describes your board design more accurately. A default simulation included in the generated HSPICE decks measures delay between the FPGA and the far-end device. You can make additions or adjustments to the default simulation in the generated files to change the parameters of the default simulation or to perform additional measurements.

Set Up and Run Simulations in Third-Party Tools

When you have generated the files, you can use them to perform simulations in your selected simulation tool. With IBIS models, you can apply them to input, output, or bidirectional buffer entities and quickly set up and run simulations. For HSPICE decks, the simulation parameters are included in the files. Open the files in Synopsys HSPICE and run simulations for each pin as required.

With HSPICE decks generated from the HSPICE Writer, the double counting problem is accounted for, which ensures that your simulations are accurate. Simulations that involve IBIS models created with anything other than the default loading settings in the Quartus II software must take the change in the size of the load between the IBIS delay and the Quartus II t_{CO} measurement into account. Warning messages during compilation alert you to this change.

Interpret Simulation Results

If you encounter timing or signal integrity issues with your high-speed signals after running simulations, you can make adjustments to I/O assignment settings in the Quartus II software. These could include such things as drive strength or I/O standard, or making changes to your board routing or topology. After regenerating models in the Quartus II software based on the changes you have made, rerun the simulations to check whether your changes corrected the problem.

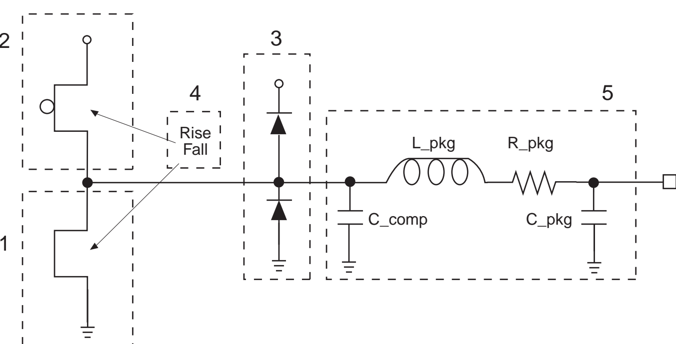
Simulation with IBIS Models

IBIS models provide a way to run accurate signal integrity simulations quickly. IBIS models describe the behavior of I/O buffers with voltage-current and voltage-time data curves. Because of their behavioral nature, IBIS models do not have to include any information about the internal circuit design of the I/O buffer. Most component manufacturers, including Altera, provide IBIS models for free download and use in signal integrity analysis simulation tools. You can download generic device family IBIS models from the Altera website for early design simulation or use the IBIS Writer to create custom IBIS models for your existing design.

Elements of an IBIS Model

An IBIS model file (**.ibs**) is a text file that describes the behavior of an I/O buffer across minimum, typical, and maximum temperature and voltage ranges with a specified test load. The tables and values specified in the IBIS file describe five basic elements of the I/O buffer. Figure 7–2 highlights each of these elements in the I/O buffer model.

Figure 7–2. Five Basic Elements in IBIS Models



The following elements correspond to each numbered block in Figure 7–2.

1. **Pulldown**—A voltage-current table describes the current when the buffer is driven low based on a pull-down voltage range of $-V_{CC}$ to 2 V_{CC}.
2. **Pullup**—A voltage-current table describes the current when the buffer is driven high based on a pull-up voltage range of $-V_{CC}$ to V_{CC}.
3. **Ground and Power Clamps**—Voltage-current tables describe the current when clamping diodes for electrostatic discharge (ESD) are present. The ground clamp voltage range is $-V_{CC}$ to V_{CC}, and the power clamp voltage range is $-V_{CC}$ to ground.
4. **Ramp and Rising/Falling Waveform**—A voltage-time (dv/dt) ratio describes the rise and fall time of the buffer during a logic transition. Optional rising and falling waveform tables can be added to more accurately describe the characteristics of the rising and falling transitions.
5. **Total Output Capacitance and Package RLC**—The total output capacitance includes the parasitic capacitances of the output pad, clamp diodes (if present), and input transistors. The package RLC is device package-specific and defines the resistance, inductance, and capacitance of the bond wire and pin of the I/O.

For more information about IBIS models and Altera-specific features, including links to the official IBIS specification, refer to *AN 283: Simulating Altera Devices with IBIS Models*.

Creating Accurate IBIS Models

There are two methods to obtain Altera device IBIS files for your board-level signal integrity simulations. You can download generic IBIS models from the Altera website or you can use the IBIS writer in the Quartus II software to create design-specific models.

Download IBIS Models

Altera provides IBIS models for almost all FPGA and FPGA configuration devices. Check the Download Center at www.altera.com for information about whether models for your selected device are available. You can use the IBIS models from the website to perform early simulations of the I/O buffers you expect to use in your design as part of a pre-layout analysis.

Downloaded IBIS models have the RLC package values set to one particular device in each device family. To simulate your design with the model accurately, you must adjust the RLC values in the IBIS model file to match the values for your particular device package by performing the following steps:

1. Download and expand the ZIP file (**.zip**) of the IBIS model for the device family you are using for your design. The **.zip** file contains the **.ibs** file along with an IBIS model user guide and a model data correlation report.
2. Download the Package RLC Values spreadsheet for the same device family.
3. Open the spreadsheet and locate the row that describes the device package used in your design.
4. From the package's **I/O** row, copy the minimum, maximum, and typical values of resistance, inductance, and capacitance for your device package.
5. Open the **.ibs** file in a text editor and locate the [Package] section of the file.
6. Overwrite the listed values copied with the values from the spreadsheet and save the file.

The **.ibs** file is now customized for your device package and can be used for any simulation. IBIS models downloaded and used for simulations in this manner are generic. They describe only a certain set of models listed for each device on the IBIS model Download Center page on the Altera website. To create customized models for your design, use the IBIS Writer as described in the next section.

