to skip the row with column headings. The `get_number_of_rows` command returns the number of rows in the report panel, including the column heading row. Because the number of rows includes the column heading row, your loop should continue as long as the loop index is less than the number of rows, as illustrated in Example 3–8.

Report panels are hierarchically arranged and each level of hierarchy is denoted by the string "||" in the panel name. For example, the name of the Fitter Settings report panel is **Fitter||Fitter Settings** because it is in the Fitter folder. Panels at the highest hierarchy level do not use the "||" string. For example, the Flow Settings report panel is named **Flow Settings**.

The code in Example 3–7 prints a list of all report panel names in your project. You can run this code with any executable that includes support for the report package.

Example 3–7. Print All Report Panel Names

```
load_package report
project_open myproject
load_report
set panel_names [get_report_panel_names]
foreach panel_name $panel_names {
post_message "$panel_name"
}
```

Example 3–8 prints the number of failing paths in each clock domain in your design. It uses a loop to access each row of the Timing Analyzer Summary report panel. Clock domains are listed in the column named **Type** with the format `Clock Setup:'`*<clock name>*`'`. Other summary information is listed in the **Type** column as well. If the **Type** column matches the pattern "`Clock Setup*`", the script prints the number of failing paths listed in the column named **Failed Paths**. You can run this script example with any executable that supports the report package.

Example 3–8. Print Number of Failing Paths per Clock

```
load_package report
project_open my-project
load_report
set report_panel_name "Timing Analyzer||Timing Analyzer Summary"
set num_rows [get_number_of_rows -name $report_panel_name]

# Get the column indices for the Type and Failed Paths columns
set type_column [get_report_panel_column_index -name \
    $report_panel_name "Type"]
set failed_paths_column [get_report_panel_column_index -name \
    $report_panel_name "Failed Paths"]

# Go through each line in the report panel
for {set i 1} {$i < $num_rows} {incr i} {

    # Get the row of data, then the type of summary
    # information in the row, and the number of failed paths
    set report_row [get_report_panel_row -name \
    $report_panel_name -row $i]
    set row_type [lindex $report_row $type_column]
    set failed_paths [lindex $report_row $failed_paths_column]
    if { [string match "Clock Setup*" $row_type] } {
        puts "$row_type has $failed_paths failing paths"
    }
}
unload_report
```

Creating .csv Files for Excel

The Microsoft Excel software is sometimes used to view or manipulate timing analysis results. You can create a **.csv** file to import into Excel with data from any Quartus II report. Example 3–9 shows a simple way to create a **.csv** file with data from a timing analysis panel in the report. You could modify the script to use command-line arguments to pass in the name of the project, report panel, and output file to use. You can run this script example with any executable that supports the report package.

Example 3–9. Create .csv Files from Reports

```
load_package report
project_open my-project

load_report

# This is the name of the report panel to save as a CSV file
set panel_name "Timing Analyzer||Clock Setup: 'clk'"
set csv_file "output.csv"

set fh [open $csv_file w]
set num_rows [get_number_of_rows -name $panel_name]

# Go through all the rows in the report file, including the
# row with headings, and write out the comma-separated data
for { set i 0 } { $i < $num_rows } { incr i } {
    set row_data [get_report_panel_row -name $panel_name \
        -row $i]
    puts $fh [join $row_data ","]
}

close $fh
unload_report
```

Timing Analysis

The Quartus II software includes comprehensive Tcl APIs for both the Classic and TimeQuest Timing Analyzers. This section includes simple and advanced script examples for the Classic Timing Analyzer and introductory scripting information about the TimeQuest Tcl API.

Classic Timing Analysis

The following example script uses the `quartus_tan` executable to perform a timing analysis on the **fir_filter** tutorial design.

The **fir_filter** design is a two-clock design that requires a base clock and a relative clock relationship for timing analysis. This script first does an analysis of the two-clock relationship and checks for t_{SU} slack between `clk` and `clkx2`. The first pass of timing analysis discovers a negative slack for one of the clocks. The second part of the script adds a multicycle assignment from `clk` to `clkx2` and re-analyzes the design as a multi-clock, multicycle design.

The script does not recompile the design with the new timing assignments, and the timing-driven compilation is not used in the synthesis and placement of this design. New timing assignments are added only for the timing analyzer to analyze the design with the `create_timing_netlist` and `report_timing` Tcl commands.

You must compile the project before running the script example shown in Example 3–10.

Example 3–10. Classic Timing Analysis

```
# This Tcl file is to be used with quartus_tan.exe
# This Tcl file will do the Quartus II tutorial fir_filter design
# timing analysis portion by making a global timing assignment and
# creating multi-clock assignments and run timing analysis
# for a multi-clock, multi-cycle design
# set the project_name to fir_filter
# set the revision_name to filtref
set project_name fir_filter
set revision_name filtref
# open the project
# project_name is the project name
project_open -revision $revision_name $project_name;
# Doing TAN tutorial steps this section re-runs the timing
# analysis module with multi-clock and multi-cycle settings
#------ Make timing assignments ------#
#Specifying a global FMAX requirement (tan tutorial)
set_global_assignment -name FMAX_REQUIREMENT 45.0MHz
set_global_assignment -name CUT_OFF_IO_PIN_FEEDBACK ON
# create a base reference clock "clocka" and specifies the
# following:
#  BASED_ON_CLOCK_SETTINGS = clocka;
#  INCLUDE_EXTERNAL_PIN_DELAYS_IN_FMAX_CALCULATIONS = OFF;
#  FMAX_REQUIREMENT = 50MHZ;
#  DUTY_CYCLE = 50;
# Assigns the reference clocka to the pin "clk"
create_base_clock -fmax 50MHZ -duty_cycle 50 clocka -target clk
# creates a relative clock "clockb" based on reference clock
# "clocka" with the following settings:
#  BASED_ON_CLOCK_SETTINGS = clocka;
#  MULTIPLY_BASE_CLOCK_PERIOD_BY = 1;
#  DIVIDE_BASE_CLOCK_PERIOD_BY = 2;clock period is half the base clk
#  DUTY_CYCLE = 50;
#  OFFSET_FROM_BASE_CLOCK = 500ps;The offset is .5 ns (or 500 ps)
#  INVERT_BASE_CLOCK = OFF;
# Assigns the reference clock to pin "clkx2"
create_relative_clock -base_clock clocka -duty_cycle 50\
-divide 2 -offset 500ps -target clkx2 clockb
# create new timing netlist based on new timing settings
create_timing_netlist
# does an analysis for clkx2
# Limits path listing to 1 path
# Does clock setup analysis for clkx2
report_timing -npaths 1 -clock_setup -file setup_multiclock.tao
# The output file will show a negative slack for clkx2 when only
# specifying a multi-clock design. The negative slack was created
# by the 500 ps offset from the base clock
# removes old timing netlist to allow for creation of a new timing
# netlist for analysis by report_timing
delete_timing_netlist
# adding a multi-cycle setting corrects the negative slack by adding a
# multicycle assignment to clkx2 to allow for more set-up time
set_multicycle_assignment 2 -from clk -to clkx2
# create a new timing netlist based on additional timing
# assignments create_timing_netlist
# outputs the result to a file for clkx2 only
report_timing -npaths 1 -clock_setup -clock_filter clkx2 \
-file clkx2_setup_multicycle.tao
# The new output file will show a positive slack for the clkx2
project_close
```

Advanced Classic Timing Analysis

There might be times when the commands available for timing analysis reporting do not provide access to specific data you require. The **advanced_timing** package provides commands to access the data structures representing the timing netlist for your design. These commands provide low-level details about timing delays, node fan-in and fan-out, and timing data. Writing procedures to traverse the timing netlist and extract information gives you the most control to get exactly the data you require.

The timing netlist is represented with a graph, which is a collection of nodes and edges. Nodes represent elements in your design such as registers, combinational nodes, pins, and clocks. Edges connect the nodes and represent the connections between the logic in your design. Edges and nodes have unique positive integer IDs that identify them in the timing netlist. All the commands for getting information about the timing netlist use node and edge IDs instead of text-based names.

As an example of how to use the **advanced_timing** package, Example 3–11 shows one way to show the register-to-pin delays from all registers that drive the pins of an output bus. Specify the name of an output bus (for example, `address`), and the script prints out the names of all registers driving the pins of the bus and the delays from registers to pins. Use the `quartus_tan` executable to run this example.

Example 3–11. Report Register-to-Pin Delays

```
load_package advanced_timing
package require cmdline

# This procedure returns a list of IDs for pins with names
# that match the bus name passed in
proc find { bus_name } {

    set to_return [list]

    foreach_in_collection node_id [get_timing_nodes -type pin] {
        set node_name [get_timing_node_info -info name $node_id]
        if { [string match $bus_name* $node_name] } {
            lappend to_return $node_id
        }
    }
    return $to_return
}

# Required arguments for the script are the name of the project and
# revision, as well as the name of the bus to analyze
set options {\
    { "project.arg" "" "Project name" } \
    { "revision.arg" "" "Revision name" } \
    { "bus_name.arg" "" "Name of the bus to get timing data for" } \
}
array set opts [::cmdline::getoptions quartus(args) $options]

project_open $opts(project) -revision $opts(revision)

# The timing netlist must be created before accessing it.
create_timing_netlist

# This creates a data structure with additional timing data
create_p2p_delays

# Walk through each pin in the specified bus
foreach pin_id [find $opts(bus_name)] {
    set pin_name [get_timing_node_info -info name $pin_id]
    puts "$pin_name source registers and delays"
    # The get_delays_from_keepers command returns a list of all the
    # non-combinational nodes in the design that fan in to the
    # specified timing node, with the associated delays.
    foreach data [get_delays_from_keepers $pin_id] {
        set source_node [lindex $data 0]
        set max_delay [lindex $data 1]
        set source_node_name \
[get_timing_node_info -info name $source_node]
        puts " $source_node_name $max_delay"
    }
}
project_close
```

Type the command shown in Example 3–12 at a system command prompt to run this script.

Example 3–12.

```
quartus_tan -t script.tcl -project fir_filter -revision filtref -bus_name yn_out ↵
```

TimeQuest Timing Analysis

The Quartus II TimeQuest Timing Analyzer includes support for SDC commands in the **::quartus::sdc** package.

Refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook* for detailed information about how to perform timing analysis with the Quartus II TimeQuest Timing Analyzer.

TimeQuest Scripting

In versions of the Quartus II software before 6.0, the **::quartus::project** Tcl package contained the following SDC-like commands for making timing assignments:

- `create_base_clock`
- `create_relative_clock`
- `get_clocks`
- `set_clock_latency`
- `set_clock_uncertainty`
- `set_input_delay`
- `set_multicycle_assignment`
- `set_output_delay`
- `set_timing_cut_assignment`

These commands are not SDC-compliant. Beginning with version 6.0, these commands are in a new package named **::quartus::timing_assignment**. To ensure backwards compatibility with existing Tcl scripts, the **::quartus::timing_assignment** package is loaded by default in the following executables:

- `quartus`
- `quartus_sh`
- `quartus_cdb`
- `quartus_sim`
- `quartus_stp`
- `quartus_tan`

The **::quartus::timing_assignment** package is not loaded by default in the `quartus_sta` executable. The **::quartus::sdc** Tcl package includes SDC-compliant versions of the commands listed above. The package is available only in the `quartus_sta` executable and it is loaded by default.

Automating Script Execution

You can configure scripts to run automatically at various points during compilation (Beginning with the Quartus II software version 4.0). Use this capability to automatically run scripts that perform custom reporting, make specific assignments, and perform many other tasks.

© March 2009 Altera Corporation

The following three global assignments control when a script is run automatically:

- `PRE_FLOW_SCRIPT_FILE` —before a flow starts
- `POST_MODULE_SCRIPT_FILE` —after a module finishes
- `POST_FLOW_SCRIPT_FILE` —after a flow finishes

The `POST_FLOW_SCRIPT_FILE` and `POST_MODULE_SCRIPT_FILE` assignments are supported beginning in version 4.0, and the `PRE_FLOW_SCRIPT_FILE` assignment is supported beginning in version 4.1.

A module is a Quartus II executable that performs one step in a flow. For example, two modules are Analysis and Synthesis (`quartus_map`), and timing analysis (`quartus_tan`).

A flow is a series of modules that the Quartus II software runs with predefined options. For example, compiling a design is a flow that typically consists of the following steps (performed by the indicated module):

1. Analysis and synthesis (`quartus_map`)
2. Fitter (`quartus_fit`)
3. Assembler (`quartus_asm`)
4. Timing Analyzer (`quartus_tan` or `quartus_sta`)

Other flows are described in the help for the `execute_flow` Tcl command. In addition, many commands in the Processing menu of the Quartus II GUI correspond to this design flow.

Making the Assignment

To make an assignment automatically run a script, add an assignment with the following form to your project's **.qsf** file:

```
set_global_assignment -name <assignment name> <executable>:<script name>
```

The assignment name is one of the following:

- `PRE_FLOW_SCRIPT_FILE`
- `POST_MODULE_SCRIPT_FILE`
- `POST_FLOW_SCRIPT_FILE`

The executable is the name of a Quartus II command-line executable that includes a Tcl interpreter.

- `quartus_cdb`
- `quartus_sh`
- `quartus_sim`
- `quartus_sta`
- `quartus_stp`
- `quartus_tan`

The script name is the name of your Tcl script.

Script Execution

The Quartus II software runs the scripts as shown in Example 3–13.

Example 3–13.

```
<executable> -t <script name> <flow or module name> <project name> <revision name>
```

The first argument passed in the argv variable (or quartus(args) variable) is the name of the flow or module being executed, depending on the assignment you use. The second argument is the name of the project and the third argument is the name of the revision.

When you use the POST_MODULE_SCRIPT_FILE assignment, the specified script is automatically run after every executable in a flow. You can use a string comparison with the module name (the first argument passed in to the script) to isolate script processing to certain modules.

Execution Example

Example 3–14 illustrates how automatic script execution works in a complete flow, assuming you have a project called **top** with a current revision called **rev_1**, and you have the following assignments in the **.qsf** file for your project.

Example 3–14.

```
set_global_assignment -name PRE_FLOW_SCRIPT_FILE quartus_sh:first.tcl
set_global_assignment -name POST_MODULE_SCRIPT_FILE quartus_sh:next.tcl
set_global_assignment -name POST_FLOW_SCRIPT_FILE quartus_sh:last.tcl
```

When you compile your project, the PRE_FLOW_SCRIPT_FILE assignment causes the following command to be run before compilation begins:

```
quartus_sh -t first.tcl compile top rev_1
```

Next, the Quartus II software starts compilation with analysis and synthesis, performed by the quartus_map executable. After the analysis and synthesis finishes, the POST_MODULE_SCRIPT_FILE assignment causes the following command to run:

```
quartus_sh -t next.tcl quartus_map top rev_1
```

Then, the Quartus II software continues compilation with the Fitter, performed by the quartus_fit executable. After the Fitter finishes, the POST_MODULE_SCRIPT_FILE assignment runs the following command:

```
quartus_sh -t next.tcl quartus_fit top rev_1
```

Corresponding commands are run after the other stages of the compilation. When the compilation is over, the POST_FLOW_SCRIPT_FILE assignment runs the following command:

```
quartus_sh -t last.tcl compile top rev_1
```

© March 2009 Altera Corporation

Controlling Processing

The `POST_MODULE_SCRIPT_FILE` assignment causes a script to run after every module. Because the same script is run after every module, you might have to include some conditional statements that restrict processing in your script to certain modules.

For example, if you want a script to run only after timing analysis, you should include a conditional test like the one shown in Example 3–15. It checks the flow or module name passed as the first argument to the script and executes code when the module is `quartus_tan`.

Example 3–15. Restrict Processing to a Single Module

```
set module [lindex $quartus(args) 0]

if [string match "quartus_tan" $module] {

    # Include commands here that are run
    # after timing analysis
    # Use the post-message command to display
    # messages
    post_message "Running after timing analysis"
}
```

Displaying Messages

Because of the way the Quartus II software runs the scripts automatically, you must use the `post_message` command to display messages, instead of the `puts` command. This requirement applies only to scripts that are run by the three assignments listed in "Automating Script Execution" on page 3–22.

Refer to "Using the post_message Command" on page 3–27 for more information about this command.

Other Scripting Features

The Quartus II Tcl API includes other general-purpose commands and features described in this section.

Natural Bus Naming

Beginning with version 4.2, the Quartus II software supports natural bus naming. Natural bus naming means that square brackets used to specify bus indexes in HDL do not have to be escaped to prevent Tcl from interpreting them as commands. For example, one signal in a bus named address can be identified as `address[0]` instead of `address\[0\]`. You can take advantage of natural bus naming when making assignments, as in Example 3–16.

Example 3–16. Natural Bus Naming

```
set_location_assignment -to address[10] Pin_M20
```

The Quartus II software defaults to natural bus naming. You can turn off natural bus naming with the `disable_natural_bus_naming` command. For more information about natural bus naming, type the following at a Quartus II Tcl prompt:

```
enable_natural_bus_naming -h ↵
```

Short Option Names

Beginning with version 6.0 of the Quartus II software, you can use short versions of command options, as long as they distinguish between the command's options. For example, the `project_open` command supports two options: `-current_revision` and `-revision`. You can use any of the following shortened versions of the `-revision` option: `-r`, `-re`, `-rev`, `-revi`, `-revis`, and `-revisio`. You can use an option as short as `-r` because no other option starts with the same letters as revision. However, the `report_timing` command includes the options `-recovery` and `-removal`. You cannot use `-r` or `-re` to shorten either of those options, because they do not uniquely distinguish between the two options. You could use `-rec` or `-rem`.

Using Collection Commands

Some Quartus II Tcl functions return very large sets of data that would be inefficient as Tcl lists. These data structures are referred to as collections and the Quartus II Tcl API uses a collection ID to access the collection. There are two Quartus II Tcl commands for working with collections, `foreach_in_collection` and `get_collection_size`. Use the `set` command to assign a collection ID to a variable.

For information about which Quartus II Tcl commands return collection IDs, see the Quartus II Help and search for the `foreach_in_collection` command.

The foreach_in_collection Command

The `foreach_in_collection` command is similar to the `foreach` Tcl command. Use it to iterate through all elements in a collection. Example 3–17 prints all instance assignments in an open project.

Example 3–17. Using Collection Commands

```
set all_instance_assignments [get_all_instance_assignments -name *]
foreach_in_collection asgn $all_instance_assignments {
    # Information about each assignment is
    # returned in a list. For information
    # about the list elements, refer to Help
    # for the get-all-instance-assignments command.
    set to [lindex $asgn 2]
    set name [lindex $asgn 3]
    set value [lindex $asgn 4]
    puts "Assignment to $to: $name = $value"
}
```

The get_collection_size Command

Use the `get_collection_size` command to get the number of elements in a collection. Example 3–18 prints the number of global assignments in an open project.

Example 3–18. get_collection_size Command

```
set all_global_assignments [get_all_global_assignments -name *]
set num_global_assignments [get_collection_size $all_global_assignments]
puts "There are $num_global_assignments global assignments in your project"
```

Using the post_message Command

To print messages that are formatted like Quartus II software messages, use the `post_message` command. Messages printed by the `post_message` command appear in the **System** tab of the Messages window in the Quartus II GUI, and are written to standard at when scripts are run. Arguments for the `post_message` command include an optional message type and a required message string.

The message type can be one of the following:

- `info` (default)
- `extra_info`
- `warning`
- `critical_warning`
- `error`

If you do not specify a type, Quartus II software defaults to `info`.

When you are using the Quartus II software in Windows, you can color code messages displayed at the system command prompt with the `post_message` command. Add the following line to your **quartus2.ini** file:

```
DISPLAY_COMMAND_LINE_MESSAGES_IN_COLOR = on
```

Example 3–19 shows how to use the `post_message` command.

Example 3–19. post_message command

```
post_message -type warning "Design has gated clocks"
```

Accessing Command-Line Arguments

Many Tcl scripts are designed to accept command-line arguments, such as the name of a project or revision. The global variable `quartus(args)` is a list of the arguments typed on the command-line following the name of the Tcl script. Example 3–20 shows code that prints all of the arguments in the `quartus(args)` variable.

Example 3–20. Simple Command-Line Argument Access

```
set i 0
foreach arg $quartus(args) {
   puts "The value at index $i is $arg"
   incr i
}
```

If you copy the script in the previous example to a file named **print_args.tcl**, it displays the following output when you type the command shown in Example 3–21 at a command prompt.

Example 3–21. Passing Command-Line Arguments to Scripts

```
quartus_sh -t print_args.tcl my_project 100MHz ↵
The value at index 0 is <my_project>
The value at index 1 is 100MHz
```

Beginning with version 4.1, the Quartus II software supports the Tcl variables `argv`, `argc`, and `argv0` for command-line argument access. Table 3–6 shows equivalent information for earlier versions of the software.

Table 3–6. Quartus II Support for Tcl Variables

Beginning with Version 4.1	Equivalent Support in Previous Software Versions
`argc`	`llength $quartus(args)`
`argv`	`quartus(args)`
`argv0`	`info nameofexecutable`

Using the cmdline Package

You can use the **cmdline** package included with the Quartus II software for more robust and self-documenting command-line argument passing. The **cmdline** package supports command-line arguments with the form `-`*<option>* *<value>*.

Example 3–22 uses the **cmdline** package.

Example 3–22. cmdline Package

```
package require cmdline
variable ::argv0 $::quartus(args)
set options {
   { "project.arg" "" "Project name" }
   { "frequency.arg" "" "Frequency" }
}
set usage "You need to specify options and values"

array set optshash [::cmdline::getoptions ::argv $options $usage]
puts "The project name is $optshash(project)"
puts "The frequency is $optshash(frequency)"
```

If you save those commands in a Tcl script called **print_cmd_args.tcl** you see the following output when you type the command shown in Example 3–32 at a command prompt.

Example 3–23. Passing Command-Line Arguments for Scripts

```
quartus_sh -t print_cmd_args.tcl -project my_project -frequency 100MHz ↵
The project name is my_project
The frequency is 100MHz
```

Virtually all Quartus II Tcl scripts must open a project. Example 3–24 opens a project, and you can optionally specify a revision name. The example checks whether the specified project exists. If it does, the example opens the current revision, or the revision you specify.

Example 3–24. Full-Featured Method to Open Projects

```
package require cmdline
variable ::argv0 $::quartus(args)
set options { \
{ "project.arg" "" "Project Name" } \
{ "revision.arg" "" "Revision Name" } \
}
array set optshash [::cmdline::getoptions ::argv0 $options]

# Ensure the project exists before trying to open it
if {[project_exists $optshash(project)]} {

    if {[string equal "" $optshash(revision)]} {

        # There is no revision name specified, so default
        # to the current revision
        project_open $optshash(project) -current_revision
    } else {

        # There is a revision name specified, so open the
        # project with that revision
        project_open $optshash(project) -revision \
            $optshash(revision)
    }
} else {
    puts "Project $optshash(project) does not exist"
    exit 1
}
# The rest of your script goes here
```

If you do not require this flexibility or error checking, you can use just the `project_open` command, as shown in Example 3–25.

Example 3–25. Simple Method to Open Projects

```
set proj_name [lindex $argv 0]
project_open $proj_name
```

For more information about the **cmdline** package, refer to the documentation for the package at <*Quartus II installation directory*> **/common/tcl/packages.**

Using the Quartus II Tcl Shell in Interactive Mode

This section presents an example of using the `quartus_sh` interactive shell to make some project assignments and compile the finite impulse response (FIR) filter tutorial project. This example assumes that you already have the FIR filter tutorial design files in a project directory.

To begin, run the interactive Tcl shell. The command and initial output are shown in Example 3–26.

Example 3–26. Interactive Tcl Shell

```
tcl> quartus_sh -s
tcl> Info:
*******************************************************************

tcl>
```

Create a new project called **fir_filter**, with a revision called **filtref** by typing the following command at a Tcl prompt:

```
project_new -revision filtref fir_filter ↵
```

If the project file and project name are the same, the Quartus II software gives the revision the same name as the project.

Because the revision named **filtref** matches the top-level file, all design files are automatically picked up from the hierarchy tree.

Next, set a global assignment for the device with the following command:

```
set_global_assignment -name family Cyclone ↵
```

To learn more about assignment names that you can use with the `-name` option, refer to the Quartus II Help.

For assignment values that contain spaces, the value should be enclosed in quotation marks.

To quickly compile a design, use the `::quartus::flow` package, which properly exports the new project assignments and compiles the design using the proper sequence of the command-line executables. First, load the package:

```
load_package flow ↵
```

It returns the following:

```
1.0
```

For additional help on the `::quartus::flow` package, view the command-line help at the Tcl prompt by typing:

```
help -pkg ::quartus::flow ↵
```

Example 3–27 shows an alternative command and the resulting output.

Example 3–27. Help Output

```
tcl> help -pkg flow
----------------------------------------------------------------
------------------------
Tcl Package and Version:
------------------------
::quartus::flow 1.0
------------
Description:
------------
This package contains the set of Tcl functions
for running flows or command-line executables.
-------------
Tcl Commands:
-------------
execute_flow
execute_module
----------------------------------------------------------------
```

This help display gives information about the flow package and the commands that are available with the package.To learn about the options available for the `execute_flow` Tcl command, type the following command at a Tcl prompt:

```
execute_flow -h ↵
```

To view additional information and example usage type the following command at a Tcl prompt:

```
execute_flow -long_help ↵
```

or

```
help -cmd execute_flow ↵
```

To perform a full compilation of the FIR filter design, use the `execute_flow` command with the `-compile` option, as shown in Example 3–28.

Example 3–28.

```
tcl> execute_flow -compile ↵
Info:*******************************************************
Info: Running Quartus II Analysis & Synthesis
Info: Version 6.0 SJ Full Version
Info: Processing started: <date><time>
Info: Command: quartus_map --import_settings_files=on --export_settings_files=of
fir_filter -c filtref
.
.
.
Info: Writing report file filtref.tan.rpt
tcl>
```

This script compiles the FIR filter tutorial project, exporting the project assignments and running `quartus_map`, `quartus_fit`, `quartus_asm`, and `quartus_tan`. This sequence of events is the same as selecting **Start Compilation** from the Processing menu in the Quartus II GUI.

When you are finished with a project, close it using the `project_close` command as shown in Example 3–29.

Example 3–29.

```
project_close ↵
```

Exit the interactive Tcl shell, type `exit` ↵ at a Tcl prompt.

Quartus II Legacy Tcl Support

Beginning with the Quartus II software version 3.0, command-line executables do not support the Tcl commands used in previous versions of the Quartus II software. These commands are supported in the GUI with the Quartus II Tcl console or by using the `quartus_cmd` executable at the system command prompt. If you source Tcl scripts developed for an earlier version of the Quartus II software using either of these methods, the project assignments are ported to the project database and settings file. You can then use the command-line executables to process the resulting project. This might be necessary if you create a **.tcl** file using EDA tools that do not generate Tcl scripts for the most recent version of the Quartus II software.

You should create all new projects and Tcl scripts with the latest version of the Quartus II Tcl API.

Using the tclsh Shell

On the UNIX and Linux operating systems, the tclsh shell included with the Quartus II software is initialized with a minimal PATH environment variable. As a result, system commands may not be available within the tclsh shell because certain directories are not in the PATH environment variable. To include other directories in the path searched by the tclsh shell, set the QUARTUS_INIT_PATH environment variable before running the tclsh shell. Directories in the QUARTUS_INIT_PATH environment variable are searched by the tclsh shell when you execute a system command.

Tcl Scripting Basics

The core Tcl commands support variables, control structures, and procedures. Additionally, there are commands for accessing the file system and network sockets, and running other programs. You can create platform-independent graphical interfaces with the Tk widget set.

Tcl commands are executed immediately as they are typed in an interactive Tcl shell. You can also create scripts (including this chapter's examples) as files and run them with a Tcl interpreter. A Tcl script does not require any special headers.

To start an interactive Tcl interpreter, type `quartus_sh -s` ↵ at a command prompt. The commands you type are executed immediately at the interpreter prompt. If you save a series of Tcl commands in a file, you can run it with a Tcl interpreter. To run a script named **myscript.tcl**, type `quartus_sh -t myscript.tcl` ↵ at a command prompt.

Hello World Example

The following shows the basic "Hello world" example in Tcl:

```
puts "Hello world"
```

Use double quotation marks to group the words `hello` and `world` as one argument. Double quotation marks allow substitutions to occur in the group. Substitutions can be simple variable substitutions, or the result of running a nested command, described in "Substitutions" on page 3–33. Use curly braces { } for grouping when you want to prevent substitutions.

Variables

Use the `set` command to assign a value to a variable. You do not have to declare a variable before using it. Tcl variable names are case-sensitive. Example 3–30 assigns the value `1` to the variable named `a`.

Example 3–30. Assigning Variables

```
set a 1
```

To access the contents of a variable, use a dollar sign before the variable name. Example 3–31 prints `"Hello world"` in a different way.

Example 3–31. Accessing Variables

```
set a Hello
set b world
puts "$a $b"
```

Substitutions

Tcl performs three types of substitution:

- Variable value substitution
- Nested command substitution
- Backslash substitution

Variable Value Substitution

Variable value substitution, as shown in Example 3–31, refers to accessing the value stored in a variable by using a dollar sign ("$") before the variable name.

Nested Command Substitution

Nested command substitution refers to how the Tcl interpreter evaluates Tcl code in square brackets. The Tcl interpreter evaluates nested commands, starting with the innermost nested command, and commands nested at the same level from left to right. Each nested command result is substituted in the outer command. Example 3–32 sets a to the length of the string foo.

Example 3–32. Command Substitution

```
set a [string length foo]
```

Backlash Substitution

Backslash substitution allows you to quote reserved characters in Tcl, such as dollar signs ("$") and braces ("[ ]"). You can also specify other special ASCII characters like tabs and new lines with backslash substitutions. The backslash character is the Tcl line continuation character, used when a Tcl command wraps to more than one line. Example 3–33 shows how to use the backslash character for line continuation.

Example 3–33. Backslash Substitution

```
set this_is_a_long_variable_name [string length "Hello \
    world."]
```

Arithmetic

Use the expr command to perform arithmetic calculations. Using curly braces ("{ }") to group the arguments of this command makes arithmetic calculations more efficient and preserves numeric precision. Example 3–34 sets b to the sum of the value in the variable a and the square root of 2.

Example 3–34. Arithmetic with the expr Command

```
set a 5
set b [expr { $a + sqrt(2) }]
```

Tcl also supports boolean operators such as && (AND), || (OR), ! (NOT), and comparison operators such as < (less than), > (greater than), and == (equal to).

Lists

A Tcl list is a series of values. Supported list operations include creating lists, appending lists, extracting list elements, computing the length of a list, sorting a list, and more. Example 3–35 sets a to a list with three numbers in it.

Example 3–35. Creating Simple Lists

```
set a { 1 2 3 }
```

You can use the `lindex` command to extract information at a specific index in a list. Indexes are zero-based. You can use the index `end` to specify the last element in the list, or the index `end-<n>` to count from the end of the list. Example 3–36 prints the second element (at index 1) in the list stored in `a`.

Example 3–36. Accessing List Elements

```
puts [lindex $a 1]
```

The `llength` command returns the length of a list. Example 3–37 prints the length of the list stored in `a`.

Example 3–37. List Length

```
puts [llength $a]
```

The `lappend` command appends elements to a list. If a list does not already exist, the list you specify is created. The list variable name is not specified with a dollar sign. Example 3–38 appends some elements to the list stored in `a`.

Example 3–38. Appending to a List

```
lappend a 4 5 6
```

Arrays

Arrays are similar to lists except that they use a string-based index. Tcl arrays are implemented as hash tables. You can create arrays by setting each element individually or by using the `array set` command. To set an element with an index of `Mon` to a value of `Monday` in an array called `days`, use the following command:

```
set days(Mon) Monday
```

The `array set` command requires a list of index/value pairs. This example sets the array called days:

```
array set days { Sun Sunday Mon Monday Tue Tuesday \
   Wed Wednesday Thu Thursday Fri Friday Sat Saturday }
```

Example 3–39 shows how to access the value for a particular index.

Example 3–39. Accessing Array Elements

```
set day_abbreviation Mon
puts $days($day_abbreviation)
```

Use the `array names` command to get a list of all the indexes in a particular array. The index values are not returned in any specified order. Example 3–40 shows one way to iterate over all the values in an array.

Example 3–40. Iterating Over Arrays

```
foreach day [array names days] {
   puts "The abbreviation $day corresponds to the day \
name $days($day)"
}
```

Arrays are a very flexible way of storing information in a Tcl script and are a good way to build complex data structures.

Control Structures

Tcl supports common control structures, including if-then-else conditions and `for`, `foreach`, and `while` loops. The position of the curly braces as shown in the following examples ensures the control structure commands are executed efficiently and correctly. Example 3–41 prints whether the value of variable `a` positive, negative, or zero.

Example 3–41. If-Then-Else Structure

```
if { $a > 0 } {
    puts "The value is positive"
} elseif { $a < 0 } {
    puts "The value is negative"
} else {
    puts "The value is zero"
}
```

Example 3–42 uses a `for` loop to print each element in a list.

Example 3–42. For Loop

```
set a { 1 2 3 }
for { set i 0 } { $i < [llength $a] } { incr i } {
    puts "The list element at index $i is [lindex $a $i]"
}
```

Example 3–43 uses a `foreach` loop to print each element in a list.

Example 3–43. foreach Loop

```
set a { 1 2 3 }
foreach element $a {
    puts "The list element is $element"
}
```

Example 3–44 uses a `while` loop to print each element in a list.

Example 3–44. while Loop

```
set a { 1 2 3 }
set i 0
while { $i < [llength $a] } {
    puts "The list element at index $i is [lindex $a $i]"
    incr i
}
```

You do not have to use the `expr` command in boolean expressions in control structure commands because they invoke the `expr` command automatically.

Procedures

Use the `proc` command to define a Tcl procedure (known as a subroutine or function in other scripting and programming languages). The scope of variables in a procedure is local to the procedure. If the procedure returns a value, use the `return` command to return the value from the procedure. Example 3–45 defines a procedure that multiplies two numbers and returns the result.

Example 3–45. Simple Procedure

```
proc multiply { x y } {
    set product [expr { $x * $y }]
    return $product
}
```

Example 3–46 shows how to use the `multiply` procedure in your code. You must define a procedure before your script calls it.

Example 3–46. Using a Procedure

```
proc multiply { x y } {
    set product [expr { $x * $y }]
    return $product
}
set a 1
set b 2
puts [multiply $a $b]
```

You should define procedures near the beginning of a script. If you want to access global variables in a procedure, use the `global` command in each procedure that uses a global variable. Example 3–47 defines a procedure that prints an element in a global list of numbers, then calls the procedure.

Example 3–47. Accessing Global Variables

```
proc print_global_list_element { i } {
    global my_data
    puts "The list element at index $i is [lindex $my_data $i]"
}
set my_data { 1 2 3}
print_global_list_element 0
```

File I/O

Tcl includes commands to read from and write to files. You must open a file before you can read from or write to it, and close it when the read and write operations are done. To open a file, use the `open` command; to close a file, use the `close` command. When you open a file, specify its name and the mode in which to open it. If you do not specify a mode, Tcl defaults to read mode. To write to a file, specify `w` for write mode as shown in Example 3–48.

Example 3–48. Open a File for Writing

```
set output [open myfile.txt w]
```

Tcl supports other modes, including appending to existing files and reading from and writing to the same file.

The `open` command returns a file handle to use for read or write access. You can use the `puts` command to write to a file by specifying a filehandle, as shown in Example 3–49.

Example 3–49. Write to a File

```
set output [open myfile.txt w]
puts $output "This text is written to the file."
close $output
```

You can read a file one line at a time with the `gets` command. Example 3–50 uses the `gets` command to read each line of the file and then prints it out with its line number.

Example 3–50. Read from a File

```
set input [open myfile.txt]
set line_num 1
while { [gets $input line] >= 0 } {
    # Process the line of text here
    puts "$line_num: $line"
    incr line_num
}
close $input
```

Syntax and Comments

Arguments to Tcl commands are separated by white space, and Tcl commands are terminated by a newline character or a semicolon. As shown in "Substitutions" on page 3–33, you must use backslashes when a Tcl command extends more than one line.

Tcl uses the hash or pound character (#) to begin comments. The # character must begin a comment. If you prefer to include comments on the same line as a command, be sure to terminate the command with a semicolon before the # character. Example 3–51 is a valid line of code that includes a `set` command and a comment.

Example 3–51. Comments

```
set a 1;# Initializes a
```

Without the semicolon, it would be an invalid command because the `set` command would not terminate until the new line after the comment.

The Tcl interpreter counts curly braces inside comments, which can lead to errors that are difficult to track down. Example 3–52 causes an error because of unbalanced curly braces.

Example 3–52. Unbalanced Braces in Comments

```
# if { $x > 0 } {
if { $y > 0 } {
    # code here
}
```

Document Revision History

Table 3–7 shows the revision history for this chapter.

Table 3–7. Document Revision History

Date / Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Removed the "EDA Tool Assignments" section ■ Added the section "Compile All Revisions" on page 3–15 ■ Added the section "Using the tclsh Shell" on page 3–32	Updated for the Quartus II software version 9.0.
November 2008 v8.1.0	Changed to 8½" × 11" page size. No change to content.	Updated for the Quartus II software version 8.1.
May 2008 v8.0.0	Updated references.	Updated for the Quartus II software version 8.0.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

4. Managing Quartus II Projects

QII52012-9.0.0

Introduction

FPGA designs once required just one or two engineers, but today's larger and more sophisticated FPGA designs are often developed by several engineers and are constantly changing throughout the project. To ensure efficient design coordination, designers must track their project changes.

To help designers manage their FPGA designs, the Quartus® II software provides the following capabilities:

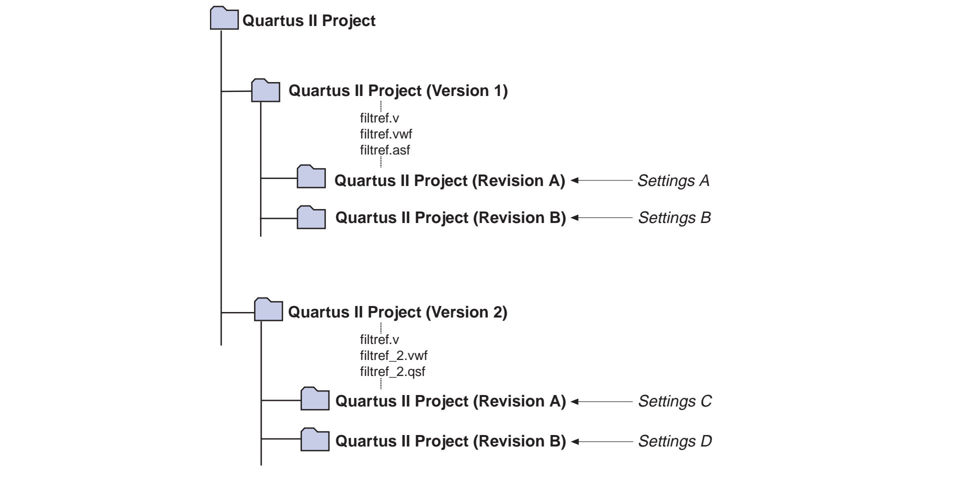
- Create revisions
- Copy and archive projects
- Make a version compatible database
- Control message suppression

In the Quartus II software, a revision is a set of assignments and settings. A project may have multiple revisions, with each revision having its own set of assignments and settings. You can create multiple revisions to change assignments and settings while preserving the previous results.

A version is a Quartus II project that includes one set of design files, and one or more revisions (assignments and settings for your project). Creating multiple versions with the Copy Project feature allows you to edit a copy of your design files while preserving the original functionality of your design in another copy.

The Quartus II software Version Compatible Database feature allows Quartus II databases to be compatible across different versions of the Quartus II software, which saves valuable design time by avoiding unnecessary compilations (Figure 4–1). This chapter also discusses how to migrate your projects from one computing platform to another, as well as message suppression.

Figure 4–1. Quartus II Version Compatible Database Structure



Creating a New Project

A Quartus II project contains all the design files, settings files, and other files necessary for the successful compilation of your design. These files include the following files that contain the project settings:

- Quartus II Project File (**.qpf**)—contains the name of your project and all revisions of your project, described in “Using Revisions with Your Design” on page 4–2.
- Quartus II Settings File (**.qsf**)—contains all assignments applied to your design, including assignments to help fit your design and meet performance requirements. For more information about the **.qsf** file, refer to “Quartus II Settings File” on page 4–21.
- Synopsys Design Constraints (**.sdc**)—contains timing assignments for the Quartus II TimeQuest Timing Analyzer.

For more information about SDC constraints, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

To start a new Quartus II project, use the **New Project Wizard**. On the File menu, click **New Project Wizard,** and add the following project information:

- Project name and directory
- Name of the top-level design entity
- Project files and user libraries
- Target device family and device
- EDA tool settings

For more information about user libraries, refer to “Specifying Libraries” on page 4–11 and “Specifying Libraries Using Scripts” on page 4–25.

Using Revisions with Your Design

The Revisions feature allows you to create a new set of assignments and settings for a set of design files without losing your previous assignments and settings. You can use the Revisions feature in the following ways:

- Create a unique revision which is not based on a previous revision. Creating a unique revision lets you optimize a design for different fundamental reasons such as to optimize by area in one revision, then optimize for f_{MAX} in another revision. When you create a unique revision (a revision that is not based on an existing revision), all default settings are turned on.
- Create a revision based on an existing revision, but try new settings and assignments in the new revision. A new revision already includes all the assignments and settings applied in the previous revision. If you are not satisfied with the results in the new revision, you can revert to the original revision. You can compare revisions manually or with the Compare feature.

Creating and Deleting Revisions

All Quartus II assignments and settings are stored in the **.qsf** file. Each time you create a new revision of a project, the Quartus II software creates a new **.qsf** file and adds the name of the new revision to the list of revisions in the **.qsf** file.

The name of a new **.qsf** file matches the revision name.

You can manage revisions with the **Revisions** dialog box, which allows you to set the current revision, and perform the following tasks:

- "Create a Revision"
- "Delete a Revision"
- "Compare Revisions"

Create a Revision

To create a revision, perform the following steps:

1. If you have not already done so, create a new project or open an existing project. On the File menu, click **New Project Wizard** or **Open Project.**
2. On the Project menu, click **Revisions**.
3. To base the new revision on an existing revision for the current design, select the existing revision in the **Revisions** list.
4. Click **Create**.
5. In the **Create Revision** dialog box, type the name of the new revision in the **Revisions name** box.
6. To base the new revision on an existing revision for the current design, if you did not select the correct revision in Step 3, select the revision in the **Based on revision** list. To create a unique revision that is not based on an existing revision of the current design, select the "blank entry" in the **Based on revision** list.
7. Optionally, edit the description of the revision in the **Description** box.
8. Turn off the **Copy database** option if you do not want the new revision to contain the database information from the existing revision. The **Copy database** option is on by default.

   Copying the database allows you to view the results from the previous compilation while you are making changes to the settings of the new revision.

9. If you do not want to use the new revision immediately, turn off the **Set as current revision** option. The **Set as current revision** option is turned on by default.
10. Click **OK**.

Delete a Revision

To delete a revision, perform the following steps:

1. If you have not already done so, open an existing project by clicking **Open Project** on the File menu and selecting **Quartus II Project File.**
2. On the Project menu, click **Revisions**.
3. In the **Revisions** list, select the revision you want to delete and click **Delete**.

You cannot delete the current revision when it is active; you must first open another revision. For example, if revision A is currently active, you must create (if the revision does not exist) and open revision B before you delete revision A.

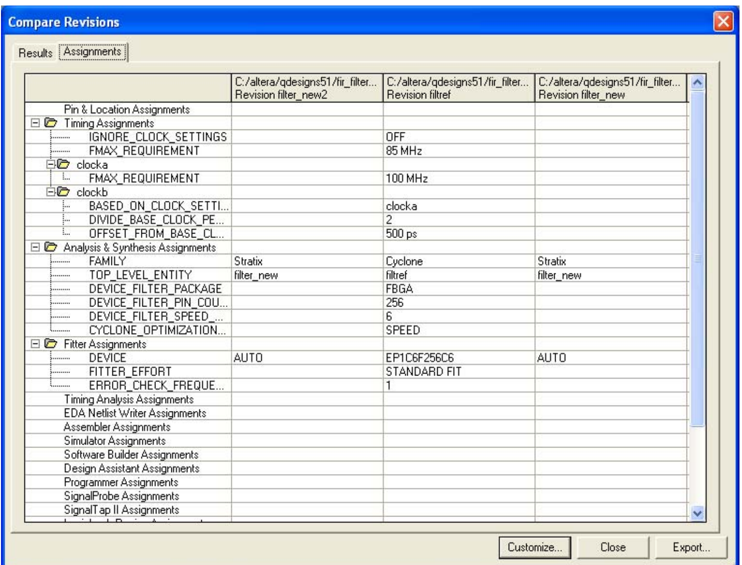
Compare Revisions

You can compare the results of multiple revisions side by side with the **Compare Revisions** dialog box.