Generate Custom IBIS Models with the IBIS Writer

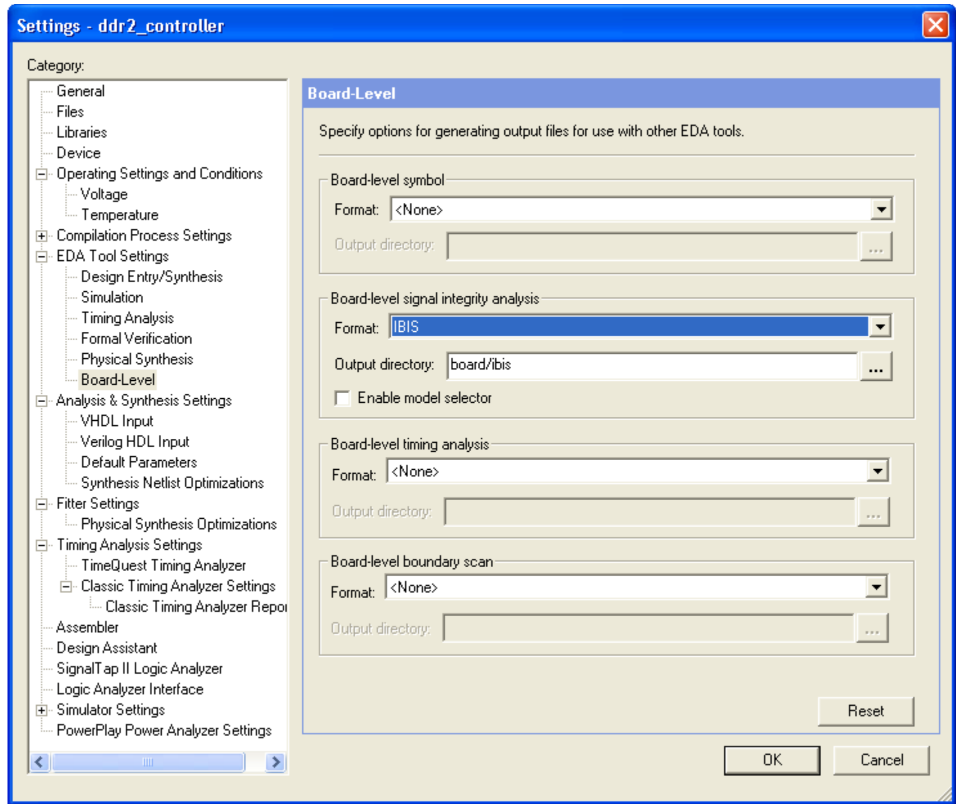
If you have started your FPGA design and have created custom I/O assignments, such as drive strength settings or the enabling of clamping diodes for ESD protection, you can use the Quartus II IBIS Writer to create custom IBIS models to accurately reflect your assignments. IBIS models created with the IBIS Writer take I/O assignment settings into account.

If the **Enable Advanced I/O Timing** option is turned off, the generated **.ibs** files are based on the load value setting for each I/O standard on the **Capacitive Loading** tab of the **Device and Pin Options** dialog box in the **Device** page of the **Settings** dialog box. With the **Enable Advanced I/O Timing** option turned on, IBIS models use an effective capacitive load based on settings found in the board trace model on the **Board Trace Model** tab in the **Device and Pin Options** dialog box or the **Board Trace Model** view in the Pin Planner. The effective capacitive load is based on the sum of the **Near capacitance**, **Transmission line distributed capacitance**, and the **Far capacitance** settings in the board trace model. Resistances and transmission line inductance values are ignored.

If you made any changes from the default load settings, the delay in the generated IBIS model cannot safely be added to the Quartus II t_{CO} measurement to account for the double counting problem. This is because the load values between the two delay measurements do not match. When this happens, the Quartus II software displays warning messages when the EDA Netlist Writer runs to remind you about the load value mismatch.

When the IBIS Writer is enabled in the **Settings** dialog box (Figure 7–3), it generates a custom **.ibs** file whenever the EDA Netlist Writer is run in the Quartus II software.

Figure 7–3. Enabling IBIS Model Generation in the Settings Dialog Box



IBIS models are stored in the *<project directory>***/board/ibis** directory by default. To change the directory, click the browse button next to the **Output directory** box, and browse to the desired location.

If the project has not been compiled, run a full compilation to create a netlist and establish I/O assignments. On the Processing menu, click **Start Compilation**. The **.ibs** file, named *<project name>***.ibs**, is saved in the specified location.

If the project has been compiled before, you only have to run the EDA Netlist Writer to create or update the **.ibs** file. On the Processing menu, point to **Start** and click **Start EDA Netlist Writer**. The **.ibs** file is created or updated in the specified location.

For more information about IBIS model generation, refer to the *AN 283: Simulating Altera Devices with IBIS Models* or to the Quartus II Help.

Design Simulation Using the Mentor Graphics HyperLynx Software

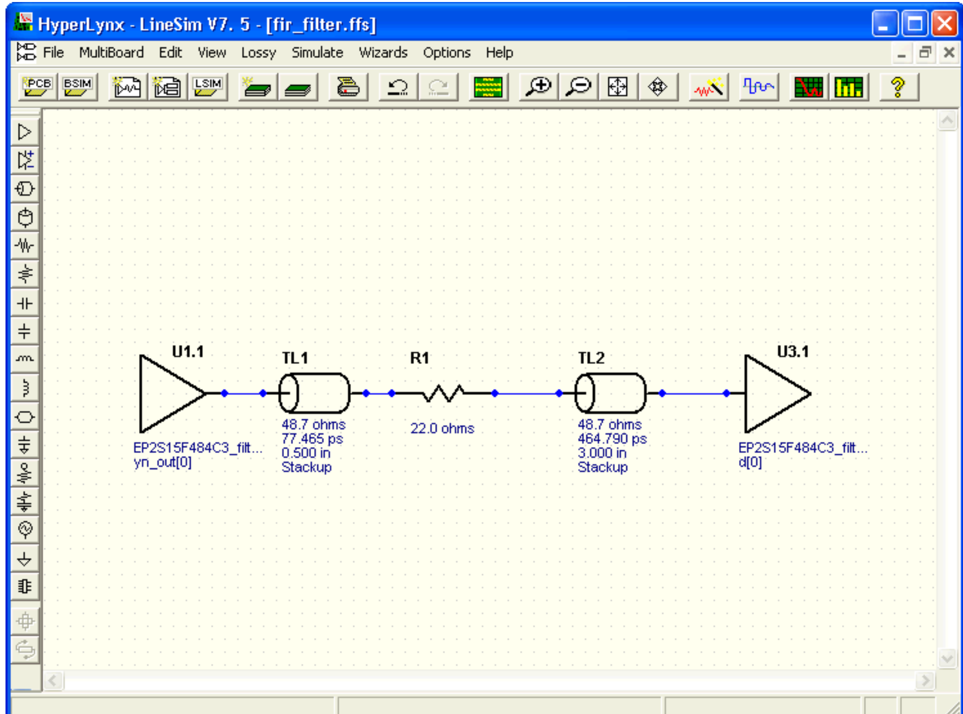
You must integrate IBIS models downloaded from the Altera website (www.altera.com) or created with the Quartus II IBIS Writer into board design simulations to accurately model timing and signal integrity. The HyperLynx software from Mentor Graphics is one of the most popular tools for design simulation. The HyperLynx software makes it easy to integrate IBIS models into simulations.

The HyperLynx software is a PCB analysis and simulation tool for high-speed designs, consisting of two products, LineSim and BoardSim. LineSim is an early simulation tool. Before any board routing takes place, LineSim is used to simulate "what if" scenarios to assist in creating routing rules and defining board parameters. BoardSim is a post-layout tool used to analyze existing board routing. Specific nets are selected from a board layout file and simulated in a manner similar to LineSim. With board and routing parameters, and surrounding signal routing known, highly accurate simulations of the final fabricated PCB are possible. This section focuses on LineSim. Because the process of creating and running simulations is very similar for both LineSim and BoardSim, the details of IBIS model use in LineSim applies to simulations in BoardSim.