1. On the Project menu, click **Revisions**.
2. In the **Revisions** dialog box, click **Compare** to compare all revisions in a single window.

The **Compare Revisions** dialog box (Figure 4–2) compares the results of each revision in three assignment categories: **Analysis & Synthesis**, **Fitter**, and **Timing Analyzer**.

Figure 4–2. Compare Revisions Dialog Box



© March 2009 Altera Corporation

In addition to viewing the results of each revision, you can show the assignments for each revision. Click the **Assignments** tab in the **Compare Revisions** dialog box to view all assignments applied to each revision (Figure 4–2). To export both **Results** and **Assignments** for your revisions, click on **Export.** When the dialog box appears, enter the name of the Comma-Separated Value (.**csv**) file in which the software will export the data when you click **OK**. View the results of each revision and their assignments to gain better understanding of how different optimization options affect your design.

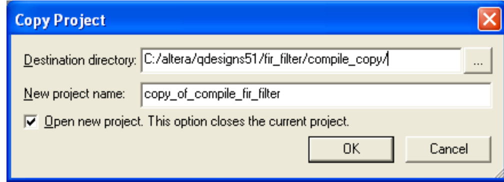
Creating New Copies of Your Design

Managing different copies of design files in a large project can become difficult. To assist you in this task, the Quartus II software provides utilities to copy and save different copies of your project. Creating a copy of your project using the Copy Project feature includes copying all your design files, your **.qsf** file, and all your associated revisions (all assignments and settings).

To create a new copy of your project with the Quartus II software, create a copy of your project and edit your design files (for example, if you have a design that is compatible with a 32-bit data bus and you require a new copy of the design to interface with a 64-bit data bus). To solve this problem, create a new copy of your project and edit the new version of the design files by performing the following steps:

1. On the Project menu, click **Copy Project**. The **Copy Project** dialog box appears (Figure 4–3).

Figure 4–3. Copy Project Dialog Box



2. Specify the path to your new project in the **Destination directory** box.
3. Type the new project name in the **New project name** box.
4. To open the new project immediately, turn on **Open new project. This option closes the current project** option.
5. Click **OK**.

When creating a new copy of your project with an EDIF or Verilog Quartus Mapping (.**vqm**) netlist file from a third-party EDA synthesis tool, create a copy of your project and then replace the previous netlist file with the newly generated netlist file. On the Project menu, click **Copy Project** to create a copy of your design. On the Project menu, click the **Add/Remove Files** command to add and remove design files, if necessary.

Archiving Projects with the Quartus II Archive Project Feature

A single project can contain hundreds of files in many directories, which can make transferring a project between engineers difficult. You can use the Quartus II Archive Project feature to create a single compressed Quartus II Archive File (**.qar**) of your project containing all your design, project, and settings files. The **.qar** file contains all the files, including the Quartus II Default Settings File (**.qdf**), required to perform a full compilation to restore the original results. The **.qdf** file contains all the project and assignment default settings from the current version of the Quartus II software. It is necessary to archive the **.qdf** file to preserve your results when you restore the archive in a different version of the Quartus II software. For more information about the **.qdf** file, refer to "Quartus II Default Settings File" on page 4–22.

You can easily share projects between engineers with the archive file generated by the Archive Project feature.

Archive a Project

To archive a project, perform the following steps:

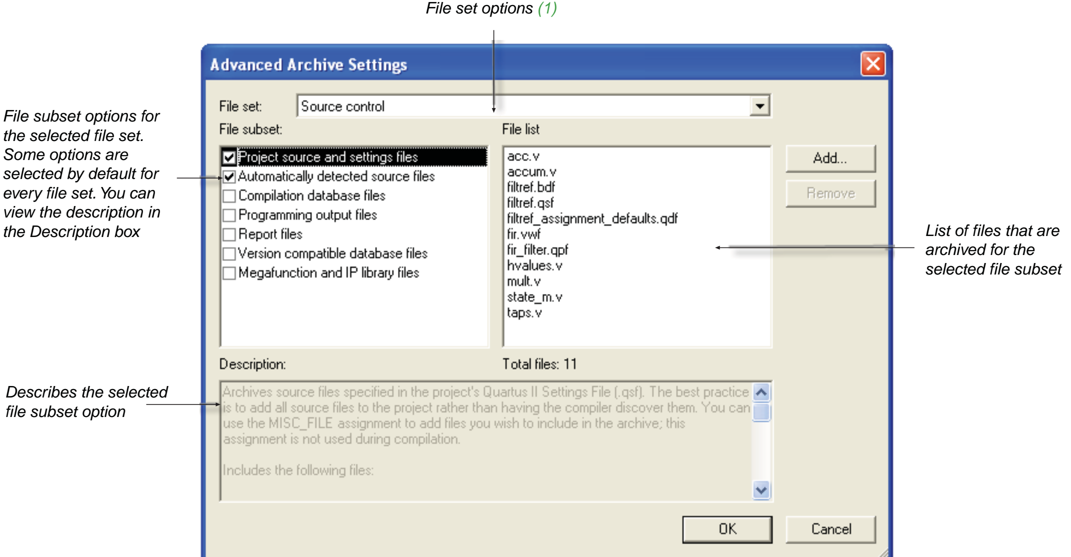
1. Create a new project or open an existing project. On the File menu, click **New Project Wizard** or **Open Project.**
2. On the Processing menu, point to **Start** and click **Start Analysis & Elaboration.**

Altera recommends that you perform analysis and elaboration before archiving a project to ensure that all design files are located and archived.

3. On the Project menu, click **Archive Project**. The **Archive Project** dialog box appears.
4. Under **Archive file name**, type the file name of the **.qar** file that you want to archive, or click **Browse** to select a **.qar** file name.
5. Click **Advanced...** for more archiving options. You can choose the type of files you want to archive by selecting the file set type from the list. The default Source Control file set includes all project source files and settings files. The default archive does not include the compilation results, or post-compilation netlists for incremental compilation. However, the imported Quartus II Exported Partition (**.qxp**) files are included by default for all file set options if you run the Quartus II incremental compilation.

© March 2009 Altera Corporation

Figure 4–4. Advanced Archive Settings Dialog Box



Note to Figure 4–4:

(1) For more information about file set options, refer to Table 4–1 on page 4–7.

Altera recommends that you include all source files in your Quartus II project rather than having the compiler discover them. Specify all your source files in the **.qsf** file, using the **Add/Remove Files in Project** command from the Project menu. If all source files are not specified in your project, you can click **Add...** to manually add files to the archive.

6. Click **Archive**.

Table 4–1 shows the types of file set options.

Table 4–1. File Set Options

File Set	Description
Source control	This is the default setting for the Quartus II software archive feature. This file set includes project source files specified in the **.qsf** and all automatically detected source files. The file set also includes any imported Quartus II Exported Partition (**.qxp**) files for incremental compilation, because top-level projects do not include source files for imported partitions.
Source control with compilation database	This file set includes files from the Source control settings, plus the compilation database files. This file set includes the previous compilation results, so you can analyze or view the results in tools such as the Chip Planner. The compilation database is required to preserve post-synthesis or post-fitter netlists for incremental compilation. However, the archived file for this setting is larger in size.
Service request	This file set includes files from the Source control settings, the report files and programming output files are included. This file set is useful when you must attach your design files to a service request with Altera technical support, and for debugging purposes.

Table 4–1. File Set Options

File Set	Description
Service request with compilation database	This file set is useful when you want to include the database files so that technical support can analyze or view the results in tools such as the Chip Planner without performing a new compilation, or to duplicate the post-synthesis or post-fitter netlists for incremental compilation.
Custom	Use this file set to select the types of files that you want to include in the archive from the file subset list. When you add or remove file subsets from one the predefined file set, the file set selection automatically changes to Custom.

Restore an Archived Project

To restore an archived project, perform the following steps:

1. On the Project menu, click **Restore Archived Project**.
2. In the **Archive file name** box, type the file name of the **.qar** file you wish to restore, or click **Browse** to select a **.qar** file.
3. In the **Destination folder** box, specify the directory path in which you will restore the contents of the **.qar** file, or browse to a directory.
4. Click **Show log** to view the Quartus II Archive Log File (**.qarlog**) for the project you are restoring from the **.qar** file (optional).
5. Click **OK**.
6. If you did not include the compilation database files in the project archive using the Advanced File Sets, you must recompile the project.

   ☞ Altera recommends that you recompile the project if the Project Navigator does not display the correct source-file paths for a restored project.

   ☞ To remove any unwanted restored megafunction files from your project, perform the following steps:

   a. Locate and delete the megafunction files in: *<drive><restored_project>*/**megafunctions**.
   b. Locate and delete the XML file in: *<drive><restored_project>/<revision.name>***.cbx.xml**. The ***_cbx.xml** file is revision-based. Altera uses the XML format to describe data in different file types for revision report, design metadata, component declaration, ports and nodes assignments, device utilization and more. For more information about the XML files, you can refer to the Quartus II Help.

Version Compatible Databases

The Version Compatible Database feature allows you to export a version compatible database and import it into a later version. For example, using one set of design files, you can export a database generated from the Quartus II software version 7.2 and import it into the Quartus II software version 8.0 and later without recompiling your design. Using this feature eliminates unnecessary compilation time.

This feature is not supported immediately for new device families added to the Quartus II software, because some device information might still be preliminary. Version compatible database support is added for each new device family in a later software release after the device family introduction.

Migrate to a New Version

To migrate a design from one Quartus II software version to a newer version, perform the following steps:

1. On the File menu, open the older version of the Quartus II software project by clicking **Open Project** and browse to select the Quartus II project file.
2. On the Project menu, click **Copy Project** to make a new copy of the project. The older version closes and the copied project opens.
3. If you have not run Analysis & Synthesis for the new version, you must do so before exporting the database. On the Project menu, click **Export Database**. By default, the database is exported to the **export_db** directory of the copied project. If desired, a new directory can be created.
4. Open the copied project from the new version of the Quartus II software. The Quartus II software deletes the existing database but not the exported database.
5. On the Project menu, click **Import Database**. By default, the directory of the database you just exported is selected. Select the exported database and the Quartus II software imports the version compatible database files.

Save the Database in a Version Compatible Format

To save the database in a version compatible format during a full compilation, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Compilation Process Settings**. The **Compilation Process Settings** page appears.
3. Turn on the **Export version compatible database** option.
4. Browse to the directory in which you want to save the database.
5. Click **OK**.

Quartus II Project Platform Migration

When moving your project from one computing platform to another, you must think about the following cross-platform issues:

- "Filenames and Hierarchies"
- "Specifying Libraries"
- "Quartus II Search Path Precedence Rules"
- "Quartus II-Generated Files for Third-Party EDA Tools"
- "Migrating Database Files between Platforms"

Filenames and Hierarchies

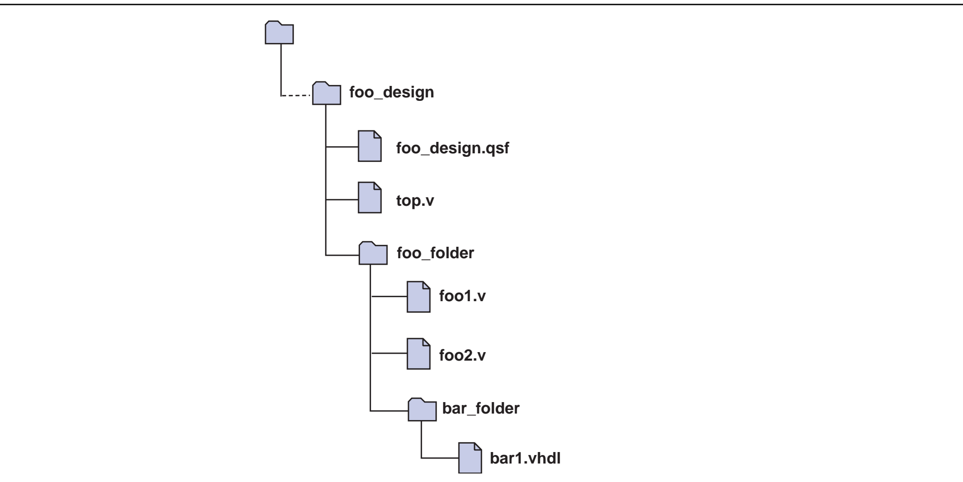
To ensure migration across platforms, you must consider a few basic differences between operating systems when naming source files, especially when interacting with these from the system-command prompt or a Tcl script:

- Some operating system file systems are case-sensitive. When writing scripts, ensure you specify paths exactly, even if the current operating system is not case-sensitive. For best results, use lowercase letters when naming files.
- Use a character set common to all the used platforms.
- Do not convert the forward-slash / and back-slash \ path separators in the **.qsf** file because the Quartus II software changes all back-slash \ path separators to forward-slashes /.
- Observe the shortest file name length limit of the different operating systems you are using.

Altera recommends that you avoid naming the project directory with spaces in between. You can rename the directory using a symbol such as the underscore (_) as a place holder instead of spaces (for example, "my_design" instead of "my design").

You can specify files and directories inside a Quartus II project as paths relative to the project directory. For instance, for a project titled **foo_design** with a directory structure shown in Figure 4–5, specify the source files as: **top.v, foo_folder/foo1.v**, **foo_folder/foo2.v**, and **foo_folder/bar_folder/bar1.vhdl**.

Figure 4–5. All-Inclusive Project Directory Structure



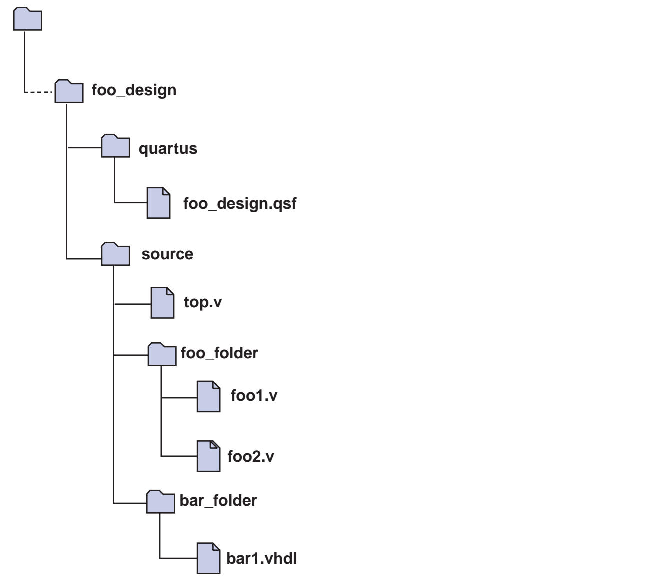
If the **.qsf** file is in a directory that is separate from the source files, you can specify paths using the following options:

- Relative paths
- Absolute paths
- Libraries

Relative Paths

If the source files are very near the Quartus II project directory, you can express relative paths using the `..` notation. For example, given the directory structure shown in Figure 4–6, you can specify **top.v** as **../source/top.v** and **foo1.v** as **../source/foo_folder/foo1.v**.

Figure 4–6. Quartus II Project Directory Separate from Design Files



When you copy a directory structure to a different platform, ensure that any subdirectories are in the same hierarchical structure and relative path as in the original platform.

Specifying Libraries

You also can specify the directory (or directories) containing source files as a library that the Quartus II software searches when you compile your project. A Quartus II library is a directory containing design files used by your Quartus II project. You can specify the following two kinds of libraries in the Quartus II software:

- User libraries, which apply to a specific project
- Global libraries, which all projects use

Use the procedures in this section to specify user or global libraries.

All files in the directories specified as libraries are relative to the libraries. For example, if you want to include the file **/user_lib1/foo1.v** and the **user_lib1** directory is specified as a user library in the project, the **foo1.v** file can be specified in the **.qsf** file as **foo1.v**. The Quartus II software searches directories that are specified as libraries and finds the file.

Specifying User Libraries

To specify user libraries from the GUI, on the Assignments menu, click **Settings**, and select **Libraries.** Type the name of the directory in the **Project Library name** box, or browse to the name of the directory. User libraries are stored in the **.qsf** file of the current revision.

Specifying Global Libraries

To specify global libraries from the GUI, on the Tools menu, click **Options**, and select **Global User Libraries (All Project).** Type the name of the directory in the **Library name** box, or browse to the name of the directory. Global libraries are stored in the **quartus2.ini** file.

The Quartus II software searches for the **quartus2.ini** file in the following order:

- USERPROFILE, for example, **C:\Documents and Settings**<*user name*>
- Directory specified by the **TMP** environmental variable
- Directory specified by **TEMP** environmental variable
- Root directory, for example, **C:**

For UNIX and Linux users, the file is created in the **altera.quartus** directory under the **<*home*>** directory, if the **altera.quartus** directory exists. If the **altera.quartus** directory does not exist, the file is created in the **<*home*>** directory.

Whenever you specify a directory name in the GUI or in Tcl, the name you use is maintained verbatim in the **.qsf** file rather than resolved to an absolute path.

If the directory is outside of the project directory, the path returned in the dialog box is an absolute path.You can use the **Browse** button in either the **Settings** dialog box or the **Options** dialog box to select a directory. You can change the absolute path to a relative path by editing the absolute path displayed in the **library name** field to create a relative path before you click **Add** to put the directory in the **Libraries** list or select from the **Libraries** list and double-click to edit the path.

When copying projects that specify user libraries, you must either copy your user library files along with the project directory or ensure that your user library files exist in the target platform.

Quartus II Search Path Precedence Rules

If two files have the same file name, the file found is determined by the Quartus II software's search path precedence rules. The Quartus II software resolves relative paths by searching for the file in the following directories and order:

1. The project directory, which is the directory containing the **.qsf** file.
2. The project's database (**db)** directory.
3. User libraries are searched in the order specified by the **SEARCH_PATH** setting of the **.qsf** file for the current revision.
4. Global user libraries are searched in the order specified by the **SEARCH_PATH** setting on the **Global User Libraries** page in the **Options** dialog box.

Beginning with the Quartus II software version 9.0, Altera recommends that you use the **SEARCH_PATH** assignment to define the user libraries. You can have multiple **SEARCH_PATH** assignments. However, you can specify only one source directory for each **SEARCH_PATH** assignment. For more information about **SEARCH_PATH** assignments, refer to Example 4–5 on page 4–25.

5. The Quartus II software **libraries** directory, for example, ***<Quartus II Software Installation directory>*\libraries**. For more information about libraries, refer to "Specifying Libraries Using Scripts" on page 4–25.

Quartus II-Generated Files for Third-Party EDA Tools

The project archive and copy feature in the Quartus II software does not include Quartus II generated files for third-party EDA tools such as the Verilog Output Files (**.vo**), VHDL Output Files (**.vho**), Standard Delay Format Output Files (**.sdo**) output netlist files, Stamp model files, PartMiner XML-Format Files (**.xml**), and IBIS Output Files (**.ibs**). When you archive the design project, you can save the database in a version compatible format during a full compilation and include the version compatible database files in your project archive. For more information about saving the database in a version compatible format and archiving projects, refer to "Save the Database in a Version Compatible Format" on page 4–9 and "Archiving Projects" on page 4–23.

If you want to copy your project to another platform, you can regenerate the output netlist or output files by performing the following steps:

1. Import the version compatible database (for more information, refer to "Migrate to a New Version" on page 4–9).
2. You can run the Classic Timing Analyzer or the TimeQuest Timing Analyzer from the Processing menu followed by the EDA Netlist Writer.

If you want to restore your project, you can regenerate the output netlist or output files by performing the following steps:

1. Restore the design project. For more information about restoring an archived project, refer to "Restore an Archived Project" on page 4–8.
2. Import the version compatible database. For more information about migrating to a new version, refer "Migrate to a New Version" on page 4–9.
3. You can run the Classic Timing Analyzer or the Quartus II TimeQuest Timing Analyzer from the Processing menu followed by the EDA Netlist Writer.

When you create version compatible databases, you do not need to recompile your design as you move across platform.

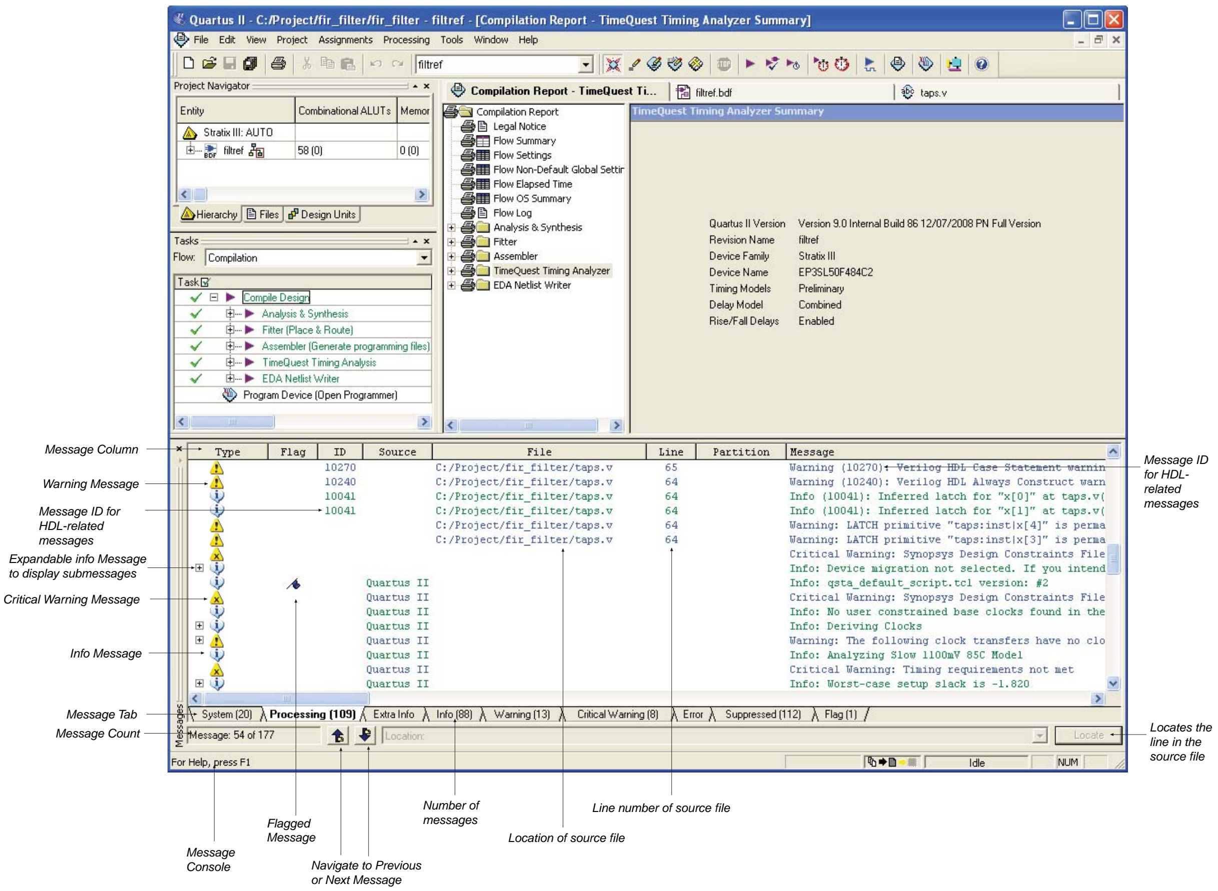
Migrating Database Files between Platforms

There is nothing inherent in the file format and syntax of the exported version compatible database files that might cause problems when migrating the files to other platforms. However, the contents of the database can cause problems for platform migration. For example, using the absolute paths in version compatible database files generated by the Quartus II software can cause problems for migration. Altera recommends that you change the absolute paths to relative paths before migrating files whenever possible.

Working with Messages

The Quartus II software generates various types of messages, including Information, Warning, and Error messages. Some messages include information on software status during a compilation and alert you to possible problems with your design. Messages are displayed in the Messages box in the Quartus II GUI (Figure 4–7), and written to standard out when you use command-line executables. In both cases, messages are written to Quartus II report files.

Figure 4–7. Viewing Quartus II Messages



You can right-click on a message in the Message window to get help for the message, locate the source of the message of your design, and manage messages.

Messages provide useful information if you take time to review them after each compilation. However, it can be tedious if there are thousands of them. The Quartus II software includes features to help you manage messages. These are described in the following subsections.

Messages Window

By default, the Messages window displays eight message tabs (Table 4–2), which makes it easy to review all messages of a certain type.

Table 4–2. Quartus II Message Tabs

Message Tab	Icon	Description
System	—	Displays messages that are unrelated to processing your design. For example: messages generated during programming are displayed in the **System** tab.
Processing	—	Displays messages that are generated when the Quartus II software processes your most recent compilation, simulation, or software build; timing analysis messages appear as part of the compilation messages.
Info	—	Displays general informational messages during a compilation, simulation, or software build. For example: compilation-success messages, and information about your design that might be helpful but is not necessarily a cause for concern such as warning or error messages.
Extra Info	—	Displays detailed informational messages about the operations for designers. For example: extra fitting information messages.
Warning		Displays strong warning messages generated during a compilation, simulation, or software build.
Critical Warning		Displays critical warning messages generated during a compilation, simulation, or software build.
Error		Displays processing and compilation error messages generated during a compilation, simulation, or software build. Error messages can sometimes stop processing and cannot be disabled.
Suppressed		Displays suppressed messages during the last processing operation.
Flag		Displays flagged messaged. In any tab, a flag icon appears in the optional **Flag** column to indicate a flagged message.

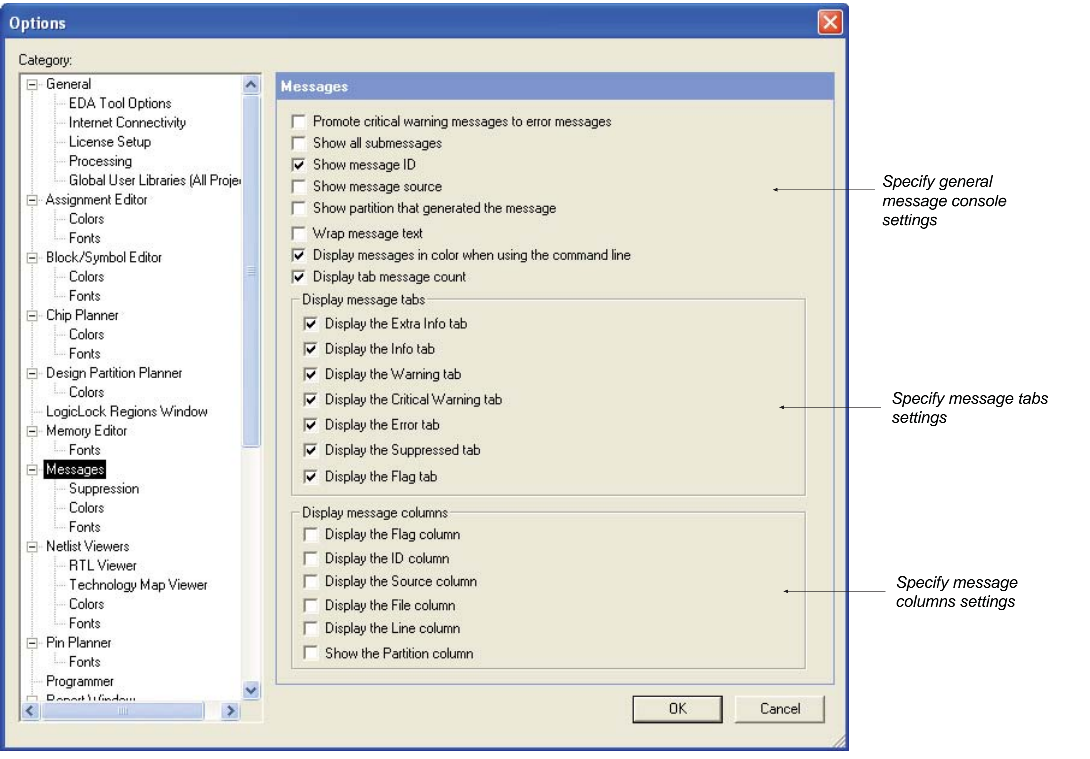
The **Info**, **Extra Info**, **Warning**, **Critical Warning**, and **Error** tabs display messages grouped by type.

A **Message ID** displays in parentheses at the beginning of some HDL-related messages, which you can use to enable or disable the specific messages. The **Message Status** box indicates the number of the message currently selected and the total number of messages. The **Message Location** list indicates the line number in the source file or files in which the message originates. For each compilation, any number of messages can be flagged and you can later choose to export or import flagged messages to or from another Quartus II project.

You can control which tabs are displayed by setting the options on the **Messages** page in the **Options** dialog box on the Tools menu (Figure 4–8). You can select the message suppression settings at the **Messages** page in the **Options** dialog box (see Figure 4–9 on page 4–17) or you can create suppression rules to suppress any set of non-critical messages with the **Message Suppression Manager** dialog box.

For more information about Message Suppression and Message Suppression Manager, refer to "Message Suppression" on page 4–17 and "Message Suppression Manager" on page 4–19.

Figure 4–8. Message Tab Options



Hiding Messages

In the Messages window, you can hide all messages of a particular type. For example, to hide Info messages, perform the following steps:

1. On the **Processing** tab, right-click in the **Processing message** dialog box and click the **Hide** option.
2. Select the **Hide** options type (point to **Hide** and click **Hide Critical Warning Messages**, for example).

All messages of the specified type are removed from the list of messages in the **Processing** tab, although they are still included in the separate tabs corresponding to the message type. For example, if you hide Info messages, no Info messages are shown in the **Processing message** dialog box, but all the Info messages are shown in the Info messages window.

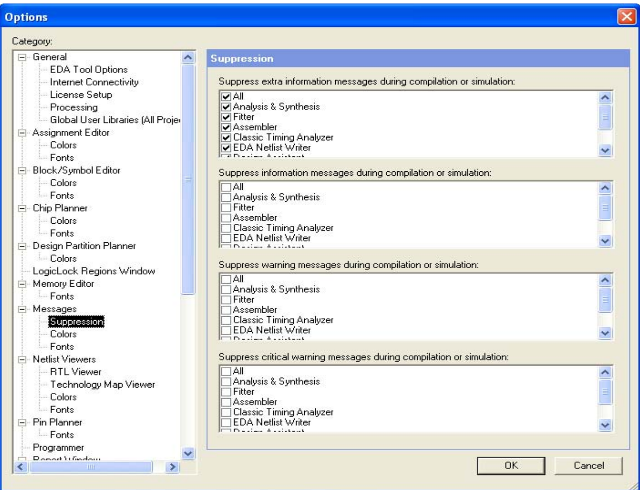
Message Suppression

You can use message suppression to reduce the number of messages to be reviewed after a compilation by preventing individual messages and entire categories of messages from being displayed. For example, if you review a particular message and determine that it is not caused by something in your design that needs to be changed or fixed, you can suppress the message so that it is not displayed during subsequent compilations. This saves time because you see only new messages during subsequent compilations.

Every time you add a message to be suppressed, a suppression rule is created. Suppressing exact selected messages adds patterns that are exact strings to the suppression rules. Suppressing all similar messages adds patterns with wildcards to the suppression rules.

Furthermore, you can suppress all messages of a particular type in a particular stage of the compilation flow. On the Tools menu, click **Options**. In the **Category** list, select **Suppression** from under the **Messages** section (Figure 4–9).

Figure 4–9. Controlling Suppression Messages



Suppressing individual messages is controlled in two locations in the Quartus II GUI. You can right-click on a message in the Messages window and choose commands in the Suppress sub-menu entry. To open the Message Suppression Manager, right-click in the Messages window. From the Suppress sub-menu, click **Message Suppression Manager**. For more information about Message Suppression Manager, refer to "Message Suppression Manager" on page 4–19.

Message Suppression Methods

There are three methods that you can use to create suppression rules:

- **Suppress Exact Selected Messages**
- **Suppress All Similar Messages**
- **Suppress All Flagged Messages**

If you suppress a message with the exact selected messages option, only messages that match the exact text are suppressed during subsequent compilations. The **All Similar Messages** option behaves like a wildcard pattern on variable fields in messages and the **Flagged Messages** option only suppresses flagged messages.

The following message is an example of suppressing all similar messages:

```
Info: Found 1 design units, including 1 entities, in source file mult.v.
```

This type of message is common during synthesis and is displayed for each source file that is processed with varying information about the number of design units, entities, and source file name.

Help for this message shows it is in the form Found <*number*> design units, including <*number*> entities, in source file <*name*>. Choosing to suppress all similar messages effectively replaces the variable parts of that message (<*number*>, <*number*>, and <*name*>) with wildcards, resulting in the following suppression rule:

```
Info: Found * design units, including * entities, in source file *.
```

As a result, all similar messages (ones that match the pattern) are suppressed.

Message Supression Details and Limitations

The following limitations apply to which messages can be suppressed and how they can be suppressed:

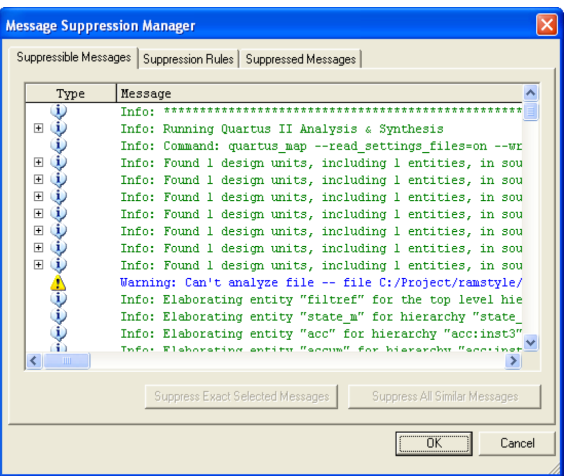
- You cannot suppress error messages or messages with information about Altera legal agreements.
- Suppressing a message also suppresses all its submessages, if any.
- Suppressing a submessage causes matching submessages to be suppressed only if the parent messages are the same.
- You cannot create your own custom wildcards to suppress messages.
- You must use the Quartus II GUI to manage message suppression, including choosing messages to suppress. These messages are suppressed during compilation in the GUI and when using command-line executables.
- Messages are suppressed on a per-revision basis, not for an entire project. Information about which messages to suppress is stored in a file called <*revision*>**.srf**. If you create a revision based on a revision for which messages are suppressed, the suppression rules file is copied to the new revision. You cannot make all revisions in one project use the same suppression rules file.
- You cannot remove messages or modify message suppression rules while a compilation is running.

Message Suppression Manager

You can use Message Suppression Manager to view and suppress messages, view and delete suppression rules, and view suppressed messages.

Right-click anywhere in the Messages window and click **Message Suppression Manager** from the Suppress sub-menu. The Message Suppression Manager has three tabs labeled **Suppression Messages**, **Suppression Rules**, and **Suppressed Messages** (Figure 4–10).

Figure 4–10. Message Suppression Manager Dialog Box



Suppressible Messages

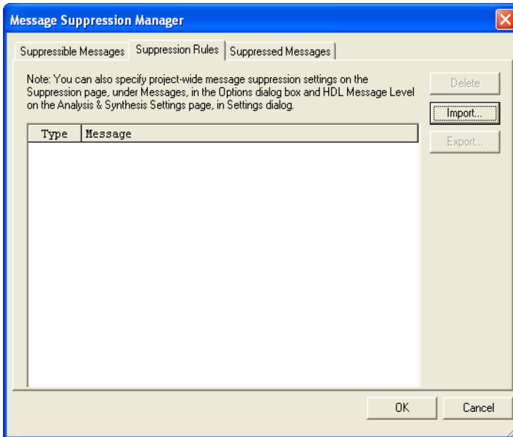
Messages that are listed in the **Suppressible Messages** tab are messages that were not suppressed during the last compilation. These messages can be suppressed. The **Select All Similar Messages** option in the right-click menu selects messages according to the example described in the "Message Suppression Methods" on page 4–18. You can select all similar messages to see which messages are suppressed if you choose to suppress all similar messages.

Suppression Rules

Items listed in the **Suppression Rules** tab are the patterns that the Quartus II software uses to determine whether to suppress a message. Messages matching any of the items listed in the **Suppression Rules** tab are suppressed during compilations (Figure 4–11). At this tab, you can also perform the following actions:

- Delete—Remove selected rules from the **Suppression Rules** tab
- Import—Open the **Import Message Suppression Rule File** dialog box. This allows you to import suppression rules from another project or a revision of the current project with the Quartus II Message Suppression Rule File (**.srf**).
- Export—Open the **Export Message Suppression Rule File** dialog box and create **.srf** file containing the suppression rules listed in the **Suppression Rules** tab for the current revision

Figure 4–11. Message Suppression Manager



An entry in the **Suppression Rules** tab that includes a message with submessages indicates the submessage is suppressed only when all of its parent messages match.

You can stop suppressing messages by deleting the suppression rules that match them (causing them to be suppressed). Merely deleting suppression rules does not cause the formerly suppressed messages to be added to the messages generated during the previous compilation; you must recompile the design for the changed suppression rules to take effect.

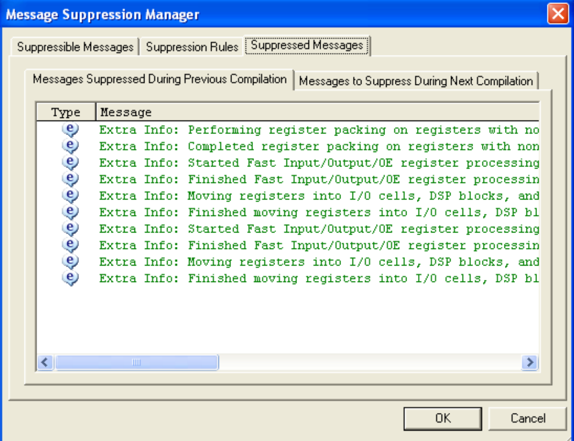
Suppressed Messages

Messages listed in the **Suppressed Messages** tab are divided into two sub-tabs:

- **Messages Suppressed During Previous Compilation**
- **Messages to Suppress During Next Compilation**

The messages listed in the **Messages Suppressed During Previous Compilation** sub-tab are all the suppressed messages from the previous compilation (Figure 4–12).

Figure 4–12. Messages Suppressed During Previous Compilation



These messages are also listed in the **Suppressed** tab in the Messages window. Messages listed in the **Messages to Suppress During Next Compilation** are messages that are suppressed during the next compilation that match suppression rules created after the last compilation finished.

In addition to appearing in the **Suppressed** tab in the Messages window, suppressed messages are included in a **Suppressed Messages** entry in the Quartus II compilation report, viewable in the GUI. Suppressed messages are not included in the <*revision*>**.**<*module*>**.rpt** text files; they are written to a separate text report file called <*revision name*>**.**<*module*>**.smsg**.

Quartus II Settings File

All assignments made in the Quartus II software are stored as Tcl commands in the **.qsf** file. The **.qsf** file is a text-based file containing Tcl commands and comments. The **.qsf** file is not a Tcl script and does not support the full Tcl scripting language.

As you make assignments in the Quartus II software, the assignments are either stored temporarily in memory or written out to the **.qsf** file. This is determined by the **Update assignments to disk during design processing only** option, which is located on the Tools menu under **Options** on the **Processing** page. If the option is turned on, all assignments are stored in memory and are written to the **.qsf** file when a compilation has started or when you save or close the project. By saving assignments to memory, the performance of the software is improved because it avoids unnecessary reading and writing to the **.qsf** file on the disk. This performance improvement is seen more dramatically when the project files are stored on a remote data disk.

You can add lines of comments into the **.qsf** file, as shown in Example 4–1:

Example 4–1.

```
# Assignments for input pin clk
# Clk is being driven by FPGA 1
set_location_assignment PIN_6 -to clk
set_instance_assignment -name IO_STANDARD "2.5 V" -to clk
```

Sourcing other **.qsf** files is supported using the following Tcl command:

```
source <filename>.qsf
```

QSF Format Preservation

The Quartus II software maintains the order of assignments in the **.qsf** file. When you make new assignments, they are appended to the end of the **.qsf** file. If you modify an assignment, the corresponding line in the **.qsf** file is modified and the order of assignments in the **.qsf** file is maintained except when you add and remove project source files, or when you add, remove, and exclude members from an assignment group. In these cases, all assignments are moved to the end of the **.qsf** file. For example, if you add a new design file to the project, the list of all your design files is removed from its current location in the file and moved to the end of the **.qsf** file.

The header at the beginning of the **.qsf** file is written only if the **.qsf** file is newly created.

The Quartus II software preserves all spaces and tabs for all unmodified assignments and comments. When you make a new assignment or modify an existing assignment, the assignment is written using the default formatting.

Quartus II Default Settings File

The **.qdf** file contains all the project and assignment default settings from the current version of the Quartus II software. The **assignment_defaults.qdf** file, located in the **bin** directory of the Quartus II installation path, is used to ensure consistent results when defaults are changed between versions of the Quartus II software.

The Quartus II software reads assignments from various files and stores the assignments in memory. The Quartus II software reads settings files in the following order and assignments in subsequent files take precedence over earlier ones:

1. **assignment_defaults.qdf** from <*Quartus II Installation directory*>**/bin or bin64**
2. **assignment_defaults.qdf** from project directory
3. <*revision name*>**_assignment_defaults.qdf** from project directory
4. <*revision name*>**.qsf** from project directory

As each new file is read, if an existing assignment from a previous file matches (following rules of case sensitivity, multi-value fields as well as other rules), the old value is removed and replaced by the new value. For example, if the first file has a non multi-valued assignment A=1, and the second file has A=2, the assignment A=1, stored in memory, is replaced by A=2.

Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For more information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp
```

The *Quartus II Scripting Reference Manual* includes the same information in Portable Document Format (**.pdf**) format.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. For more information about all settings and constraints in the Quartus II software, refer to the *Quartus II Settings File Reference Manual*. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

 © March 2009 Altera Corporation

Managing Revisions

You can use the following commands to create and manage revisions. For more information about managing revisions, including creating and deleting revisions, setting the current revision, and getting a list of revisions, refer to "Creating and Deleting Revisions" on page 4–3.

Creating Revisions

The `-based_on` and `-set_current` options are optional. You can also use `-copy_results` option to copy results from "based_on" revision. The following Tcl command creates a new revision called **speed_ch**, based on a revision called **chiptrip**, and sets the new revision as the current revision:

```
create_revision speed_ch -based_on chiptrip -set_current
```

Setting the Current Revision

The `-force` option enables you to open the revision that you specify under revision name and overwrite the compilation database if the database version is incompatible. Use the following Tcl command to specify the current revision:

```
set_current_revision-force <revision name>
```

Getting a List of Revisions

Use the following Tcl command to get a list of revisions in the opened project:

```
get_project_revisions <project_name>
```

Deleting Revisions

Use the following Tcl command to delete a revision:

```
delete_revision <revision name>
```

Archiving Projects

You can archive projects with a Tcl command or with a command run at the system command prompt.

The following Tcl command creates a project archive with the default settings and overwrites the specified archived file if it already exists:

```
project_archive archive.qar -overwrite
```

You can change default settings with the `project_archive` command by using options such as `-all_revisions`, `-include_libraries`, `-include_outputs`, `-use_file_set` <*file_set*> and `-version_compatible_database`. Type the following command at a command prompt to create a project archive called **top**:

```
quartus_sh --archive top ↵
```

You can use the `-overwrite` option to overwrite the existing archive file.

Restoring Archived Projects

You can restore archived projects with a Tcl command or with a command run at a command prompt. For more information about restoring archived projects, refer to "Restore an Archived Project" on page 4–8.

The following Tcl command restores the project archive named **archive.qar** in the **restored** subdirectory and overwrites existing files:

```
project_restore archive.qar -destination restored -overwrite
```

Type the following command at a command prompt to restore a project archive:

```
quartus_sh --restore archive.qar ↵
```

Importing and Exporting Version Compatible Databases

You can import and export version compatible databases with either a Tcl command or a command run at a command prompt. For more information about importing and exporting version compatible databases, refer to "Version Compatible Databases" on page 4–8.

The `flow` and `database_manager` packages contain commands to manage version compatible databases.

Use the following Tcl commands from the `database_manager` package to import or export version compatible databases.

```
export_database <directory>
import_database <directory>
```

Example 4–2 shows the Tcl commands from the `flow` package to import or export version compatible databases. If you use the flow package, you must specify the database directory variable name.

Example 4–2.

```
set_global_assignment -name VER_COMPATIBLE_DB_DIR <directory>
execute_flow -flow export_database
execute_flow -flow import_database
```

Example 4–3 shows Tcl commands to automatically generate version compatible databases after every compilation.

Example 4–3.

```
set_global_assignment -name AUTO_EXPORT_VER_COMPATIBLE_DB ON
set_global_assignment-name VER_COMPATIBLE_DB_DIR <directory>
```

The **quartus_cdb** and the **quartus_sh** executables provide commands to manage version compatible databases (Example 4–4).

Example 4–4.