Simulations in LineSim are configured using a schematic GUI to create connections and topologies between I/O buffers, route trace segments, and termination components. LineSim provides two methods for creating routing schematics: cell-based and free-form. Cell-based schematics are based on fixed cells consisting of typical placements of buffers, trace impedances, and components. Parts of the grid-based cells are filled with the desired objects to create the topology. A topology in a cell-based schematic is limited by the available connections within and between the cells.

A more robust and expandable way to create a circuit schematic for simulation is to use the free-form schematic format in LineSim as shown in Figure 7–4. The free-form schematic format makes it easy to place parts into any configuration and edit them as required. This section describes the use of IBIS models with free-form schematics, but the process is nearly identical for cell-based schematics.

Figure 7–4. HyperLynx LineSim Free-Form Schematic Editor



When you use HyperLynx software to perform simulations, you typically perform the following steps:

1. Create a new LineSim free-form schematic document and set up the board stackup for your PCB using the Stackup Editor. In this editor, specify board layer properties including layer thickness, dielectric constant, and trace width.
2. Create a circuit schematic for the net you want to simulate. The schematic represents all the parts of the routed net including source and destination I/O buffers, termination components, transmission line segments, and representations of impedance discontinuities such as vias or connectors.
3. Assign IBIS models to the source and destination I/O buffers to represent their behavior during operation.
4. Attach probes from the digital oscilloscope that is built in to LineSim to points in the circuit that you want to monitor during simulation. Typically, at least one probe is attached to the pin of a destination I/O buffer. For differential signals, you can attach a differential probe to both the positive and negative pins at the destination.
5. Configure and run the simulation. You can simulate a rising or falling edge and test the circuit under different drive strength conditions.
6. Interpret the results and make adjustments. Based on the waveforms captured in the digital oscilloscope, you can adjust anything in the circuit schematic to correct any signal integrity issues, such as overshoot or ringing. If necessary, you can make I/O assignment changes in the Quartus II software, regenerate the IBIS file with the IBIS Writer, and apply the updated IBIS model to the buffers in your HyperLynx software schematic.
7. Repeat the simulations and circuit adjustments until you are satisfied with the results. When the operation of the net meets your design requirements, implement changes to your I/O assignments in the Quartus II software and/or adjust your board routing constraints, component values, and placement to match the simulation.

For more information about HyperLynx software, including schematic creation, simulation setup, model usage, product support, licensing, and training, refer to HyperLynx Help or the Mentor Graphics website at www.mentor.com.

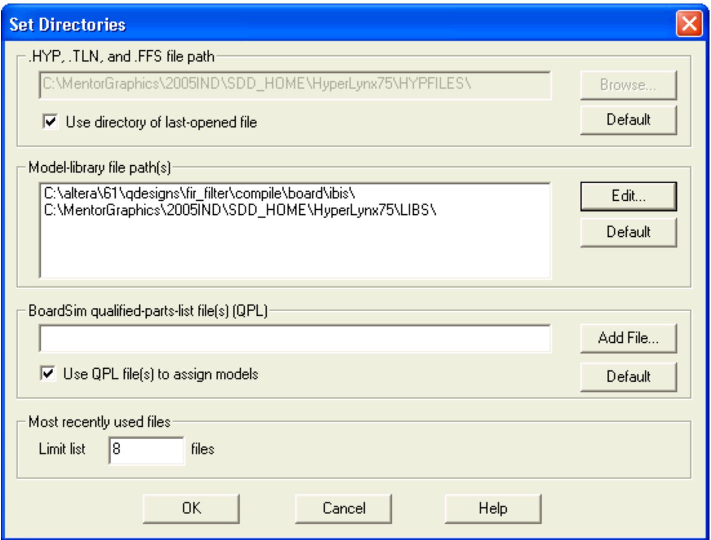
Configuring LineSim to Use Altera IBIS Models

You must configure LineSim to find and use the downloaded or generated IBIS models for your design. To do this, add the location of your **.ibs** file or files to the LineSim Model Library search path. Then you apply a selected model to a buffer in your schematic.

To add the Quartus II software's default IBIS model location, <*project directory*>**/board/ibis**, to the HyperLynx LineSim model library search path, perform the following steps in LineSim:

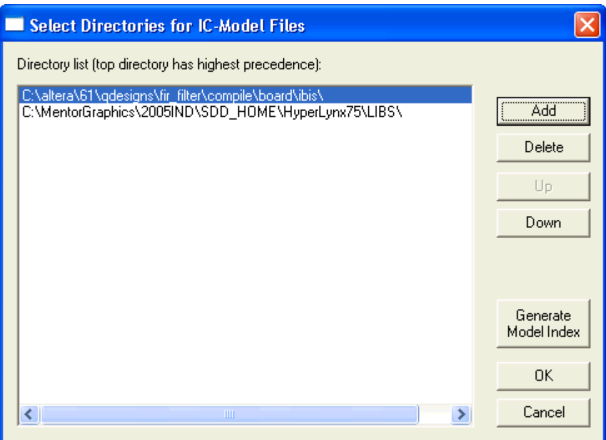
1. From the Options menu, click **Directories**. The **Set Directories** dialog box appears (Figure 7–5). The **Model-library file path(s)** list displays the order in which LineSim searches file directories for model files.

Figure 7–5. LineSim Set Directories Dialog Box



2. Click **Edit**. A dialog box appears where you can add directories and adjust the order in which LineSim searches them (Figure 7–6).

Figure 7–6. LineSim Select Directories Dialog Box



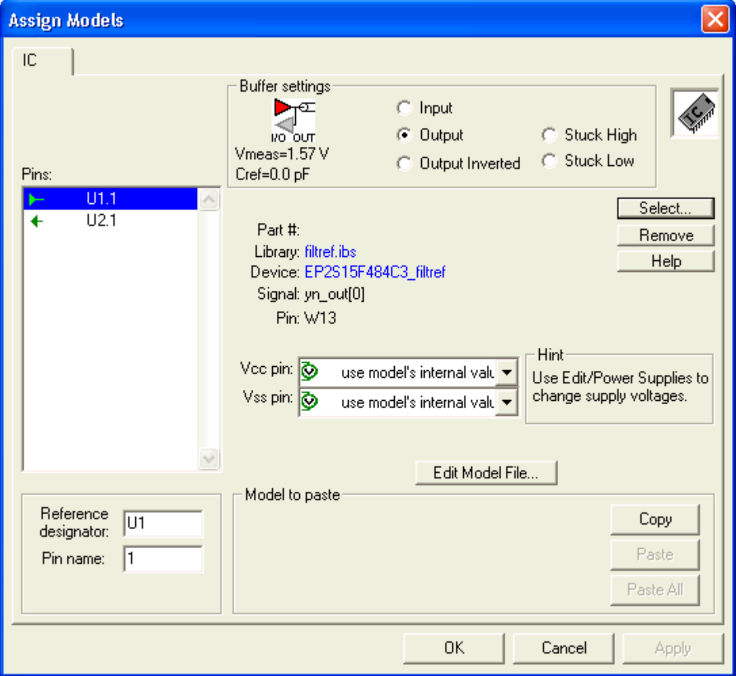
3. Click **Add**
4. Browse to the default IBIS model location, <*project directory*>**/board/ibis**. Click **OK**.
5. Click **Up** to move the IBIS model directory to the top of the list. Click **Generate Model Index** to update LineSim's model database with the models found in the added directory.
6. Click **OK**. The IBIS model directory for your project is added to the top of the Model-library file path(s) list.
7. To close the **Set Directories** dialog box, click **OK**.