```
quartus_cdb <project> -c <revision>--export_database=<directory> ↵
quartus_cdb <project> -c <revision> --import_database=<directory>↵
quartus_sh -flow export_database <project> -c \ <revision> ↵
quartus_sh -flow import_database <project> -c \ <revision> ↵
```

Specifying Libraries Using Scripts

In Tcl, use commands in the `::quartus::project` package to specify user libraries. To specify user libraries, use the `set_global_assignment` command. To specify global libraries, use the `set_user_option` command. Example 4–5 shows the typical usage of the `set_global_assignment` and `set_user_option` commands.

Example 4–5. Commands to Specify User Libraries using the SEARCH_PATH Assignment

```
set_global_assignment -name SEARCH_PATH "../other_dir/library1"
set_global_assignment -name SEARCH_PATH "../other_dir/library2"
set_global_assignment -name SEARCH_PATH "../other_dir/library3"
set_user_option -name SEARCH_PATH "../other_dir/library1"
set_user_option -name SEARCH_PATH "../other_dir/library2"
set_user_option -name SEARCH_PATH "../other_dir/library3"
```

To report any user libraries specified for a project and any global libraries specified for the current installation of the Quartus II software, use the `get_global_assignment` and `get_user_option` Tcl commands. Example 4–6 shows the Tcl script outputs the user paths and global libraries for an open Quartus II project.

Example 4–6. Commands to Report Specified User Libraries

```
get_global_assignment -name SEARCH_PATH
get_user_option -name SEARCH_PATH
```

Conclusion

Designers often try different settings and versions of their designs throughout the development process. Quartus II project revisions facilitate the creation and management of different assignments and settings. Project archives are useful to save your results, or pass designs between different members of a team. In addition, understanding how to smoothly migrate your projects from one computing platform to another, controlling messages, and reducing compilation time are important as well. The Quartus II software facilitates efficient management of your design to accommodate today’s sophisticated FPGA designs.

Document Revision History

Table 4–3 shows the revision history for this chapter.

Table 4–3. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	Updated for the Quartus II software version 9.0.	—
November 2008 v8.1.0	Changed to 8½” × 11” page size. No change to content.	Updated for the Quartus II software version 8.1.
May 2008 v8.0.0	Updated references.	Updated for the Quartus II software version 8.0.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

Section II. I/O and PCB Tools

This section provides an overview of the I/O planning process, Altera's FPGA pin terminology, as well as the various methods for importing, exporting, creating, and validating pin-related assignments using the Quartus® II software. This section also describes the design flow that includes making and analyzing pin assignments using the **Start I/O Assignment Analysis** command in the Quartus II software, during and after the development of your HDL design. It also describes interfaces with third-party PCB design tools

This section includes the following chapters:

- Chapter 5, I/O Management
- Chapter 6, Simultaneous Switching Noise (SSN) Analysis and Optimizations
- Chapter 8, Mentor Graphics PCB Design Tools Support
- Chapter 7, Signal Integrity Analysis with Third-Party Tools
- Chapter 9, Cadence PCB Design Tools Support

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

5. I/O Management

QII52013-9.0.0

Introduction

The process of managing I/Os for current leading FPGA devices involves more than just fitting design pins into a package. The increasing complexity of I/O standards and pin placement guidelines are just some of the factors that influence pin-related assignments. The I/O capabilities of the FPGA device and board layout guidelines influence pin location and other types of assignments for each of your design pins. Therefore, it is necessary to begin I/O planning and PCB development even before starting the FPGA design.

Altera provides many resources for I/O Planning. This chapter provides information about entering pin and pin assignment information in the Quartus® II software. You can consult the device-specific pin connection guidelines available on the Altera® website for your board layout. You can also benefit from the Pin Advisors available in the Quartus II software version 8.1 and later. To get updated information about all the resources on I/O planning and board design, refer to the Board Design and I/O Resource Center on the Altera website.

This chapter provides an overview of the I/O planning process, Altera FPGA pin terminology, and the various methods for importing, exporting, creating, and validating pin-related assignments.

For guidelines about PCB designs for Altera high-speed FPGAs, refer to *AN 315: Guidelines for Designing High-Speed FPGA PCBs*.

This chapter contains the following topics:

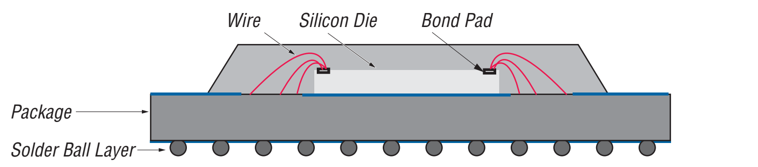
- "Understanding Altera FPGA Pin Terminology" on page 5–2
- "I/O Planning Overview" on page 5–5
- "Device Selection" on page 5–7
- "Early I/O Planning Using the Pin Planner" on page 5–8
- "Importing and Exporting Pin Assignments" on page 5–16
- "Creating Pin-Related Assignments" on page 5–19
- "Validating Pin Assignments" on page 5–56
- "Accepting Fitter Placements—Back-Annotating Assignments" on page 5–74
- "I/O Timing Analysis" on page 5–75
- "Incorporating PCB Design Tools" on page 5–83

Understanding Altera FPGA Pin Terminology

Altera FPGA devices are available in a variety of packages to meet all of your complex design requirements. To describe Altera FPGA pin terminology, this chapter uses a wire bond ball grid array (BGA) package in its examples. On the top surface of the silicon die, there is a ring of bond pads that connect to the I/O pins of the silicon. In a wire bond BGA package, the device is placed in the package and copper wires connect the bond pads to the solder balls of the package. Figure 5–1 shows a cross section of a wire bond BGA package.

For a list of all BGA packages available for each Altera FPGA device, refer to the *Altera Device Package Information Data Sheet*.

Figure 5–1. Wire Bond BGA

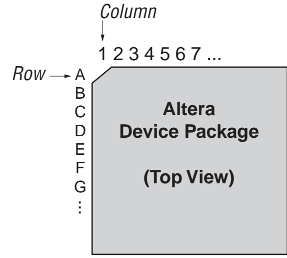


Package Pins

The pins of a BGA package are small solder balls arranged in a grid pattern on the bottom of the package. In the Quartus II software, the package pins are represented as pin numbers. The pin numbers are determined by their locations using a coordinate system with letters and numbers identifying the row and column of the pins, respectively.

The upper-most row of pins is labeled “A” and continues alphabetically as you move downward (Figure 5–2). The left-most column of pins is labeled “1” and continues with increments of 1 as you move to the right. For example, pin number “B4” represents row “B” and column “4.”

Figure 5–2. Row and Column Labeling



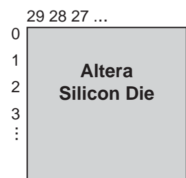
The letters I, O, Q, S, X, and Z are never used in pin numbers. If there are more rows than letters of the alphabet, the alphabet is repeated, prefixed with the letter “A.”

For more information about the pin numbers for your Altera device, refer to the device pin-out information available on the Altera website at www.altera.com.

Pads

Package pins are connected to pads located on the perimeter of the top metal layer of the silicon die (Figure 5–1). Each pad is identified by a pad ID, which is numbered starting at 0, incrementing by 1 in a counterclockwise direction (Figure 5–3).

Figure 5–3. Pad Number Ordering



To prevent signal integrity issues, the Quartus II software uses pin placement rules to validate your pin placements and pin-related assignments. It is important that you understand which pad locations your pins were assigned to, because some pin placement rules describe pad placement restrictions. For example, in certain devices, there is a restriction on the number of I/O pins supported by a VREF pad to ensure signal integrity. There are also restrictions on the number of pads between single-ended input or output pins and a differential pin. The Quartus II software performs pin placement analysis, and if pins are not placed according to pin placement rules, the design compilation fails and the Quartus II software reports an error.

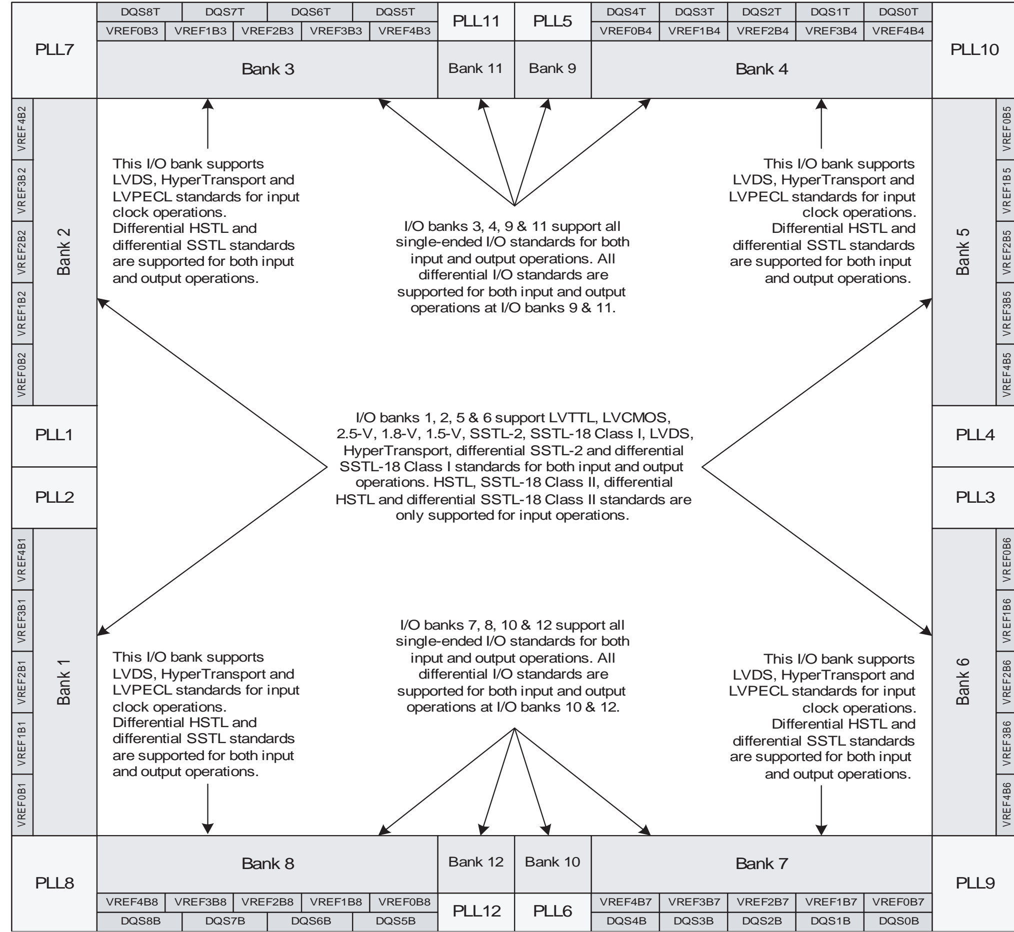
For more information about pin placement guidelines, refer to the *Selectable I/O Standards* chapter in volume 1 of the appropriate device handbook.

I/O Banks

I/O pins are organized into I/O banks designed to facilitate various supported I/O standards. Each I/O bank is numbered and has its own voltage source pins, called `VCCIO`, to offer the highest I/O performance. Depending on the device and I/O standards for the pins within the I/O bank, the specified voltage of the `VCCIO` pin is between 1.5 V and 3.3 V. Each I/O bank can support multiple pins with different I/O standards that share the same V_{CCIO}.

It is important to refer to the appropriate device handbook to determine the capabilities of each I/O bank. For example, the pins in the I/O banks on the left and right side of a Stratix® II device support high-speed I/O standards such as LVDS, whereas the pins on the top and bottom I/O banks support all single-ended I/O standards, including data strobe signaling (DQS) (Figure 5–4). Pins belonging to the same I/O bank must use the same `VCCIO` signal.

Figure 5–4. Stratix II I/O Banks *(Note 1), (2), (3), (4)*



Notes to Figure 5–4:

(1) This figure shows a top view of the silicon die that corresponds to a reverse view for flip chip packages. It is a graphical representation only.

(2) Depending on the size of the device, different device members have a different number of VREF groups. Refer to the pin list and the Quartus II software for exact locations.

(3) Banks 9 through 12 are enhanced phase-locked loop (PLL) external clock output banks.

(4) Horizontal I/O banks feature serializer/deserializer (SERDES) and dynamic phase alignment (DPA) circuitry for high-speed differential I/O standards. For more information about differential I/O standards, refer to the *High-Speed Differential I/O Interfaces with DPA in Stratix II and Stratix II GX Devices* chapter in volume 2 of the *Stratix II Device Handbook*.

VREF Groups

A VREF group is a group of pins that includes one dedicated `VREF` pin as required by voltage-referenced I/O standards. A VREF group is made up of a small number of pins, as compared to the I/O bank, to maintain the signal integrity of the `VREF` pin. One or more VREF group(s) exist in an I/O bank. The pins in a VREF group share the same V_{CCIO} and VREF voltages.

For more information about I/O banks, VREF groups, and supported I/O standards, refer to the *Architecture* and *Selectable I/O Standards* chapters in the appropriate device handbook.

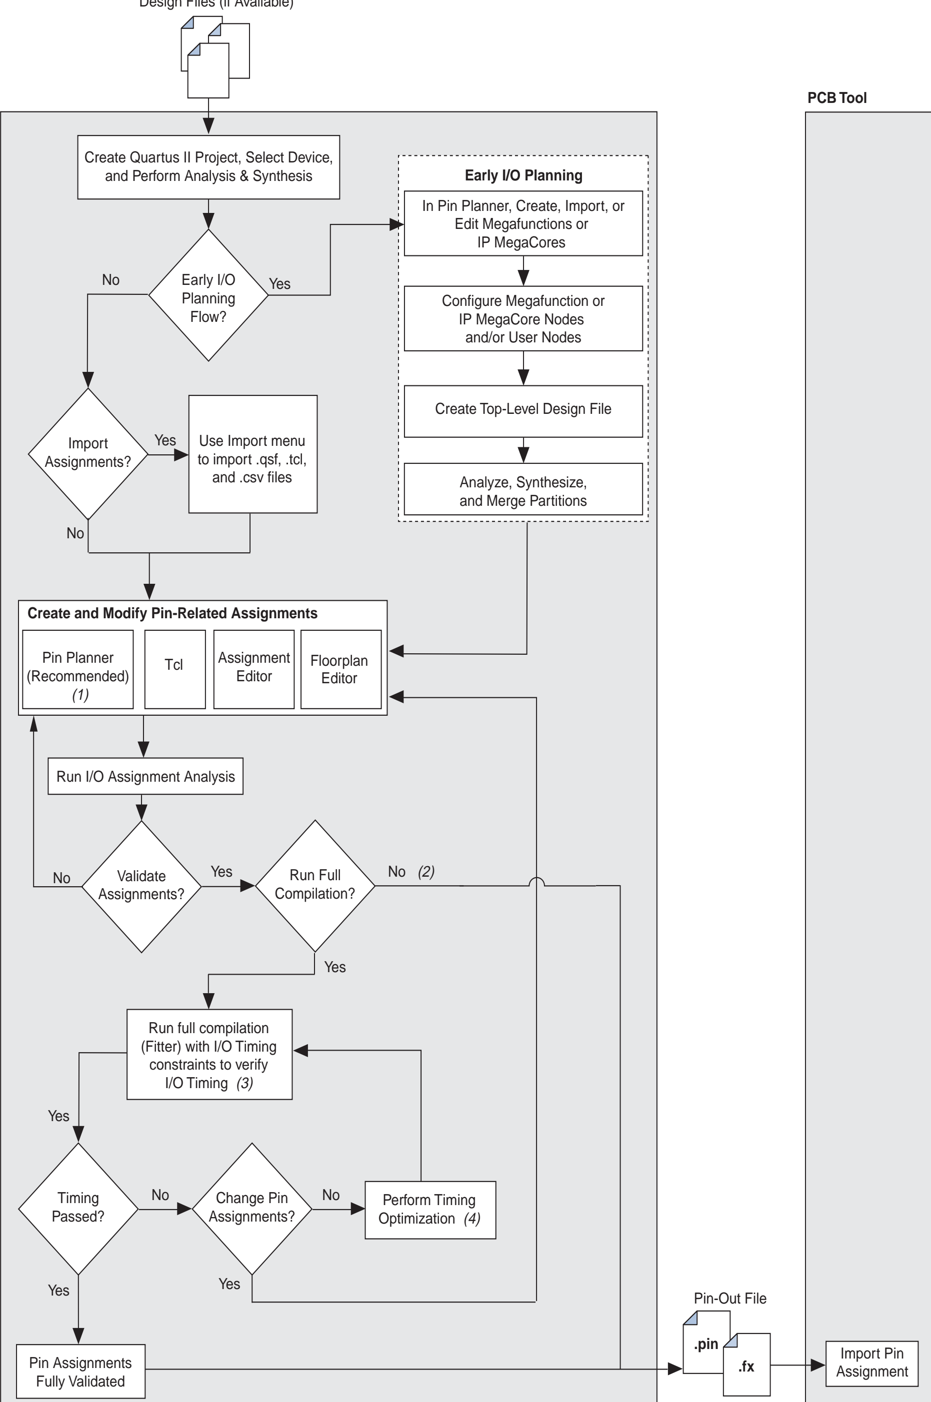
I/O Planning Overview

I/O planning of your FPGA design in Quartus II software includes:

- Selecting a device that meets your logic and I/O requirements, based on the device's supported I/O standards, I/O bank structure, supply voltage requirements such as VREF and V_{CCIO} requirements in I/O banks, available pins for user I/O, power supply requirements, and more.
- Getting your design files ready. The design files contain the top-level ports or top-level interface information. If you do not have the design files, you can use the Early I/O Planning flow to generate a top-level HDL wrapper file.
- Importing any existing assignments from a Tcl script, **.csv**, or **.qsf** file.
- Creating, modifying, and completing all pin-related assignments that include pin location assignments, I/O standards, output loading assignments for output and bidirectional pins, slew rates, current strengths, and more.
- Validating your pin-related assignments while creating them by using the Live I/O Check feature, then running I/O assignment analysis, and finally running the Fitter with timing constraints.
- Generating a validated ***.pin** file for third-party PCB tools.

The method you use to create pin assignments depends on your requirements. If you have not yet designed the PCB, create and validate your I/O assignments in the Quartus II software, then export them to the PCB tool (Figure 5–5). This is the recommended design flow for creating I/O assignments for an FPGA design.

Figure 5–5. Quartus II Software I/O Planning Flow



Notes to Figure 5–5:

(1) Use the Live I/O Check feature in the Pin Planner to validate pin assignments as you create them.

(2) To create the FPGA Xchange file (**.fx**), on the Processing menu, point to **Start** and click **EDA Netlist Writer**. The **.pin** file is created at the *<project_dir>* level. The **.fx** file is created at the *<project_dir/board/.../>* level.

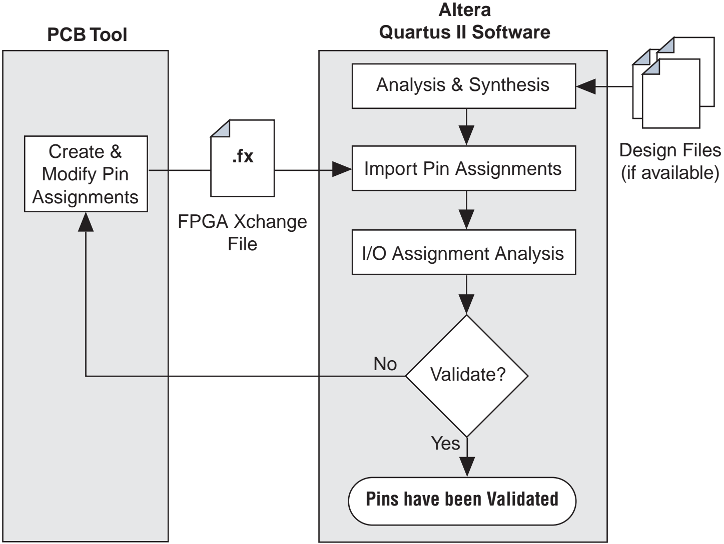
(3) Your design files and constraints must be complete before you begin full compilation. To learn how to create I/O timing constraints, refer to the *TimeQuest Timing Analyzer* and *Classic Timing Analyzer* chapters in the *Timing Analysis* section in volume 3 of the *Quartus II Handbook*.

(4) Refer to the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*.

If your PCB is partially designed, create your FPGA assignments in your PCB tool and import them into the Quartus II software for validation (Figure 5–6).

Currently, only the Mentor Graphics® I/O Designer PCB tool and the Cadence Allegro PCB tool are supported in this reverse I/O planning flow.

Figure 5–6. I/O Planning Flow Using an FPGA Xchange File from a PCB Tool

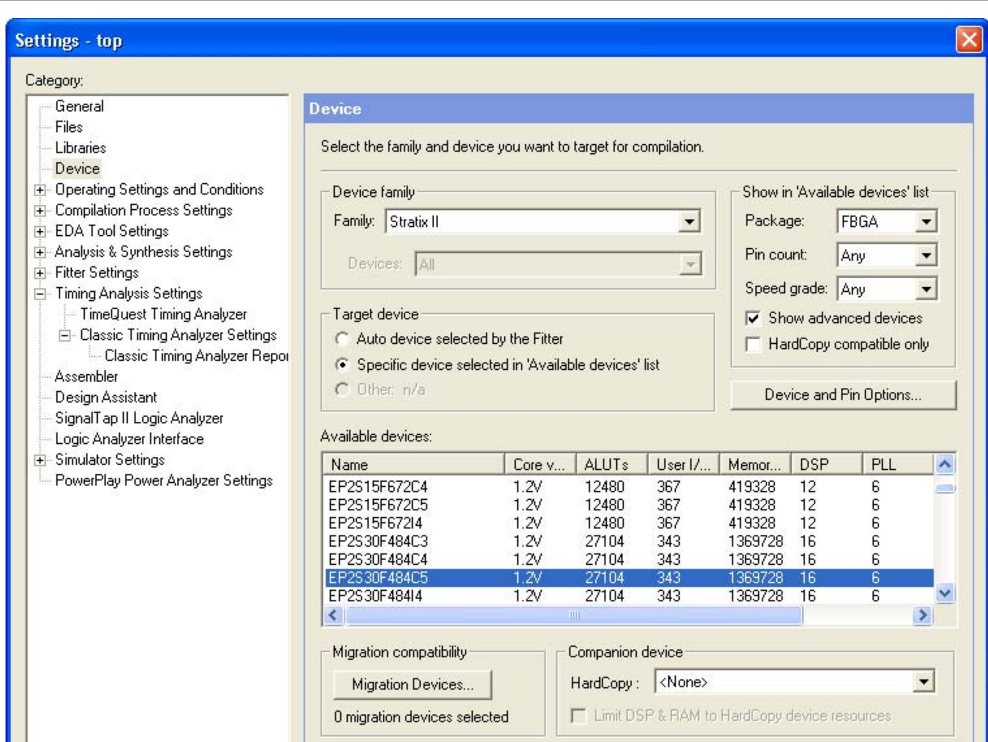


You must refer to the appropriate device handbook, available on the Altera website at www.altera.com to learn about the I/O architecture, supported I/O standards, and their requirements in your device. In the Quartus II software design flow, the most important step in I/O planning is to create, modify, complete, and validate pin-related assignments. The Quartus II software includes the Pin Planner and I/O Assignment Analysis to assist you in I/O planning.

Device Selection

Before you begin pin planning or I/O assignment analysis in the Quartus II software, refer to the device handbooks at www.altera.com to understand the I/O structure, supported I/O standards, available pins for user I/O, clocking schemes and options, and I/O bank structure for different devices. Then, choose an appropriate device from a supported device family for your design. To select a device, on the Assignments menu, click **Device** to open the **Settings** dialog box (Figure 5–7). In the **Family** list, select the device. You can set the other controls under **Show in 'Available devices list'** to filter the **Available devices** list and to select any migration devices. Under the **Available devices** list, select a device.

Figure 5–7. Device Page of the Settings Dialog Box



Early I/O Planning Using the Pin Planner

It might be difficult to plan your I/Os early in the design cycle because the design files, including the top-level design, might not be available yet. However, the interfaces between your FPGA and other devices are typically determined and documented in the design specifications. By adding those interfaces required to connect your FPGA with these other devices in the Pin Planner, you can plan your FPGA I/Os efficiently without design files. The Early I/O Planning flow allows you to create a top-level wrapper file in Verilog HDL or VHDL. The flow includes importing and/or creating any Altera IP MegaCore® functions or Altera megafunctions in the Pin Planner, as well as creating or adding additional top-level pins information, configuring the top-level pins of the design, and creating the top-level HDL file.

Creating a top-level file using the Early I/O planning flow is an optional step in your I/O planning. If you have design files that have complete information about the top-level interfaces and ports, you can skip the Early I/O planning flow step and proceed to making pin-related assignments. The top-level file you create using the Early I/O planning flow serves as the top-level file for your Quartus II software project. If you do not use the Early Pin Planning flow to create a top-level HDL file, you must analyze and elaborate your design files in the Quartus II software before importing or modifying your pin assignments.

The following sections describe the typical steps involved in the early I/O planning flow to generate a top-level wrapper file in Verilog HDL or VHDL:

- "Create or Import a Megafunction or IP MegaCore Variation from the Pin Planner"
- "Configure Nodes" on page 5–10
- "I/O Analysis for Designs with Pins Only" on page 5–14

Create or Import a Megafunction or IP MegaCore Variation from the Pin Planner

The Pin Planner can interface with the MegaWizard™ Plug-In Manager, allowing you to create or import custom megafunctions and intellectual property (IP) cores. You can add many types of interfaces, including megafunctions such as ALTPLL and ALTDDIO, and IP MegaCore functions such as PCI Compiler, QDR II, and RapidIO. Adding the interface information while planning your I/Os allows you to assign each required pin without manually creating each pin individually in the Pin Planner. Furthermore, you can add and configure your own user ports that are top-level ports in your design.

You can create or customize some megafunction variations from within the Pin Planner. When you do this, some of the pin assignments of the top-level pins of the IP MegaCore function or megafunction get transferred to the Pin Planner. To create a megafunction or IP MegaCore variation from the Pin Planner, perform the following steps:

1. In the Pin Planner, right-click anywhere in the Groups list or All Pins list.
2. On the shortcut (right-click) menu, click **Create/Import Megafunction**. The **Create/Import Megafunction** dialog box appears. You can also open this dialog box from the Edit menu or directly from the Toolbar.
3. To create a new megafunction, select **Create a new custom megafunction** and click **OK**. The **MegaWizard Plug-In Manager** appears.
4. In the list of supported megafunctions and IP MegaCore functions, select the megafunction or IP MegaCore function you want to create and complete the MegaWizard Plug-In Manager pages.
5. After you complete the wizard, a new group, based on the file name you provided, is created and all the I/O names, directions, and I/O standards are listed as members of the group in the Groups list. Any IP megafunction that has a pin planning file (**.ppf**) can be imported to the Pin Planner.

For more information about a particular megafunction, refer to the appropriate megafunction user guide, available on the User Guides literature page of the Altera website.

Besides creating an IP MegaCore function or megafunction variation directly from the Pin Planner, you can import an IP MegaCore function's or megafunction's **.ppf** file into the Pin Planner. This would import a **.ppf** file when you have generated a MegaCore function or megafunction variation and its **.ppf** file.

Or

You have generated the variation in the Pin Planner and want to import its **.ppf** in the Pin Planner for other instances of the same variation. When you import an existing **.ppf** file into the Pin Planner, you have to provide a unique instance name so that in the final top-level HDL, all instances of the same variation remain unique.

To import a megafunction variation to the Pin Planner, perform the following steps:

1. In the Pin Planner, right-click anywhere in the Groups list or All Pins list.
2. On the right-click menu, click **Create/Import Megafunction**. The **Create/Import Megafunction** dialog box appears. You can also open this dialog box from the Edit menu.
3. Select **Import an existing custom megafunction** and click the browse button. Select the Pin Planner File (**.ppf**) that was generated along with your megafunction variation or your IP MegaCore files.
4. In the **Instance name** box, type in an instance name and click **OK**.

To avoid pin name conflicts when there is more than one instance of a megafunction or IP MegaCore function, the instance name is appended to the beginning of each pin name.

When the wizard is complete, a new group based on the file name you provided is created and all the I/Os that are used externally are listed as members of the group.

Configure Nodes

Before you create a top-level design file, you must first configure the user ports, megafunction nodes, and IP MegaCore function nodes created in the Pin Planner for integration with each other and the rest of the design. This step is similar to making connections in a schematic.

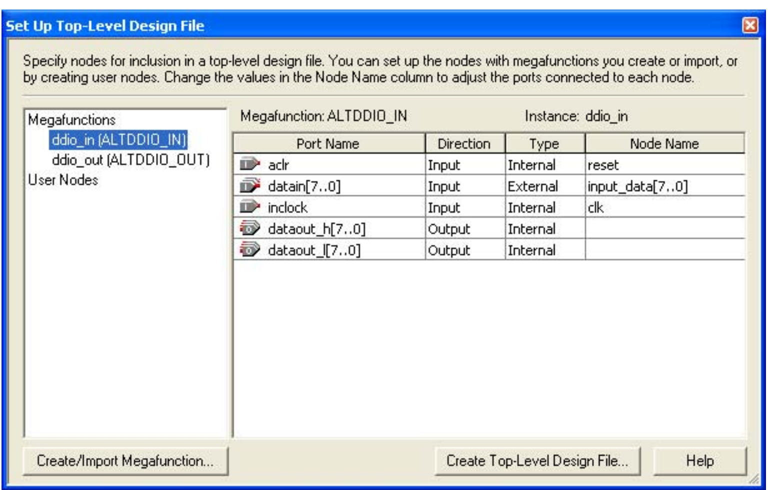
Configure Megafunction Nodes

After creating or importing custom megafunctions or IP MegaCore functions in the Pin Planner, you must configure how they will be connected to each other. You do this by specifying matching node names for selected ports of the megafunctions or IP MegaCore functions.

In this section, ports and port names refer to the generic port names of megafunctions and IP MegaCore functions in the MegaWizard Plug-In Manager. Node names refer to the unique names assigned to ports when the megafunction or IP MegaCore function is created based on the instance name given when the MegaWizard Plug-In Manager is started. By default, node names are the original port names prefixed with *<instance name>*_.

To configure your custom megafunctions and IP MegaCore functions for creating a top-level design file, on the Edit menu of the Package View, click **Set Up Top-Level Design File**. The **Set Up Top-Level Design File** dialog box appears (Figure 5–8).

Figure 5–8. Set Up Top-Level Design File Dialog Box



Click the name of a megafunction or IP MegaCore function in the list on the left. The list on the right contains all the ports for the selected megafunction.

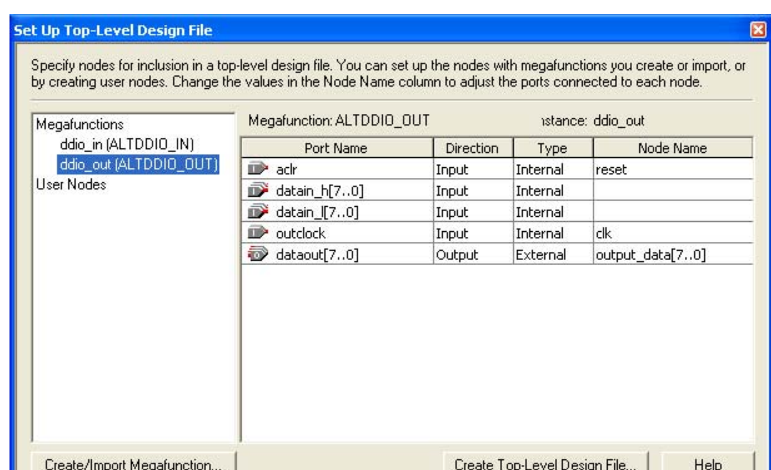
The columns in the **Set Up Top-Level Design File** dialog box provide information about megafunctions created in or imported to the Pin Planner and allow you to make adjustments to connect megafunctions together. The **Direction** column indicates the direction of the port or port group as defined by the megafunction. The direction of a port cannot be changed.

The **Type** column indicates whether a port is available externally to the device. By default, all ports on all megafunctions created through the Pin Planner are of the **External** type, meaning they appear in the Groups list and All Pins list and can be assigned to I/O pins. You can change the port type by double-clicking the cell in the **Type column** for a port and selecting **Internal** or **External** from the list. Any ports on any megafunction connected to a port that has its type changed have their type changed to match automatically. This prevents internal and external megafunction ports from being connected to each other accidentally. Internal ports do not appear in the Groups list or All Pins list. If all the ports of a megafunction are internal, the megafunction does not appear in the Groups list.

The **Node Name** column is used to assign node names or device pins to ports. To connect a port to an existing location, double-click the cell in the **Node Name** column and select an existing node or device pin. To rename the selected port, enter a new node name in the **Node Name** column. This procedure only changes the name as it appears as a group member in the Groups list. To connect ports to each other, enter a node name that matches the node name of the ports of other megafunctions or an existing node.

Figure 5–9 shows an example of the port names of the DDIO_OUT megafunction.

Figure 5–9. Port Names of the DDIO_OUT Megafunction



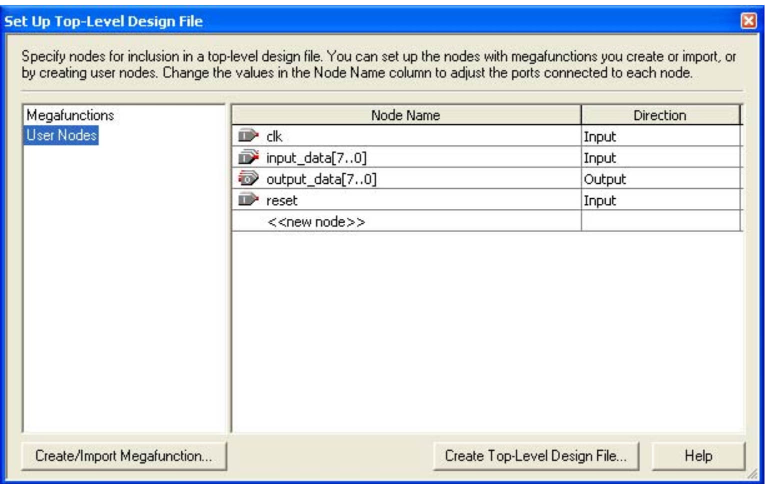
To edit the megafunction or IP MegaCore function you created in the Pin Planner, select it in the Groups list. On the Edit menu, click **Edit Megafunction** to reopen the MegaWizard Plug-In Manager and make changes as necessary. If you make changes to a megafunction, you must import it again and reconfigure its node connections in the **Set Up Top-Level Design File** dialog box.

If you edit the megafunction outside of the Pin Planner, you must re-import its **.ppf** file to the Pin Planner.

Configure User Nodes

If you use the Early I/O Pin Planning flow and start with a top-level file, either complete or partial, and analyze and elaborate that file in Quartus II software, all the top-level pins in that file appear under **User Nodes**, as shown in Figure 5–10. If you do not have any top-level files, you will not see any top-level node names under **User Nodes**.

Figure 5–10. User Nodes

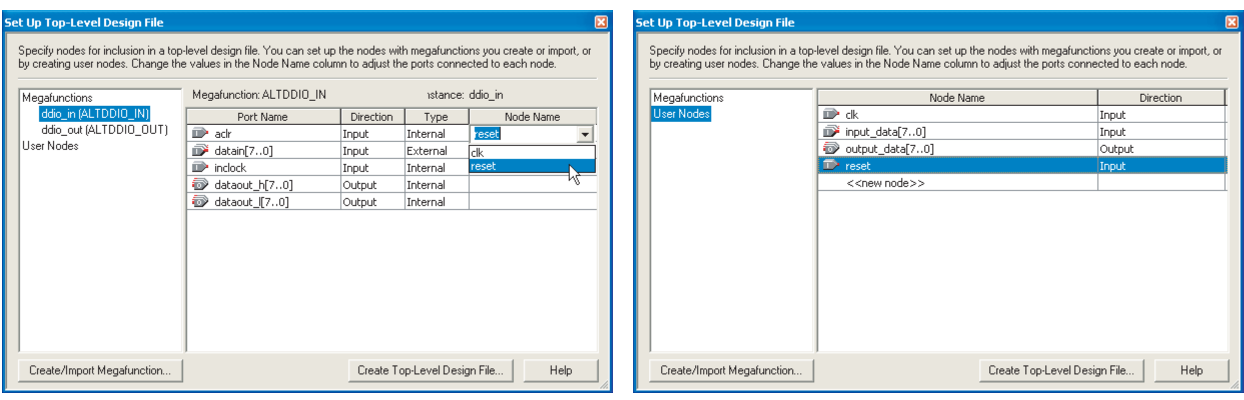


You can add new or additional nodes in the Set-Up Top Level Design File window. To create a new node, double-click in the **<<new node>>** row and enter the new node's name. When you generate the top-level file in HDL, the new or additional nodes appear as ports in your HDL file.

Each user node is associated with a node name and a direction. The direction is input, output, bidirectional, or unknown. If you do not select a direction, the node's direction is unknown. When you enter new node names in this window, the All Pins list and Groups list in the Pin Planner are also updated.

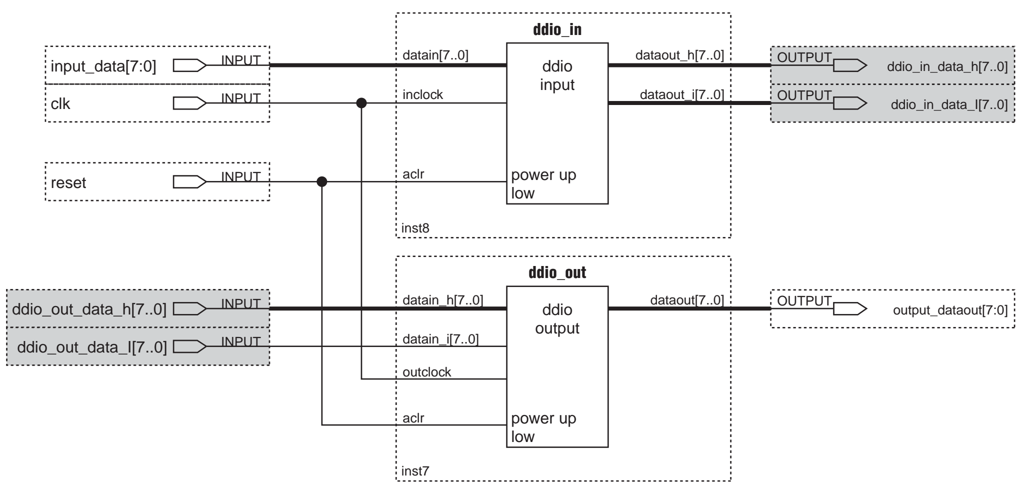
The user nodes are also displayed when you configure node names for megafunctions. For example, to connect a user node named **reset** to a megafunction's reset input port, in the **Node Name** column, select **reset** to make this connection, as shown in Figure 5–11.

Figure 5–11. Connecting a User Node to a Megafunction Port



When the port types and node names for both the input and output megafunctions and user nodes are configured as in Figure 5–8 on page 5–11, Figure 5–9 on page 5–12, and Figure 5–11, they create a circuit similar to the one shown in Figure 5–12. In this way, you can connect megafunctions to each other and to other nodes in the design, improving the thoroughness of an I/O assignment analysis. This is especially useful for clock networks that are typically attached to multiple megafunctions or IP MegaCore functions.

Figure 5–12. Connections between Input and Output Megafunctions and User Nodes *(Note 1)*



Note to Figure 5–12:

(1) Gray pins indicate internal nodes of the design.

I/O Analysis for Designs with Pins Only

You can create a top-level design file after you add or modify user ports, megafunction nodes, or IP MegaCore function nodes in your project with the Pin Planner. Whether the internal logic is complete or not, the top-level design file enables you to validate your I/O assignments and provides a base on which to build the rest of your design.

After you configure the user nodes, megafunctions, and IP MegaCore functions created in the Pin Planner, you must create a top-level design file in an HDL format. Use this file as the basis for the rest of your project and use it to validate the I/O assignments.

To generate a top-level design file, right-click in the Package View and click **Create Top-Level Design File**. You can also generate a top-level file on the File menu by pointing to **Create/Update** and clicking **Create Top-Level Design File From Pin Planner**. The **Create Top-Level Design File** dialog box appears. Enter a name and select an HDL format (Verilog HDL or VHDL). If the file already exists, you can choose to create a backup of the original file.

Example 5–1 shows a sample of an top-level HDL wrapper file as depicted in Figure 5–12.

Example 5–1. HDL Wrapper File Generated with the Early I/O Planning Flow

```
module top
(
   reset,
   input_data,
   clk,
   output_data,
   ddio_in_dataout_h, // Internal
   ddio_in_dataout_l, // Internal
   ddio_out_datain_h, // Internal
   ddio_out_datain_l  // Internal
);

input reset;
input[7:0]input_data;
input clk;
output[7:0]output_data;

output[7:0]ddio_in_dataout_h /* synthesis altera_attribute="-name VIRTUAL_PIN ON" */;
output[7:0]ddio_in_dataout_l /* synthesis altera_attribute="-name VIRTUAL_PIN ON" */;
input[7:0]ddio_out_datain_h /* synthesis altera_attribute="-name VIRTUAL_PIN ON" */;
input[7:0]ddio_out_datain_l /* synthesis altera_attribute="-name VIRTUAL_PIN ON" */;

ddio_in ddio_in_inst
(
   .aclr(reset),
   .datain(input_data),
   .inclock(clk),
   .dataout_h(ddio_in_dataout_h),
   .dataout_l(ddio_in_dataout_l)
);

ddio_out ddio_out_inst
(
   .aclr(reset),
   .datain_h(ddio_out_datain_h),
   .datain_l(ddio_out_datain_l),
   .outclock(clk),
   .dataout(output_data)
);

endmodule
```

The top-level HDL file contains all the top-level pins. When any internal type nodes are not connected to any logic inside the design, they appear in the port list of the top-level file, but are declared as virtual pins. The lines of code in Example 5–2 show examples of virtual pins in the top-level HDL file.

Example 5–2. Examples of Virtual Pins in the Top-Level HDL File

```
output[7:0]input_dataout_h /* synthesis altera_attribute="-name VIRTUAL_PIN ON" */;
output[7:0]input_dataout_l /* synthesis altera_attribute="-name VIRTUAL_PIN ON" */;
input[7:0]output_datain_h /* synthesis altera_attribute="-name VIRTUAL_PIN ON" */;
input[7:0]output_datain_l /* synthesis altera_attribute="-name VIRTUAL_PIN ON" */;
```

The synthesis attribute notifies the Quartus II software that these are virtual pins and that they should be connected to internal logic as the design is completed or finalized. These virtual pins would not be shown in the All Pins list or Groups in the Pin Planner as they are not the actual external ports of the design. The Pin Planner makes virtual pin assignments to internal nodes, so internal nodes are not assigned to device pins during compilation.

The top-level design file must be updated whenever changes are made to the design's top-level ports, including any node changes made in the **Set Up Top-Level Design File** dialog box.

After you generate the top-level file in HDL, you can continue with your design flow to modify or create pin assignments using the Pin Planner.

Importing and Exporting Pin Assignments

After analysis and synthesis of your Quartus II project, you can transfer pin-related assignments between the Quartus II software and other tools by importing and exporting these assignments in the following file formats: Comma Separated Value (**.csv**) file, Quartus II Settings File (**.qsf**), Tcl (**.tcl**), FPGA Xchange (**.fx**) file, and Pin-Out (**.pin**) file (export only).

Spreadsheets and .csv Files

You can transfer pin-related assignments as a **.csv** file. This file consists of a row of column headings followed by rows of comma-separated data. The row of column headings in the exported file is in the same order and format as the columns displayed in the **Pin** category in the Assignment Editor or in the All Pins list in the Pin Planner. Do not modify the row of column headings if you plan to import the **.csv** file later.

To import a **.csv** file into your project, on the Assignment menu, click **Import Assignments** and browse to the file.

You can export pin-related assignments from the Quartus II Pin Planner or the Assignment Editor. To export your pin-related assignments to a **.csv** file, on the Assignment menu, click **Pin Planner** or **Assignment Editor**. For the Pin Planner, make sure the All Pins list is visible. If the list is not visible, on the View menu, click **All Pins List**. For the Assignment Editor, from the **Category** list, select the **Pin** category. Then, to create the **.csv** file, on the File menu, click **Export**.

The All Pins list in the Quartus II Pin Planner, the **Pin** category in the Quartus II Assignment Editor, and the device **.pin** files all display detailed properties about each pin of the device, in addition to the pin name and pin number. The device **.pin** files are available on the Altera website at www.altera.com.

Quartus II Settings Files

When you make pin assignments with the Pin Planner or the Assignment Editor in the Quartus II software, all your pin-related assignments are written to the Quartus II Settings File (**.qsf**). You can also export pin-related assignments to a **.qsf** file. The pin-related assignments are stored as Tcl commands in the **.qsf** file.

To import a **.qsf** file, on the Assignments menu, click **Import Assignments** and browse to the **.qsf** file, or source the **.qsf** file in the Tcl console. To export a **.qsf** file, on the Assignments menu, click **Export Assignments**, type in a file name, and click **OK**. When you export assignments to a **.qsf** file, the **.qsf** file contains all the pin-related assignments along with other Quartus II project-related assignments.

For more information about **.qsf** files, refer to the *Managing Quartus II Projects* chapter in volume 2 of the *Quartus II Handbook*.

Tcl Script

You can export pin-related assignments from the Quartus II Pin Planner or the Assignment Editor. To export pin-related assignments as a Tcl script, on the Assignments menu, click **Pin Planner** or **Assignment Editor**. For the Pin Planner, make sure the All Pins list is visible. If the list is not visible, on the View menu, click **All Pins List**. For the Assignment Editor, select the **Pin** category from the **Category** list. Then, to create the **.tcl** file, on the File menu, click **Export**. In the **Export** dialog box, type a file name, select **Tcl Script File** (***.tcl**), and click **OK**. All pin-related assignments displayed in the All Pins list of the Pin Planner and the spreadsheet of the Assignment Editor are saved as Tcl commands in the Tcl script.

For more information about the All Pins list in the Pin Planner, refer to "Using the Pin Planner" on page 5–20.

To import the pin-related assignments from a Tcl script, source the Tcl script in the Tcl console or run the Tcl script with the `quartus_sh` executable. For example, type the following command at a system command prompt:

```
quartus_sh -t my_pins.tcl ↵
```

For more information about Quartus II scripting support, including examples, refer to the *Tcl Scripting* and *Command-Line Scripting* chapters in volume 2 of the *Quartus II Handbook*.

FPGA Xchange File

An **.fx** file contains device and pin-related information that allows you to transfer information between the Quartus II software and the Mentor Graphics I/O Designer software. To transfer pin information between the I/O Designer and the Quartus II software, use an **.fx** file. The **.fx** file format is imported with the ***.pin** file produced in the Quartus II software and I/O Designer. However, the Quartus II software requires only the **.fx** file to import back from the I/O Designer.

To learn more about the I/O Designer and the DxDesigner interface and support, refer to *Mentor Graphics PCB Tools Support* chapter in volume 2 of the *Quartus II Handbook*.

To import an **.fx** file into the Quartus II software, perform the following steps:

1. On the Assignments menu, click **Import Assignments**.
2. In the **File name** box, click the browse button and click **FPGA Xchange Files (*.fx**) in the **Files of type** list.
3. Select the **.fx** file and click **Open**.

4. Click **OK**.

To generate an **.fx** file in the Quartus II software, perform the following steps:

1. Perform an I/O Assignment Analysis or a full compilation in the Quartus II software.
2. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
3. Select **Board-Level**. The **Board-Level** page appears.
4. Under **Board-level symbol**, in the **Format** list, select **FPGA Xchange**.
5. Set the Output directory to the location where you want to save the file. The default output file path is <*project directory*>**/symbols/fpgaxchange**.
6. Click **OK**.
7. On the Processing menu, point to **Start** and click **Start EDA Netlist Writer**.

The output directory you selected is created when you generate the **.fx** file using the Quartus II software.

.pin File

A **.pin** file is an ASCII text file containing pin location results and other pin information. To generate a **.pin** file for your project, you must successfully perform an I/O Assignment Analysis or full compilation in the Quartus II software. The **.pin** file of your project is written at the <*project directory*> level.

Use the **.pin** file to transfer your project's pin information into third-party PCB tools for board development. Figure 5–13 shows an example **.pin** file, and Table 5–1 describes the columns in a **.pin** file.

Figure 5–13. Example of a .pin File

Pin Name/Usage	Location	Dir.	I/O Standard	Voltage	I/O Bank	User Assignment
VCCA_PLL1	9	power		1.5V		
clk	10	input	LVTTL		1	N

Table 5–1. .pin File Header Description

Column Name	Description
Pin Name/Usage	The name of a design pin, ground, or power
Location	The pin number of the location on the device package
Dir	The direction of the pin
I/O Standard	The name of the I/O standard to which the pin is configured
Voltage	The voltage level that is required to be connected to this pin
I/O Bank	The I/O bank number that the pin belongs to
User Assignment	Y or N indicating if the location assignment for the design pin was user assigned (Y) or assigned by the Fitter (N)

For more information about Pin Name/Usage, refer to the Device Pin-Out tables for the targeted device, available on the Altera website at www.altera.com.

Creating Pin-Related Assignments

A pin-related assignment is any assignment applied to a top-level pin. For example, a pin location assignment is a pin-related assignment that assigns a top-level port or node to a pin number (location) on the targeted device. Other examples of pin-related assignments include assigning an I/O standard, assigning current drive strength, or assigning slew rates to a pin.

The recommended approach for making pin-related assignments is to have all the top-level pins in the Pin Planner and create pin-related assignments for these pins.

If you do not have complete information for all the top-level pins, you can reserve certain device pins to temporarily represent your top-level design I/O pins until the I/O pins are defined in your design files. Reserved pins are intended for future use but do not currently perform a function in your design. Reserved pins require a unique pin name and pin location. Using reserved pins as place holders for future design pins increases the accuracy of the I/O assignment analysis.

The Quartus II software offers many tools and features for creating reserved pins and other pin-related assignments (Table 5–2). Each tool and feature is described in more detail in the following sections.

Table 5–2. Overview of Quartus II Tools and Features to Create Pin-Related Assignments (Part 1 of 2)

Feature	Overview
Pin Planner	■ Make pin location assignments to one or more node names by dragging and dropping unassigned pins into the Package View ■ Edit pin location assignments for one or more node names by dragging and dropping groups of pins within the Package View ■ Visually analyze pin resources in the Package View ■ Display I/O banks and VREF groups ■ View the function of package pins using the pin legend ■ Make correct pin location decisions by referring to the Pad View window ■ Create, import, and edit megafunctions and IP MegaCore functions for early I/O planning ■ Generate a top-level wrapper file without design files based on early I/O assignments ■ Configure board trace models of selected pins for use in “board-aware” signal integrity reports generated with the **Enable Advanced I/O Timing** option
Assignment Editor	■ Create and edit all types of pin-related assignments ■ Create and edit multiple assignments simultaneously with the Edit bar ■ Create pin assignments efficiently by viewing the different font styles used to display assigned and unassigned node names, as well as occupied and available pin locations ■ Provides user-selectable information about each pin, including the pad number, t_{CO} requirement, and t_H requirement
Tcl	■ Create any pin-related assignments for multiple pins ■ Store and reapply all pin-related assignments with Tcl scripts ■ Make assignments from the command line

Table 5–2. Overview of Quartus II Tools and Features to Create Pin-Related Assignments (Part 2 of 2)

Feature	Overview
Chip Planner or Timing Closure Floorplan	■ Create and change pin locations by dragging and dropping pins into the floorplan ■ Make correct pin location decisions by referring to the pad ID number and spacing ■ Display I/O banks, VREF groups, and differential pin pairing information
Synthesis Attributes	■ Embed pin-related assignments using attributes in the design files to pass assignments to the Quartus II software

Using the Pin Planner

The Pin Planner is the main interface for creating and editing pin-related assignments. Use the Pin Planner Package View to make pin location and other assignments using a device package view instead of pin numbers. With the Pin Planner, you can identify I/O banks, VREF groups, and differential pin pairings to help you through the I/O planning process.

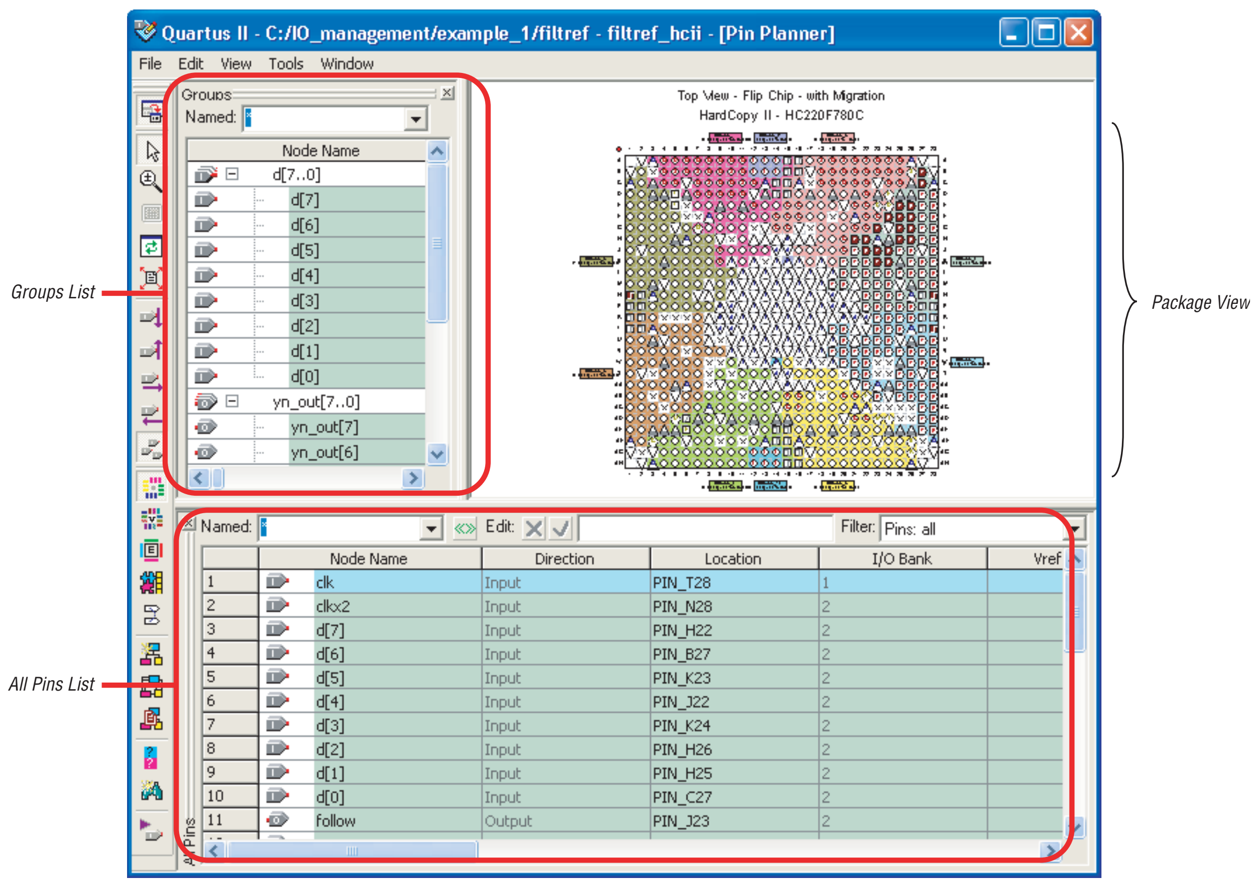
When planning your I/Os, it can be cumbersome to try to correlate pin numbers with their relative location on the package and their pin properties. The Pin Planner provides an intuitive graphical representation of the targeted device, also known as the Package View, that makes it easy to plan your I/Os, create reserved pins, and make pin location assignments. When deciding on a pin location, use the Pin Planner to gather information about available resources, as well as the functionality of each individual pin, I/O bank, and VREF group. You can assign locations to design pins by dragging and dropping each pin into the Package View.

Maintaining good signal integrity (SI) requires that you follow pad distance and pin placement rules. Complementing the Pin Planner is the Pad View window, which displays the pads in order around the silicon die.

The Pin Planner includes the following sections (refer to Figure 5–14 through Figure 5–19):

■ "Groups List" on page 5–21
■ "All Pins List" on page 5–24
■ "Pad View Window" on page 5–26
■ "Package View" on page 5–28
■ "Pin Migration View" on page 5–30
■ "Using the Pin Finder to Find Compatible Pin Locations" on page 5–33
■ "Creating Reserved Pin Assignments" on page 5–34
■ "Creating Pin Location Assignments" on page 5–35
■ "Changing Pin Locations" on page 5–42
■ "Show I/O Banks" on page 5–44
■ "Show VREF Groups" on page 5–45
■ "Show Edges" on page 5–47
■ "Show DQ/DQS Pins" on page 5–48
■ "Displaying and Accepting Fitter Placements" on page 5–49

Figure 5–14. Pin Planner



The Pin Planner feature supports cross-probing that allows you to select a pin in one view while simultaneously highlighting the pin in all of the different views. For example, if you select a pin in the Package View of the Pin Planner, the corresponding pad in the Pad View window is highlighted. If the pin has an assigned node name, the node name in the All Pins list and the Groups list is highlighted.

The Pin Planner and the Assignment Editor get their I/O Bank colors from Timing Closure Floorplan colors, which you can customize by performing the following steps:

1. On Tools menu, click **Options**. The **Options** dialog box appears.
2. In the **Category** list, under **Timing Closure Floorplan**, select **Colors**. The **Colors** page appears.
3. Make your color selections and click **OK**.

Groups List

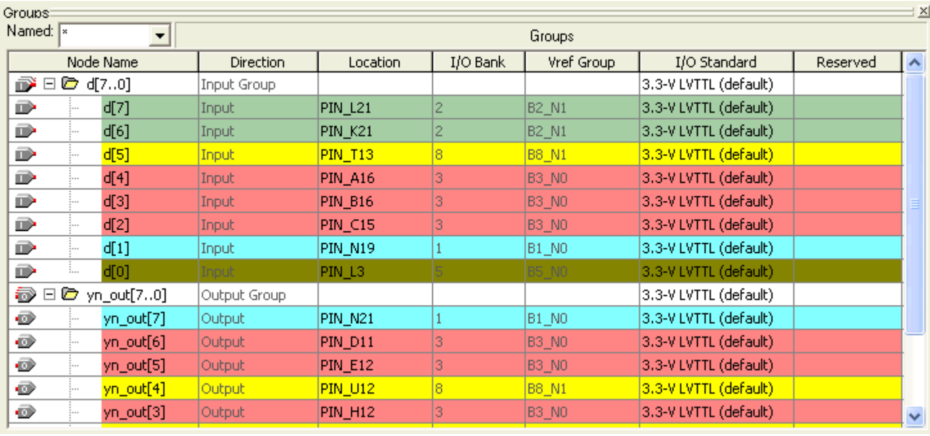
The Groups list displays all of the buses from the top-level pins of your design and all the assignment groups in your project (Figure 5–15). Filter the group names displayed by typing in a wild card filter into the **Named** list. The Groups list allows you to create your own custom groups of pins and make location assignments to groups by dragging them into the Package View of the Pin Planner.

In the Groups list, all members of an assignment group are displayed, regardless of whether the member is a pin or an internal node.

The background color of pin locations in the Groups list easily identifies which pins belong to which I/O banks. The colors match the I/O bank colors in the Package View when **Show I/O Banks** is enabled. You can turn off the colors in both the Groups list and the All Pins list. On the Tools menu, click **Options**. In the **Category** list, select **Pin Planner**, and turn off **Show I/O bank color in lists**.

You can create and organize custom groups and group members in the **Assignment Groups** dialog box or directly in the Groups list in the Pin Planner. To open the **Assignment Groups** dialog box, on the Assignments menu, click **Assignment (Time) Groups**.

Figure 5–15. Groups List



Groups
Named: *
Groups

Node Name	Direction	Location	I/O Bank	Vref Group	I/O Standard	Reserved
d[7..0]	Input Group				3.3-V LVTTL (default)	
d[7]	Input	PIN_L21	2	B2_N1	3.3-V LVTTL (default)	
d[6]	Input	PIN_K21	2	B2_N1	3.3-V LVTTL (default)	
d[5]	Input	PIN_T13	8	B8_N1	3.3-V LVTTL (default)	
d[4]	Input	PIN_A16	3	B3_N0	3.3-V LVTTL (default)	
d[3]	Input	PIN_B16	3	B3_N0	3.3-V LVTTL (default)	
d[2]	Input	PIN_C15	3	B3_N0	3.3-V LVTTL (default)	
d[1]	Input	PIN_N19	1	B1_N0	3.3-V LVTTL (default)

yn_out[7..0]	Output Group				3.3-V LVTTL (default)	
yn_out[7]	Output	PIN_N21	1	B1_N0	3.3-V LVTTL (default)	
yn_out[6]	Output	PIN_D11	3	B3_N0	3.3-V LVTTL (default)	
yn_out[5]	Output	PIN_E12	3	B3_N0	3.3-V LVTTL (default)	
yn_out[4]	Output	PIN_U12	8	B8_N1	3.3-V LVTTL (default)	
yn_out[3]	Output	PIN_H12	3	B3_N0	3.3-V LVTTL (default)	

To add a new group to the Groups list without opening the **Assignment Groups** dialog box, perform the following steps:

1. In the Groups list, in the **Node Name** column, double-click **<<new node>>**.
2. Type the group name.
3. Press **Enter**. The **Add Members** dialog box appears.
4. Type node names, wild cards, and assignment groups in the **Members** box, or browse to and select the node names from the **Node Finder** dialog box.
5. Click **OK**.

For more information about using Assignment Groups, refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook*.

You can also create a new group by selecting one or more node names within the Groups list or All Pins list. Right-click one of the selected node names, and on the right-click menu, click **Add to Group**.

As you plan your I/O placement, you might decide to add and remove members from a group.

© March 2009 Altera Corporation

To add a member to a custom group in the Groups list without opening the **Assignment Groups** dialog box, perform the following steps:

1. Right-click a group name in the Groups list and click **Add Members**.
2. Type in the name of the member or click the browse button to select one or more nodes from the **Node Finder** dialog box.

To remove a member from a group in the Groups list, perform the following steps:

1. Expand the group from which you want to remove a member.
2. Select one or more members that you want to remove.
3. Right-click the selected members, point to **Edit** and click **Delete**.

The Groups list provides many columns, some for information purposes and others to make assignments. You can edit the following columns only:

- **Node Name**
- **Location**
- **I/O Standard**
- **Reserved**
- **Enable**

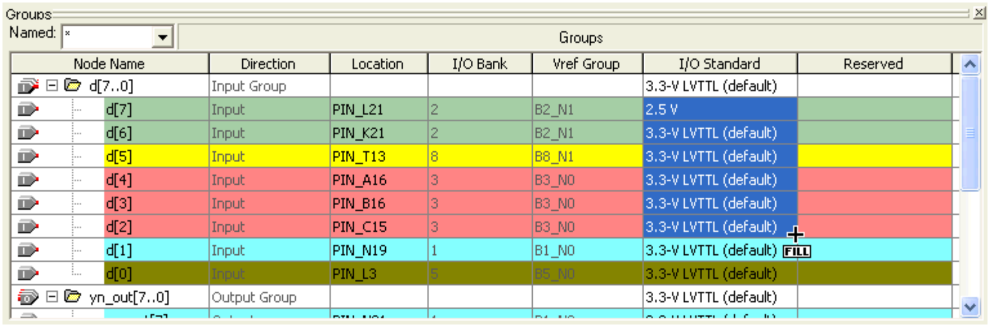
Make changes to any of the values in these columns to adjust pin-related assignments. Other columns provide useful information during I/O planning, including the I/O Bank number, the VREF group, and the direction. To show or hide a column, right-click the column and click **Customize Columns**. You can also reorder and sort the columns from this menu.

If an assignment group contains pins with different directions, the direction of the assignment group is a bidir group.

You can edit the columns in the Groups list in the same manner as a spreadsheet. You can copy and paste the **Location**, **I/O Standard**, and **Reserved** assignments to other rows in the list within the same column. You can also use **Auto Fill** to copy these assignments to other rows quickly.

To automatically fill a block of rows, set the desired assignment in one row and select the assignment's cell. Place the cursor over the lower right-hand corner of the cell until it changes to a cross with the word **FILL** (Figure 5–16). Click and drag up or down the column to select which cells to fill. When all the desired cells are selected, release the mouse button. The selected assignment is copied to all of the selected cells.

Figure 5–16. Auto Fill the Groups List

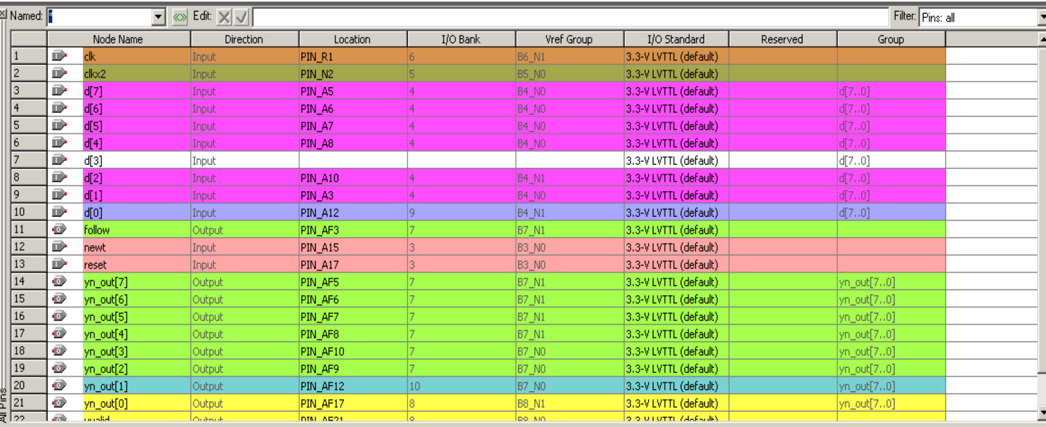


All Pins List

The All Pins list displays all of the pins in your design, including user-created pins (Figure 5–17). The All Pins list does not display buses; instead, it displays each individual pin of the bus. The background color of pin locations in the All Pins list easily identifies which pins belong to which I/O banks. The colors match the I/O bank colors in the Package View when **Show I/O Banks** is turned on. You can turn off the colors in both the All Pins list and the Groups list. On the Tools menu, click **Options**. In the **Category** list, select **Pin Planner**, and turn off **Show I/O bank color in lists**.

You must perform Analysis and Elaboration successfully to display pins in your design in the All Pins list. Individual user-reserved pins and nodes with pin-related assignments are always shown in the All Pins list.

Figure 5–17. All Pins List



You can filter the list of pins in the All Pins list based on their node names by typing in a portion of the pin name in combination with wild card characters in the **Named** list. You can also filter the list of pins in the All Pins list based on the pins' attributes by selecting from the **Filter** list.

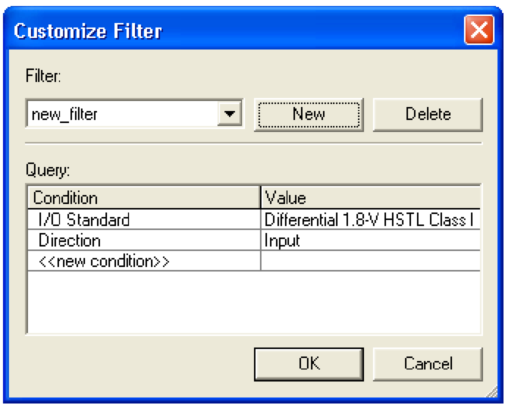
To create your own custom filter in the **Filter** list, specify a set of conditions from the following list:

- Assigned or unassigned

- Current strength
- Direction
- Edge location
- I/O Bank location
- I/O Standard
- VREF Group

To create a new filter in the All Pins list, in the **Filter** list in the All Pins list, select **<<new filter>>**. The **Customize Filter** dialog box appears (Figure 5–18).

Figure 5–18. Customize Filter Dialog Box



To create a custom filter for the All Pins list, perform the following steps:

1. In the **Customize Filter** dialog box, click **New**. The **New Filter** dialog box appears.
2. Enter the name of your custom filter in the **Filter name** text box.
3. You can base your new custom filter on existing filters by selecting from the **Based on Filter** list. If you do not want to base your custom filter on any other filter, select **Pins: all** from the **Based on Filter** list.
4. Click **OK**.
5. Add as many conditions as you require to the **Query** list. To add a condition, double-click **<<new condition>>** and select a condition from the **Condition** list. Select a value for the condition by double-clicking the cell next to your selected condition under the **Value** column.

To remove a condition from your filter, right-click the condition in the **Query** list and select **Delete**.

After specifying your conditions, the pins meeting the specified conditions are the only pins shown in the All Pins list. If the set of conditions contains a condition with more than one value, the pins displayed must meet at least one of the values for that multiple-value condition.

To edit an existing custom filter, select **<<new filter>>** from the **Filter** list in the All Pins list. In the **Customize Filter** dialog box, select the custom filter you want to edit from the **Filter** list and add and remove conditions to the **Query** list.

Pins generated from a compilation or from a bus group are not editable. All other user-created pins are editable.

The All Pins list provides many columns, some for information purposes and others to make assignments. To show or hide a column, right-click the column heading and select **Customize Columns**. In addition, you can reorder and sort the columns from this menu.

You can edit the columns in the Groups list in the same manner as a spreadsheet. You can copy and paste assignments to other rows in the list within the same column. You can also use Auto Fill to quickly copy these assignments to other rows. To automatically fill a block of rows, set the desired assignment in one row and select the assignment's cell. Place the cursor over the lower right-hand corner of the cell until it changes to a cross with the word **FILL**, as shown with the Groups list in Figure 5–16 on page 5–24. Click and drag up or down the column to select which cells to fill. When all the desired cells are selected, release the mouse button. The selected assignment is copied to all the selected cells.

Pad View Window

To maintain good signal integrity in designs, use the Pad View window to guide your pin placement decisions. Each device family is accompanied with pin placement rules, including pad spacing between various pin types.

For more information about pin placement rules, refer to the appropriate device handbook.

Edit or make pin assignments in the Pad View window by dragging and dropping a design pin into an available pad location.

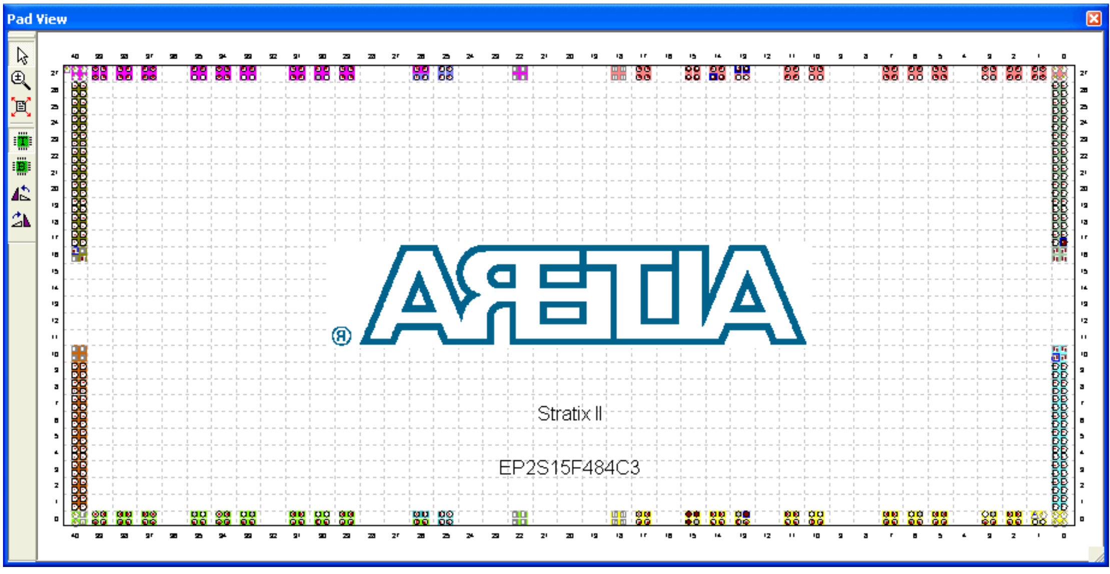
When you drag and drop a design pin into an available pad location, the corresponding pin number of the pad is assigned to the design pin. To assign a pad number to the design pin, perform the following steps:

1. On the Tools menu, click **Options**. The **Options** dialog box appears.
2. Click **Pin Planner** and turn on **Create pad assignment in the Pad View window**.

The column and row numbering around the Pad View window helps identify the pad row or pad column where each pad is located. This is useful when the pin placement guidelines for your targeted device refer to pad rows and columns.

Since the Pad View window is a view of the I/O ring of the silicon within the package, flip chip packages appear inverted. Notice the reversed ALTERA logo in Figure 5–19. To understand the correlation between the package pins and the pads on the silicon die, the Pad View window and Package View are closely integrated. When a pad is selected, the corresponding pin in the Package View is highlighted. Similarly, when a pin is selected in the Package View, the corresponding pad is highlighted in the Pad View window.

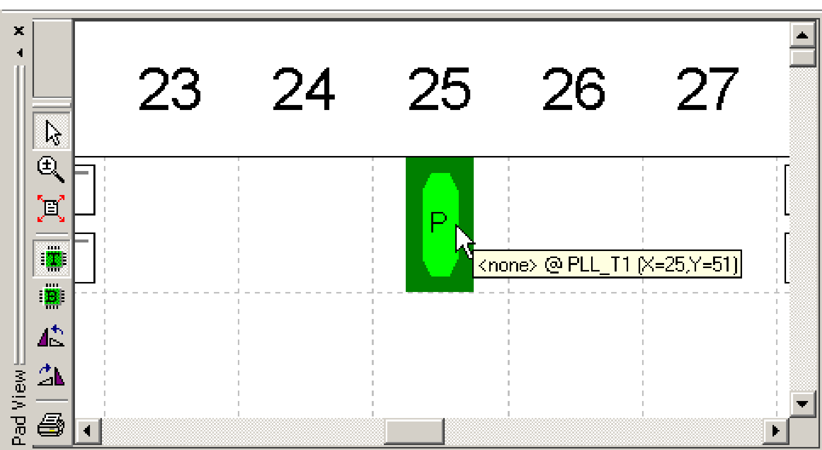
Figure 5–19. Pad View Window of a Stratix II Flip Chip Device



In the Quartus II software version 9.0 and later, you can see the PLLs and DLLs of your device in the Pad View and make location assignments to them. The flexibility of making or deleting location assignments directly to the PLLs and DLLs from the Pin Planner provides you finer control over your design.

PLLs and DLLs appear as an oval in a rectangle, as shown in Figure 5–20. This is the same way they are shown in the Chip Planner in the Quartus II software.

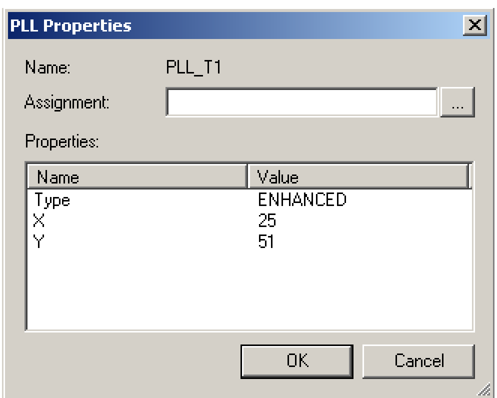
Figure 5–20. PLLs and DLLs in Pad View of Pin Planner



In the Pad view, global PLLs are shown with the letter "P," HSSI PLLs are shown with the letter "H," and DLLs are shown with the letter "D" in the oval symbol. The Tooltip of the PLLs or DLLs shows the name, location assignment, and XY locations.

To view the properties window of the PLLs and DLLs shown in Figure 5–20, double-click the P, H, or D symbol in the Pad View. The PLL Properties window (Figure 5–21) shows the PLL name, location assignment, and its properties, which includes the PLL type and its X and Y location values. You can create or delete the location assignment from this window.

Figure 5–21. PLL Properties

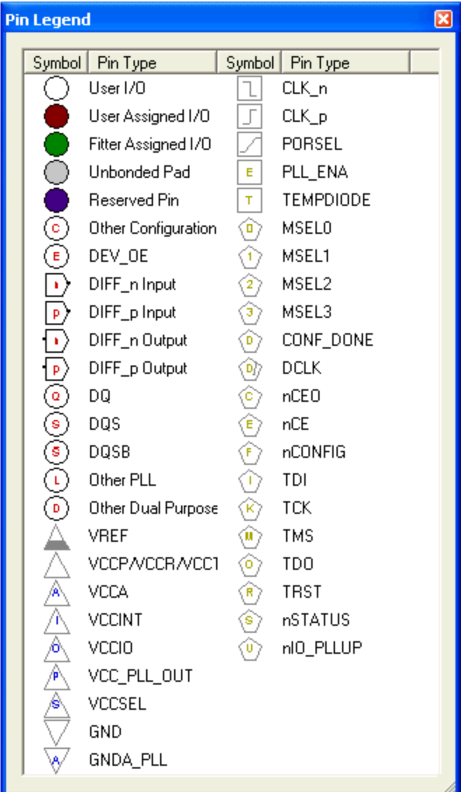


Package View

The Package View in the Pin Planner uses annotated pin symbols in different shapes and colors as visual representations of pins of the actual package (Figure 5–14 on page 5–21). The Package View eliminates the need to cross-reference each pin number with its physical location on the package described in the device package datasheet. When making pin location assignments in the Package View, switch between the different views to help you decide on a pin location. The different views in the Package View include I/O banks, VREF groups, Edges, DQ/DQS pins, and differential pin pairs. For more information about the different views in the Package View, refer to the section in this chapter about the specific view you want to use. The sections are listed on page 5–20.

The Pin Legend window provides a quick reference to the meanings of the pin symbol shapes, notations, and colors in the Package View. To view the Pin Legend window, on the View menu, click **Pin Legend Window** (Figure 5–22). You can also open the Pin Legend window from the Pin Planner toolbar or from the right-click menu in the Package View.

Figure 5–22. Pin Legend Window



Planning your FPGA I/O assignments with your board design is necessary. If your FPGA device is oriented differently than in the Package View and Pad View windows of the Pin Planner, rotate the Package View.

To rotate the Package View, on the View menu, point to **Show** and click **Rotate Left 90°** or **Rotate Right 90°** until your FPGA is shown in the desired orientation in the Package View. The red dot in the Package View indicates the location of the first pin. For example, the red circle identifies where Pin A1 is located on a BGA package and where Pin 1 is located on a TQFP package.

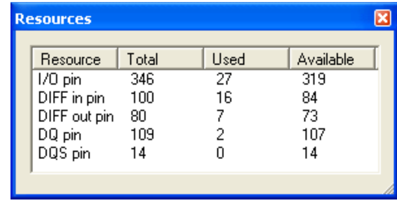
You can also print the Package View with the pin names and pin types visible (Figure 5–23). To show the pin name (if available) or pin type for each pin in the Package View, on the View menu, click **Show Node Names** and **Show Pin Types**.

Figure 5–23. Package View with Show Node Names and Show Pin Types

To view pin resource usage, on the View menu, click **Resources Window**. The Resources window appears (Figure 5–24).

For more detailed information about resources, view the **Resource** section of the Compilation Report.

Figure 5–24. Resources Window



Resources

Resource	Total	Used	Available
I/O pin	346	27	319
DIFF in pin	100	16	84
DIFF out pin	80	7	73
DQ pin	109	2	107
DQS pin	14	0	14

If a HardCopy® II companion device is selected, the Pin Planner shows the Package View for the Stratix II device. To ensure correct pin migration between Stratix II and HardCopy II devices, run the **I/O Assignment Analysis** command or the Fitter.

Pin Migration View

If a migration device is selected, the Pin Planner shows only pins that are available for migration. Selecting a migration device allows you to either vertically migrate to a different density, while using the same package, or to migrate between packages with different densities and ball counts.

The Pin Migration View in the Pin Planner shows the pins that change function in a migration device if you select one or more migration devices for your project. You can see changes for a pin by checking the **Show migration differences** box in the migration view. On the View menu, click **Pin Migration View** to open the Pin Migration View window. A pin is also highlighted in other views of the Pin Planner when you select any pin in the Pin Migration View.

The migration view provides detailed information about the pins that are affected in the migrated device. To select migration devices, perform the following steps:

1. On the Assignments menu, click **Device**. The **Settings** dialog box appears.
2. Click **Migration Devices**. The **Migration Devices** dialog box appears.
3. Make your migration device selections and click **OK**.

The Pin Migration View helps you identify the difference in pins that can exist between migration devices. For example, in Figure 5–25, the highlighted pin `AC24` existed in the original EP2S30 device selected, but does not exist in one of the migration devices. Therefore, the migration result is a No Connect (NC). If you select your migration devices after you have successfully compiled a design and these migration devices have certain differences, an error occurs if you try to recompile your design.

For example, if you have a pin assignment on a pin in the original design, that pin might not be present in a migration device. If you do not select migration devices early in the design cycle, you might get a successful fit initially. However, if you select a migration device or devices later in your design cycle for which the pin assignment cannot be honored because the pin does not exist in the migration device, an error occurs when you try to recompile. Therefore, Altera recommends you choose the supported migration devices early in the design planning process. When you select migration devices early in the design process, only the pins that exist in all migration devices are available in the Pin Planner and the Assignment Editor.

Additional differences can exist between migration devices, as shown in Figure 5–25.

Figure 5–25. Pin Migration View

Device... Pin Finder... Show only highlighted pins Show migration differences Export...

Notice that for PIN_AC23, the Migration Result for Pin Function is not an NC but a voltage reference VREFB1N2. This is because it is an NC in one of the migration devices, but a VREFB1N2 in the other migration device. In this type of result, VREF standards have a higher priority than an NC and the result is VREFB1N2. You might not be making use of that pin for a port connection in your design, but you must tie the VREF standard for I/O standards that require it on the actual board for the migration device.

To see the migration differences in the migration result, in the Pin Migration View window, turn on **Show migration differences**. This option is useful if you are vertically migrating your device to a package with less or more I/O counts than your original device. You can also export the migration view spreadsheet as a ***.csv** file. To do this, in the Pin Migration View window, select a file name and click **Export**.

You can see additional I/O features in the Pin Migration View window in the Clocks, DQ/DQS, Differential, and Configuration columns with the Quartus II software 8.0 and later. To hide or view additional columns, right-click in the Pin Migration View window, point to **Show Columns**, and select the appropriate column.

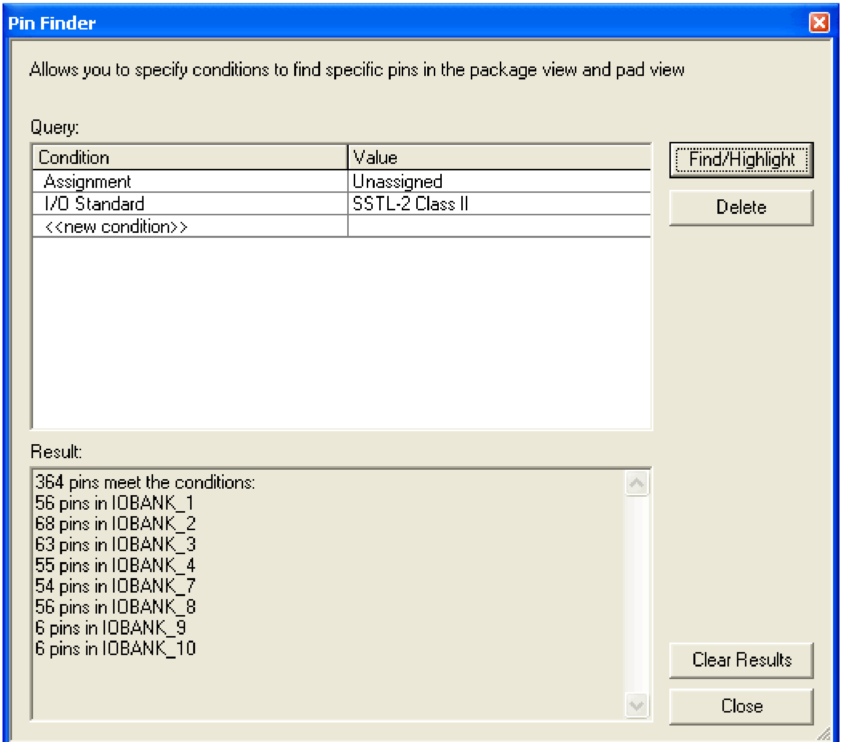
For more information about migration, refer to *AN90: SameFrame Pin-Out Design for FineLine BGA Packages*. For more information about designing for HardCopy II devices, refer to the *Quartus II Support for HardCopy Series Devices* chapter in volume 1 of the *Quartus II Handbook*.

Using the Pin Finder to Find Compatible Pin Locations

As FPGA pin-counts and I/O capabilities continue to increase, it becomes more difficult to understand the capabilities of each I/O pin and to correctly assign your design I/Os. To help you address this problem, the Pin Planner highlights all pins that match the list of conditions that you enter. To enter your conditions, perform the following steps with the Pin Planner open:

1. On the View menu, click **Pin Finder**. The Pin Finder window appears (Figure 5–26).

Figure 5–26. Pin Finder Window



2. In the Pin Finder window, create a list of conditions in the **Query** list.

   To add a condition to the **Query** list, double-click **<<new condition>>** and select a condition from the list. Double-click the cell next to the new condition and select a desired value. For example, if you want to highlight all available pins that support the SSTL-2 Class II I/O standard, create an assignment condition and an I/O standard condition as shown in Figure 5–26.

   If the same condition type occurs more than once in the list, the Pin Finder searches for results that match any of its specified values. If you add more than one condition type, the Pin Finder searches for results that match all of the specified conditions.

3. In the Pin Finder window, click **Find/Highlight**. All of the pins that meet the specified conditions are highlighted in the Package View and Pad View windows.

   At the same time, the **Results** list in the Pin Finder window displays a summary of the number of pins in each I/O Bank that meet the specified conditions.

SSN Visualization View

In the Quartus II software version 9.0 and later, you can view the simultaneous switching noise (SSN) visualization in the Pin Planner by right-clicking in the Package View and selecting **Show SSN Analyzer results**. The SSN Analyzer is a new tool introduced in the Quartus II software version 9.0 to estimate SSN on the input and output pins of your FPGA device. Refer to the Quartus II Help to find out the devices supported for SSN analysis. The integration of the SSN Analyzer and Pin Planner in the Quartus II software allows you to perform SSN analysis while planning your I/O pins.

For more information about the SSN Analyzer, refer to the *Simultaneous Switching Noise (SSN) Analysis and Optimization* chapter in volume 2 of the *Quartus II Handbook*.

Creating Reserved Pin Assignments

You can make reserved pin assignments to act as place holders for future design pins in the Package View or in the All Pins list. To create a reserved pin in the Package View, right-click an available pin, point to **Reserve** and click one of the available configurations.

When you reserve a pin from the Package View, the name of the reserved pin is set to `user_reserve_`<*number*> by default and the pin symbol is filled with a dark purple color. The number increments by 1 for each additional reserved pin.

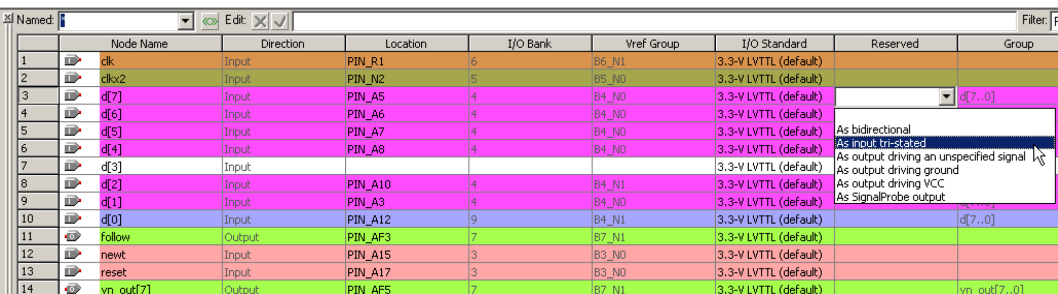
Alternately, you can reserve a pin in the All Pins list by performing the following steps:

1. Type the pin name into an empty cell in the **Node Name** column. The pin name must not already exist in your design.
2. Select a pin configuration from the **Reserved** list (Figure 5–27).

   The following configurations are available:

   - **As bidirectional**
   - **As input tri-stated**
   - **As output driving an unspecified signal**
   - **As output driving ground**
   - **As output driving VCC**
   - **As SignalProbe output**

Figure 5–27. Reserving a Pin in the All Pins List in the Pin Planner



Release reserved pins by selecting the blank entry from the **Reserved** column.

The **Direction** column is a read-only column and changes direction depending on the reserved selection.

Creating Pin Location Assignments

You can create pin location assignments for one or more pins with the following methods:

- Assigning a location for unassigned pins
- Assigning a location for differential pins
- Assigning an unassigned pin to a pin location

You can disable or prevent any of these assignments using the **Enable** column in either the Groups list or the All Pins list. The **Enable** column is a special column that allows you to disable only the location assignment for a selected pin. Change the value of the cell in the **Enable** column for a selected pin from **Yes** to **No** by double-clicking the cell and selecting **No** from the list. A disabled pin only prevents location assignments when signals are assigned using drag-and-drop, as described below. You can still make assignments directly in the **Location** columns in both the Groups list and All Pins list. To enable the location assignment again, change the **Enable** column back to **Yes**.

Assigning Locations for Unassigned Pins

To assign locations for all of your design pins, perform the following steps:

1. On the Edit menu, select an assignment direction.

   You can assign several pins simultaneously by choosing an assignment direction (Table 5–3). When assigning an entire bus, assignments are made in order from the most significant bit (MSB) to the least significant bit (LSB).

Table 5–3. Multiple Pins

Assignment	Pin Group
Assign Down	From the selected group of unassigned design pins, assign the pins downwards starting from the selected pin.
Assign Up	From the selected group of unassigned design pins, assign the pins upwards starting from the selected pin.
Assign Right	From the selected group of unassigned design pins, assign the pins from left to right starting from the selected pin.
Assign Left	From the selected group of unassigned design pins, assign the pins from right to left starting from the selected pin.
Assign One by One	Select a pin location for each of the design pins selected from the **Pins: unassigned** list in the **Filter** list.

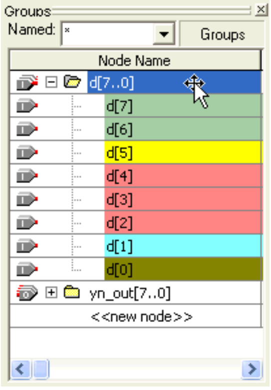
If there is an unassignable location in the path of the selected assignment direction, pins are assigned as far in the assignment direction as possible. Assign the rest of the pins in a separate location.

2. In the **Filter** list, select **Pins: unassigned**.

3. In the All Pins list, select one or more unassigned node names, or in the Groups list, select one or more buses.

   You can click on multiple node names using the control and shift keys. When you click on a pin or bus in the All Pins list or Groups list, the node name is highlighted and a crossing arrow displays above the cursor. Drag the selected cells into the Package View (Figure 5–28).

Figure 5–28. Drag Node Name in the Groups List



4. Drag and drop the selected pins or buses from the All Pins list or Groups list to a location in the Package View.

Before you drag-and-drop your pins, you can optionally use the Pin Finder to locate pin locations that support your selected pins. When creating a query in the Pin Finder, add an Assignment condition and set it to **Unassigned**.

If you do not use the Pin Finder, you can drop pins directly into any of the following locations in the Pin Planner Package View:

- Available user I/O pin
- I/O Bank
- VREF Group
- Edge

On the View menu, you can display either I/O banks, VREF groups, or edges by going to the Show submenu and toggling between **Show I/O Banks**, **Show VREF Groups**, and **Show Edges**. You can also toggle between these views from the Pin Planner toolbar or from the right-click menu in the Package View.

Available single-ended user I/O pins are represented by empty circles in the Package View. The letter inside the circle provides information about the user I/O pin. Negative and positive differential pins are shaped like hexagons and contain the letters "n" and "p", respectively. For a complete listing of I/O pin shapes, notations, and colors, from the View menu, toolbar, or Package View right-click menu, open the Pin Legend window.

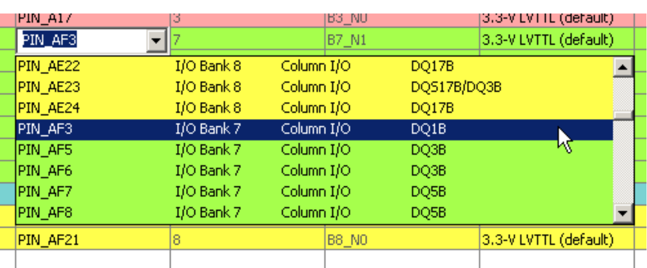
In the Package View, I/O banks are displayed as rectangles labeled `IOBANK_`<*number*> (Figure 5–35 on page 5–44). In each I/O bank, there are one or more VREF groups. VREF groups are displayed as rectangles labeled `VREFGROUP_B`<*I/O Bank number*>`_N`<*index*> (Figure 5–37 on page 5–46).

Edge locations are displayed as rectangles labeled `EDGE_`<*direction*>. To make an edge assignment, drag and drop pins into one of the four edges, `EDGE_TOP`, `EDGE_BOTTOM`, `EDGE_LEFT`, or `EDGE_RIGHT`.

You can drag-and-drop pins from the **Node Finder** dialog box or from the Block Diagram/Schematic File into the Package View.

Click on the **New Node** button ( ) in the All Pins list to jump directly to the new node row without scrolling all the way down. When you click on the **Location Assignment** cell in the All Pins list, a drop-down combo box with all the assignable pins is opened (Figure 5–29).

Figure 5–29. Combo Box in the Pin Planner



The combo box shown in Figure 5–29 displays each row in a color matching its I/O bank color. In the combo box, each pin location row displays the location assignment column, its I/O bank column, and its special function column. While making assignments for a node, if you double click the **Edit** field in the All Pins list, a pull-down box appears with all the possible values for the assignment.Choose a value and click the green check button ( ) to make the assignment or click the red cross button ( ) to cancel the assignments change.

Creating Exclusive Group Assignments

In the Quartus II software version 9.0 and later, you can create exclusive groups comprised of pins by using the following assignment:

```
set_instance_assignment -name "EXCLUSIVE_IO_GROUP" -to pin
```

When you create exclusive I/O group(s) in your FPGA design and use the Quartus II software to map the signals onto device pins, the Fitter does not place the I/O pins belonging to one exclusive group in an I/O bank if the pins belong to another exclusive I/O group. To understand this, consider an example in which you have a set of signals assigned exclusively to a group called `group_a`, and another set of signals assigned to `group_b`. In both exclusive groups you might have pins with different I/O standards. When you create these groups, the Quartus II software maps the pins of both groups in such a way that they are placed in different I/O banks.

Assigning a Location for Differential Pins

You can assign the top-level pins of your design as differential pins in Altera devices using the Pin Planner. Before you assign the top-level pins of your design as differential pins in the Pin Planner, it is important to understand the process for creating differential pins in your design. If your design has top-level pins that are single ended, you can use the Pin Planner to assign the required differential standard to that pin. The Quartus II software automatically creates the negative pin of the differential standard. For example, if you have a top-level pin defined as `lvds_in` in your design, the Quartus II software creates a `lvds_in(n)` pin when you assign a differential standard to `lvds_in`, as shown in Figure 5–30.

Figure 5–30. Creating a Differential Pin Pair in the Pin Planner

Named: * Edit: lvds_in Filter: Pins: all

	Node Name	Differential Pair	I/O Standard	Direction
5	input_data[4]		3.3-V LVTTL (default)	Input
6	input_data[3]		3.3-V LVTTL (default)	Input
7	input_data[2]		3.3-V LVTTL (default)	Input
8	input_data[1]		3.3-V LVTTL (default)	Input
9	input_data[0]		3.3-V LVTTL (default)	Input
10	lvds_in	lvds_in(n)	LVDS	Input
11	output_data[7]		3.3-V LVTTL (default)	Output
12	output_data[6]		3.3-V LVTTL (default)	Output
13	output_data[5]		3.3-V LVTTL (default)	Output
14	output_data[4]		3.3-V LVTTL (default)	Output
15	output_data[3]		3.3-V LVTTL (default)	Output
16	output_data[2]		3.3-V LVTTL (default)	Output
17	output_data[1]		3.3-V LVTTL (default)	Output
18	output_data[0]		3.3-V LVTTL (default)	Output
19	reset		3.3-V LVTTL (default)	Input

All Pins

For Stratix III and Cyclone® III FPGA families, you can use low-level I/O differential primitives to define both positive and negative pins of a differential pair in your design's HDL code.

For more information about supported I/O primitives and details about their assignments, refer to the *Designing with Low-Level Primitives Users Guide* or the Quartus II Help.

When you use low-level I/O primitives to define various pin-related assignments for I/Os, the assignments are honored after you perform full compilation. These assignments are not shown in the Pin Planner after analysis and synthesis. After a full compilation, you can populate these assignments in the Pin Planner by back-annotating pin assignments. To back annotate your pin assignments, on the Assignments menu, click **Back-Annotate Assignments**.

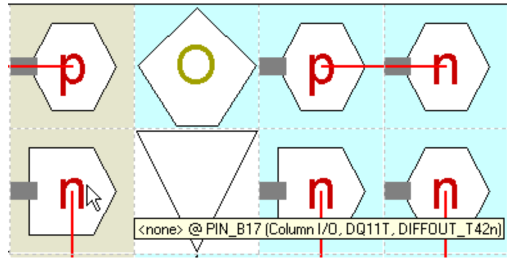
To identify and assign differential pins using the Pin Planner, perform the following steps:

1. On the View menu, click **Show Differential Pin Pair Connections**.

   A red line connects the positive and negative pins of the differential pin pairing. The positive and negative pins are labeled in the Package View with the letters "p" and "n", respectively (Figure 5–31).

2. Use the tool tips to identify LVDS-compatible pin locations by holding the mouse pointer over a differential pin in the Package View (Figure 5–31).

Figure 5–31. Tool Tip of a Differential Pin



The tool tip shows the design pin name and pin number, as well as its general and special functions.

For more information about the general and special functions of pins displayed by the tool tip, refer to the device pin-out tables for your device family at www.altera.com.

3. From the All Pins list or Groups list, drag-and-drop the selected pin of the differential pair to a differential pin location in the Package View.

Pay attention when you drag the positive or negative pin of the differential pin pair to the Package View. Connect the positive pin to the “p” pin on the device and negative pin to the “n” pin on the device. An error appears in the Quartus II software if you do not connect the differential pins properly.

Optionally, before you drag-and-drop your pins, you can use the Pin Finder to locate pin locations that support your selected pins. When creating a query in the Pin Finder, add an assignment condition set to **Unassigned** and an I/O standard condition set to your differential I/O standard.

The Quartus II software recognizes the negative pin as part of the differential pin pair assignment. The location assignment for the negative pin pair is written to the **.qsf** file. However, the assignment I/O standard is not entered in the **.qsf** file for the negative pin of the differential pair.

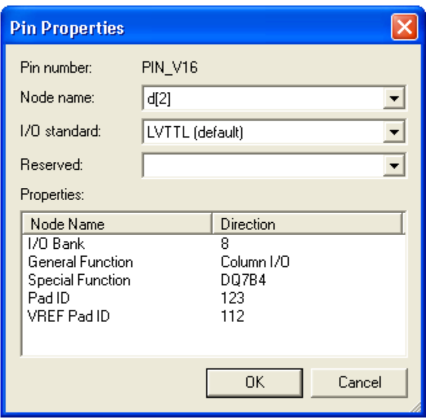
If you have a single-ended clock that feeds a PLL, assign the pin only to the positive clock pin of a differential pair in the targeted device. Single-ended pins that feed a PLL and are assigned to the negative clock pin in the targeted device cause the design to not fit.

Assigning an Unassigned Pin to a Pin Location

Perform the following steps to select a pin location and assign a design pin to that location:

1. In the Package View, select an available pin location.
2. On the View menu, click **Pin Properties.** The **Pin Properties** dialog box appears (Figure 5–32).

Figure 5–32. Pin Properties Dialog Box



You can use the **Pin Properties** dialog box to create pin location and I/O standard assignments. The **Pin Properties** dialog box also displays the properties of the pin location, including the pad ID (Table 5–4). The pad ID is important information when following pin spacing guidelines. Adjacent pin numbers do not always represent adjacent pads on the die. Use the Pad View window to help correlate pad location and the distance between your user I/O pins and VREF pins.

3. Select a pin from the **Node Name** list.
4. To assign or change the I/O standard, select an I/O standard from the **I/O standard** list.
5. Click **OK**.

For more information about pin placement, refer to the appropriate device handbook.

Table 5–4 provides a description of each field in the **Pin Properties** dialog box.

Table 5–4. Pin Properties

Pin Property	Description
Pin Number	Pin number used in the package *(1)*
Node Name	Node name assigned to the pin location
I/O Standard	I/O standard assigned to the pin name and location
Reserved	If reserved, determines how to reserve this pin
I/O Bank	I/O bank number of the pin
General Function	General function of the pin (row and column I/O, dedicated clock pin V_{CC}, GND)
Special Function	Special function of the pin (LVDS, PLL)
Pad ID	Pad number connected to pin
VREF Pad ID	The pad ID for the VREF pin used for voltage referenced I/O standards

Note to Table 5–4:

(1) For more information about how pin numbers are derived, refer to the device pin-out on the Altera website, www.altera.com.

© March 2009 Altera Corporation

You can also open the **Pin Properties** dialog box by double-clicking on a pin in the Package View of the Pin Planner, or by right-clicking the pin in the Package View of the Pin Planner, and clicking **Pin Properties**.

Changing the Slew Rate and Current Drive Strength in Pin Planner

Current strength is an important property of an I/O pin. It affects the integrity of the signal going out of the device. You can set the current strengths as part of the I/O planning flow in the Pin Planner. You can also change the current strength after the compilation of your design. In the Pin Planner's All Pins list, you can view or edit the current strengths for each of the output and bidirectional pins in the **Current Strength** column. If the **Current Strength** column is not visible in All Pins list, right-click in the All Pins list and use the **Customize Columns** dialog box to add the **Current Strength** column. The settings you make in Pin Planner are honored during Live I/O Check, I/O Assignment analysis, and full compilation.

To make changes to the current drive strength after compilation has finished, you can perform engineering change orders (ECOs). To perform ECOs, use the Resource Property Editor (RPE) tool in the Quartus II software. Performing ECO compilation does not recompile the whole design, but compiles only the changes.

For more information about ECOs, refer to the Quartus II Help or the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

The slew rate is another important property of an I/O pin that affects the outgoing signal integrity of the device. Slew rate options are not supported for all device families. To learn more about the supported families for slew rates, refer to the specific device handbooks. You can set the slew rate as part of the I/O planning flow in the Pin Planner. You can also change the slew rate setting after compiling your design.

In the Pin Planner's **All Pins** list, you can view or edit the slew rate for each of the output and bidirectional pins in the **Slew Rate** column. If the **Slew Rate** column is not visible in the All Pins list, right-click in the All Pins list and use the **Customize Columns** dialog box to add the **Slew Rate** column. The settings you make in Pin Planner are honored during Live I/O Check, I/O Assignment Analysis, and full compilation. To change the slew rate after compilation has finished, you can perform an ECO by using the RPE tool in the Quartus II software. Performing ECO compilation does not perform place-and-route on the whole design, but only on the changes.

For more information about ECOs, refer to the Quartus II Help or the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

You can also set the current drive strength and slew rate settings by using the following Tcl assignments in the **.qsf** file:

```
set_instance_assignment -name CURRENT_STRENGTH_NEW 8MA -to e[0]
set_instance_assignment -name SLEW_RATE 2 -to e[0]
```

For more information about the effect of I/O settings on Signal Integrity on the board for Stratix III devices, refer to *AN 476: Impact of I/O Settings on Signal Integrity in Stratix III Devices*.

Error Checking Capability

The Pin Planner has basic pin placement checking capability, preventing pin placements that violate the fitting rules. The following checks are performed by the Pin Planner as you make pin-related assignments:

- An I/O bank or VREF group is an unassignable location if there are no available pins in the I/O bank or VREF group.
- The negative pin of a differential pair is unassignable if the positive pin of the differential pair has been assigned with a node name with a differential I/O standard.
- Dedicated input pins (for example, dedicated clock pins) are an unassignable location if you attempt to assign an output or bidirectional node name.
- Pin locations that do not support the I/O standard assigned to the selected node name become unassignable.
- All nodes in the same VREF group must have the same VREF voltage. Apply this only to HSTL- and SSTL-type I/O standards.

To perform a more comprehensive check on your pin placements, perform I/O assignment analysis.

For more information about assignment analysis, refer to "Using I/O Assignment Analysis to Validate Pin Assignments" on page 5–59.

To display live information about the warnings and errors in your pin-related assignments, enable the live I/O check feature in the Quartus II software. For more information about the live I/O check feature, refer to the section "Using the Live I/O Check Feature to Validate Pin Assignments" on page 5–57.

After creating a pin location, the **Location**, **I/O Bank**, and **VREF Group** columns are populated in both the All Pins list and the Groups list. In the Package View, the occupied pins are filled with a dark brown color.

Changing Pin Locations

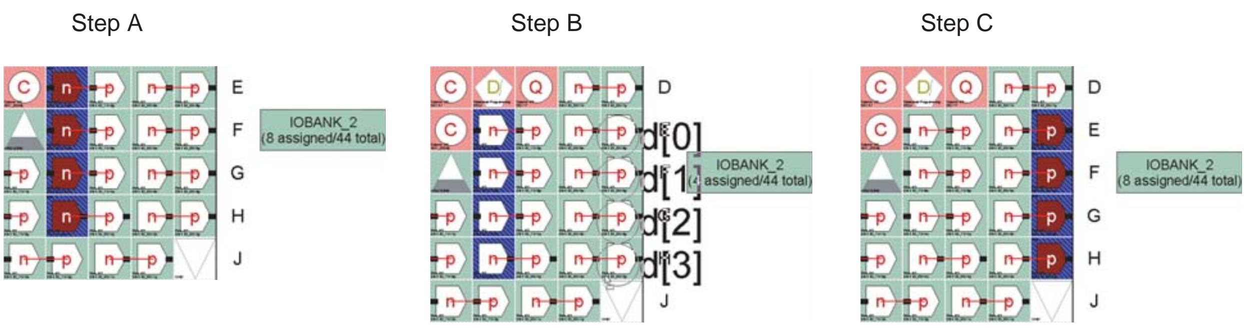
The Pin Planner allows you to change the location of multiple pins simultaneously. To change pin locations, select one or more pins in the Package View or Pad View window, and drag the pins to a new location.

You can change pin locations more quickly and easily if you understand which user I/O pins are available and where they are physically on the device. For example, in the Package View, you can move a column of pins closer to the edge of the device for easier PCB routing (Figure 5–33). In this example, you are moving multiple I/O pins to the area closest to the edge of the I/O bank. To change pin locations, perform the following steps:

1. In the Package View, select multiple pins by holding down the left mouse button and dragging over the pins you want to move (Figure 5–33, step A).
2. Drag the group of pins to the placement area (Figure 5–33, step B).
3. Drop the pins into the area closest to the edge of the I/O bank (Figure 5–33, step C).

© March 2009 Altera Corporation

Figure 5–33. Changing the Locations for a Group of Pins

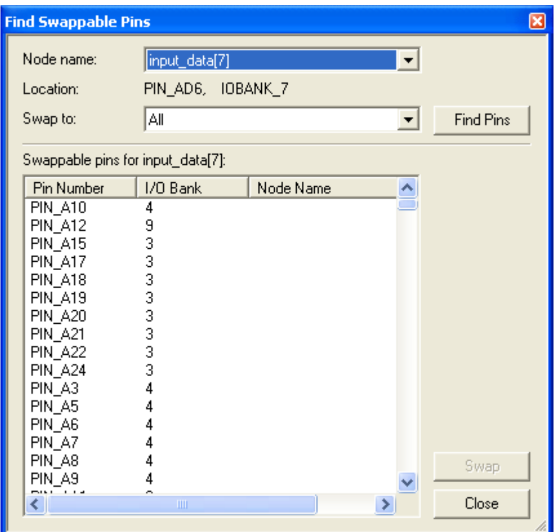


Swapping Pin Locations

In Quartus II software version 8.0 and later, you can use the Pin Planner to swap pin locations in your design. The Pin Swapping feature can help you move one or more pins from one location to another for last minute PCB layout or design changes after you have made most of your pin assignments.

To use the Pin Swapping feature, right click in the Pin Planner's Package View and click **Find Swappable Pins**. The **Find Swappable Pins** dialog box appears (Figure 5–34). As shown in Figure 5–34, the **Node Name** field drop down list shows all the nodes in your design, a **Location** field, which gives information of any existing location assignment of the node selected in the **Node Name** field, a **Swap To** filter that you can use to narrow down the searchable pins in a particular I/O bank or VREF group, and a **Swap** button.

Figure 5–34. Find Swappable Pins Dialogue Box in the Pin Planner



In the **Find Swappable Pins** dialog box, **Node name** enables you to choose one of the top-level pins or nodes of your design and shows you all the possible swappable locations in your selected device when you click **Find Pins**. The list of swappable pins returned to you depends on what filter you use in the **Swap to** filter to find the swappable pins. For example, if you select **All**, a list of all the swappable locations for

that node will resemble the pins shown in Figure 5–34. The returned list contains all the assigned and unassigned pin locations. If you want to swap or move a signal name to a certain pin location in the list, select the pin location and click **Swap**. The **Swap** button is only enabled and highlighted when you select a pin location in the list. When you click the **Swap** button, the node in the "Node Name" is assigned to that pin location. If the selected pin location is assigned to another node, the original node in the **Node name** list and your selected node get swapped.

The Pin Swap feature requires the **Live Check** option to be turned on; therefore, you might get warnings or errors if any pin placement rules are violated during pin swapping. The warning and errors are printed in the Messages window. You must run I/O Assignment Analysis after performing any pin swapping.

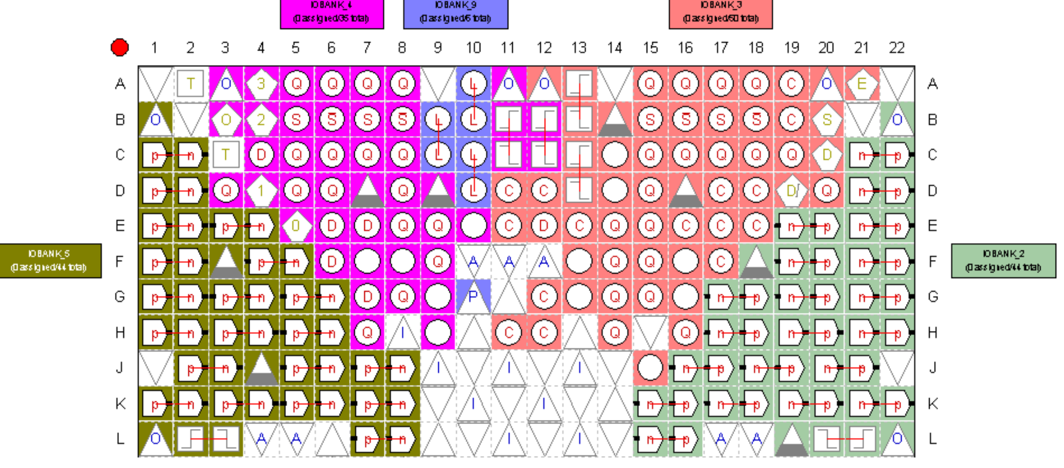
When you select the pin location, the pin location is highlighted in the Package View of Pin Planner. This helps you locate the physical location where you intend to swap.

Show I/O Banks

When you turn on Show I/O Banks in the View menu, in the Show submenu, or on the right-click menu in the Package View, the Package View groups I/O pins that share the same `VCCIO` pin using different colors (Figure 5–35). When planning your I/O pins, it is important to guide your pin placement decisions by placing pins with compatible I/O standards into the same I/O bank. For example, you cannot place an `LVTTL` pin with an I/O standard of LVTTL in the same bank as another pin with an I/O standard of 1.5 V HSTL Class I.

For more information about compatible I/O standards, refer to the appropriate device handbook.

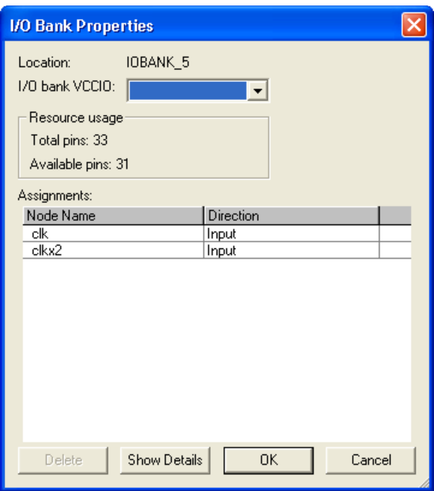
Figure 5–35. Package View with I/O Banks



When you turn on **Show I/O Banks**, the Package View allows you to view the properties of each I/O bank. Select an I/O bank in the Package View. On the View menu, click **I/O Bank Properties.** The **I/O Bank Properties** dialog box appears (Figure 5–36). The **I/O Bank Properties** dialog box lists all node names assigned to that I/O bank.

To view all node names that are assigned within the I/O bank, click **Show Details** in the **I/O Bank Properties** dialog box. You can also assign the V_{CCIO} for the I/O bank by selecting a voltage from the **I/O bank VCCIO** list.

Figure 5–36. I/O Bank Properties



Under **Resource Usage**, the total number of pins in the I/O banks is displayed, including assignable and unassignable pins, as well as the total number of available assignable pins. Adjust the intensity of colors of the I/O banks in the Package View by performing the following steps:

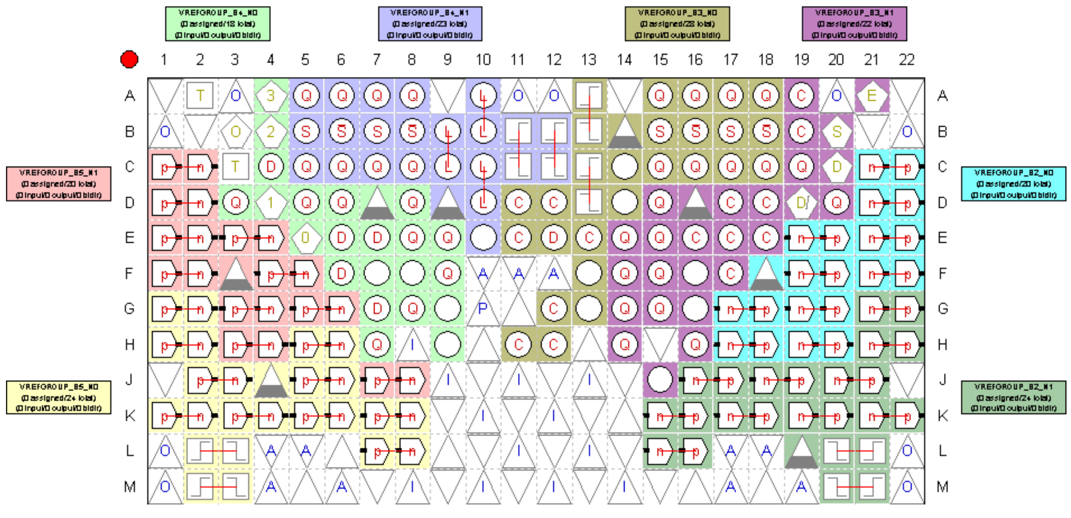
1. On the Tools menu, click **Options**. The **Options** dialog box appears.
2. In the **Category** list, select **Pin Planner**. The **Pin Planner** page appears.
3. Under **I/O banks color setting**, adjust the **I/O bank color intensity** using the slide bar.
4. Click **OK**.

Show VREF Groups

You can use different colors to indicate different groups of I/O pins sharing the same `VCCIO` and `VREF` pins in the package view (Figure 5–37). When planning your I/O pins, it is important to place pins with compatible voltage-referenced I/O standards in the same I/O bank. To guide your pin placement decisions by placing compatible I/O standards requiring `VREF` pins into the same VREF group, on the View menu, point to **Show** and click **Show VREF Groups**. For example, pins with I/O standards SSTL-18 Class II and 1.8V-HSTL Class II are compatible and can be placed into the same VREF group. It is also important to be aware of the number and direction of pins within a VREF group for simultaneous switching noise (SSN) analysis.

For more information about compatible I/O standards, refer to the appropriate device handbook.

Figure 5–37. Package View with VREF Groups

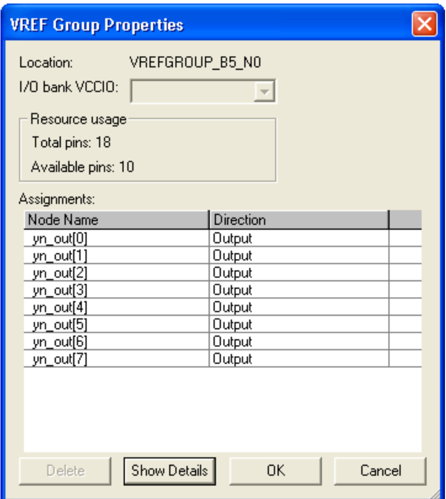


When you turn on **Show VREF Groups**, the Package View allows you to show the properties of each VREF group. Select a VREF group in the Package View, and on the View menu, click **VREF Group Properties**. The **VREF Group Properties** dialog box appears (Figure 5–38).

In the VREF **Group Properties** dialog box, all node names assigned to the VREF group are listed. Click **Show Details** to view node names that are assigned to pin numbers within the VREF group.

Any design pins that are assigned to the VREF group and not to a pin number are listed in the **Assignments** list. The **Resource usage** section describes the total number of pins in the VREF group and the total number of available assignable pins. It also keeps a running tally of the input, output, and bidirectional pins.

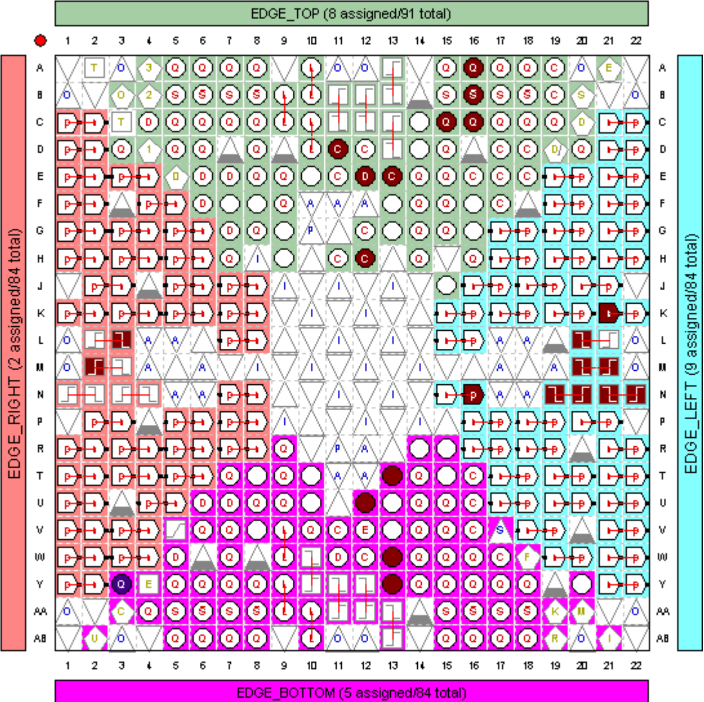
Figure 5–38. VREF Group Properties



Show Edges

You can use different colors to indicate the four edges of the package in the Package View (Figure 5–39). To do this, on the View menu, point to **Show** and click **Show Edges**, or from the right-click menu, click **Show Edges**. If the exact location of a pin is not a priority when planning your I/O pins, use an Edge assignment.

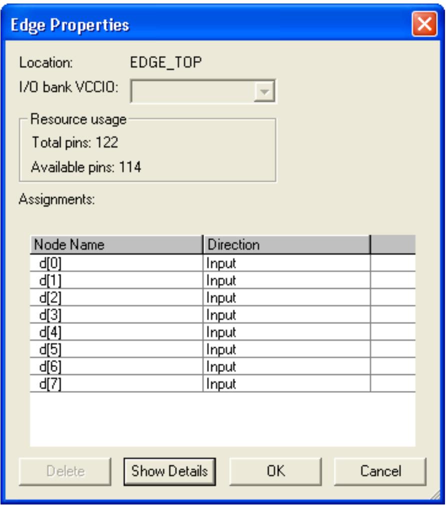
Figure 5–39. Package View with Edges



When you turn on **Show Edges**, the Package View allows you to show the properties of each Edge. Select an Edge in the Package View. On the View menu, click **Edge Properties.** The **Edge Properties** dialog box appears.

In the **Edge Properties** dialog box, all node names assigned to the Edge are listed (Figure 5–40). To view all node names assigned to a pin number within an Edge, in the **Edge Properties** dialog box, click **Show Details**.

Figure 5–40. Edge Properties



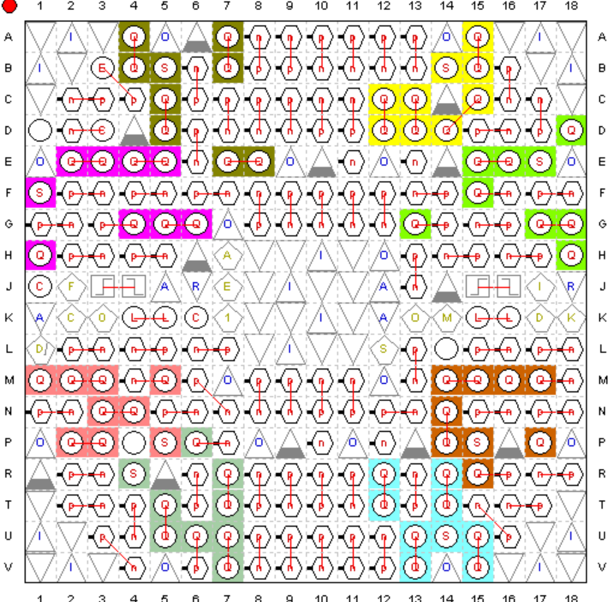
Show DQ/DQS Pins

You can use different colors to highlight groups of DQ and DQS pins in the Package View (Figure 5–41). To do this, on the View menu, point to **Show** and click **Show DQ/DQS Pins**, or from the right-click menu, click **Show DQ/DQS Pins**. Highlighting these DQ/DQS groups easily identifies which DQ pins are associated with a specific DQS strobe pin. Select between the following DQ/DQS modes:

- ×4 Mode
- ×8/×9 Mode
- ×16/×18 Mode
- ×32/×36 Mode

© March 2009 Altera Corporation

Figure 5–41. DQ/DQS Pins *(Note 1)*



Note to Figure 5–41:

(1) This DQ/DQS view shows an ×8 mode.

For example, when implementing DDR II in a Stratix II device, there are dedicated pins designed specifically to be used as DQ and DQS pins.

For information about using the ALTDQ and ALTDQS megafunctions to configure DQ and DQS pins, refer to the *Data (DQ) and Data Strobe (DQS) Megafunction User Guide (ALTDQ and ALTDQS)*.

Displaying and Accepting Fitter Placements

In addition to the **Show I/O Banks**, **Show VREF Groups**, and **Show Edge** views, you can also show pins placed by the Fitter. To display these pins, on the View menu, or in the Pin Planner toolbar, or on the right-click menu in the Package View, point to **Show** and click **Show Fitter Placements**.

The Fitter provides optimal placement to unassigned pins based on design constraints when you perform a compilation or an I/O Assignment Analysis. When you choose **Show Fitter Placements**, the Fitter-placed pins are shown as green-filled pins in the Package View. You can create a copy of the Fitter placements in your project **.qsf** file using the **Back-Annotate Assignments** command. Refer to "Accepting Fitter Placements—Back-Annotating Assignments" on page 5–74.

Altera recommends you use the Pin Planner to create and edit pin-related assignments. However, you might find some of the other tools provided for use with the Quartus II software to be useful for working with pin-related assignments. The following sections describe these tools.

Assignment Editor

The Assignment Editor provides a spreadsheet-like interface that allows you to create and change all pin-related assignments.

Two methods are available for making pin assignments with the Assignment Editor. The first involves selecting from all assignable pin numbers of the device and assigning a pin name from your design to this location.

The second involves selecting from all pin names in your design and assigning a device pin number to the design pin name. In either method, take advantage of row background coloring (pin numbers within the same I/O bank have a common background color), auto fill node names, and pin numbers to assist in making your assignments.

Setting Pin Locations from the Device Pin Number List

It is important to understand the properties of a pin location before assigning that location to a pin in your design. For example, you must know which I/O bank or VREF group the pin belongs to when following pin placement guidelines.

For more information about pin placement guidelines, refer to the appropriate device handbook.

Before creating pin-related assignments, perform analysis and elaboration or analysis and synthesis on your design to create a database of your design pin names. Then perform the following steps:

1. To open the Assignment Editor, on the Assignments menu, click **Assignment Editor.**
2. In the **Category list**, select **Pin**.

   Creating pin assignments can be difficult when you must check which I/O bank the pin belongs to or which VREF pad the pin uses. By selecting the **Pin** category, more pin-related information is visible in the spreadsheet to help you create pin location assignments.

   The Assignment Editor does not show assignments to individual nodes made with wildcards or assignment groups.

3. On the View menu, click **Show All Assignable Pin Numbers**.

You can also view all assignable pins in the All Pins list in the Pin Planner. Right-click anywhere in the Groups list or All Pins list and click **Show Assignable Pins**. When the All Pins list filter is set to **Pins: unassigned** or **Pins: all**, a list of all assignable pin numbers for the targeted device is shown in the **Location** column (Figure 5–42).

Figure 5–42. Assignment Editor with Show All Assignable Pin Numbers

	To	Location	I/O Bank	I/O Standard	General Function	Special Function	Reserv
1		PIN_A6	4	3.3-V LVTTL	Column I/O	DQ7T	
2		PIN_C21	2	3.3-V LVTTL	Row I/O	DIFFIO_RX22n	
3		PIN_C22	2	3.3-V LVTTL	Row I/O	DIFFIO_RX22p	
4		PIN_E20	2	3.3-V LVTTL	Row I/O	DIFFIO_TX22p	
5		PIN_A6	4	3.3-V LVTTL	Column I/O	DQ7T	
6		PIN_A16	3	3.3-V LVTTL	Column I/O	DQ11T	
7		PIN_A18	3	3.3-V LVTTL	Column I/O	DQ13T	
8	<<new>>	<<new>>					

4. Find a pin number in the spreadsheet. In the same row, double-click the cell in the **To** column. Type the pin name or select a pin from the pull-down list. If analysis and elaboration has been performed, your design pins are listed in the pull-down list.

As you type in a pin name, the Assignment Editor automatically completes the field by looking up the pin names stored in the database created from the initial analysis and elaboration. Pin names already assigned to a pin location are shown in italics.

Setting Pin Locations from the Design Signal Name List

It is important to understand the properties of a pin location before assigning that location to a pin in your design. For example, you must know which I/O bank or VREF group the pin belongs to when following pin placement guidelines.

For more information about pin placement guidelines, refer to the appropriate device handbook.

To set the pin locations from the design pin name list, perform the following steps:

1. To open the Assignment Editor, on the Assignments menu, click **Assignment Editor**.
2. In the **Category** list, select **Pin**.

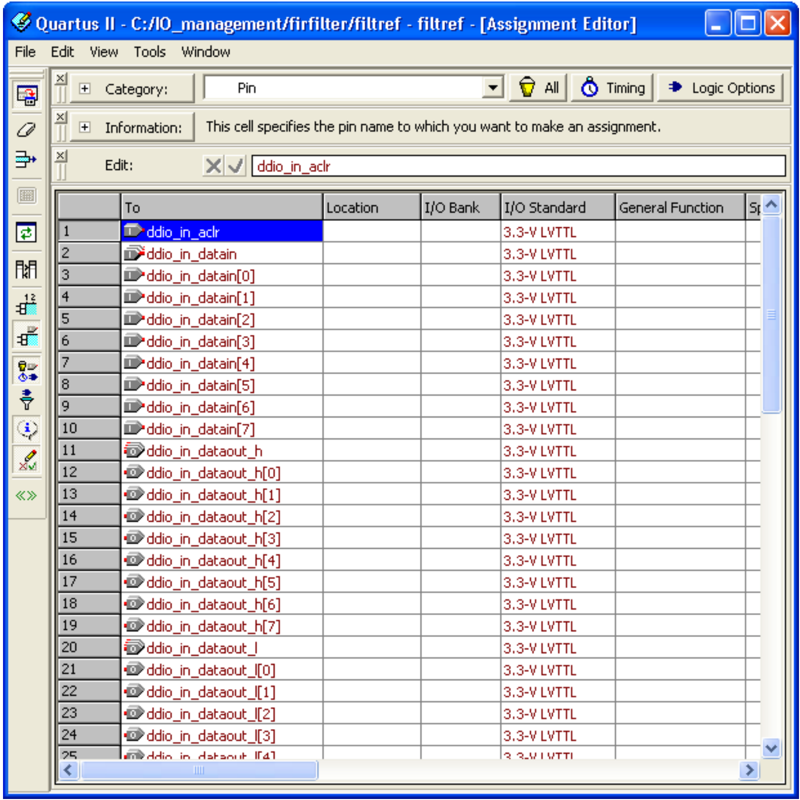
   Creating pin assignments can be difficult when you have to check which I/O bank the pin belongs to, or which VREF pad the pin uses. By selecting the **Pin** category, more pin-related information is visible in the spreadsheet to help you create pin location assignments.

   The Assignment Editor does not show assignments to nodes made with wildcards or assignment groups.

3. On the View menu, click **Show All Known Pin Names**.

   A list of all pin names in your design is shown in the **To** column (Figure 5–43).

Figure 5–43. Assignment Editor with Show All Known Pin Names



To list a selection of pin names from your design into the spreadsheet of the Assignment Editor, type the pin names with or without wild cards into the **Node Filter** bar. This is effective when you want to assign common pin-related assignments to a selection of pins in your design.

For more information about using the **Node Filter** bar, refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook*.

4. Find a pin name in the spreadsheet and double-click the cell in the same row of the **Location** column. Select a pin number from the pull-down list that contains all assignable pin numbers in the selected device. You can also start typing the pin number and let the Assignment Editor automatically complete it for you. Instead of typing `PIN_AA3`, type `AA3` and let the Assignment Editor auto complete the pin number to `PIN_AA3`.

   Pin locations that already have a pin name assignment appear in the Assignment Editor in italics.

For more information about using the Assignment Editor, refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook*.

Tcl Scripts

Tcl scripting allows you to write scripts to create pin-related assignments. To run a Tcl script with your project, type the following command at a system prompt:

```
quartus_sh -t my_tcl_script.tcl ↵
```

You can also type individual Tcl commands into the Tcl console window. To use the Tcl console, on the View menu, point to **Utility Windows** and click **Tcl Console**. In the Tcl Console window, type your Tcl commands. Example 5–3 shows a list of Tcl commands that creates pin-related assignments to the input pin `address[10]`.

Example 5–3. Tcl Commands to Create Pin-Related Assignments

```
set_location_assignment PIN M20 -to address[10] -comment"Address pin to Second FPGA"
set_instance_assignment -name IO_STANDARD "2.5 V" -to address[10]
set_instance_assignment -name CURRENT_STRENGTH_NEW "MAXIMUM CURRENT" -to address[10]
```

When you make an assignment in the Assignment Editor or the Pin Planner, display the equivalent Tcl command in the Messages window by performing the following steps:

1. On the Tools menu, click **Options**. The **Options** dialog box appears.
2. In the **Category** list, select **Assignment Editor**. The **Assignment Editor** page opens.
3. Turn on **Echo Tcl Commands**.
4. Click **OK**.

For more information about using Tcl scripts to create pin-related assignments, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook* and to the *Quartus II Scripting Reference Manual*.

Chip Planner or Timing Closure Floorplan

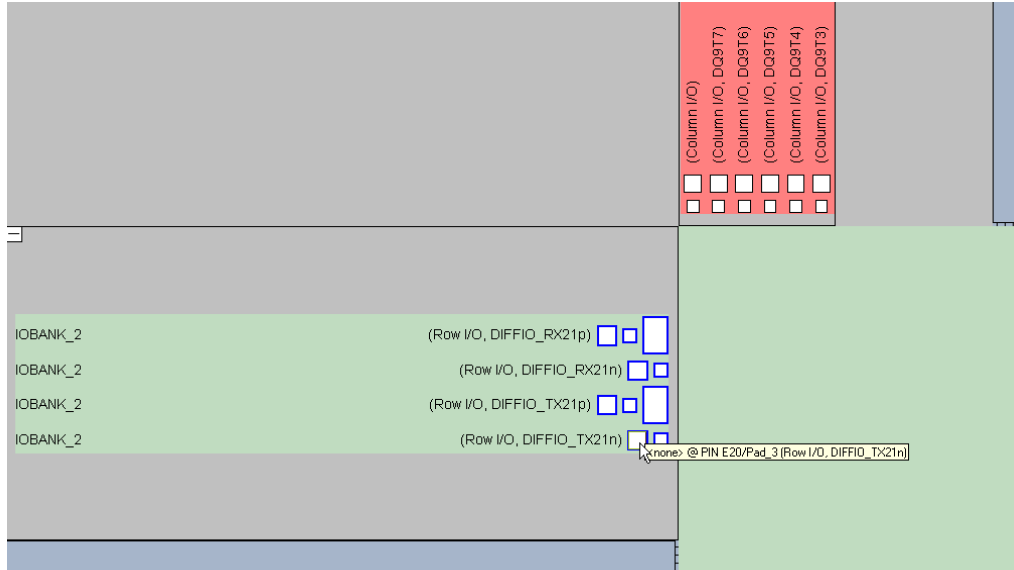
The floorplan of the device shows the pins in the same order as the pads of the device. Understanding the relative distance between a pad and related logic can help you meet your timing requirements.

You can view the floorplan of the device in the Chip Planner or Timing Closure Floorplan. For more information about supported device families in the Chip Planner or Timing Closure Floorplan, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

Use either tool to find the distances between user I/O pads and V_{CC}, GND, and VREF pads to avoid signal integrity issues (Figure 5–44).

For more information about pin placement guidelines, refer to the *Selectable I/O Standards* chapter of the appropriate device handbook.

Figure 5–44. Timing Closure Floorplan of EP1C6F256I7



You can create a pin location assignment by selecting a pin and selecting a desired location. To do this, perform the following steps:

1. To open the Timing Closure Floorplan, on the Assignment menu, click **Timing Closure Floorplan**. To open the Chip Planner, on the Tools menu, click **Chip Planner (Floorplan & Chip Editor)**.
2. On the View Chip Planner, point to **Utility Windows** and click **Node Finder**. The **Node Finder** dialog box appears.
3. In the **Filter** list, select **Pins: all** and click **List** to see all the nodes in the design.
4. Select a node from the **Nodes Found** list and drag the selection into a pin location in the floorplan.

For more information about using the Timing Closure Floorplan, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

Using HDL

You can use synthesis attributes or I/O primitives to embed pin-related assignments in your HDL code directly. When you analyze and synthesize your HDL code, the information in the HDL code is converted into appropriate assignments. There are two ways to specify pin related assignments using HDL:

- Using synthesis attributes for signal names that are top-level pins
- Using low-level I/O primitives such as ALT_BUF_IN to specify input, output, and differential buffers, and setting their parameters or attributes

The following sections explain how to use synthesis attributes and I/O primitives for your top-level pins.

Synthesis Attributes

Synthesis attributes allow you to embed assignments in your HDL code. The Quartus II software reads these synthesis attributes and translates them into assignments. The Quartus II integrated synthesis supports `chip_pin`, `useioff`, and `altera_attribute` synthesis attributes.

For more information about integrated synthesis, refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*.

For synthesis attributes support by third-party synthesis tools, contact your vendor.

chip_pin and useioff

You can use the `chip_pin` and `useioff` synthesis attributes to embed pin location and fast output and input register assignments, respectively. For all other assignments, including pin-related assignments, use the `altera_attribute` synthesis attribute as discussed in the "altera_attribute" section.

Example 5–4 and Example 5–5 embed a location and fast input assignment into both a Verilog HDL and VHDL design file using the `chip_pin` and `useioff` synthesis attributes.

Example 5–4. Verilog HDL Example