Integrating Altera IBIS Models into LineSim Simulations

When the location for IBIS files has been set, you can assign the downloaded or generated IBIS models to the buffers in your schematic. To do this, perform the following steps:

1. Double-click a buffer symbol in your schematic to open the **Assign Models** dialog box (Figure 7–7). You can also click **Assign Models** from the buffer symbol's right-click menu.

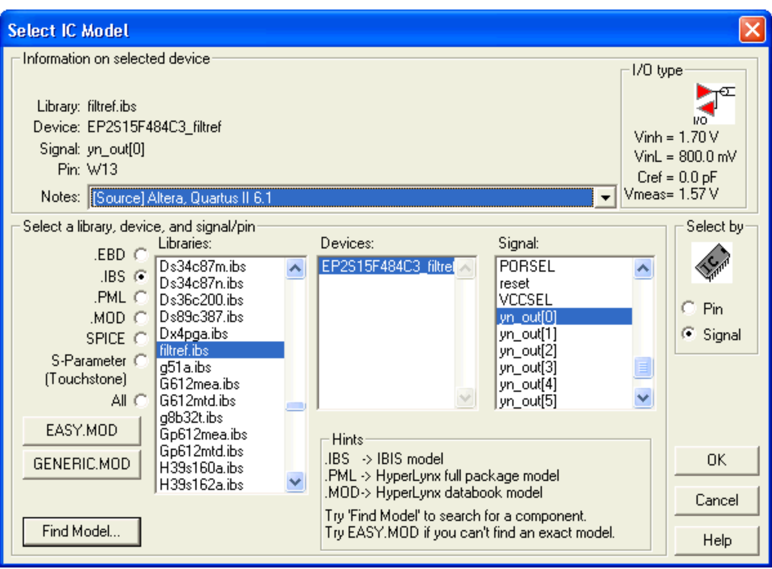
Figure 7–7. LineSim Assign Model Dialog Box



2. The pin of the buffer symbol you selected should be highlighted in the **Pins** list. If you want to assign a model to a different symbol or pin, select it from the list.

3. Click **Select**. The **Select IC Model** dialog box appears (Figure 7–8).

Figure 7–8. LineSim Select IC Model Dialog Box

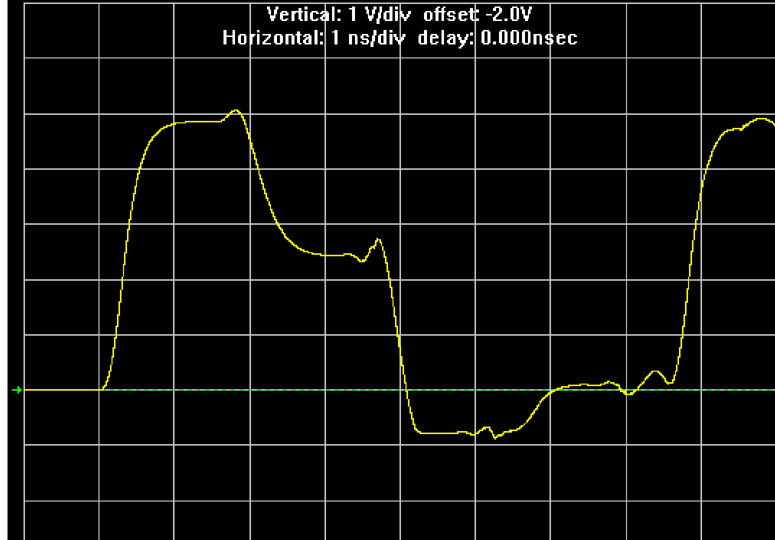


4. To filter the list of available libraries to display only IBIS models, select **.IBS**. Scroll through the **Libraries** list, and click the name of the library for your design. By default, this is <*project name*>**.ibs**.
5. The device for your design should be selected as the only item in the **Devices** list. If not, select your device from the list.
6. From the **Signal** list, select the name of the signal you want to simulate. You can also choose to select by device pin number.
7. Click **OK**. The **Assign Models** dialog box displays the selected **.ibs** file and signal.
8. If applicable to the signal you chose, adjust the buffer settings as required for the simulation.
9. Select and configure other buffer pins from the **Pins** list in the same manner.
10. Click **OK** when all I/O models are assigned.

Running and Interpreting LineSim Simulations

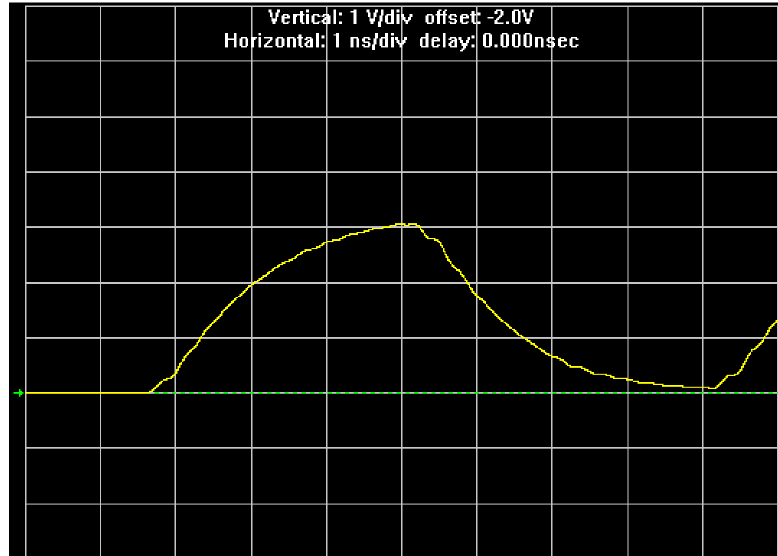
You can now run any desired simulations and make adjustments to the I/O assignments or simulation parameters as required. For example, if you see too much overshoot in the simulated signal at the destination buffer after running a simulation (as shown in Figure 7–9), you could adjust the drive strength I/O assignment setting to a lower value. Regenerate the **.ibs** file, and run the simulation again to verify whether the change fixed the problem.