```
input my_pin1 /* synthesis chip_pin = "C1" useioff = 1 */;
```

Example 5–5. VHDL Example

```
entity my_entity is
       port(
                 my_pin1: in std_logic
       );
end my_entity;

architecture rtl of my_entity is
attribute useioff : boolean;
attribute useioff of my_pin1 : signal is true;
attribute chip_pin : string;
attribute chip_pin of my_pin1 : signal is "C1";
begin -- The architecture body
end rtl;
```

altera_attribute

To create other pin-related assignments, use the `altera_attribute` attribute. The `altera_attribute` attribute is understood only by Quartus II integrated synthesis and supports all types of instance assignments. Example 5–6 and Example 5–7 use `altera_attribute` to embed the fast input register and I/O standard assignments into both a Verilog HDL and a VHDL design file.

Example 5–6. Verilog HDL Example

```
input my_pin1 /* synthesis altera_attribute = "-name FAST_INPUT_REGISTER ON; -name
IO_STANDARD \"2.5 V\" " */ ;
```

Example 5–7. VHDL Example

```
entity my_entity is
       port(
              my_pin1: in std_logic
       );
end my_entity;
architecture rtl of my_entity is
begin

attribute altera_attribute : string;
attribute altera_attribute of my_pin1: signal is "-name FAST_INPUT_REGISTER ON;
-- The architecture body
end rtl;
```

In Quartus II software version 8.0 and later, the pin-related assignments made using synthesis attributes are shown in Pin Planner's All Pins list and Package views. When you modify or delete these pin assignments in the Pin Planner, you get an informational message suggesting that the pin-related assignments have been changed. If you recompile your project, your pin-related assignment in the Pin Planner, which is contained in your **.qsf** file, has precedence over the assignments you made using synthesis attributes in your HDL file.

For detailed information about synthesis attributes and their usage syntax, refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook* or the Quartus II Help.

Using Low-Level I/O Primitives

You can make pin related assignments for your top-level nodes using low-level primitives, which allow you to create pin location assignments, and set I/O standards, current drive strengths, slew rates, and on-chip termination (OCT).

For more information about using low-level I/O primitives in your design, refer to *Designing with Low-Level Primitives User Guide* or the Quartus II Help.

The pin-related assignments made using primitives do not appear in the Pin Planner.

During and after pin-related assignments creation, you must validate your pin-related assignments using the **Enable Live I/O Check** option and running I/O Assignment Analysis.

Validating Pin Assignments

The Quartus II software includes built-in I/O rules to guide you in pin placement. The Quartus II software checks your pin-related assignments against these rules during pin planning. You must validate all pin-related assignments in your design. You can enable the live I/O check feature and must use I/O Assignment Analysis to validate pin-related assignments against the predefined I/O rules encoded in the Quartus II software. To fully validate these assignments against all the I/O timing checks, you must perform full compilation.

Using the Live I/O Check Feature to Validate Pin Assignments

In Quartus II software version 7.2 and later, the live I/O check feature provides live I/O rules checking capability. When the live I/O check feature is enabled, pin-related assignment error and warning messages appear immediately in the Quartus II Messages window as you create pin-related assignments in the Pin Planner. This feature enhances your productivity by showing you warnings and errors as you create pin-related assignments, before you proceed to the next step in your design flow.

The most basic I/O rules are the I/O buffer rules. The I/O buffer rules checked by the live I/O Check feature include:

- V_{CCIO} voltage compatibility rules
- VREF voltage compatibility rules
- Electromigration (current density rules)
- Simultaneous Switching Output (SSO) rules
- I/O properties compatibility rules such as drive strength compatibility, I/O standard compatibility, `PCI_IO` clamp diode compatibility, and I/O direction compatibility

An additional category of I/O rules is the set of I/O system rules. These rules can be checked only after you generate a synthesized (mapped) netlist of your design. The I/O system rules are checked when you perform I/O assignment analysis as described in "Using I/O Assignment Analysis to Validate Pin Assignments" on page 5–59.

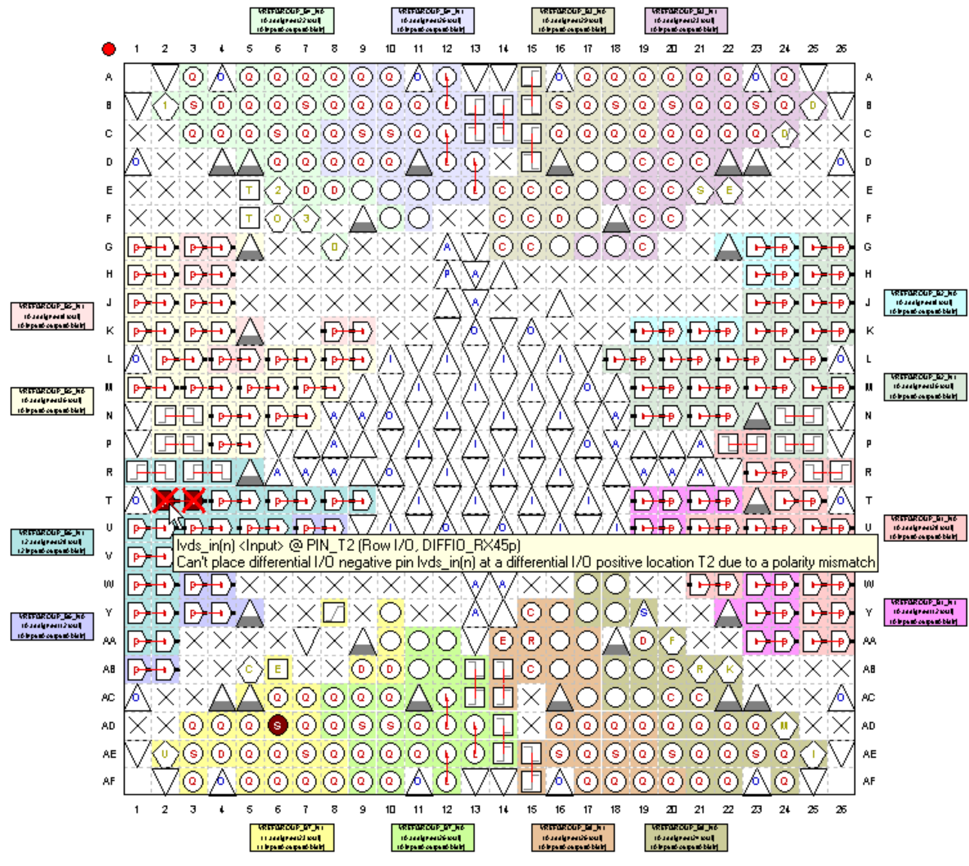
You can enable or disable the live I/O check feature at any time. By default, the live I/O check feature is turned off.

To enable or disable the live I/O check feature in the Quartus II user interface:

1. Verify the Pin Planner tool in the Quartus II software is active.
2. In the Quartus II View menu, select **Live I/O Check,** or, in the Pin Planner, click on the Live I/O Check icon.

While the live I/O check feature is enabled, the Quartus II software immediately checks whether your new pin-related assignments and revisions pass the basic I/O buffer rules. The detailed messages are printed in the Messages window of the Quartus II software and shown in Package View (Figure 5–45).

Figure 5–45. Live I/O Check Results in Package View

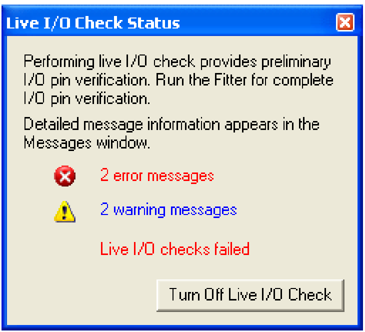


The Live I/O Check Status window displays the total numbers of errors and warnings while you create and edit pin-related assignments. To open the Live I/O Check Status window, shown in Figure 5–46, in the Quartus II View menu, click **Live I/O Check Status**.

For details about a specific message, refer to the Quartus II Help.

© March 2009 Altera Corporation

Figure 5–46. Live I/O Check Status Window in the Quartus II Software



Though the live I/O check feature checks all the basic I/O buffer rules, you must run I/O assignment analysis to validate your pin-related assignments against the complete set of I/O system rules. All rules including the basic I/O buffer rules and I/O system rules can be found in Table 5–5 on page 5–71 and Table 5–6 on page 5–72.

Using I/O Assignment Analysis to Validate Pin Assignments

This section describes a design flow that includes making and analyzing pin assignments with the **Start I/O Assignment Analysis** command in the Quartus II software during and after the development of your HDL design.

The **Start I/O Assignment Analysis** command allows you to check your I/O assignments early in the design process. With this command, you can check the legality of pin assignments before, during, or after you compile your design. If design files are available, you can use this command to perform more thorough legality checks on your design's I/O pins and surrounding logic. These checks include proper reference voltage pin usage, valid pin location assignments, and acceptable mixed I/O standards.

The **Start I/O Assignment Analysis** command can be used for designs that target Stratix series, Cyclone series, and MAX® II device families.

I/O Assignment Analysis Design Flows

The I/O assignment analysis design flows depend on whether your project contains design files. The following examples show two different circumstances in which I/O Assignment Analysis can be used:

- Use the flow shown in Figure 5–47 on page 5–61 if the board layout must be complete before starting the FPGA design. This flow does not require design files and checks the legality of your pin assignments.
- With a complete design, use the flow shown in Figure 5–49 on page 5–63. This flow thoroughly checks the legality of your pin assignments against any design files provided.

Each flow involves creating pin assignments, running analysis, and reviewing the report file.

You should run the analysis each time you add or modify a pin-related assignment. You can use the **Start I/O Assignment Analysis** command frequently because it completes quickly.

The analysis checks pin assignments and surrounding logic for illegal assignments and violations of board layout rules. For example, the analysis checks whether your pin location supports the assigned I/O standard, current strength, supported VREF voltages, and whether a PCI diode is permitted.

Along with the pin-related assignments, the **Start I/O Assignment Analysis** command also checks blocks that directly feed or are fed by resources such as a PLLs, LVDS, or gigabit transceiver blocks.

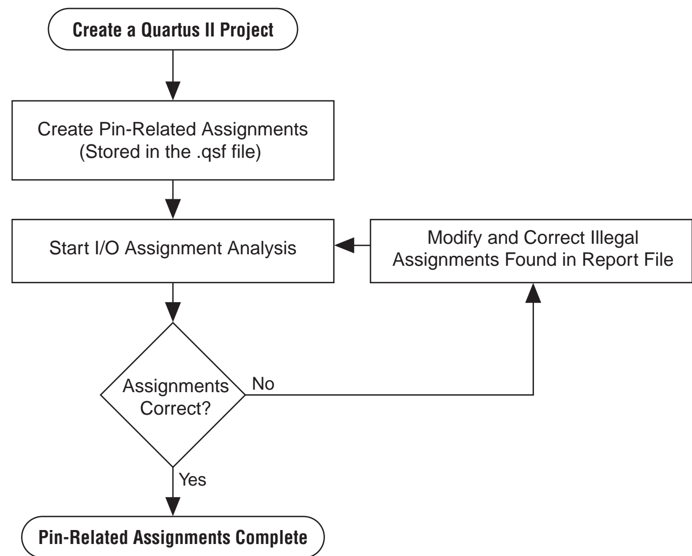
I/O Assignment Analysis without Design Files

During the early stages of developing an FPGA device, board layout engineers might request preliminary or final pin-outs. It is time consuming to manually check whether the pin-outs violate any design rules. Instead, use the **Start I/O Assignment Analysis** command to quickly perform basic checks on the legality of your pin assignments.

Without a complete design, the analysis performs limited checks and cannot guarantee that your assignments do not violate design rules.

The **I/O Assignment Analysis** command can perform limited checks on pin assignments made in a Quartus II project that has a device specified, but might not yet include any HDL design files. For example, you can create a Quartus II project with only a target device specified and create pin-related assignments based on circuit board layout considerations that are already determined. Even though the Quartus II project does not yet contain any design files, you can reserve input and output pins and make pin-related assignments for each pin using the Pin Planner or Assignment Editor. After you assign an I/O standard to each reserved pin, run the I/O Assignment Analysis to ensure that there are no I/O standard conflicts in each I/O bank. Figure 5–47 shows the work flow for assigning and analyzing pin-outs without design files.

Figure 5–47. Assigning and Analyzing Pin-Outs without Design Files



To assign and analyze pin-outs using the **Start I/O Assignment Analysis** command without design files, perform the following steps:

1. In the Quartus II software, create a project.
2. Use the Pin Planner, Assignment Editor, or a Tcl script to create pin locations and related assignments. For I/O Assignment Analysis to determine the type of pin, you must reserve your I/O pins. For information about reserving pins in the Pin Planner, refer to "Creating Reserved Pin Assignments" on page 5–34. For information about reserving pins in the Assignment Editor, refer to "Reserving Pins" on page 5–65.

If you make pin-related assignments in Mentor Graphics I/O Designer software, you can import an **.fx** file into the Quartus II software.

3. To start the analysis, on the Processing menu, point to **Start** and click **Start I/O Assignment Analysis**.

For information about using a Tcl script or command prompt to start the analysis, refer to "Scripting Support" on page 5–72.

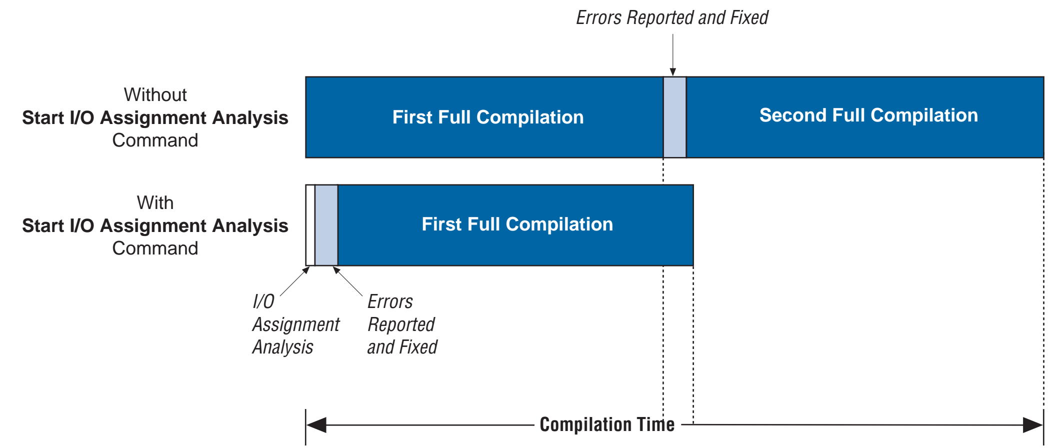
4. View the messages in the Compilation Report window, Fitter report file (<*project name*>**.fit.rpt**), or in the Messages window.
5. Correct any errors and violations reported by the I/O Assignment Analysis.

Repeat steps 1 through 5 until all of the errors are corrected.

I/O Assignment Analysis with Design Files

During a full compilation, the Quartus II software does not report illegal pin assignments until the Fitter stage. To validate pin assignments sooner, run the **Start I/O Assignment Analysis** command after performing analysis and synthesis and before performing a full compilation. Typically, the analysis runs quickly. Figure 5–48 shows the benefits of using the **Start I/O Assignment Analysis** command.

Figure 5–48. Saving Compilation Time with the Start I/O Assignment Analysis Command

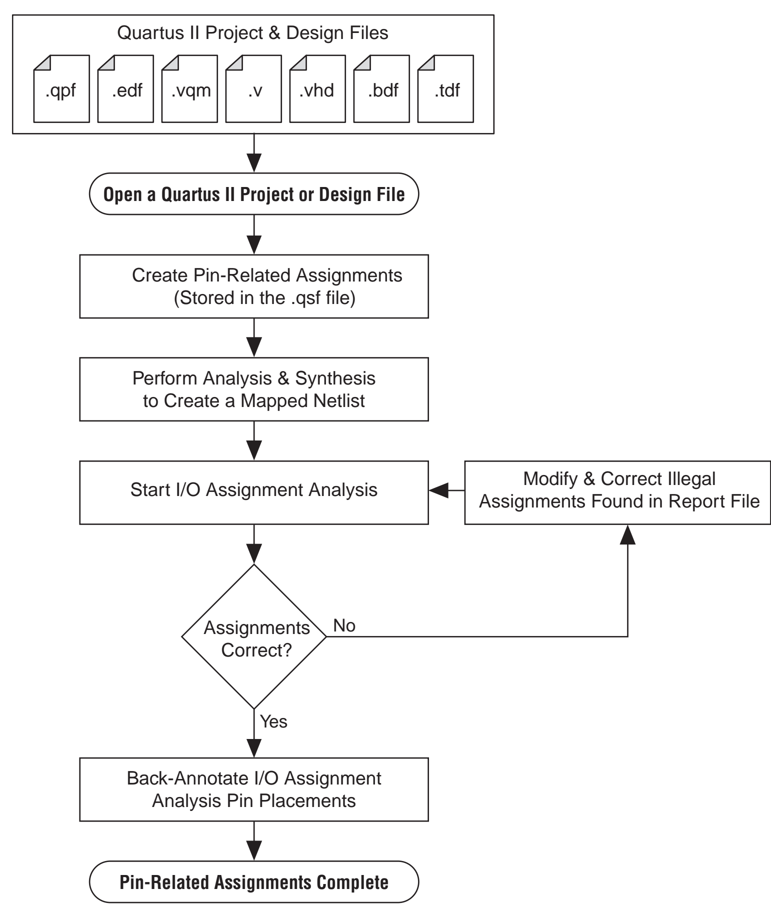


The rules that are checked by the I/O assignment analysis depend on the completeness of the design. With a complete design, the **Start I/O Assignment Analysis** command thoroughly checks the legality of all pin-related assignments. With a partial design, which can be just the top-level wrapper file, the **Start I/O Assignment Analysis** command checks the legality of those pin-related assignments for which it has enough information.

For example, you might assign a clock to a user I/O pin instead of assigning it to a dedicated clock pin, or design the clock to drive a PLL that has not yet been instantiated in the design. Because the **Start I/O Assignment Analysis** command does not account for the logic that the pin drives, it is not able to check that only a dedicated clock input pin can drive the clock port of a PLL.

To obtain better coverage, analyze as much of the design as possible, especially logic that connects to pins. For example, if your design includes PLLs or LVDS blocks, you should include these MegaWizard Plug-In Manager-generated files in your project for analysis (Figure 5–49).

Figure 5–49. Assigning and Analyzing Pin-Outs with Design Files



To assign and analyze pin-outs using the **Start I/O Assignment Analysis** command with design files, perform the following steps:

1. Create a project including your design files.
2. Create pin-related assignments with the Pin Planner or Assignment Editor.

You can also create pin-related assignments by importing them from a **.csv** or **.fx** file, executing Tcl commands, or editing the **.qsf** file directly. On the Processing menu, point to **Start** and click **Start Analysis & Synthesis** to generate an internal mapped netlist.

For information about using a Tcl script or the command prompt to start the analysis, refer to "Scripting Support" on page 5–72.

3. On the Processing menu, point to **Start** and click **Start I/O Assignment Analysis** to start the analysis.
4. View the messages in the Compilation Report or in the Messages window.
5. Use the Pin Planner or Assignment Editor to correct any errors and violations reported.
6. Use the **Start I/O Assignment Analysis** command until all the errors are corrected.

Using Output Enable Group Logic Option Assignments with I/O Assignment Analysis

Each device has a certain number of VREF pins, and each VREF pin supports a certain number of I/O pins. Check the device pin-outs to locate the VREF pins and their associated I/O pins. A VREF pin and its supported I/O pins are called a VREF bank. The VREF pins are only used for VREF I/O standards; for example, SSTL and HSTL input pins. VREF outputs do not require the VREF pin. When a voltage-referenced input is present in a VREF bank, only a certain number of outputs can be present in that VREF bank. For the Stratix II flip chip package, only 20 outputs can be present in a VREF bank when a VREF I/O standard input is present in that bank.

For interfaces that use bidirectional VREF I/O pins, the VREF restriction must be met when the pins are driving in either direction. If a set of bidirectional signals are controlled by different output enables, the **I/O Assignment Analysis** command treats these as independent output enables. Use the output enable group logic option assignment to treat the set of bidirectional signals as a single output enable. This is important in the case of external memory interfaces.

For example, in the case of a DDR2 interface in a Stratix II device, a Stratix II device can have 30 pins in a VREF group. Each byte lane for a ×8 DDR2 interfaces has 1 DQS pin and 8 DQ pins, for a total of 9 pins per byte lane. DDR2 uses SSTL18 as its I/O standard, which is a VREF I/O standard. In typical interfaces, each byte lane has its own output enable. In this example, the DDR2 interface has 4 byte lanes. Using 30 I/O pins in a VREF group, there are 3 byte lanes and an extra byte lane that supports the 3 remaining pins. If you do not use the output enable group logic option assignment, the **I/O Assignment Analysis** command analyzes each byte lane as an independent group driven by a unique output enable. With this arrangement, the worst-case scenario is when the 3 pins are inputs, and the other 27 pins are outputs. In this case, the 27 output pins violate the 20-output pin limit.

In a DDR2 interface, all DQS and DQ pins are always driven in the same direction. Therefore, the I/O Assignment Analysis reports an error that is not applicable to your design. Assigning an output enable group logic option assignment to the DQS and DQ pins forces the I/O Assignment Analyzer to check these pins as a group driven by a common output enable. When using the output enable group logic option assignment, the DQS and DQ pins are checked as all input pins or all output pins. This does not violate the rules described in Table 5–5 on page 5–71 and Table 5–6 on page 5–72.

The value for the output enable group logic option assignment should be an integer value. All sets of signals that are driving in the same direction should be given the same integer value. You can also use the output enable group logic option assignment with pins that are driven only at certain times. For example, the data mask signal in DDR2 interfaces is an output signal, but it is driven only when the DDR2 is writing (bidirectional signals are outputs). Therefore, an output enable group logic option assignment should assign to the data mask the same value as to the DQ and DQS signals.

Output enable groups can also be used on VREF input pins. If the VREF input pins are not active during the time the outputs are driving, add the VREF input pins to the output enable group. This procedure removes the VREF input pins from the VREF analysis. For example, the QVLD signal for RLDRAM II is only active during a read. During a write, the QVLD pin is not active and so it does not count as an active VREF input pin within the VREF group. The QVLD pins can be placed in the same output enable group as the RLDRAM II data pins.

Inputs for I/O Assignment Analysis

The **Start I/O Assignment Analysis** command reads the following inputs:

- Internal mapped netlist
- **.qsf** file

The internal mapped netlist is used when you have a partial or complete design. The **.qsf** file is always used to read all pin-related assignments for analysis.

Generating a Mapped Netlist

The **Start I/O Assignment Analysis** command uses a mapped netlist, if available, to identify the pin type and the surrounding logic. The mapped netlist is stored internally in the Quartus II software database.

To generate a mapped netlist, on the Processing menu, point to **Start** and click **Start Analysis & Synthesis**.

To use the `quartus_map` executable to run analysis and synthesis, type the following command at a system command prompt:

```
quartus_map <project name> ↵
```

Creating Pin-Related Assignments

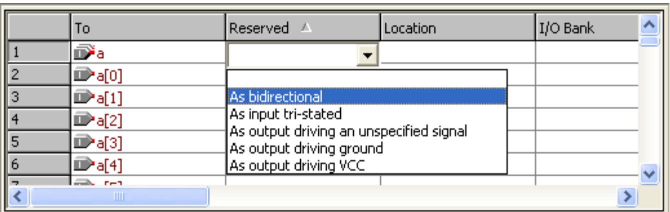
The **I/O Assignment Analysis** command reads a **.qsf** file containing all of your pin-related assignments. These pin-related assignments include pin settings such as I/O standards, drive strength, and location assignments. The following sections highlight some of the location assignments you can make.

Reserving Pins

If you do not have any design files, you can still reserve pin locations and create pin-related assignments. Reserving pins is necessary so that the **Start I/O Assignment Analysis** command has information about the pin and the pin type (input, output, or bidirectional) to correctly analyze the pins.

To reserve a pin, on the Assignments menu, click **Assignment Editor**. In the **Category** list, click **Pin** to open the Pin assignment category. Double-click the cell in the **Reserved** column that corresponds to the pin that you want to reserve. Use the drop-down arrow to select from the reserved pin options (Figure 5–50).

Figure 5–50. Reserving an Input Pin with the Assignment Editor



For more information about using the Assignment Editor, refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook*.

You can also reserve pins using the Pin Planner. For more information about the Pin Planner, refer to "Creating Reserved Pin Assignments" on page 5–34.

Location Assignments

You can create the following types of location assignments for your design and its reserved pins:

- Pin number
- I/O bank
- VREF group
- Edge

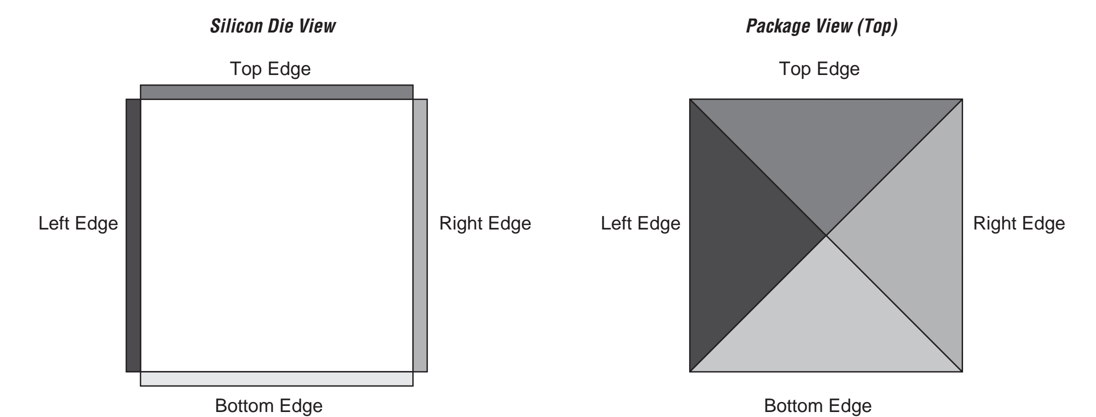
I/O bank, VREF group, and Edge location assignments are supported only for Stratix and Cyclone series device families.

You can assign a location to your pins using the Pin Planner or the Assignment Editor. To make a pin location assignment using the Assignment Editor, on the Assignments menu, click **Assignment Editor** and select the **Pin** category from the **Category** list. Type the pin name and select a location from the **Location** list.

It is common to place a group of pins (or bus) with compatible I/O standards in the same I/O bank or VREF group. For example, two buses with two compatible I/O standards, such as 2.5 V and SSTL-II, can be placed in the same I/O bank.

An easy way to place large buses that exceed the pins available in a particular I/O bank is to use edge location assignments. Edge location assignments improve the circuit board routing ability of large buses, because they are close together near an edge. Figure 5–51 shows Altera device package edges.

Figure 5–51. Die View and Package View of the Four Edges on an Altera Device



Suggested and Partial Placement

The **Start I/O Assignment Analysis** command automatically assigns suggested pin locations to unassigned pins in your design so it can perform pin legality checks. For example, if you assign an edge location to a group of LVDS pins, the **I/O Assignment Analysis** command assigns pin locations for each LVDS pin in the specified edge location and then performs legality checks.

To accept these suggested pin locations, on the Assignments menu, click **Back-Annotate Assignments**, select **Pin & device assignments**, and click **OK**. Back-annotation saves your pin and device assignments in the **.qsf** file.

Understanding the I/O Assignment Analysis Report and Messages

The **Start I/O Assignment Analysis** command generates detailed analysis reports and a **.pin** file. The detailed messages in the reports help you quickly understand and resolve pin assignment errors. Each message includes a related node name and a description of the problem.

To view the report file, on the Project menu, click **Compilation Report.** The Fitter section of the Compilation Report contains the following sections:

- Summary
- Settings
- Resource Section
- I/O Rules Section
- Device Options
- Advanced Fitter Data
- Pin-Out File
- Fitter Messages

The Resource Section categorizes the pins as Input Pins, Output Pins, and Bidir Pins. View the utilization of each I/O bank in your device in the I/O Bank Usage section (Figure 5–52).

Figure 5–52. I/O Bank Usage Summary in the I/O Assignment Analysis Report

	I/O Bank	Usage	VCCIO Voltage	VREF Voltage
1	1	0 / 40 (0 %)	3.3V	--
2	2	0 / 44 (0 %)	3.3V	--
3	3	3 / 52 (6 %)	3.3V	--
4	4	7 / 42 (17 %)	3.3V	--
5	5	1 / 44 (2 %)	3.3V	--
6	6	1 / 40 (3 %)	3.3V	--
7	7	7 / 42 (17 %)	3.3V	--
8	8	2 / 50 (4 %)	3.3V	--
9	9	1 / 6 (17 %)	3.3V	--
10	10	1 / 6 (17 %)	3.3V	--

The I/O Rules Section includes detailed information about the I/O rules tested during I/O Assignment Analysis, in three sub-reports. The I/O Rules Summary report provides a quick summary of the number of I/O rules tested and how many applicable rules passed, how many failed, and how many were unchecked because of other failing rules (Figure 5–53).

Figure 5–53. I/O Rules Summary Report

	I/O Rules Statistic	Total
1	Total I/O Rules	31
2	Number of I/O Rules Passed	0
3	Number of I/O Rules Failed	2
4	Number of I/O Rules Unchecked	7
5	Number of I/O Rules Inapplicable	22

The I/O Rules Details report provides detailed information on all I/O rules. Applicable rules indicate whether they passed, failed, or could not be checked (Figure 5–54). All rules are given a level of severity from Low to Critical to indicate their level of importance for an effective analysis.

Figure 5–54. I/O Rules Details Report

	Status	ID	Category	Rule Description	Severity
1	Unchecked	IO_000001	Capacity Checks	Number of pins in an I/O bank should not exceed the number of locations available.	Critical
2	Inapplicable	IO_000002	Capacity Checks	Number of clocks in an I/O bank should not exceed the number of clocks available.	Critical
3	Unchecked	IO_000003	Capacity Checks	Number of pins in a Vrefgroup should not exceed the number of locations available.	Critical
4	Inapplicable	IO_000004	Voltage Compatibility Checks	The I/O bank should support the requested VCCIO.	Critical
5	Inapplicable	IO_000005	Voltage Compatibility Checks	The I/O bank should not have competing VREF values.	Critical
6	Unchecked	IO_000006	Voltage Compatibility Checks	The I/O bank should not have competing VCCIO values.	Critical
7	Unchecked	IO_000007	Valid Location Checks	Checks for unavailable locations.	Critical
8	Inapplicable	IO_000008	Valid Location Checks	Checks for reserved locations.	Critical
9	Unchecked	IO_000009	I/O Properties Checks for One I/O	The location should support the requested I/O standard.	Critical
10	Unchecked	IO_000010	I/O Properties Checks for One I/O	The location should support the requested I/O direction.	Critical
11	Fail	IO_000011	I/O Properties Checks for One I/O	The location should support the requested Current Strength.	Critical
12	Inapplicable	IO_000012	I/O Properties Checks for One I/O	The location should support the requested On Chip Termination value.	Critical
13	Inapplicable	IO_000013	I/O Properties Checks for One I/O	The location should support the requested Bus Hold value.	Critical
14	Inapplicable	IO_000014	I/O Properties Checks for One I/O	The location should support the requested Weak Pull Up value.	Critical
15	Inapplicable	IO_000015	I/O Properties Checks for One I/O	The location should support the requested PCI Clamp Diode.	Critical
16	Fail	IO_000018	I/O Properties Checks for One I/O	The I/O standard should support the requested Current Strength.	Critical
17	Inapplicable	IO_000019	I/O Properties Checks for One I/O	The I/O standard should support the requested On Chip Termination value.	Critical
18	Inapplicable	IO_000020	I/O Properties Checks for One I/O	The I/O standard should support the requested PCI Clamp Diode.	Critical
19	Inapplicable	IO_000021	I/O Properties Checks for One I/O	The I/O standard should support the requested Weak Pull Up value.	Critical
20	Inapplicable	IO_000022	I/O Properties Checks for One I/O	The I/O standard should support the requested Bus Hold value.	Critical
21	Inapplicable	IO_000023	I/O Properties Checks for One I/O	The I/O standard should support the Open Drain value.	Critical
22	Inapplicable	IO_000024	I/O Properties Checks for One I/O	The I/O direction should support the On Chip Termination value.	Critical
23	Inapplicable	IO_000026	I/O Properties Checks for One I/O	On Chip Termination and Current Strength should not be used at the same time.	Critical
24	Inapplicable	IO_000027	I/O Properties Checks for One I/O	Weak Pull Up and Bus Hold should not be used at the same time.	Critical
25	Inapplicable	IO_000032	I/O Properties Checks for Multiple I/Os	I/O registers and SERDES should not be used at the same XY location.	Critical
26	Unchecked	IO_000033	Electromigration Checks	Current density for consecutive I/Os should not exceed 250mA for row I/Os and 250mA for column I/Os.	Critical
27	Inapplicable	IO_000034	SI Related Distance Checks	Single-ended outputs should be 1 LAB row(s) away from a differential I/O.	High
28	Inapplicable	IO_000037	SI Related Distance Checks	Single-ended I/O and differential I/O should not coexist in a PLL output I/O bank.	High
29	Inapplicable	IO_000038	SI Related SSO Limit Checks	Single-ended outputs and High-speed LVDS should not coexist in an I/O bank.	High
30	Inapplicable	IO_000042	SI Related SSO Limit Checks	No more than 20 outputs are allowed in a VREF group when VREF is being read from.	High
31	Inapplicable	IO_000040	SI Related SSO Limit Checks	The total drive strength of single ended outputs in a DPA bank should not exceed 120mA.	High

The I/O Rules Matrix shows how each I/O rule was tested on each pin in the design (Figure 5–55). Applicable rules that could be checked either pass or fail for each pin.

To find and make pin assignment adjustments on a pin that fails an I/O rule, right-click the pin name. Point to **Locate** and select a location where the pin exists, such as the Pin Planner. Make appropriate changes to fix the pin assignments and rerun I/O Assignment Analysis. Check the resulting I/O Rules Matrix to verify that your changes fixed the problem and allowed the failing pin assignment to pass. To rerun I/O rule analysis, on the Processing menu, point to **Start** and click **Start I/O Assignment Analysis**.

The **Fitter Messages** page stores all messages including errors, warnings, and information messages.

You can view the detailed messages in the **Fitter Messages** page in the Compilation Report and in the **Processing** tab in the Messages window. To open the Messages window, on the View menu, point to **Utility windows** and click **Messages**.

Use the **Location** box to help resolve error messages. Select from the **Location** list and click **Locate**.

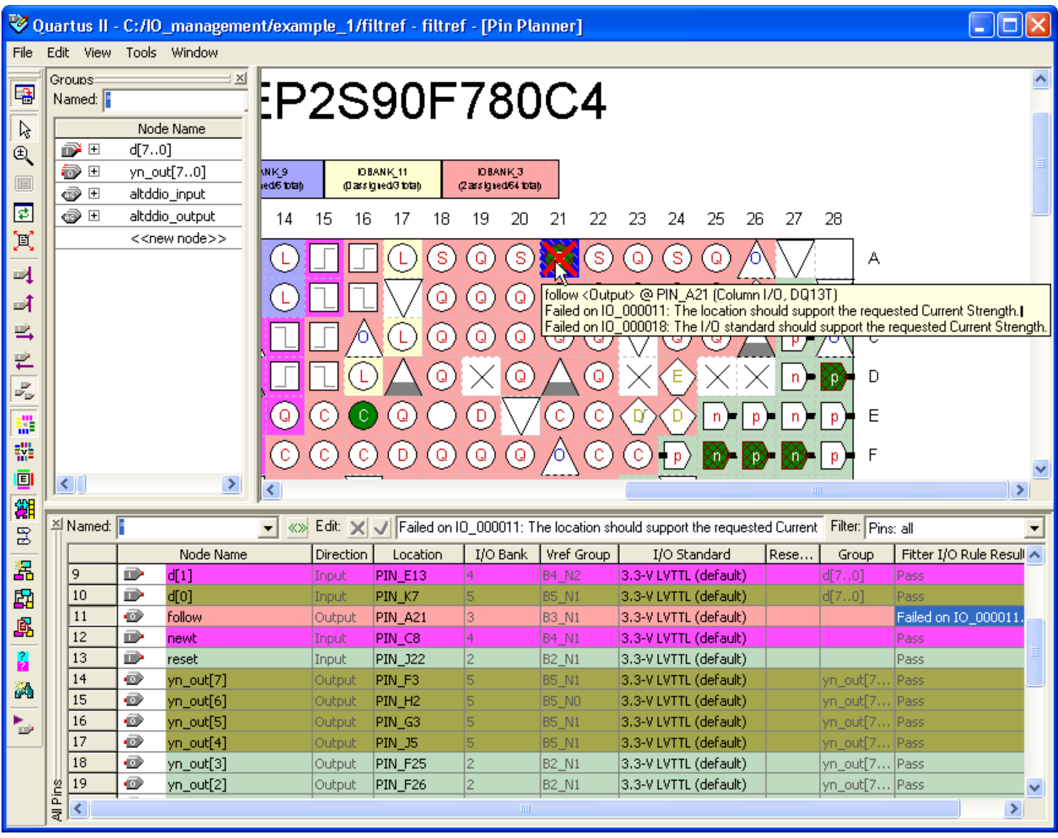
Figure 5–56 shows an example of error messages reported by I/O Assignment Analysis.

Figure 5–56. Error Message Report by I/O Assignment Analysis

```
Error: Current Strength logic option is set to 10mA for pin follow, but setting  is not supported by I/O standard 3.3-V LVTTL
Error: Pin AF3 does not support I/O standard 3.3-V LVTTL with Current Strength 10mA for location follow
Error: Can't fit design in device
Error: Quartus II I/O Assignment Analysis was unsuccessful. 3 errors, 1 warning
```

Fitter messages can also be seen in the Package View (Figure 5–57). Right click in the Package View and click **Show Fitter Placements** to see the failing pins. The failing pins are shown with a cross sign, as shown in Figure 5–57. A tool tip is displayed when the mouse cursor is pointed over the failing pin. The tooltip displays the failed I/O rules.

Figure 5–57. Tool Tip



You can correct the I/O Assignment Analysis failure shown for the pin in Figure 5–56 and Figure 5–57 easily by setting the proper current drive strength for the I/O standard assigned for that pin. Current drive strength can be set in the Assignment Editor using the “Current Drive Strength” assignment.

For more information about the Assignment Editor, refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook*.

The effectiveness of I/O Assignment Analysis is relative to the completeness of your pin-related assignments and design. To ensure your design functions correctly, include all pin-related assignments and as many design files as possible in your Quartus II project.

Table 5–5 on page 5–71 and Table 5–6 on page 5–72 list a subset of the I/O rule checks performed when you run I/O Assignment Analysis with and without design files.

For more detailed information about each I/O rule, refer to the appropriate device handbook.

Table 5–5. Examples of I/O Rule Checks *(Note 1)*

Rule	Description	Device Families	HDL Required?
I/O bank capacity	Checks the number of pins assigned to an I/O bank against the number of pins allowed in the I/O bank.	All	No
I/O bank V_{CCIO} voltage compatibility	Checks that no more than one V_{CCIO} is required for the pins assigned to the I/O bank.	All	No
I/O bank VREF voltage compatibility	Checks that no more than one VREF is required for the pins assigned to the I/O bank.	All	No
I/O standard and location conflicts	Checks whether the pin location supports the assigned I/O standard.	All	No
I/O standard and signal direction conflicts	Checks whether the pin location supports the assigned I/O standard and direction. For example, certain I/O standards on a particular pin location can only support output pins.	All	No
Differential I/O standards cannot have open drain turned on	Checks that open drain is turned off for all pins with a differential I/O standard.	All	No
I/O standard and drive strength conflicts	Checks whether the drive strength assignments are within the specifications of the I/O standard.	All	No
Drive strength and location conflicts	Checks whether the pin location supports the assigned drive strength.	All	No
`BUSHOLD` and location conflicts	Checks whether the pin location supports `BUSHOLD`. For example, dedicated clock pins do not support `BUSHOLD`.	All	No
`WEAK_PULLUP` and location conflicts	Checks whether the pin location supports `WEAK_PULLUP` (for example, dedicated clock pins do not support `WEAK_PULLUP`)	All	No
Electromigration check	Checks whether combined drive strength of consecutive pads exceeds a certain limit. For example, the total current drive for 10 consecutive pads on a Stratix II device cannot exceed 200 mA.	All	No
`PCI_IO` clamp diode, location, and I/O standard conflicts	Checks whether the pin location along with the I/O standard assigned supports `PCI_IO` clamp diode.	All	No
SERDES and I/O pin location compatibility check	Checks that all pins connected to a SERDES in your design are assigned to dedicated SERDES pin locations.	All	Yes
PLL and I/O pin location compatibility check	Checks whether pins connected to a PLL are assigned to the dedicated PLL pin locations.	All	Yes

Note to Table 5–5:

(1) The supported device families are: Arria® GX, Stratix III, Stratix II, Stratix II GX, Stratix, Stratix GX, Cyclone III, Cyclone II, Cyclone, HardCopy, and MAX II devices.

Table 5–6. SSN-Related Rules

Rule	Description	Device Families (1)	HDL Required?
I/O bank can not have single-ended I/O when DPA exists	Checks that no single-ended I/O pin exists in the same I/O bank as a DPA.	Stratix II Stratix GX	No
A PLL I/O bank does not support both a single-ended I/O and a differential signal simultaneously	Checks that there are no single-ended I/O pins present in the PLL I/O Bank when a differential signal exists.	Stratix II	No
Single-ended output is required to be a certain distance away from a differential I/O pin	Checks whether single-ended output pins are a certain distance away from a differential I/O pin.	All	No
Single-ended output has to be a certain distance away from a VREF pad	Checks whether single-ended output pins are a certain distance away from a VREF pad.	Cyclone II Cyclone	No
Single-ended input is required to be a certain distance away from a differential I/O pin	Checks whether single-ended input pins are a certain distance away from a differential I/O pin.	Cyclone II Cyclone	No
Too many outputs or bidirectional pins in a VREFGROUP when a VREF is used	Checks that there are no more than a certain number of outputs or bidirectional pins in a VREFGROUP when a VREF is used.	All	No
Too many outputs in a VREFGROUP	Checks whether too many outputs are in a VREFGROUP.	All	No

Note to Table 5–6:

(1) "All" includes the following device families: Arria GX, Stratix III, Stratix II, Stratix II GX, Stratix, Stratix GX, Cyclone III, Cyclone II, Cyclone, HardCopy, and MAX II devices.

Scripting Support

A Tcl script allows you to run procedures and determine settings described in this chapter. You can also run some of these procedures at a command prompt.

For detailed information about specific scripting command options and Tcl API packages, type the following command at a system command prompt to run the Quartus II Command-Line and Tcl API Help browser:

```
quartus_sh --qhelp ↵
```

For more information about Quartus II scripting support, including examples, refer to the *Tcl Scripting* and *Command-Line Scripting* chapters in volume 2 of the *Quartus II Handbook*.

Running the I/O Assignment Analysis

You can run I/O Assignment Analysis with a Tcl command or with a command run at a command prompt. For more information about running the I/O Assignment Analysis, refer to "Understanding the I/O Assignment Analysis Report and Messages" on page 5–67.

Enter the following in a Tcl console or script:

```
execute_flow -check_ios ↵
```

Type the following at a (non-Tcl) system command prompt:

```
quartus_fit <project name> --check_ios ↵
```

Generating a Mapped Netlist

You can generate a mapped netlist with a Tcl command or with a command-line command. For more information about generating a mapped netlist, refer to "Generating a Mapped Netlist" on page 5–65.

Enter the following in the Tcl console or in a script:

```
execute_module -tool map
```

The `execute_module` command is in the flow package.

Type the following at a system command prompt:

```
quartus_map <project name> ↵
```

Reserving Pins

Use the following Tcl command to reserve a pin:

```
set_instance_assignment -name RESERVE_PIN <value> -to <signal name>
```

For more information about reserving pins, refer to "Reserving Pins" on page 5–65.

Valid values are:

- `"AS BIDIRECTIONAL"`
- `"AS INPUT TRI-STATED"`
- `"AS OUTPUT DRIVING AN UNSPECIFIED SIGNAL"`
- `"AS OUTPUT DRIVING GROUND"`
- `"AS SIGNALPROBE OUTPUT"`

Include the quotes when specifying the value.

Location Assignments

Use the following Tcl command to assign a signal to a pin or device location.