Figure 7–9. Example of Overshoot in HyperLynx with IBIS Models



If you see a discontinuity or other anomalies at the destination, such as slow rise and fall times (as shown in Figure 7–10), adjust the termination scheme or termination component values. After making these changes, rerun the simulation to check whether your adjustments solved the problem. In this case, it is not necessary to regenerate the **.ibs** file.

Figure 7–10. Example of Signal Integrity Anomaly in HyperLynx with IBIS Models



For more information about board-level signal integrity and to learn about ways to improve it with simple changes to your design, visit the Altera Signal Integrity Center.

Simulation with HSPICE Models

HSPICE decks are used to perform highly accurate simulations by describing the physical properties of all aspects of a circuit precisely. HSPICE decks describe I/O buffers, board components, and all of the connections between them, as well as defining the parameters of the simulation to be run. By their nature, to be effective, HSPICE decks are highly customizable and require a detailed description of the circuit under simulation. For devices that support advanced I/O timing, when **Enable Advanced I/O Timing** is turned on, the HSPICE decks generated by the Quartus II HSPICE Writer automatically include board components and topology defined in the Board Trace Model. Configure the board components and topology in the Pin Planner or in the **Board Trace Model** tab of the **Device and Pin Options** dialog box. All HSPICE decks generated by the Quartus II software include compensation for the double count problem. For more information about the double count problem, refer to "The Double Counting Problem in HSPICE Simulations" on page 7–18. You can simulate with the default simulation parameters built in to the generated HSPICE decks or make adjustments to customize your simulation.

Supported Devices and Signaling

Beginning with Quartus II software version 6.1 and later, the HSPICE Writer supports the devices and signaling defined in Table 7–2. Only Stratix III, Stratix II, and Cyclone III devices support the creation of a board trace model in the Quartus II software for automatic inclusion in an HSPICE deck. Other devices require the board description to be manually added to the HSPICE file.

Table 7–2. HSPICE Writer Device and Signaling Support

Device	Input	Output	Single-Ended	Differential	Automatic Board Trace Model Description
Stratix III	✓	✓	✓	✓	✓
Stratix II GX (non-HSSI pins)	✓	✓	✓	✓	—
Stratix II	✓	✓	✓	✓	✓
HardCopy® II	✓	✓	✓	✓	—
Cyclone III	✓	✓	✓	✓	✓

If you are using a Stratix II device for your design, you can turn on **Enable Advanced I/O Timing** and configure the board trace model for each I/O standard used in your design. Newer families have this feature turned on by default and it cannot be turned off. The HSPICE files include the board trace description you create in the Board Trace Model view in the Pin Planner or the **Board Trace Model** tab in the **Device and Pin Options** dialog box.

For more information about the **Enable Advanced I/O Timing** option and configuring board trace models for the I/O standards in your design, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

Accessing HSPICE Simulation Kits

You can access the available HSPICE models at the SPICE Models for Altera Devices web page and also with the Quartus II software's HSPICE Writer tool. The Quartus II software HSPICE Writer tool removes many common sources of user error from the I/O simulation process. The HSPICE Writer tool automatically creates preconfigured I/O simulation spice decks that only require the addition of a user board model. All the difficult tasks required to configure the I/O modes and interpret the timing results are handled automatically by the HSPICE Writer tool.

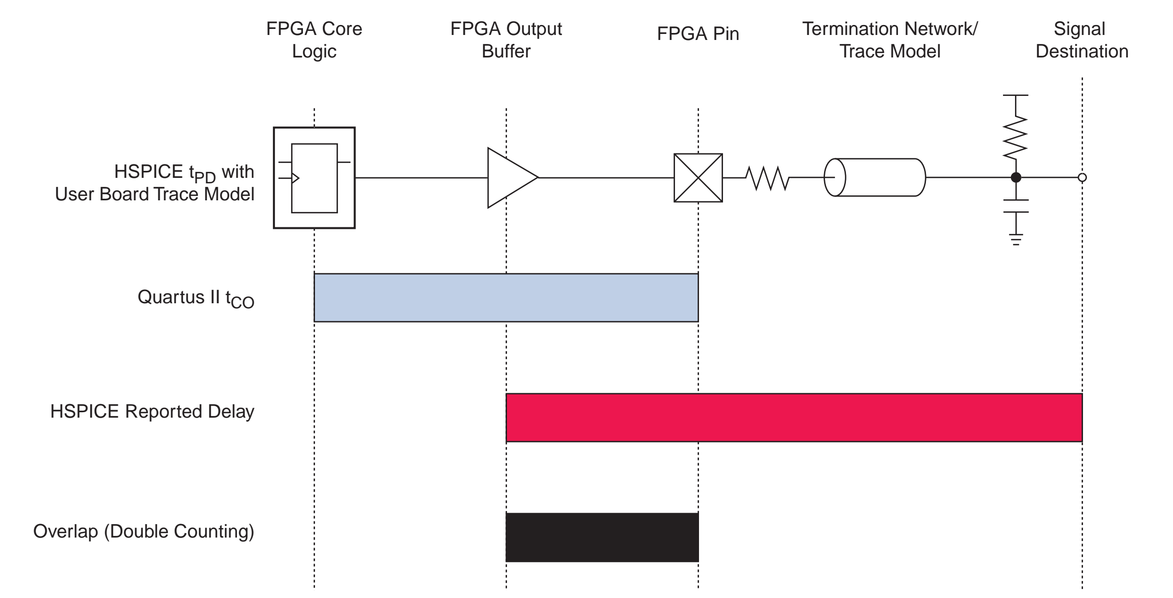
The Double Counting Problem in HSPICE Simulations

Simulating I/Os using accurate models is extremely helpful for finding and fixing FPGA I/O timing and board signal integrity issues before any boards are built. However, the usefulness of such simulations is directly related to the accuracy of the models used and whether the simulations are set up and performed correctly. To ensure accuracy in models and simulations created for FPGA output signals, the timing hand-off between t_{CO} timing in the Quartus II software and simulation-based board delay must be taken into account. If this hand-off is not handled correctly, the calculated delay could either count some of the delay twice or even miss counting some of the delay entirely.

Defining the Double Counting Problem

The double counting problem is inherent to the method output timing is analyzed versus the method used for HSPICE models. The timing analyzer tools in the Quartus II software measure delay timing for an output signal from the core logic of the FPGA design through the output buffer ending at the FPGA pin with a default capacitive load or a specified value for the selected I/O standard. This measurement is the t_{CO} timing variable as shown in Figure 7–11.

Figure 7–11. Double Counting Problem



HSPICE models for board simulation measure t_{PD} (propagation delay) from an arbitrary reference point in the output buffer, through the device pin, out along the board routing, and ending at the signal destination.

It is apparent immediately that if these two delays were simply added together, the delay between the output buffer and the device pin would be counted twice in the calculation. A model or simulation that does not account for this double count would create overly pessimistic simulation results, because the double-counted delay can limit I/O performance artificially. To fix the problem, it might seem that simply subtracting the overlap between t_{CO} and t_{PD} would account for the double count. However, this adjustment would not be accurate because each measurement is based on a different load.

Input signals do not exhibit this problem because the HSPICE models for inputs stop at the FPGA pin instead of at the input buffer. In this case, simply adding the delays together produces an accurate measurement of delay timing.

The Solution to Double Counting

To adjust the measurements to account for the double-counting, the delay between the arbitrary point in the output buffer selected by the HSPICE model and the FPGA pin must be subtracted from either t_{CO} or t_{PD} before adding the results together. The subtracted delay must also be based on a common load between the two measurements. This is done by repeating the HSPICE model measurement, but with the same load used by the Quartus II software for the t_{CO} measurement. This second measurement, called $t_{TESTLOAD}$, is illustrated with the top circuit in Figure 7–12.

Figure 7–12. Common Test Loads Used for Output Timing

FPGA Core Logic
FPGA Output Buffer
FPGA Pin
Quartus Test Load
Termination Network/ Trace Model
Signal Destination
HSPICE Netlist with Quartus Test Load
HSPICE Netlist with User Board Trace Model
Quartus II t_{CO}
HSPICE t_{PD} with User Specified Board Trace Model
Overlap (HSPICE Delay with Test Load)
HSPICE t_{PD} Adjusted by $t_{TESTLOAD}$
Total Delay

With $t_{TESTLOAD}$ known, the total delay for the output signal from the FPGA logic to the signal destination on the board, accounting for the double count, is calculated as shown in Equation 7–1.

Equation 7–1.

$$t_{delay} = t_{CO} + (t_{PD} - t_{TESTLOAD})$$

The preconfigured simulation files generated by the HSPICE Writer in the Quartus II software are designed to account for the double-counting problem based on this calculation automatically. Performing accurate timing simulations is easy without having to make adjustments for double counting manually.

HSPICE Writer Tool Flow

This section includes information to help you get started using the Quartus II software HSPICE Writer tool. The information in this section assumes you have a basic knowledge of the standard Quartus II software design flow, such as project and assignment creation, compilation, and timing analysis.

For additional information about standard design flows, refer to the appropriate sections of the *Quartus II Handbook*.

Applying I/O Assignments

The first step in the HSPICE Writer tool flow is to configure the I/O standards and modes for each of the pins in your design properly. In the Quartus II software, these settings are represented by assignments that map I/O settings, such as pin selection, and I/O standard and drive strength, to corresponding signals in your design.

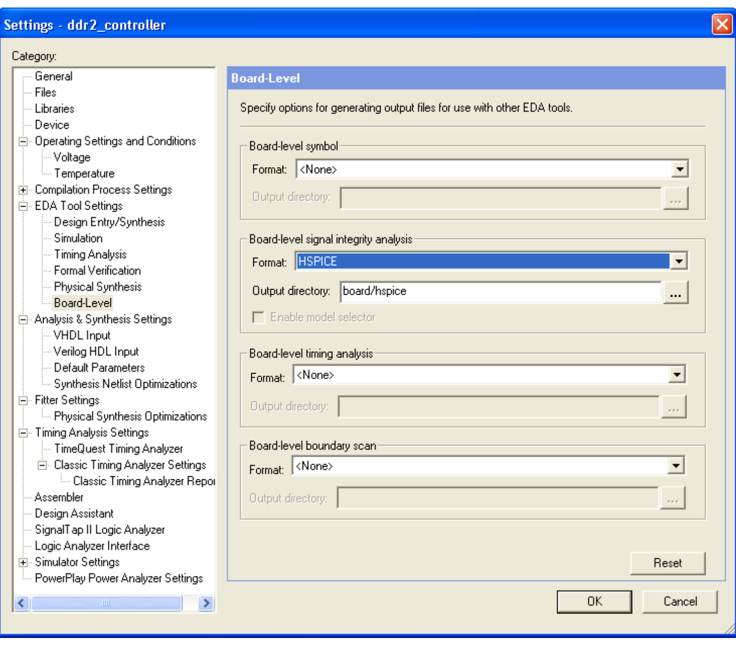
The Quartus II software provides multiple methods for creating these assignments:

- Using the Pin Planner
- Using the assignment editor
- Manually editing the **.qsf** file
- By making assignments in a scripted Quartus II flow using Tcl

Enabling HSPICE Writer

You must enable the HSPICE Writer in the **Settings** dialog box of the Quartus II software (Figure 7–13) to generate the HSPICE decks from the Quartus II software.

Figure 7–13. EDA Tool Settings: Board Level Options Dialog Box



Enabling HSPICE Writer Using Assignments

You can also use HSPICE Writer in conjunction with a scripted Tcl flow. To enable HSPICE Writer during a full compile, include the lines shown in Example 7–1 in your Tcl script.

Example 7–1. Enable HSPICE Writer

```
set_global_assignment -name EDA_BOARD_DESIGN_SIGNAL_INTEGRITY_TOOL \
"HSPICE (Signal Integrity)"

set_global_assignment -name EDA_OUTPUT_DATA_FORMAT HSPICE \
-section_id eda_board_design_signal_integrity

set_global_assignment -name EDA_NETLIST_WRITER_OUTPUT_DIR <output_directory> \
-section_id eda_board_design_signal_integrity
```

As with command-line invocation, specifying the output directory is optional. If not specified, the output directory defaults to **board/hspice**.

Naming Conventions for HSPICE Files

HSPICE Writer automatically generates simulation files and names them using the following naming convention:

*<device>_<pin #>_<pin_name>_<in/out>***.sp**

For bidirectional pins, two spice decks are produced; one with the I/O buffer configured as an input, and the other with the I/O buffer configured as an output.

The Quartus II software supports alphanumeric pin names that contain the underscore (_) and dash (-) characters. Any illegal characters used in file names are converted automatically to underscores.

The contents of the HSPICE files are described in detail in "Sample Output for I/O HSPICE Simulation Deck" on page 7–32 and "Sample Input for I/O HSPICE Simulation Deck" on page 7–28.

Invoking HSPICE Writer

After HSPICE Writer is enabled, the HSPICE simulation files are generated automatically each time the project is completely compiled. The Quartus II software also provides an option to generate a new set of simulation files without having to recompile manually. In the Processing menu, click **Start EDA Netlist Writer** to generate new simulation files automatically.

You must perform both Analysis & Synthesis and Fitting on a design before invoking the HSPICE Writer tool.

Invoking HSPICE Writer from the Command Line

If you use a script-based flow to compile your project, you can create HSPICE model files by including the commands shown in Example 7–2 in your Tcl script (**.tcl** file).