```
set_location_assignment <location> -to <signal name> ↵
```

For more information about location assignments, refer to "Location Assignments" on page 5–66.

Valid locations are pin location names, such as `PIN_A3`. The Stratix and Cyclone series of devices also support edge and I/O bank locations. Edge locations are `EDGE_BOTTOM`, `EDGE_LEFT`, `EDGE_TOP`, and `EDGE_RIGHT`. I/O bank locations include `IOBANK_1` up to `IOBANK_`*n*, in which *n* is the number of I/O banks in a particular device.

In Stratix III devices only, I/O bank names have the form `IOBANK_`*nx* where `n` is a number and *x* is the letter *A*, *B*, or *C*. Though I/O banks can share the same number with different letters, such as 1A and 1C, they are separate banks and not related to each other.

For more information, refer to the *Stratix III Device Handbook*.

Validating Pin Assignments after Full Compilation

If you used the Live I/O check feature during pin placements, many of the I/O assignments have been verified immediately as you made the assignment. There are some placement rules that are checked only during I/O assignment analysis and full compilation of your design. The Quartus II software validates I/O assignments at three levels. The first level checking is done with the Live I/O check feature ON. A more comprehensive level of checking is performed with I/O Assignments Analysis. The final I/O timing check is done when you fully compile your design. (To better understand I/O timing analysis, refer to "I/O Timing Analysis" on page 5–75.)

To avoid costly board re-spins, you must perform full validation with full compilation with complete design files and constraints. With timing information, the Quartus II Fitter makes intelligent placements and routing to achieve optimal timing performance in your design. Use the TimeQuest SDC editor to create timing constraints for inputs, outputs, and bidirectional pins. If you are using the Quartus II Classic Timing Analyzer, specify timing constraints on the **Classic Timing Analyzer Settings** page of the **Settings** dialog box (Assignments menu).

For more information about the Quartus II TimeQuest Timing Analyzer and the Classic Timing Analyzer, refer to the *Timing Analysis* section of volume 3 of the *Quartus II Handbook*.

Accepting Fitter Placements—Back-Annotating Assignments

To create assignments for all Fitter-placed pins into your project **.qsf** file, perform the following steps:

1. On the Processing menu, click **Start Compilation**, or on the Processing menu, point to **Start** and click **I/O Assignment Analysis**.
2. On the Assignments menu, click **Pin Planner**. The Pin Planner appears.
3. On the View menu, point to **Show** and click **Show Fitter Placements**. You can also access this command from the Pin Planner toolbar or on the right-click menu in the Package View.
4. Review the Fitter placements.
5. To create location assignments for these Fitter placements, perform the following steps:
   a. On the Assignments menu, click **Back-Annotate Assignments**. The **Back-Annotate Assignments** dialog box appears.
   b. Select **Pin & device assignments** (Figure 5–58).
   c. Click **OK**.

Figure 5–58. Back-Annotate Assignments Dialog Box

To create assignments for a selection of the Fitter-placed pins, perform the following steps:

1. On the Processing menu, click **Start Compilation**, or on the Processing menu, point to **Start**, and click **I/O Assignment Analysis**.
2. On the Assignments menu, click **Pin Planner**.
3. On the View menu, point to **Show** and click **Show Fitter Placements**. Review the placements.
4. In the Pin Planner, select one or more Fitter-placed pins for which you want to create assignments.
5. Right-click one of the selected pins and click **Back Annotate**.
6. On the File menu, click **Save Project**. The Assignments are written to the **.qsf** file.

For more information about how the Quartus II software writes and updates the **.qsf** file, refer to the *Managing Quartus II Projects* chapter in volume 2 of the *Quartus II Handbook*.

I/O Timing Analysis

Timing analysis is usually run during a full compilation of your design or with early timing estimate runs. You can also run timing analysis independently after full compilation from the Processing menu. For example, if you change the slew rates or current strengths of some I/O pins as ECOs, you do not have to recompile the entire design, but only run timing analysis to verify the timing of your design.

As part of I/O planning in your FPGA design, you must understand I/O timing results in the Quartus II software that are reported after performing timing analysis on your design. If you have all your design files complete and have completed full compilation, all the timing checks related to I/O timing are covered during timing analysis of your design. Static timing analysis is performed when you compile your design in the Quartus II software. You must understand I/O timing and what factors affect I/O timing paths in your design. One important factor that counts greatly in I/O timing results is how accurately you specify the output loads at the output and bidirectional pins in your FPGA design. Incomplete I/O constraints can affect your I/O timing results.

The Quartus II software supports three different methods of I/O timing analysis:

- I/O timing using a default or user-specified capacitive load with no signal integrity analysis (default)

  The Quartus II TimeQuest Timing Analyzer and the Quartus II Classic Timing Analyzer create timing reports that measure t_{CO} to an I/O pin using a default or user-specified value for a capacitive load.

- The Quartus II software **Enable Advanced I/O Timing** option utilizing a user-defined board trace model to produce enhanced timing reports from accurate, "board-aware" simulation models

  The Quartus II software **Enable Advanced I/O Timing** option enables you to configure a complete board trace model for each I/O standard or pin used in your design. With **Enable Advanced I/O Timing** turned on, the Quartus II TimeQuest Timing Analyzer uses the results of simulations of the I/O buffer, package, and board trace model to generate more accurate I/O delays and extra reports to give insight into signal behavior at the system level. You can use these advanced timing reports as a guide to make changes to your I/O assignments and board design to improve timing and signal integrity.

- Full board routing simulation in third-party tools using Altera-provided or Quartus II software generated IBIS or HSPICE I/O models

  The creation of simulation model files for use by third-party board simulation tools is achieved with the IBIS and HSPICE Writers. The IBIS and HSPICE Writers in the Quartus II software can export accurate simulation models for use in applications such as Mentor Graphics HyperLynx and Synopsys HSPICE.

This section describes the first and second methods.

I/O timing using a default or user-specified capacitive load is not supported for Stratix III and Cyclone III devices. Use the **Enable Advanced I/O Timing** option for Stratix III and Cyclone III devices.

For information about creating IBIS and HSPICE models with the Quartus II software and integrating those models into HyperLynx and HSPICE simulations, refer to the *Signal Integrity Analysis with Third Party Tools* chapter in volume 2 of the *Quartus II Handbook*.

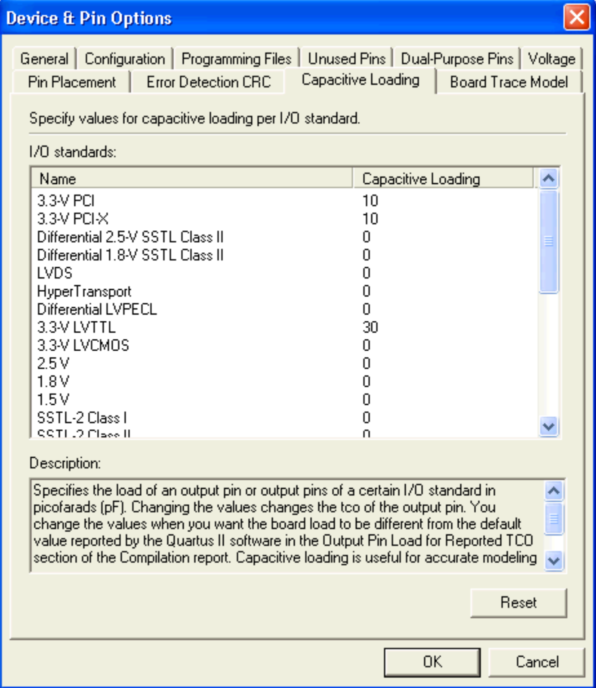
I/O Timing and Power with Capacitive Loading

When calculating t_{CO} and power for output and bidirectional pins, the Quartus II TimeQuest Timing Analyzer, the Quartus II Classic Timing Analyzer, and power analysis use a bulk capacitive load. This is the default method for these pins. You can adjust the value of the capacitive load per I/O standard to get t_{CO} and power measurements that more accurately reflect the behavior of the output or bidirectional net on your PCB. Input pins ignore this setting. To adjust the value of the capacitive load, on the Assignments menu, click **Device**. Click **Device & Pin Options** and click the **Capacitive Loading** tab (Figure 5–59).

Figure 5–59. Capacitive Tab of the Device and Pin Options Dialog Box



All of the available I/O standards for your selected device are listed with their default loading values in picofarads (pF). Adjust the loading values as desired for the I/O standards used in your design. Power and t_{CO} measurements in the Compilation Report are adjusted based on the settings.

You can also adjust the load on any individual pin in the Groups list or All Pins list in the Pin Planner by adding the **Output Pin Load** column. Right-click anywhere in either list and select **Customize Columns**. Select **Output Pin Load** from the list of available custom columns and add it to the list of visible columns. You can customize the load for individual pins or multiple pins with different I/O standards.

For more information about capacitive loading, the devices that support it, and how t_{CO} and power are adjusted based on the setting, refer to the Quartus II Help.

Advanced I/O Timing in the Quartus II Software

As part of I/O planning, especially with high-speed designs, you should take board-level signal integrity and timing into account. When adding an FPGA device with high-speed interfaces to a board design, the quality of the signal at the far end of the board route, as well as the propagation delay in getting there, is vital for proper system operation.

Enabling and Configuring Advanced I/O Timing

With the Quartus II software **Enable Advanced I/O Timing** option turned on, you can expand upon the basic timing and power measurements made with the **Capacitive Loading** settings. The **Enable Advanced I/O Timing** option gives you the ability to fully define not only the capacitive load, but also any termination components and trace impedances in the board routing for any output pin or bidirectional pin in output mode. You can configure an overall board trace model for each I/O standard as well as customize the model for specific pins using a graphical interface.

When the **Enable Advanced I/O Timing** option is turned on, the board trace model replaces the **Capacitive Loading** tab settings because the load is included in the model. For timing measurements, the entire board trace model is taken into account when calculating I/O delays. For power measurements, an effective capacitive load is used based on the sum of the capacitive elements in the model. This includes the **Near capacitance**, **Far capacitance**, and **Transmission line distributed capacitance** elements of the model.

For Stratix III and Cyclone III devices, advanced I/O timing is the only way to measure I/O timing. Advanced I/O timing is supported for Stratix II devices also. All other devices use capacitive loading for I/O t_{CO} and power measurements. Check the Altera website at www.altera.com to determine which devices are supported in newer versions of the Quartus II software.

Before you configure a board trace model for advanced I/O timing, you must turn on **Enable Advanced I/O Timing** if your selected device supports it. All devices in each supported family work with advanced I/O timing.

Turn on **Enable Advanced I/O Timing**. If the **Settings** dialog box is not currently open, on the Assignments menu, click **Settings**. In the **Category** list, click the “+” icon to expand **Timing Analysis Settings**. Select **TimeQuest Timing Analyzer**. The **TimeQuest Timing Analysis** page appears. Turn on **Enable Advanced I/O Timing**.

For Stratix III and Cyclone III devices, the **Enable Advanced I/O Timing** option is turned on by default and is always performed when you run the Quartus II TimeQuest Timing Analyzer.

Define Overall Board Trace Models

You can now define an overall board trace model for each I/O standard in your design. This is the default model for all pins that use a particular I/O standard. After configuring the overall board trace model, customize the model for specific pins using the Board Trace Model view in the Pin Planner.

With the **Settings** dialog box open, in the **Category** list, click **Device**. Click **Device & Pin Options** and click the **Board Trace Model** tab (Figure 5–60).

Figure 5–60. Board Trace Model Tab of the Device and Pin Options Dialog Box

You can still click the **Capacitive Loading** tab. However, because you can configure all capacitive loading settings as part of the board trace model, the tab indicates that you must use the settings in the **Board Trace Model** tab.

All of the I/O standards available to the device are listed. Select any I/O standard from the list. The **Board trace model** list displays the names and values of all configurable components of the board trace for the selected I/O standard. Components of the model are initially set to **short**, **open**, or a numeric value depending on the component. The default settings for components in the model for each I/O standard are device-specific and match the default test model used for calculating delay when the **Enable Advanced I/O Timing** option is turned off. In this way, default delay measurements are the same whether or not the **Enable Advanced I/O Timing** option is used.

For information about the default models used for measuring I/O delay, refer to the *DC & Switching Characteristics* chapter in the relevant device handbook.

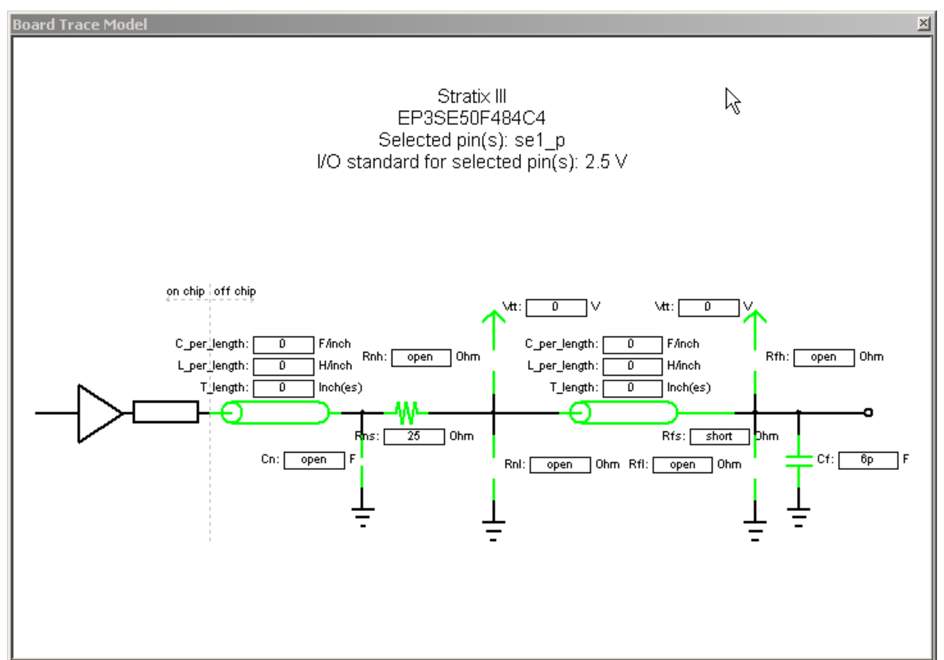
All of the component values listed in Figure 5–60 are adjustable. For differential I/O standards, the component values you set are used for both the positive and negative signals of a differential pair. An additional component, **Far differential resistance**, is also included. To reset individual settings to their defaults, leave the setting blank. If you want all the settings for an I/O standard to revert to their original settings, click **Reset**. Click **OK** to close the **Device & Pin Options** dialog box. Click **OK** again to close the **Settings** dialog box.

Any component value changes made in the **Board Trace Model** tab for a particular I/O standard are reflected in the Board Trace Model view in the Pin Planner of all pins assigned with the same I/O standard (described in "Customize the Board Trace Model in the Pin Planner"). However, custom component value changes made to selected pins in the Board Trace Model view in the Pin Planner take priority and are not affected by changes made to an I/O standard in the **Board Trace Model** tab.

Customize the Board Trace Model in the Pin Planner

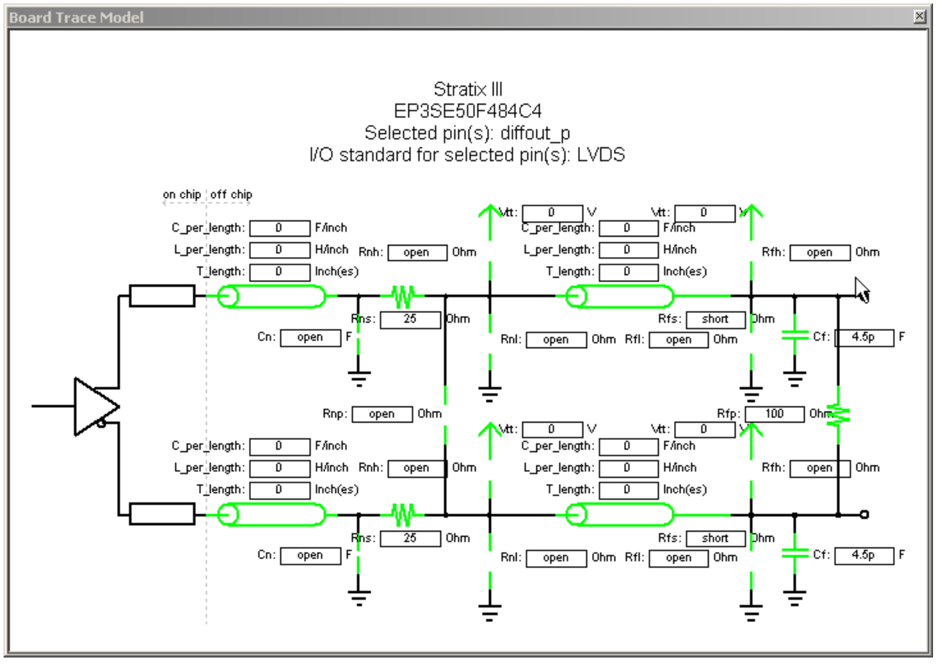
In addition to the views available in the Package View in the Pin Planner, you can also view a graphical representation of the board trace model you have configured using the Board Trace Model view. To open the Board Trace Model view, right-click on an output or bidirectional pin in the Groups list, All Pins list, or Package View and click **Board Trace Model**. The Board Trace Model view opens in a floating window (Figure 5–61).

Figure 5–61. Board Trace Model View



For differential signals, the Board Trace Model view displays the routing and components for both the positive and negative signals of the differential pair (Figure 5–62).

Figure 5–62. Differential Board Trace Model View



Any changes made to the Board Trace Model view for a differential signal pair must be performed on the positive signal of the pair. The settings must match between the positive and negative signals of a differential pair, so the changes are automatically reflected in the settings for the negative signal.

Double-click a component value to edit it. For numerical values, use standard unit prefixes such as *p*, *n*, and *k* to represent pico, nano, and kilo, respectively. To short a series component or have an open circuit for a parallel component, double-click the component value and select **short** or **open** from the list.

All the assignments for board trace models you specify in the schematic are saved to the Quartus II Settings File (**.qsf**). You can also enter these Tcl assignment commands in the **.qsf** to specify the board trace parameters for an output or bidirectional pin. The examples in Example 5–8 use Tcl assignments to specify board trace models.

Example 5–8. Specifying Board Trace Models

```
## setting the near end series resistance model of sel_p output pin to 25 ohms
set_instance_assignment -name BOARD_MODEL_NEAR_SERIES_R 25 -to sel_p
## Settting the far end capacitance model for sel_p output signal to 6 picofarads
set_instance_assignment -name BOARD_MODEL_FAR_C 6P -to sel_
```

For more details about configuring component values for a board trace model, including a complete list of the supported unit prefixes and setting the values using Tcl scripts, refer to the Quartus II Help.

To view a display of the model for a particular pin, in the Package View, Groups list, or All Pins list, click on the pin. This changes the Board Trace Model view to display the model of the pin. To select multiple pins that share the same I/O standard, open the Board Trace Model view and edit the model for all of the selected pins. If an input pin or multiple pins with different I/O standards are selected, the Board Trace Model view window indicates that it cannot display the model for the selected pin or pins.

The components in the Board Trace Model view correspond to the components listed in the **Board Trace Model** tab directly and the settings match initially. You can click and edit any value in the Board Trace Model view to customize the model for the selected pin or pins. Changes made in the Board Trace Model view do not affect the settings in the **Board Trace Model** tab.

To configure board trace models for the pins in your design efficiently with these two methods of entry, define the model for each I/O standard in the **Board Trace Model** tab. With the overall model defined, use the Board Trace Model view in the Pin Planner to customize individual pins as required. These customizations take priority over the settings in the **Board Trace Model** tab on a per pin and per model component basis, so they do not affect the settings on any other pin.

Create Signal Integrity Result Reports

After you have turned on **Enable Advanced I/O Timing** and configured board trace models for the pins you want to analyze, compile your project or run the Quartus II TimeQuest Timing Analyzer after a full compilation. The **Enable Advanced I/O Timing** option creates signal integrity subreports under TimeQuest Timing Analyzer in the Compilation Report window.

The Board Trace Model Assignments report (Figure 5–63) summarizes the board trace model component settings for each output and bidirectional signal.

Figure 5–63. Board Trace Model Assignments Report

Compilation Report - Board Trace Model Assignments

Board Trace Model Assignments

	Pin	I/O Standard	Near Series R	Near Pull-up R	Near Pull-down R	Near C	Tline Length	Tline L per Length	Tline C per Length	Far Series R	Far Pull-up R	Far Pull-down R
1	yvalid	3.3-V LVTTL	short	open	open	open	0	0	0	short	open	open

2	follow	3.3-V LVTTL	0	0	3.46	-0.000827	4.63	-1.71	1.1	1.53
3	yn_out[7]	3.3-V LVTTL	0	0	3.46	-0.000827	4.63	-1.71	1.1	1.53
4	yn_out[6]	3.3-V LVTTL	0	0	3.46	-0.000827	4.63	-1.71	1.1	1.53
5	yn_out[5]	3.3-V LVTTL	0	0	3.46	-0.000827	4.63	-1.71	1.1	1.53
6	yn_out[4]	3.3-V LVTTL	0	0	3.46	-0.000827	4.63	-1.71	1.1	1.53
7	yn_out[3]	3.3-V LVTTL	0	0	3.46	-0.000827	4.63	-1.71	1.1	1.53
8	yn_out[2]	3.3-V LVTTL	0	0	3.46	-0.000827	4.63	-1.71	1.1	1.53
9	yn_out[1]	3.3-V LVTTL	0	0	3.46	-0.000827	3.48	-0.13	0.0305	0.16
10	yn_out[0]	3.3-V LVTTL	0	0	3.46	-0.000827	4.63	-1.71	1.1	1.53

The Slow- and Fast-Corner Signal Integrity Metrics reports are generated by the **Enable Advanced I/O Timing** option. They list, in tabular format, all of the signal integrity metrics calculated by the **Enable Advanced I/O Timing** option, based on the board trace model settings for each output or bidirectional pin. The reports contain many metrics, including measurements at both the FPGA and at the far-end load of board delay, steady state voltages, and rise and fall times.

The Slow- or Fast-Corner Signal Integrity Metrics reports are generated depending on the **Timing Netlist** option in the Quartus II TimeQuest Timing Analyzer. To select whether to create a slow- or a fast-corner report, in the TimeQuest Timing Analyzer on the Netlist menu, click **Create Timing Netlist**. Under **Delay model**, select **Slow corner** or **Fast corner** to create reports of that type.

For complete descriptions of all of the metrics calculated when the **Enable Advanced I/O Timing** option is turned on and diagrams illustrating the metrics on output waveforms, refer to the Quartus II Help. For more information about board-level signal integrity and tips on how to improve signal integrity in your high-speed designs, refer to the Altera Signal Integrity Center.

For information about the configuration and use of the Quartus II TimeQuest Timing Analyzer, refer to the Quartus II Help or *Section III: Timing Analysis* in volume 3 of the *Quartus II Handbook*.

Incorporating PCB Design Tools

Signal and pin assignments are initially made by the FPGA or ASIC designer and it is up to the board designer to transfer these assignments to the symbols used in their system circuit schematics and board layout correctly. As the board design progresses, pin reassignments might be requested or required to optimize the layout. These reassignments must in turn be relayed to the FPGA designer, so that the new assignments can be validated with the I/O Assignment Analyzer and processed through an updated place-and-route of the FPGA.

The Quartus II software interacts with board layout tools by importing and exporting pin information files, including the **.qsf**, **.pin**, and **.fx** files.

For more information about incorporating PCB design tools, refer to the *Cadence PCB Design Tools Support* and *Mentor Graphics PCB Design Tools Support* chapters in volume 2 of the *Quartus II Handbook*.

Conclusion

The Quartus II software provides many tools and features to help you with the I/O planning process. The I/O assignment analysis process offers the ability to validate pin assignments in all design stages, even before the development of the design. The ability to import and export assignments between the Quartus II software and other PCB tools also enables you to make iterative changes efficiently. Finally, the ability to enter a board trace model and create advanced timing reports based on how I/O signals are routed on a board truly makes the Quartus II software "board-aware."

6. Simultaneous Switching Noise (SSN) Analysis and Optimizations

QII52018-9.0.0

Introduction

FPGA design has evolved from small programmable circuits to competing with multimillion-gate ASICs. At the same time, the I/O counts on FPGAs and logic density requirements have increased exponentially. Higher-speed interfaces in FPGAs that include high-speed serial interfaces and memory interfaces require careful interface design on the PCB. The timing and signal integrity requirements of these interfaces are pushing designers to address the effects early in the design development cycle. One example is the effect of simultaneous switching noise (SSN). SSN is defined as a noise voltage induced onto a victim I/O pin of a device due to the switching behavior of other aggressor I/O pins in the device. SSN noise often leads to the degradation of signal integrity by causing signal distortion, thereby reducing the noise margin of a system.

Today's complex FPGA system design is incomplete without addressing the integrity of signals coming in and out of the FPGA. SSN is one of the signal integrity problems faced during FPGA design. Altera recommends that you perform SSN analysis early in your FPGA design and tape out your PCB with complete SSN analysis of your FPGA in the Quartus® II software. This chapter describes the SSN Analyzer and Optimization tool introduced in the Quartus II software version 9.0 and covers the following topics:

- "Definitions"
- "Understanding SSN and Its Effects" on page 6–2
- "SSN Estimation Tools from Altera" on page 6–5
- "Design Factors Affecting SSN Results" on page 6–5
- "Using the SSN Analyzer in the Quartus II Software" on page 6–5
- "SSN Analyzer Usage Models" on page 6–14
- "Scripting Support" on page 6–18
- "Run Time Considerations in SSN Analysis" on page 6–18
- "SSN Optimization" on page 6–20

Definitions

The terminology used in this chapter includes:

Aggressor: Output or bidirectional signal that contributes to the noise for a victim.

PDN: Power Distribution Network

QH: Quiet High signal level on a pin

QHN: Quiet High Noise on a pin in volts

QL: Quiet Low signal level on a pin

QLN: Quiet Low Noise on a pin in volts

SI: Signal Integrity (a superset of SSN covering all noise sources)

SSN: Simultaneous Switching Noise

SSOs: Simultaneous Switching Outputs (which are either the output or bidirectional pins)

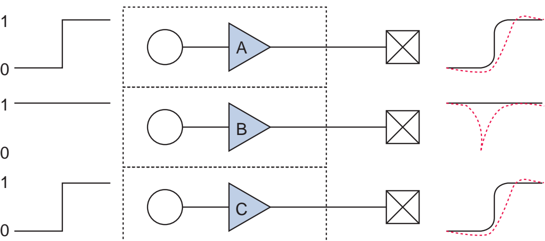
Victim: An input, output, or bidirectional pin that is analyzed during SSN analysis. During SSN analysis, each pin is analyzed as a victim. If it is an output or bidirectional pin, the same pin acts as an aggressor for other pins.

Understanding SSN and Its Effects

SSN is defined as a noise voltage induced onto a single victim I/O pin in your FPGA device. The voltage is induced by the switching behavior of other aggressor I/O pins in the device. SSN can be divided into two types of noise: voltage noise and timing noise.

Figure 6–1 shows a system with three pins. Two of the pins (A and C) are switching, while one pin (B) is quiet. If the pins are driven in isolation, the voltage waveforms at the output of the buffers appear as the solid curves at the left of the figure. However, when the pins are switched simultaneously, the noise generated by pins A and C switching is injected onto the other pins, manifesting itself as a voltage noise on pin B and a timing noise on pins A and C, as shown by the dotted curves in the figure.

Figure 6–1. System with Three Pins



Voltage noise is measured as the worst-case change in voltage of a signal due to SSN. When a signal is quiet high (QH), it is measured as the change in voltage toward 0 V. When a signal is quiet low (QL), it is measured as the change in voltage toward V_{CC}.

In the Quartus II software, only voltage noise is analyzed. Voltage noise can be caused by SSOs under two worst-case conditions:

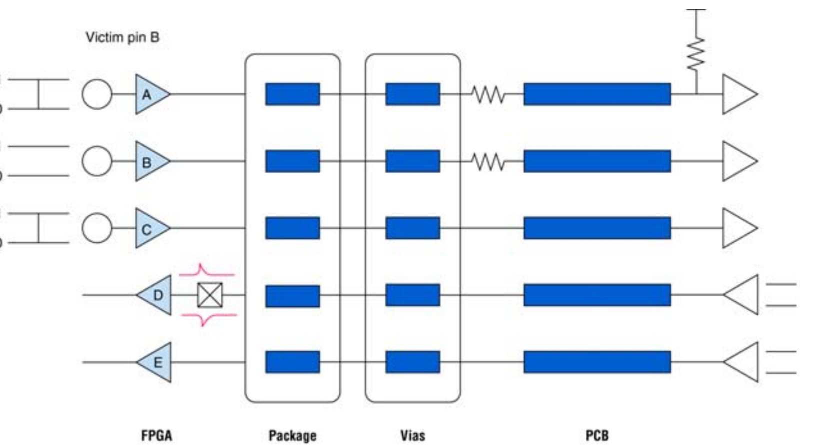
- Victim pin is high and aggressors (SSOs) are switching from low to high
- Victim pin is low and aggressors (SSOs) are switching from high to low

For outputs, the noise is computed at the far-end receiver as shown in Figure 6–2 for pin B.

Figure 6–2. Quiet High Output Noise Estimation

For inputs, the noise is computed at the FPGA bumps as shown in Figure 6–3 for pin D.

Figure 6–3. Quiet Low Input Noise Estimation



SSN can occur in any system, but the induced noise does not always result in failures. The voltage functional errors are caused by SSN on quiet victims only when the voltage values on the quiet pins change by a large enough voltage such that the logic listening to that signal reads a change in the logic value. For QH signals, noise events that cause the voltage on those signals to fall below V_{IH} are a voltage functional error. Similarly, for QL signals, noise events that cause the voltage to rise above V_{IL} are a voltage functional error (Figure 6–4). Because V_{IH} and V_{IL} are different for different I/O standards and signals have different quiet voltage values, the absolute amount of SSN in volts cannot be used to determine if a voltage failure occurs. Instead, to quantify whether an SSN event will cause a voltage error, the Quartus II software uses the amount of noise as a percent of signal margin when reporting noise margins in SSN analysis (Figure 6–4).

Figure 6–4. Reporting Noise Margins

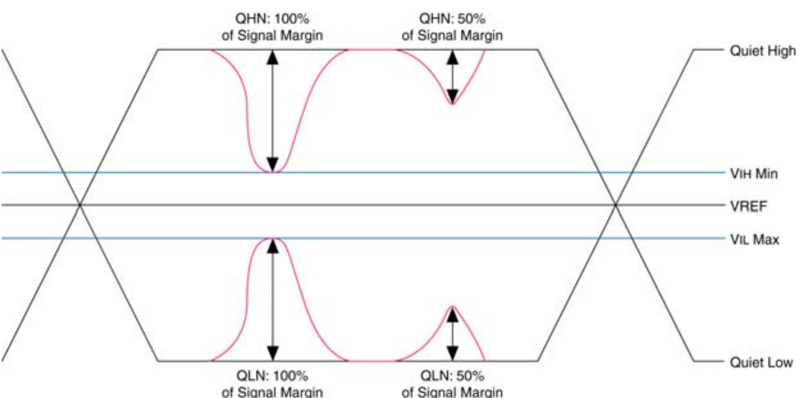


Figure 6–4 shows four noise events, two on QH signals and two on QL signals. The two noise events on the right-side of the figure consume 50% of the signal margin and do not cause voltage functional errors. However, the two noise events on the left side of the figure consume 100% of the signal margin and can cause a voltage functional error.

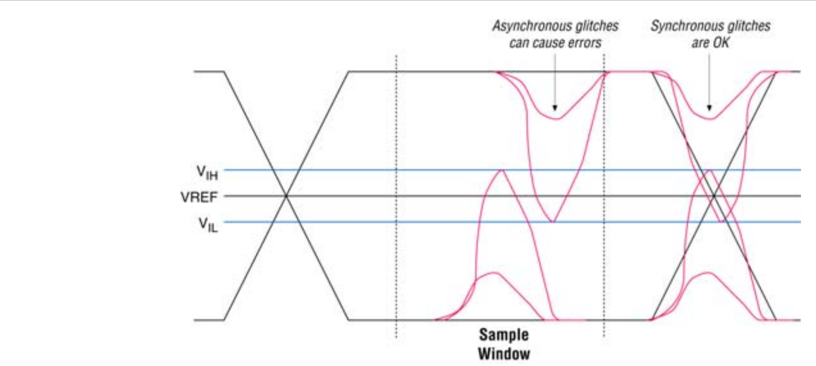
Another situation where a voltage noise cannot result in an error in your system is when the voltage noise happens synchronously, as shown in Figure 6–5. If noise or glitches, caused by aggressors, are synchronously related to the victim and occur outside of the sampling window of a receiver, the switching time of a victim can be affected but should not be considered as an input threshold violation failure.

Figure 6–5. Synchronous Voltage Noise



When you perform SSN analysis in the Quartus II software, there are a number of design factors that affect the noise margins. These design factors are described in "Design Factors Affecting SSN Results".

SSN Estimation Tools from Altera

Not addressing SSN early in your FPGA design and PCB layout could result in a respin of your board and lost time, which can impact your time to market. Therefore, the best approach is to address SSN early in your system design. Altera provides many tools for SSN analysis and estimation, including SSN characterization reports, an Early SSN Estimator (ESE) tool, and the SSN Analyzer in the Quartus II software. The ESE tool is available for various device families.

You can get more information on the spreadsheet tool and device support at Altera's Signal Integrity Center.

The SSN Analyzer and Optimization tool is available in the Quartus II software version 9.0 and later. In the Quartus II software version 9.0, only Stratix® III devices are supported. To get the latest information on device support for the SSN Analyzer with the Quartus II software you are using, refer to its help.

The ESE tool is a good starting point with which to estimate SSN in your FPGA design. To get more accurate results, you must use the SSN Analyzer tool in the Quartus II software to analyze SSN. Table 6–1 compares some of the differences between the SSN spreadsheet tool and the SSN Analyzer tool.

Table 6–1. Comparison of SSN Spreadsheet Tool and SSN Analyzer Tool

SSN Spreadsheet Tool	SSN Analyzer Tool
Is not integrated with the Quartus II software.	Integrated with the Quartus II software, allowing you to perform what-if analysis for SSN while making I/O assignment changes in the Quartus II software.
QL and QH levels are computed assuming a worst case pattern of I/O placements.	QL and QH levels are computed based on the I/O placements provided by the user or Fitter.
No support for entering board information.	Supports board trace models and board layer information that result in a more accurate SSN analysis.
No visualization feature.	Integrated with the Quartus II software Pin Planner, in which an SSN map shows the QL and QH levels on victim pins.
Good for doing an early SSN estimate. Does not require you to use the Quartus II software for early SSN estimate.	Requires you to create a Quartus II software project and provide the top-level port information.

Design Factors Affecting SSN Results

To understand what contributes to SSN voltage noise in your FPGA design, refer to *AN 472: Stratix II GX SSN Design Guidelines* and *AN 508: Cyclone III Simultaneous Switching Noise (SSN) Design Guidelines*.

Using the SSN Analyzer in the Quartus II Software

The SSN Analyzer introduced in the Quartus II software version 9.0 enables you to estimate the SSN (QLN and QHN) levels for your FPGA pins. The SSN optimization feature helps you optimize your design for SSN when you are compiling your design. The following sections explain the user requirements and how to use the tool to get the results you want.

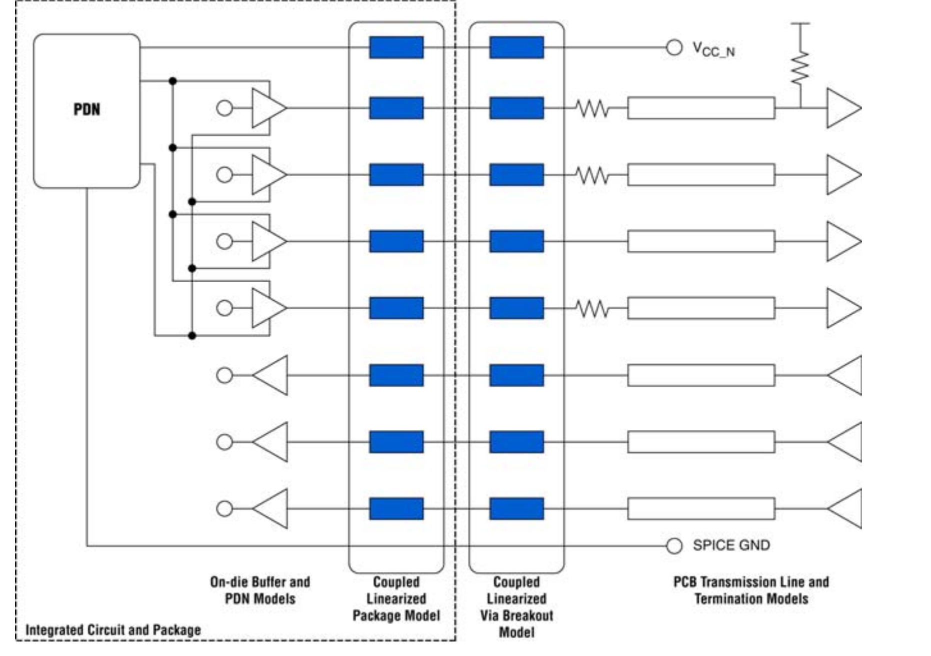
Tools Overview

The Altera® Quartus II SSN Analyzer gives you much flexibility in precisely defining the system to obtain accurate SSN results. Because the SSN Analyzer is integrated into the Quartus II software, it can automatically set up a system topology that matches a given Quartus II design. The tool accounts for different I/O standards and slew rate settings for each buffer in the design, as well as modelling different board traces for each signal. Furthermore, it correctly models the state of the unused pins in the design. These features leverage the previously existing Quartus II Advanced I/O Timing (AIOT) assignments that allowed custom board traces to be specified in the Quartus II software.

The SSN Analyzer tool also models the package and vias in the design. Models for the different packages that Altera FPGAs support are integrated into the Quartus II software. With respect to the via models, the tool supports the ability to specify different layers on which signals break out, each with its own thickness, and then specify which signal breaks out on which layer.

After automatically constructing the correct circuit topology as shown in Figure 6–6, the SSN Analyzer uses a simulation-based methodology to determine the SSN for each victim pin in the design.

Figure 6–6. Circuit Topology for SSN Analysis



I/O Standards Supported in the Quartus II SSN Analyzer

Altera device families support a wide range of I/O standards. To learn more about the I/O standards, refer to the device handbooks at www.altera.com. The Quartus II SSN Analyzer supports most I/O standards in a device family, such as LVTTL, LVCMOS, HSTL, and SSTL. Differential standards, such as LVDS and its variations, are not supported, because these standards contribute a small amount of SSN, which needs to be accounted for in your design.

For more information about the I/O standard support with your version of the Quartus II software, refer to the Quartus II Help.

Tool Inputs

The SSN Analyzer uses circuit models while performing SSN analysis. As shown in Figure 6–6, the circuit topology is incomplete if board trace information and layer information are not entered. To compute the SSN accurately in your FPGA device, you must describe these parameters in your FPGA design. However, if you do not specify some or all of the board trace parameters and PCB layer information, the Quartus II software uses default parameters during SSN analysis. These default parameters are listed in the Confidence Metric report.

For more information about the Confidence Metric Report, refer to "Confidence Metric Details Report" on page 6–13.

Board Trace Models

The board trace models required for the SSN Analyzer include the board trace termination resistors, pin loads (capacitance), and transmission line parameters. You can enter the board circuit models, which are also known as board trace models in the Quartus II software. The board trace model settings are shared with the models used during AIOT analysis.

For more information about AIOT analysis, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

In the Quartus II software, you can specify the board trace models using the board trace schematic template, the Pin Planner's All Pins list, or Tcl assignments. For every I/O standard, there is a built-in template that you can use to fill transmission line parameters, far and near end resistances, far and near end capacitances, and more. To open the board trace model schematic, right-click a pin in the Pin Planner's All Pins list and click **Board Trace Model**. Alternatively, you can enter the parameters in the All Pins list columns. The parameters entered in the board trace model schematic or the Pin Planner's columns are saved as Tcl assignments in the **.qsf** file and are also used in Advanced I/O Timing analysis (AIOT) with TimeQuest in the Quartus II software. If you have already specified the board trace models for AIOT, the same parameters are used during SSN analysis. Following are some examples of Tcl assignments that are used to specify the transmission line parameters:

```
set_instance_assignment -name BOARD_MODEL_TLINE_L_PER_LENGTH "3.041E-7" -to e[0]
set_instance_assignment -name BOARD_MODEL_TLINE_LENGTH 0.1391 -to e[0]
set_instance_assignment -name BOARD_MODEL_TLINE_C_PER_LENGTH "1.463E-10" -to e[0]
```

You can also create or edit the Tcl assignment directly in the **.qsf** file. If you do not specify the board trace parameters, the Quartus II software uses default parameters during SSN analysis. The default parameters used are listed in the Confidence Metric Details Report.

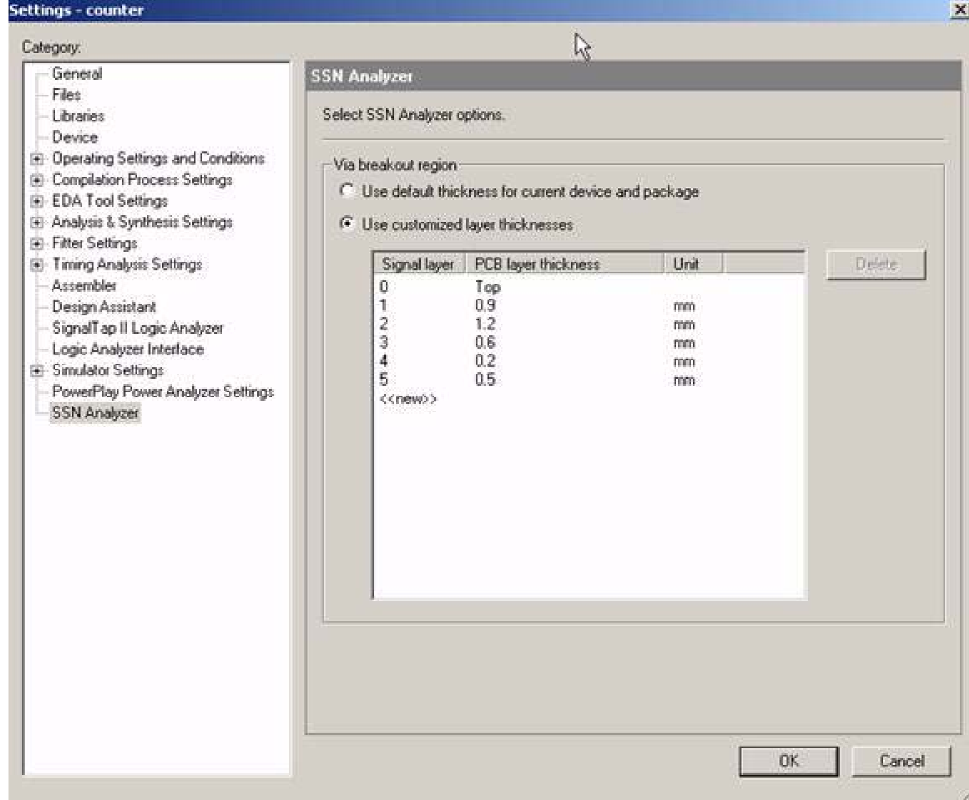
The best way to calculate transmission line parameters is to use a 2D-solver to estimate the line's inductance per inch and capacitance per inch. The termination resistor topology information can be obtained from the PCB schematics. The near-end and far-end pin load (capacitance) values can be obtained from the PCB schematic and other device data sheets. For example, if you know that an FPGA pin is driving a DIMM or some other package, you can get the loading information at the far end by looking at the data sheet of that device.

PCB Layers and PCB Layer Thickness

Every PCB board is fabricated using a number of layers. You can specify the number of layers and their thickness in the Quartus II software. The PCB layer information is used only during SSN analysis and is not required in other parts of the Quartus II software. The **SSN Analyzer** page in the **Settings** dialog box contains controls for setting values for a custom via breakout region (Figure 6–7). You can double-click on **<<new>>** to add a new signal layer. When you click on **<<new>>**, the signal layer number is automatically entered and you can enter a thickness value. To delete a layer, press the **Delete** key.

If a custom PCB breakout region is not described, you can select the default thickness, causing a single-layer PCB breakout region to be used during SSN analysis. Selecting the default option disables the maximum layer edit control and the list box.

Figure 6–7. Specifying the Number of Board Layers and Layer Thickness



Layers are numbered sequentially, starting from 0 (layer 0 is the top layer). Each layer has a thickness associated with it. You can specify the thickness on the **SSN Analyzer** page in the **Settings** dialog box. The **Unit** column shown in Figure 6–7 can be mils or millimeters (mm). For example, in Figure 6–7, layer 3 has a thickness of 0.6 mm. You must specify a thickness value greater than 0.

The Quartus II software saves the GUI settings as Tcl assignments in the **.qsf** file. You can also create or edit the Tcl assignments in the **.qsf** file. The number of layers is not fixed, but the layers must be consecutive. There is no maximum number of layers. For example, your **.qsf** file might contain the following assignments:

```
set_global_assignment -name PCB_LAYER_THICKNESS 0.00099822M -section_id 1
set_global_assignment -name PCB_LAYER_THICKNESS 0.00034036M -section_id 2
set_global_assignment -name PCB_LAYER_THICKNESS 0.00034036M -section_id 3
set_global_assignment -name PCB_LAYER_THICKNESS 0.00055372M -section_id 4
set_global_assignment -name PCB_LAYER_THICKNESS 0.00034036M -section_id 5
set_global_assignment -name PCB_LAYER_THICKNESS 0.00034036M -section_id 6
set_global_assignment -name PCB_LAYER_THICKNESS 0.00082042M -section_id 7
```

These statements tell the Quartus II software that there are 7 layers in the design. In each assignment, the letter `M` is the unit of thickness and stands for millimeters.

The assignments in the **.qsf** file must contain thickness information for consecutive layers. For example, suppose the **.qsf** file contains only the following assignments:

```
set_global_assignment -name PCB_LAYER_THICKNESS 0.00099822M -section_id 1
set_global_assignment -name PCB_LAYER_THICKNESS 0.00082042M -section_id 7
```

The Quartus II software generates the following error message when you start the SSN Analyzer:

```
Error: Nonconsecutive board stackup layers have been specified.
```

Signal Breakout Layers

Each user I/O pin in your FPGA device can break out at different layers on your PCB. In the Quartus II software, you can specify on which layers the I/O pins in your design break out. This information is only used during SSN analysis and is not required for other parts of the Quartus II software.

You can use the Pin Planner’s All Pins list or Tcl assignments to specify how pins break out. In the Pin Planner’s All Pins list, enter the layer number for the corresponding signal in the **PCB Layer** column. This action specifies the connection of that signal to that layer. The number you enter in the All Pins list is stored as a Tcl assignment in the **.qsf** file as follows:

```
set_instance_assignment -name PCB_LAYER 10 -to e[2]
set_instance_assignment -name PCB_LAYER 3 -to e[3]
```

You can also specify this information directly in the Tcl assignments in the **.qsf** file. If you do not specify this information for a pin, the Quartus II software breaks the signal out at the bottommost layer. While you can specify the number of layers using the GUI or Tcl assignments, the **PCB Layer** column in the All Pins list allows you to enter a layer that you may not yet have defined in the GUI. If there is a **.qsf** assignment that specifies a pin to break out at a layer that does not exist, the Quartus II software gives you a warning that the layer does not exist and it uses the bottommost layer:

```
Warning: Pin "e[2]" has an invalid assignment "10" made on the board stackup breakout
layer, using the bottommost layer for this pin.
```

I/O Assignments

The I/O assignments in the Quartus II software are also known as pin assignments. These assignments are required in FPGA design and are also used during SSN analysis in the Quartus II software. Each input, output, or bidirectional signal in your design is assigned a physical pin location on the device using pin location assignments. Each signal has a physical I/O buffer that has a specific I/O standard, pin location, current strength, and slew rate.

Altera device families support a wide variety of I/O standards. You can specify the I/O standard using the Pin Planner, Assignment Editor, or Tcl assignments.

To learn more about specifying the I/O standard, current strength, slew rate, and pin location, refer to the Pin Advisor in the Quartus II software, the Quartus II Help, or the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

Automatic Aggressor Identification

The Quartus II software looks for the following situations to determine whether a pin can be an aggressor for a specific victim pin:

- If the aggressor pin is a complement of the victim pin, it is not considered an aggressor for the victim. This is the case for pins that have differential standards.
- If the aggressor pin is a programming or JTAG pin, it does not aggress on any victim pin because it is not active in user mode.
- If the victim pin is a bidirectional pin and analyzed for SSN as an input, the pins that have the same Output Enable (OE) cannot be aggressors, because those other pins also act as inputs and cannot aggress at the same time. Refer to "Group Assignments" for information about grouping bidirectional pins.
- If the victim pin is an output pin and belongs to a synchronous group, the pins that are specified in the same synchronous group cannot be aggressors for that victim pin. Refer to "Group Assignments" for information about grouping output pins.

Group Assignments

In the absence of any specific timing information, SSN analysis must assume worst-case conditions. Typically, this involves assuming that all pins act as aggressors on all possible victim pins. Similarly, all aggressor pins are assumed to be switching with the worst possible timing relationship. In reality, there are many relationships between I/O pins that make this assumption very pessimistic. The following relationships can help lessen that pessimism:

- **Common output enable signals**—If all the pins in a group are always either inputs or outputs, it is impossible for an output pin in the group to cause SSN noise on an input pin in the group. To do so violates the restriction that all pins are either inputs or outputs.
- **Synchronously related signals**—I/O pins that are part of a synchronous group (signals that switch at the same time) may cause SSN, but do not result in any failures because the noise glitch occurs during the switching period of the signal. The noise, therefore, does not occur in the sampling window of that signal.

 © March 2009 Altera Corporation

In some cases, the Quartus II software can detect the grouping for bidirectional pins by looking at the OE of the bidirectional pins. However, Altera recommends that you explicitly specify the bidirectional groups and output groups using Tcl assignments for your design.

You can specify a bidirectional group with the following Tcl assignment in the **.qsf** file:

```
set_instance_assignment -name OUTPUT_ENABLE_GROUP 1 -to DATAINOUT
```

where DATAINOUT is a bidirectional bus.

You can specify the an output group with the following SYNCHRONOUS_GROUP assignment:

```
set_instance_assignment -name SYNCHRONOUS_GROUP 1 -to PCI_AD_io
```

In this case, the PCI_AD_io bus may have 32 pins that all belong to the same group. In a real operation, the bus switches at the same time, so any voltage noise induced by a pin on its groupmate does not matter, because it does not fall in the sampling window. If this assignment is not used, the other 31 pins can act as aggressors for the first pin in that group, leading to higher QL and QH noise levels in SSN analysis. Specifying the correct grouping yields less pessimistic results in your SSN analysis.

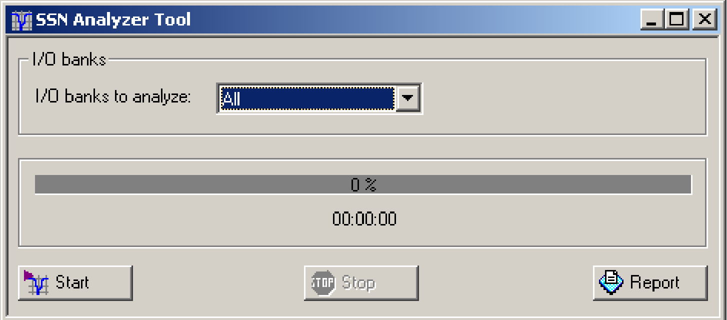
You can use the Assignment Editor to make these assignments. You can also use the Node Finder utility in the Quartus II software to find bidirectional or output buses.

Running the SSN Analyzer

You can start the SSN analysis in several ways:

- On the Processing menu in the Quartus II software, click **SSN Analyzer Tool**. The **SSN Analyzer Tool** dialog box appears (Figure 6–8).

Figure 6–8. SSN Analyzer Tool Dialog Box



- On the Processing menu, point to **Start** and click **Start SSN Analyzer**.
- On the command line, type the following commands:

```
quartus_si <project revision> ↵
quartus_si counter ↵
```

where counter is the project revision.

On the command line, you can run just one I/O bank, as follows:

```
quartus_si <project revision> <--bank = bank id> ↵
quartus_si counter --bank=2A ↵
```

To learn more about I/O bank numbering, refer to the package view for the device in the Pin Planner or refer to the device handbook.

For more information about the `quartus_si` package, type `-quartus_si -h` in the console window or command prompt, refer to the Quartus II Help, or refer to the *Quartus II Scripting Reference Manual*.

Understanding the SSN Reports

At the end of SSN analysis, various reports are printed in the Compilation Report section. You can view the reports by clicking the Compilation Report button on the Quartus II toolbar.

Settings Report

The Settings Report states whether or not smart compilation was used. To learn more about smart compilation, refer to the Quartus II Help.

Summary Report

The Summary Report summarizes the SSN analysis run and gives information such as whether or not the SSN run was successful, which Quartus II software version was used, the revision of the project used, and so forth. The report also rates the SSN Analyzer confidence level as low, medium, or high. The confidence level depends on how completely you have specified the user assignments described in “Tool Inputs” on page 6–7.

The more assignments you complete, the higher the confidence level. However, the confidence level does not always contribute to the accuracy of the QL and QH levels you get on a victim pin. The accuracy of QH and QL noise levels depends on how accurately you have defined your user assignments.

Input Pins Report

The Input Pins Report lists all of the input pins and bidirectional pins that are treated as inputs during SSN analysis, their location assignments on the FPGA device, the QL and QH noise in volts, and what percentage the QL and QH margins are for the I/O standard used for that signal. The QH and QL noise margins that fall in the critical range (> 90%) are shown in red. The QH and QL noise margins that fall in the range of 70% to 90% are shown in gray. You cannot change the color settings in this report.

Output Pins Report

The Output Pins Report lists all of the output pins and bidirectional pins that are treated as output pins during SSN analysis of your design, their location assignments on the FPGA device, the QL and QH noise in volts, and what percentage the QL and QH margins are for the I/O standard used for that signal. The QH and QL noise margins that fall in the critical range (> 90%) are shown in red. The QH and QL noise margins that fall in the range of 70% to 90% are shown in gray. You cannot change the color settings in this report.

Confidence Metric Details Report

The SSN Analyzer confidence level is reported in the Summary Report. The Confidence Metric Details Report lists the I/O, board, and PCB assignments that have not been specified by the user and the value that was used in its place by the SSN Analyzer.

Unanalyzed Pins Report

In the Quartus II software version 9.0, not all pins are analyzed for SSN analysis. The following pins are not analyzed and are reported in the Unanalyzed Pins Report:

- LVDS pins and any pins that have LVDS variations, such as mini-LVDS
- Pins created in the migration flow that cover power and supply pins in other packages
- The negative terminals of pseudo-differential standards; the noise on differential standards is reported as the differential noise and is reported on the positive terminal

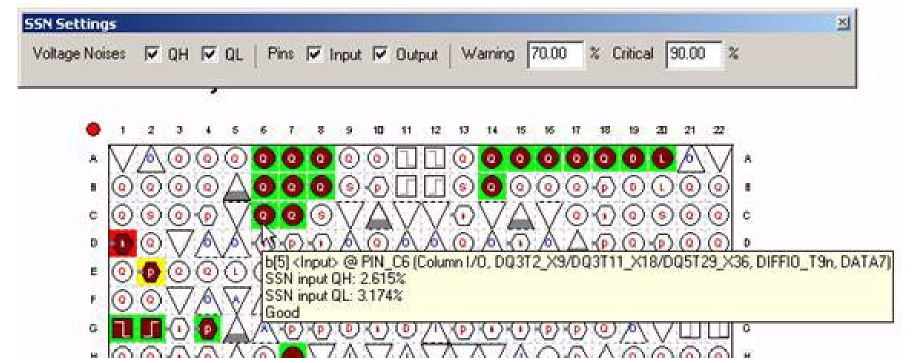
Visualizing SSN in the Pin Planner

After SSN analysis finishes, the results can be analyzed in the Quartus II Pin Planner. You can quickly identify the SSN hotspots in the package view of your device by using the Pin Planner's package view. In addition to viewing the QL and QH results in the reports, you can see the QL and QH noise levels in the Pin Planner. The QL and QH results for each pin are displayed with a color. This color representation is also referred to as the SSN map of your FPGA device. Besides the visualization, the integration of the SSN Analyzer with the Pin Planner provides you a what-if SSN analysis where you change I/O assignments and board trace information and rerun the SSN Analyzer.

Invoking the SSN Map

To view the SSN map of your device pins, right-click in the package window in the Pin Planner and click **Show SSN Analyzer Results**, as shown in Figure 6–9.

Figure 6–9. SSN Map



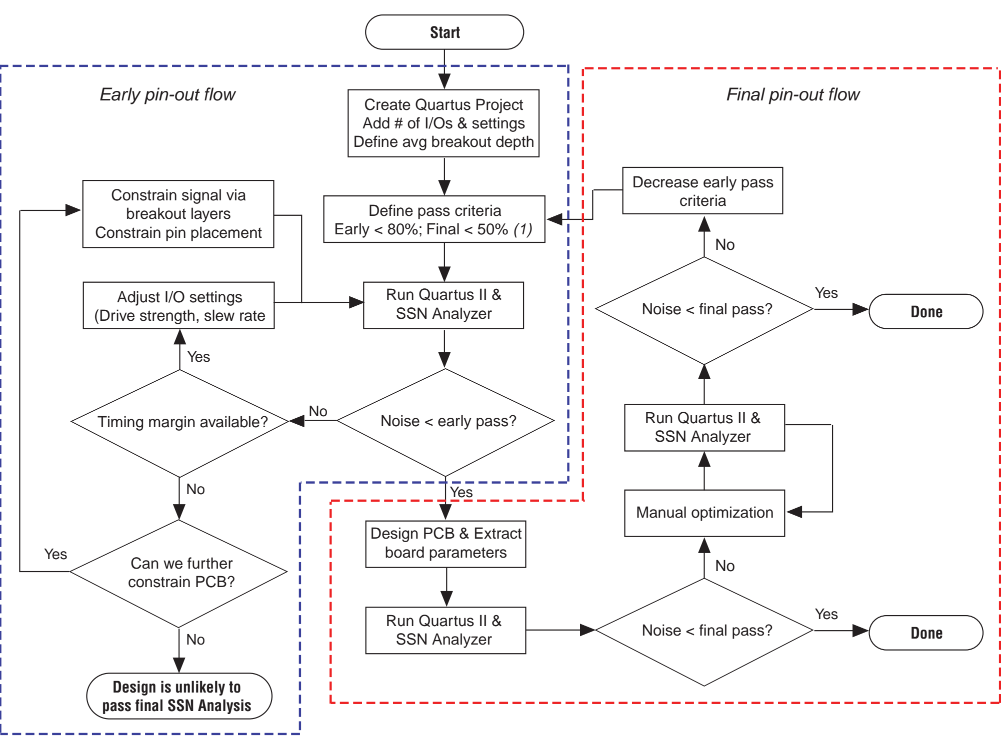
Along with the SSN map, the SSN toolbar is displayed. The toolbar lets you select only input pins, only output pins, or both, and to view QH, QL, or both noise levels. It also lets you change the threshold levels for QH and QL noise voltages. For example, by default noise levels that consume more than 90% of the signal margin of a pin are shown in red. Similarly, noise levels that consume 70% to 90% of the signal margin are shown in yellow and levels below 70% are shown in green. If you change this threshold, the results are updated in the SSN map. Changing the threshold levels in the SSN toolbar does not change the threshold levels in the SSN reports. The threshold levels in the SSN reports are fixed. For example, if you change the critical threshold level in the Pin Planner to be 80% instead of 90% (which is the default), some pins might appear as red instead of yellow, but the SSN reports will still show their noise levels in gray. When you hover your mouse over a pin, the QH and QL noise levels are displayed, as shown in Figure 6–9.

SSN Analyzer Usage Models

Based on which stage your design cycle is in, you can run the SSN Analyzer at a very early stage of your design cycle or at a stage where your PCB design is almost complete. Altera recommends that you start your SSN analysis early in the design (an early pin-out analysis) and later do a fully constrained SSN analysis with complete information about your board (a final pin-out analysis).

The basic methodology of early pin-out and final pin-out analysis, shown in Figure 6–10, assumes conservative design rules initially, then lets you analyze the design and iteratively apply tighter design rules until SSN analysis indicates a passable design. You must define a pass criterion for the SSN analysis as a percent of signal margin for both the early and final analysis. The early pass criterion may be higher than the final pass criterion, so that you do not spend too much time optimizing the on-FPGA portions of your design when the SSN metrics for the design may improve after the design is fully specified.

Figure 6–10. Pin-Out Analysis



Note to Figure 6–10:

(1) Pass criteria to be determined by customer requirements.

Early Pin-Out SSN Analysis

Early pin-out SSN analysis occurs before you have placed I/Os in your Quartus II project. In this SSN analysis, you might not have all the design files ready but you have the interface information ready. If you know what I/O standards and signaling standards are to be applied to those interfaces, you can use either the early SSN spreadsheet tool or the SSN Analyzer in the Quartus II software to perform an initial SSN evaluation of your design.

Early Pin-Out SSN Analysis Using the Early SSN Estimator Spreadsheet

The Altera Early SSN Estimator (ESE) spreadsheet provides basic early pin-out SSN analysis using simple equation-based SSN models. To learn more about the SSN spreadsheet tool, refer to the Signal Integrity Center on the Altera website.

Early Pin-Out SSN Analysis Using the Quartus II SSN Analyzer

The integration of the SSN Analyzer in the Quartus II software enables you to do an early SSN analysis without having any design files ready. If you have complete information for your top-level interface, you can enter that information in the Quartus II software and run the SSN Analyzer to view the early results.

If you plan to use the SSN Analyzer, you must create the Quartus II software project and have at least the information for all the top-level ports or interfaces of your FPGA design. Your top-level port information can be entered in the Quartus II software project in a number of ways. You can use the schematic entry method, or if you have the top-level design file in HDL, you can use that in the Quartus II software directly. If you have a top-level file, you can generate a top-level wrapper file in the Quartus II software in HDL.

To learn more about how to generate a top-level file in the Quartus II software, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

To learn more about how to create projects, refer to the Quartus II Help or the *Managing Quartus II Projects* chapter in volume 2 of the *Quartus II Handbook*.

When you have the top-level ports ready in any of these forms, you can analyze and synthesize your Quartus II project. In an early pin-out analysis, pin location assignments are assumed not to exist. In the Pin Planner, you can make other I/O assignments such as I/O standard assignments for the top-level ports.

The SSN Analyzer requires you to run the Fitter. In an early pin-out analysis, you may not have all the design files and timing constraints complete. You can run I/O Assignment analysis to place all the I/Os in your FPGA device. During I/O Assignment analysis, the Fitter places all the unplaced pins on the device, and all the I/O placement rules are checked. After the I/O Assignment completes successfully, you are ready to start the SSN analysis.

The I/O rules and their validation process are discussed in the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

In an early pin-out analysis, you might not have all the board information, such as board trace parameters, layers information, and on which layer the pins break out. You can run the SSN Analyzer without this information, but the SSN Analyzer confidence level will be low. At this point the SSN Analyzer can be run and the results analyzed. If the noise amounts are larger than the early pass criteria, you can check whether the SSN noise violations are true failures or false failures. Although the Quartus II SSN Analyzer can sometimes determine whether pins are switching synchronously and use that information to filter false positives, it may not be able to determine all the synchronous groups. You can help the SSN Analyzer by entering assignments that indicate which pins are switching synchronously, such as large buses, and rerun the SSN Analyzer.

After filtering out false positives, if the SSN results are still larger than the pass criterion, you can change design settings to improve the design.

If timing margin is available on various signals, those signal edge rates can be slowed down by changing their drive strength or slew rate setting and rerunning the SSN Analyzer. If timing margin is not available, you can further constrain the PCB breakout depth or adjust the pin placements. With an early SSN analysis, you can see what QL and QH noise levels exist in your FPGA device based on your existing I/O

placements and assignments. The integration of the SSN Analyzer with the Quartus II software allows you to perform a what-if analysis to see how I/O placement changes and I/O assignment changes vary the QL and QH levels in your FPGA device. This capability allows you to manage SSN in your device and system early in the PCB development because you know the noise margin on your FPGA pins.

When you change any I/O assignments in the Pin Planner, you must run I/O Assignment analysis or full compilation before you perform SSN analysis.

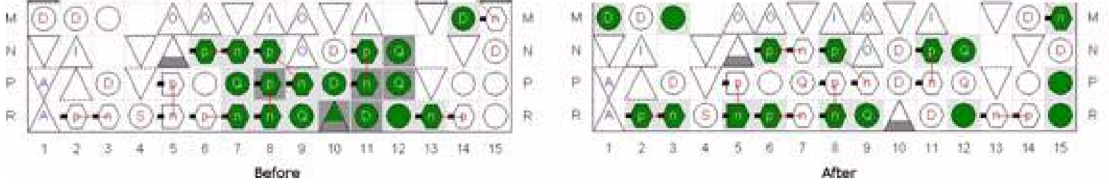
SSN Aware Fitter

In the early pin-out SSN analysis, when you perform I/O assignment analysis or full compilation, if you have not assigned physical locations for your I/Os, the Fitter places the I/Os in various pin locations such that I/O rules are not violated. In the Quartus II software version 9.0 and later, you can run the I/O assignments analysis or full compilation in SSN aware mode to provide an I/O placement that reduces SSN. Refer to “SSN Optimization” on page 6–20 for information about using the SSN aware Fitter.

You can choose an effort level for SSN aware fitting. The Fitter tries to spread out the pins to minimize the worst-case SSN-induced noise. If your I/O pin locations are assigned, the Fitter does not change the pin locations. For the Fitter to spread out the pins for SSN, you must either not have assignments made or if the assignments exist, you must delete the pin location assignments from the **.qsf** file and rerun I/O assignment analysis or full compilation.

With regard to pin placements, the Quartus II software has an SSN aware Fitter that automatically adjusts the pin placements to reduce the amount of SSN in the design. Figure 6–11 shows an example design run through the SSN Analyzer before and after the SSN aware Fitter is used.

Figure 6–11. SSN Results Before and After Using the SSN aware Fitter



Default Assignments Used in Early SSN Analysis

Early in your design cycle, you may not have any board trace model or board layer information. When you run SSN analysis without this information, the Quartus II software uses default board trace models and board layer information. This information is reported in the Confidence Metric report. After the design has been optimized such that it passes the early criteria, the PCB can be designed.

Final Pin-Out Analysis: Fully Constrained Design SSN Analysis

A final pin-out analysis is performed when you or the Fitter have placed the I/O in your design and you want to perform an SSN analysis with complete information of board traces and layers. As a pre-tapeout check for your PCB, the board parameters can be extracted, including the PCB layer thicknesses, the layers on which different signals break out, and the board trace topologies and parameters, and reanalyzed by the SSN Analyzer. If sufficient margin is available, given the early criteria, the extraction of the PCB parameters is optional and can be skipped.

These parameters should be entered into the Quartus II software using both the **Settings** dialog box and the **Board Trace Model Settings** dialog box, as described in "Tool Inputs" on page 6–7. The Quartus II software allows for the specification of near- and far-end loads, near- and far-end pull-up and pull-down resistors, and near- and far-end series resistors, as well as specifying the parameters of near- and far-end transmission lines that can model striplines and micro-striplines.

After entering the parameters, you can run the SSN Analyzer again. If the results pass the final criteria, the design is complete. If the design does not pass the criteria, the design must be micro-optimized by changing the board and design parameters and rerunning the SSN Analyzer. After all of these optimizations, if the design still does not pass the criteria, the early pass criteria should be reduced, and the process restarted. By reducing the early pass criteria, there is a larger emphasis placed on reducing the SSN through I/O settings and I/O placement that will then allow the design to pass the final SSN criteria after the actual PCB board parameters have been specified.

Scripting Support

To run SSN analysis using the command line, use the `quartus_si` package that is provided with the Quartus II software. You can use the Tcl console in the Quartus II software or type the following command to start the SSN Analyzer:

```
-quartus_si <project revision> ↵
```

The Quartus II software provides several packages to compile your design and run I/O assignments for analysis and fitting. You can create a custom Tcl script that maps the design and runs SSN analysis on your design.

For more information about Tcl scripting, refer to the Quartus II Help or the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Run Time Considerations in SSN Analysis

FPGA designs are getting larger in density, logic, and I/O count. The time it takes to complete a process of either synthesis or SSN analysis affects your development time. Faster run times can reduce your design cycle time. Following are some guidelines to consider when performing SSN analysis to reduce the run time.

Running SSN Analyzer with Multi-CPU machines

The Quartus II software has many algorithms that are multi-threaded. The SSN Analyzer in the Quartus II software is also multi-threaded, and can use two or more CPUs in a machine. The SSN run time analysis scales down directly with the number of CPUs used during the analysis.

Running the Complete Design for SSN Analysis after I/O Assignment Analysis

If your design files and constraints are ready but you do not want to run a full compilation, you can run SSN analysis after performing I/O assignment analysis in the Quartus II software. This can save you time if you are interested in looking at the SSN results early in the design and want to perform what-if analysis for your I/O placements.

Running the Complete Design for SSN Analysis after a Full Fit

When you run full compilation, the Quartus II Fitter runs all the tasks for fitting your design. You should always perform a full compilation to get complete and accurate I/O assignments validation and SSN results. However, full compilation of your design can take more time, depending on the logic density and timing requirements of your design. You can also choose to run just the Fitter but not the assembler and timing analysis if you want to run SSN analysis after just the fitting process.

Making ECO Changes and Rerunning SSN Analysis

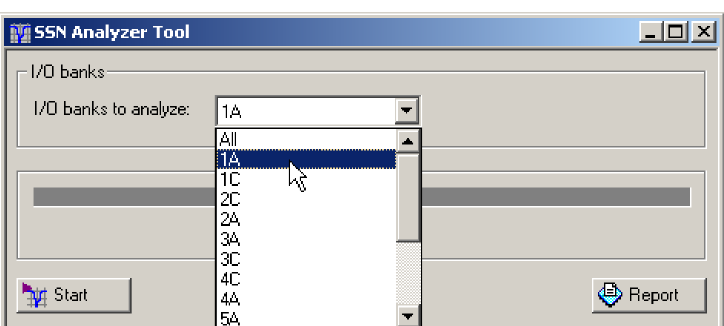
If you have performed SSN analysis after a full compilation and you want to rerun SSN analysis to see what happens to QL and QH noise levels after some changes to the I/O assignments, the best way is to perform ECOs on your design. ECOs do not compile the whole design. Instead, they compile the design for the new changes only. This can save a lot of compilation time.

For more information about performing ECOs on your design, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

Running SSN Analysis for One I/O Bank

You can run SSN analysis on the full design or on one I/O bank only. Figure 6–12 shows how to select a particular I/O bank before running SSN analysis with the SSN Analyzer tool.

Figure 6–12. Selecting an I/O Bank before Running SSN Analysis



The following Tcl command line runs SSN analysis for one I/O bank:

```
quartus_si <project revision> <--bank=bank id>
```

If you know the problem area for SSN is within one bank and you are performing I/O placement or assignment changes to only that bank, running SSN analysis for just that one bank can save you run time.

SSN Optimization

The Quartus II software has a built-in feature to optimize your design for SSN. To select an effort level for SSN optimization, in the **Settings** dialog box, select **Fitter Settings** from the **Category** list (Figure 6–13). Click **More Settings** to bring up the **More Fitter Settings** dialog box shown as in Figure 6–14.

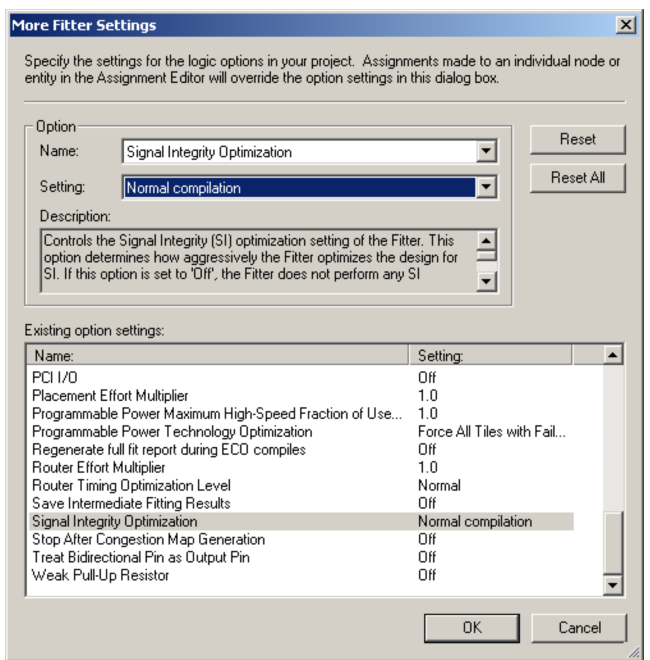
Figure 6–14. SSN Optimization Settings



In the **More Fitter Settings** dialog box, set the **Signal Integrity Optimization** option. The I/O placements in your design may be affected when you use this feature. Choosing the **Normal compilation** level does not affect the f_{MAX} of your design during compilation. Choosing the **Extra effort** level might impact the f_{MAX} of your design during compilation.

In the Quartus II software, you can assign your signal to the pin locations on the device using the Pin Planner or Assignment Editor. When you assign the pin locations, the information is saved as pin location assignments in the **.qsf** file.

You must not set any user location assignments for your pins; instead, let the Fitter place the pins while compiling your design. During compilation, if you have not made any pin location assignments in your project, the Fitter places the pins to meet the timing performance of your design. The pins that are placed by the Fitter can be viewed in the Pin Planner's package view by selecting **Show Fitter Placements**. When the Fitter places the pins automatically, no pin location assignments are created in the **.qsf** file unless you back-annotate them.

There are various optimization options available in the Quartus II software. For more information about these optimization features, refer to the Quartus II Help or the *Area, Timing and Power Optimization* section in volume 2 of the *Quartus II Handbook*.

You can also specify the effort level by using the following Tcl command:

```
set_global_assignment -name OPTIMIZE_SIGNAL_INTEGRITY "Normal Compilation"
```

Back-Annotating the Fitter Results

Back-annotating after the Fitter finishes its task saves the Fitter-placed results in the **.qsf** file. There are various options available when back-annotating. When you back-annotate the Fitter placements, the pin location assignments are saved in the **.qsf** file. To learn more about back-annotation, refer to the Quartus II Help.

SSN Optimization in Your System

This chapter discussed various tools available in the Quartus II software to analyze SSN and optimize SSN with SSN aware Fitter and I/O assignments settings. There are other optimization techniques to manage SSN in your PCB.

To learn more about managing SSN in your system, refer to *AN 472: Stratix II GX SSN Design Guidelines*, *AN 508: Cyclone III Simultaneous Switching Noise (SSN) Design Guidelines*, and high-speed board design guidelines available at www.altera.com.

Conclusion

In the Quartus II software version 9.0 and later, you can estimate SSN in your design using the fast and accurate SSN Analyzer. There are tools in the Quartus II software that allow you to estimate the SSN performance of your FPGA both early in the design cycle and when your PCB is complete. The SSN methodology discussed in this chapter gives you confidence that your FPGA design meets your SSN requirements.

7. Signal Integrity Analysis with Third-Party Tools

QII53020-9.0.0

Introduction

With the ever-increasing operating speed of interfaces in traditional FPGA design, the timing and signal integrity margins between the FPGA and other devices on the board must be within specification and tolerance before a single PCB is built. If the board trace is designed poorly or the route is too heavily loaded, noise in the signal can cause data corruption, while overshoot and undershoot can potentially damage input buffers over time.

As FPGA devices are used in high-speed applications, signal integrity and timing margin between the FPGA and other devices on the printed circuit board (PCB) are important aspects to consider to ensure proper system operation. To avoid time-consuming redesigns and expensive board respins, the topology and routing of critical signals must be simulated. The high-speed interfaces available on current FPGA devices must be modeled accurately and integrated into timing models and board-level signal integrity simulations. The tools used in the design of an FPGA and its integration into a PCB must be "board-aware"—able to take into account properties of the board routing and the connected devices on the board.

This chapter contains the following topics:

- "I/O Model Selection: IBIS or HSPICE" on page 7–3
- "FPGA to Board Signal Integrity Analysis Flow" on page 7–3
- "Simulation with IBIS Models" on page 7–7
- "Simulation with HSPICE Models" on page 7–17

The Quartus® II software provides methodologies, resources, and tools to ensure good signal integrity and timing margin between Altera® FPGA devices and other components on the board. Three types of analysis are possible with the Quartus II software:

- I/O timing with a default or user-specified capacitive load and no signal integrity analysis (default)
- The Quartus II **Enable Advanced I/O Timing** option utilizing a user-defined board trace model to produce enhanced timing reports from accurate "board-aware" simulation models
- Full board routing simulation in third-party tools using Altera-provided or generated Input/Output Buffer Information Specification (IBIS) or HSPICE I/O models

I/O timing using a specified capacitive test load requires no special configuration other than setting the size of the load. I/O timing reports from the Quartus II TimeQuest or the Quartus II Classic Timing Analyzer are generated based only on point-to-point delays within the I/O buffer and assume the presence of the capacitive test load with no other details about the board specified. The default size of the load is based on the I/O standard selected for the pin. Timing is measured to the FPGA pin with no signal integrity analysis details.

The **Enable Advanced I/O Timing** option expands the details in I/O timing reports by taking board topology and termination components into account. A complete point-to-point board trace model is defined and accounted for in the timing analysis. This ability to define a board trace model is an example of how the Quartus II software is "board-aware."

In this case, timing and signal integrity metrics between the I/O buffer and the defined far end load are analyzed and reported in enhanced reports generated by the Quartus II TimeQuest Timing Analyzer.

For more information about defining capacitive test loads or how to use the **Enable Advanced I/O Timing** option to configure a board trace model, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

This chapter focuses on the third type of analysis. The Quartus II software can export accurate HSPICE models with the built-in HSPICE Writer. You can run signal integrity simulations with these complete HSPICE models in Synopsys HSPICE. IBIS models of the FPGA I/O buffers are also created easily with the Quartus II IBIS Writer. You can integrate IBIS models into any third-party simulation tool that supports them, such as the Mentor Graphics® Hyperlynx software. With the ability to create industry-standard model definition files quickly, you can build accurate simulations that can provide data to help improve board-level signal integrity.

The I/O's IBIS and HSPICE model creation available in the Quartus II software can help prevent problems before a costly board respin is required. In general, creating and running accurate simulations is difficult and time consuming. The tools in the Quartus II software automate the I/O model setup and creation process by configuring the models specifically for your design. With these tools, you can set up and run accurate simulations quickly and acquire data that helps guide your FPGA and board design.

The information about signal integrity in this chapter refers to board-level signal integrity based on I/O buffer configuration and board parameters, not simultaneous switching noise (SSN), also known as ground bounce or V_{CC} sag. SSN is a product of multiple output drivers switching at the same time, causing an overall drop in the voltage of the chip's power supply. This can cause temporary glitches in the specified level of ground or V_{CC} for the device.

For a more information about SSN and ways to prevent it, refer to *AN 315: Guidelines for Designing High-Speed FPGA PCBs*.

This chapter is intended for FPGA and board designers and includes details about the concepts and steps involved in getting designs simulated and how to adjust designs to improve board-level timing and signal integrity. Also included is information about how to create accurate models from the Quartus II software and how to use those models in simulation software.

The information in this chapter is meant for those who are familiar with the Quartus II software and basic concepts of signal integrity and the design techniques and components in good PCB design. Finally, you should know how to set up simulations and use your selected third-party simulation tool.

For information about basic signal integrity concepts and signal integrity details pertaining to Altera FPGA devices, refer to the Altera Signal Integrity Center.

I/O Model Selection: IBIS or HSPICE

The Quartus II software can export two different types of I/O models that are useful for different simulation situations. IBIS models define the behavior of input or output buffers through the use of voltage-current (V-I) and voltage-time (V-t) data tables. HSPICE models, often referred to as HSPICE decks, include complete physical descriptions of the transistors and parasitic capacitances that make up an I/O buffer along with all the parameter settings required to run a simulation. The HSPICE decks generated by the Quartus II software are preconfigured with the I/O standard, voltage, and pin loading settings for each pin in your design.

The choice of I/O model type is based on many factors. Table 7–1 shows a detailed comparison of the two I/O model types and information and examples of situations in which they might be used.

Table 7–1. IBIS and HSPICE Model Comparison

Feature	IBIS Model	HSPICE Model
I/O Buffer Description	**Behavioral**—I/O buffers are described by voltage-current and voltage-time tables in typical, minimum, and maximum supply voltage cases.	**Physical**—I/O buffers and all components in a circuit are described by their physical properties, such as transistor characteristics and parasitic capacitances, as well as their connections to one another.
Model Customization	**Simple and limited**—The model completely describes the I/O buffer and does not usually have to be customized.	**Fully customizable**—Unless connected to an arbitrary board description, the description of the board trace model must be customized in the model file. All parameters of the simulation are also adjustable.
Simulation Set Up and Run Time	**Fast**—Simulations run quickly after set up correctly.	**Slow**—Simulations take time to set up and take longer to run and complete.
Simulation Accuracy	**Good**—For most simulations, accuracy is sufficient to make useful adjustments to the FPGA and/or board design to improve signal integrity.	**Excellent**—Simulations are highly accurate, making HSPICE simulation almost a requirement for any high-speed design where signal integrity and timing margins are tight.
Third-Party Tool Support	**Excellent**—Almost all third-party board simulation tools support IBIS.	**Good**—Most third-party tools that support SPICE support HSPICE. However, Synopsys HSPICE is required for simulations of Altera's encrypted HSPICE models.

For more information about IBIS files created by the Quartus II IBIS Writer and IBIS files in general, as well as links to websites with detailed information, refer to *AN 283: Simulating Altera Devices with IBIS Models*.

FPGA to Board Signal Integrity Analysis Flow

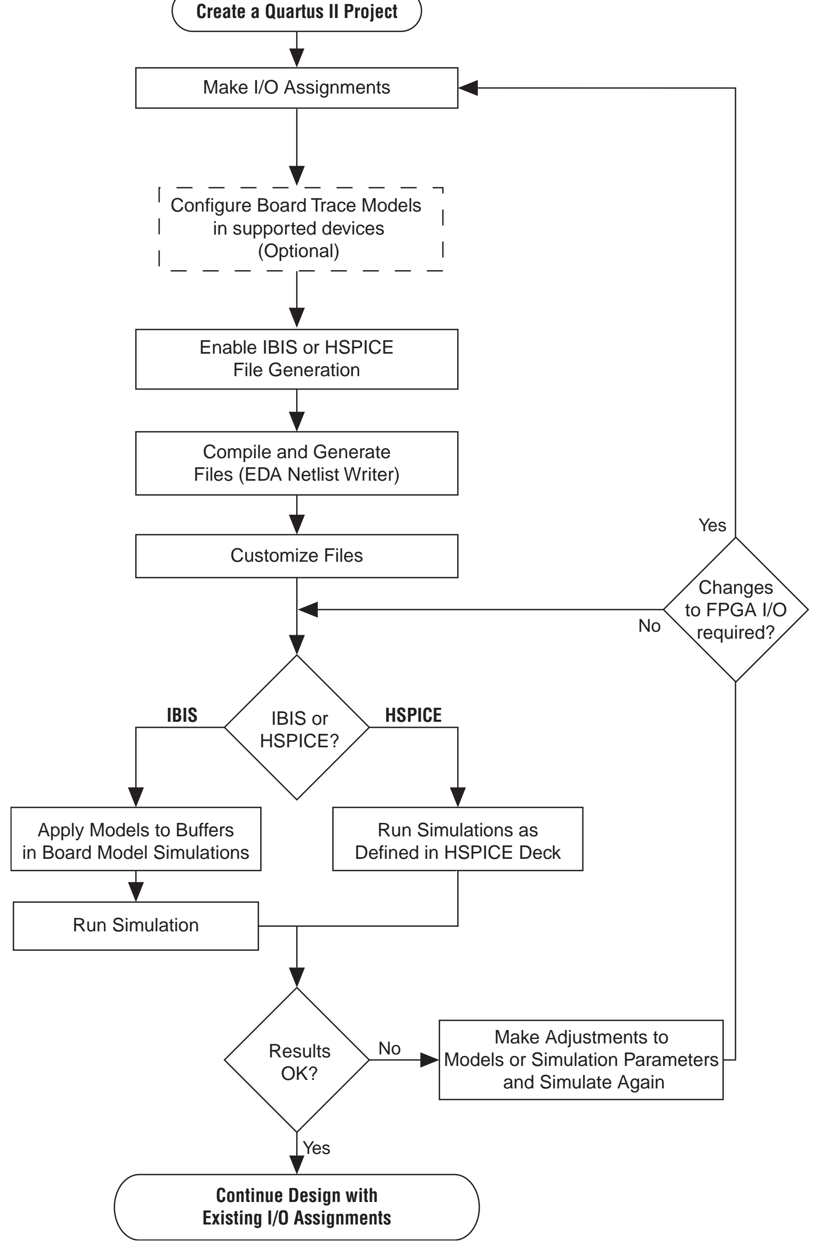
Board signal integrity analysis can take place at any point in the FPGA design process and is often performed before and after board layout. If it is performed early in the process as part of a pre-PCB layout analysis, the models used for simulations can be more generic and can be changed as much as required to see how adjustments improve timing or signal integrity and help with the design and routing of the PCB.

Simulations and the resulting changes made at this stage allow you to analyze "what if" scenarios to plan and implement your design better. To assist with early board signal integrity analysis, you can download generic IBIS model files for each device family and obtain HSPICE buffer simulation kits from the "Board Level Tools" section of the Download center on the Altera website at www.altera.com.

Typically, if board signal integrity analysis is performed late in the design, it is used for a post-layout verification. The inputs and outputs of the FPGA are defined, and required board routing topologies and constraints are known. Simulations can help you find problems that might still exist in the FPGA or board design before fabrication and assembly. In either case, a simple process flow illustrates how to create accurate IBIS and HSPICE models from a design in the Quartus II software and transfer them to third-party simulation tools. Figure 7–1 shows this flow.

This chapter is organized around the type of model, IBIS or HSPICE, that you use for your simulations. When you understand the steps in the analysis flow, refer to the section of this chapter that corresponds to the model type you are using.

Figure 7–1. Third-Party Board Signal Integrity Analysis Flow



Create I/O and Board Trace Model Assignments

If your design uses a Stratix® III, Stratix II, or Cyclone® III device, you can configure a board trace model for output signals or for bidirectional signals in output mode and automatically transfer its description to HSPICE decks generated by the HSPICE Writer. This helps improve simulation accuracy.

To configure a board trace model, in the **Settings** dialog box, in the **TimeQuest Timing Analyzer** page, turn on the **Enable Advanced I/O Timing** option and configure the board trace model assignment settings for each I/O standard used in your design. You can add series or parallel termination, specify the transmission line length, and set the value of the far-end capacitive load. You can configure these parameters either in the Board Trace Model view of the Pin Planner, or click **Device and Pin Options** in the **Device** page of the **Settings** dialog box.

For information about how to use the **Enable Advanced I/O Timing** option and configure board trace models for the I/O standards used in your design, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

The Quartus II software can generate IBIS models and HSPICE decks without having to configure a board trace model with the **Enable Advanced I/O Timing** option. In fact, IBIS models ignore any board trace model settings other than the far-end capacitive load. If any load value is set other than the default, the delay given by IBIS models generated by the IBIS Writer cannot be used to account correctly for the double counting problem. The load value mismatch between the IBIS delay and the t_{CO} measurement of the Quartus II software prevents the delays from being safely added together. Warning messages displayed when the EDA Netlist Writer runs indicate when this mismatch occurs.

Output File Generation

IBIS and HSPICE model files are not generated by the Quartus II software by default. To generate or update the files automatically during each project compilation, select the type of file to generate and a location where to save the file in the project settings. These settings can also be specified with commands in a Tcl script.

The IBIS and HSPICE Writers in the Quartus II software are run as part of the EDA Netlist Writer during normal project compilation. If either writer is turned on in the project settings, IBIS or HSPICE files are created and stored in the specified location. For IBIS, a single file is generated containing information about all assigned pins. HSPICE file generation creates separate files for each assigned pin. You can run the EDA Netlist Writer separately from a full compilation in the Quartus II software or at the command line. However, you must fully compile the project or perform I/O Assignment Analysis at least once for the IBIS and HSPICE Writers to have information about the I/O assignments and settings in the design.

Customize the Output Files

The files generated by either the IBIS or HSPICE Writer are text files that you can edit and customize easily for design or experimentation purposes. IBIS files downloaded from the Altera website must be customized with the correct RLC values for the specific device package you have selected for your design. IBIS files generated by the IBIS Writer do not require this customization because they are configured automatically with the RLC values for your selected device. HSPICE decks require modification to include a detailed description of your board. With **Enable Advanced I/O Timing** turned on and a board trace model defined in the Quartus II software, generated HSPICE decks automatically include that model’s parameters. However, Altera recommends that you replace that model with a more detailed model that