Example 7–2. Create HSPICE Model Files

```
set_global_assignment -name EDA_BOARD_DESIGN_SIGNAL_INTEGRITY_TOOL \
"HSPICE (Signal Integrity)"

set_global_assignment -name EDA_OUTPUT_DATA_FORMAT HSPICE \
-section_ideda_board_design_signal_integrity

set_global_assignment -name EDA_NETLIST_WRITER_OUTPUT_DIR <output_directory> \
-section_id eda_board_design_signal_integrity
```

The <*output_directory*> option specifies the location where HSPICE model files are saved. By default, the <*project directory*>**/board/hspice** directory is used.

To invoke the HSPICE Writer tool through the command line, type the syntax shown in Example 7–3.

Example 7–3. Invoke HSPICE Writer

```
quartus_eda.exe <project_name> --board_signal_integrity=on --format=HSPICE \
--output_directory=<output_directory>
```

<*output_directory*> specifies the location where the generated spice decks will be written (relative to the design directory). This is an optional parameter and defaults to **board/hspice**.

Customizing Automatically Generated HSPICE Decks

HSPICE models generated by the HSPICE Writer can be used for simulation as generated. A default board description is included, and a default simulation is set up to measure rise and fall delays for both input and output simulations, which compensates for the double counting problem. However, Altera recommends that you customize the board description to more accurately represent your routing and termination scheme.

The sample board trace loading in the generated HSPICE model files must be replaced by your actual trace model before you can run a correct simulation. To do this, open the generated HSPICE model files for all pins you want to simulate and locate the section shown in Example 7–4.

Example 7–4. Sample Board Trace Section

```
* I/O Board Trace and Termination Description
* - Replace this with your board trace and termination description
```

You must replace the example load with a load that matches the design of your PCB board. This includes a trace model, termination resistors, and, for output simulations, a receiver model. The spice circuit node that represents the pin of the FPGA package is called **pin**. The node that represents the far pin of the external device is called **load-in** (for output SPICE decks) and **source-in** (for input SPICE decks).

For an input simulation, you must also modify the stimulus portion of the spice file. The section of the file that must be modified is indicated in the comment block shown in Example 7–5.

Example 7–5. Sample Source Stimulus Section

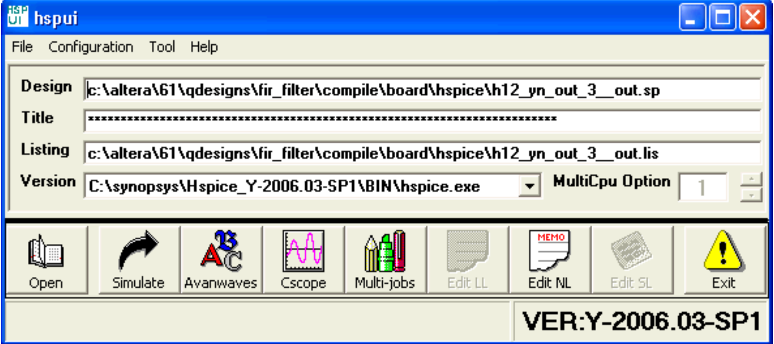
```
* Sample source stimulus placeholder
*  - Replace this with your I/O driver model
```

Replace the sample stimulus model with a model for the device that will drive the FPGA.

Running an HSPICE Simulation

Because simulation parameters are configured directly in the HSPICE model files, running a simulation requires only that you open an HSPICE file in the HSPICE user interface and start the simulation. The HSPICE user interface window is shown in Figure 7–14.

Figure 7–14. HSPICE User Interface Window



Click **Open** and browse to the location of the HSPICE model files generated by the Quartus II HSPICE Writer. The default location for HSPICE model files is <*project directory*>**/board/hspice**. Select the **.sp** file generated by the HSPICE Writer for the signal you want to simulate. Click **OK**.

To run the simulation, click **Simulate**. The status of the simulation is displayed in the window and saved in an **.lis** file with the same name as the **.sp** file when the simulation is complete. Check the **.lis** file if an error occurs during the simulation requiring a change in the **.sp** file to fix.

Interpreting the Results of an Output Simulation

By default, the automatically generated output simulation spice decks are set up to measure three delays for both rising and falling transitions. Two of the measurements, **tpd_rise** and **tpd_fall**, measure the double-counting corrected delay from the FPGA pin to the load pin. To determine the complete clock-edge to load-pin delay, add these numbers to the Quartus II software reported default loading t_{CO} delay.

The remaining four measurements, **tpd_uncomp_rise**, **tpd_uncomp_fall**, **t_dblcnt_rise**, and **t_dblcnt_fall**, are required for the double-counting compensation process and are not required for further timing usage. Refer to "Simulation Analysis" on page 7–32 for a description of these measurements.

Interpreting the Results of an Input Simulation

By default, the automatically generated input simulation SPICE decks are set up to measure delays from the source's driver pin to the FPGA's input pin for both rising and falling transitions. The propagation delay is reported by HSPICE measure statements as `tpd_rise` and `tpd_fall`. To determine the complete source driver pin-to-FPGA register delay, add these numbers to the Quartus II software reported T_H and T_{SU} input timing numbers.

Viewing and Interpreting Tabular Simulation Results

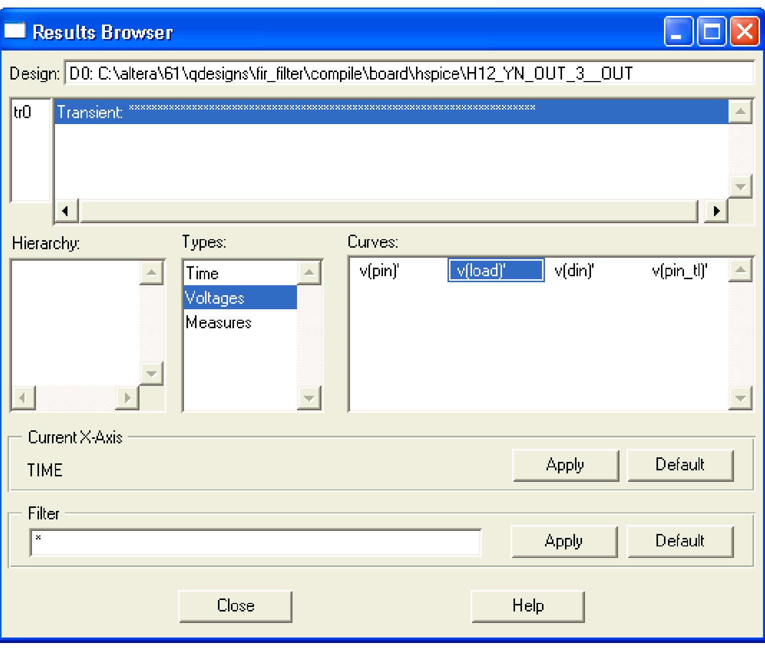
The **.lis** file stores the collected simulation data in tabular form. The default simulation configured by the HSPICE Writer produces delay measurements for rising and falling transitions on both input and output simulations. These measurements are found in the **.lis** file and named `tpd_rise` and `tpd_fall`. For output simulations, these values are already adjusted for the double count. To determine the complete delay from the FPGA logic to the load pin, add either of these measurements to the Quartus II t_{CO} delay. For input simulations, add either of these measurements to the Quartus II t_{SU} and t_H delay values to calculate the complete delay from the far end stimulus to the FPGA logic. Other values found in the **.lis** file, such as `tpd_uncomp_rise`, `tpd_uncomp_fall`, `t_dblcnt_rise`, and `t_dblcnt_fall`, are parts of the double count compensation calculation. These values are not necessary for further analysis.

Viewing Graphical Simulation Results

You can view the results of the simulation quickly as a graphical waveform display using the AvanWaves viewer included with HSPICE. With the default simulation configured by the HSPICE Writer, you can view the simulated waveforms at both the source and destination in input and output simulations.

To see the waveforms for the simulation, in the HSPICE user interface window, click **AvanWaves**. The AvanWaves viewer opens and displays the **Results Browser** as shown in Figure 7–15.

Figure 7–15. HSPICE AvanWaves Results Browser



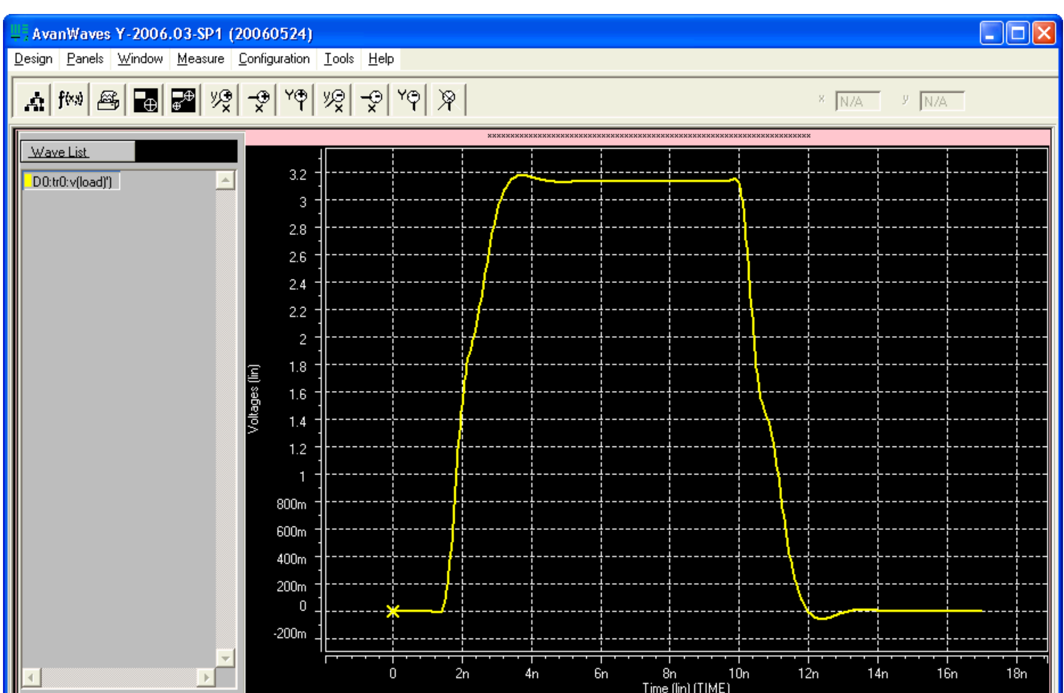
The **Results Browser** lets you select which waveform to view quickly in the main viewing window. If multiple simulations are run on the same signal, the list at the top of the **Results Browser** displays the results of each simulation. Click the simulation description to select which simulation to view. By default, the descriptions are derived from the first line of the HSPICE file, so the description might appear as a line of asterisks.

Select the type of waveform to view, by performing the following steps:

1. To see the source and destination waveforms with the default simulation, from the **Types** list, select **Voltages**.
2. On the **Curves** list, double-click the waveform you want to view. The waveform appears in the main viewing window.

You can zoom in and out and adjust the view as desired (Figure 7–16).

Figure 7–16. AvanWaves Waveform Viewer

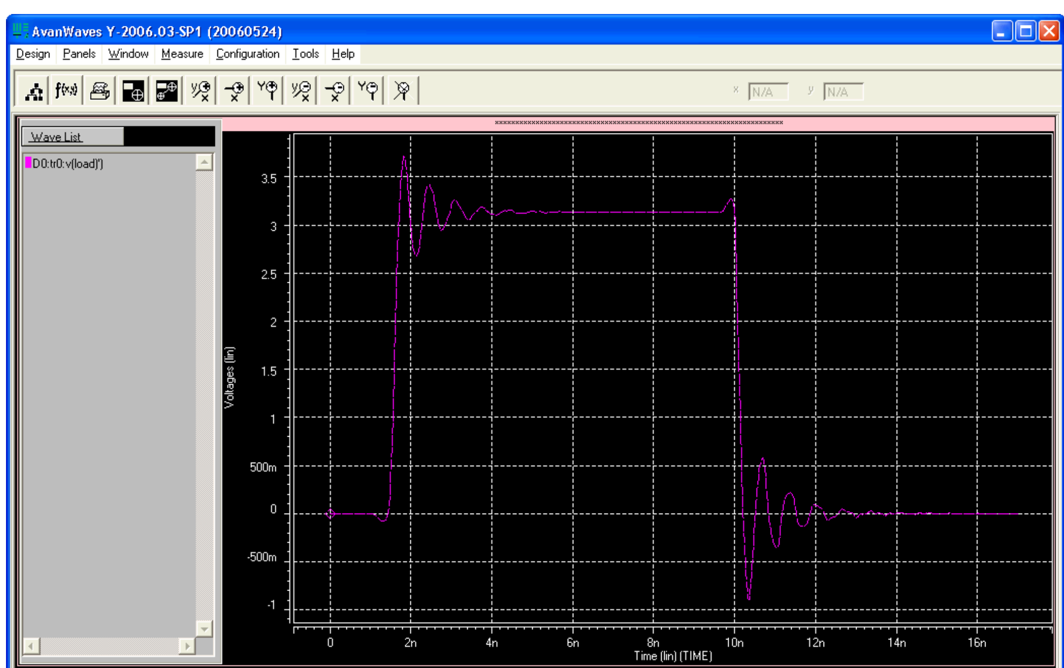


Making Design Adjustments Based on HSPICE Simulations

Based on the results of your simulations, you can make adjustments to the I/O assignments or simulation parameters if required. For example, after you run a simulation and see overshoot or ringing in the simulated signal at the destination buffer as shown in the example in Figure 7–17, you can adjust the drive strength I/O assignment setting to a lower value. Regenerate the HSPICE deck, and run the simulation again to verify that the change fixed the problem.

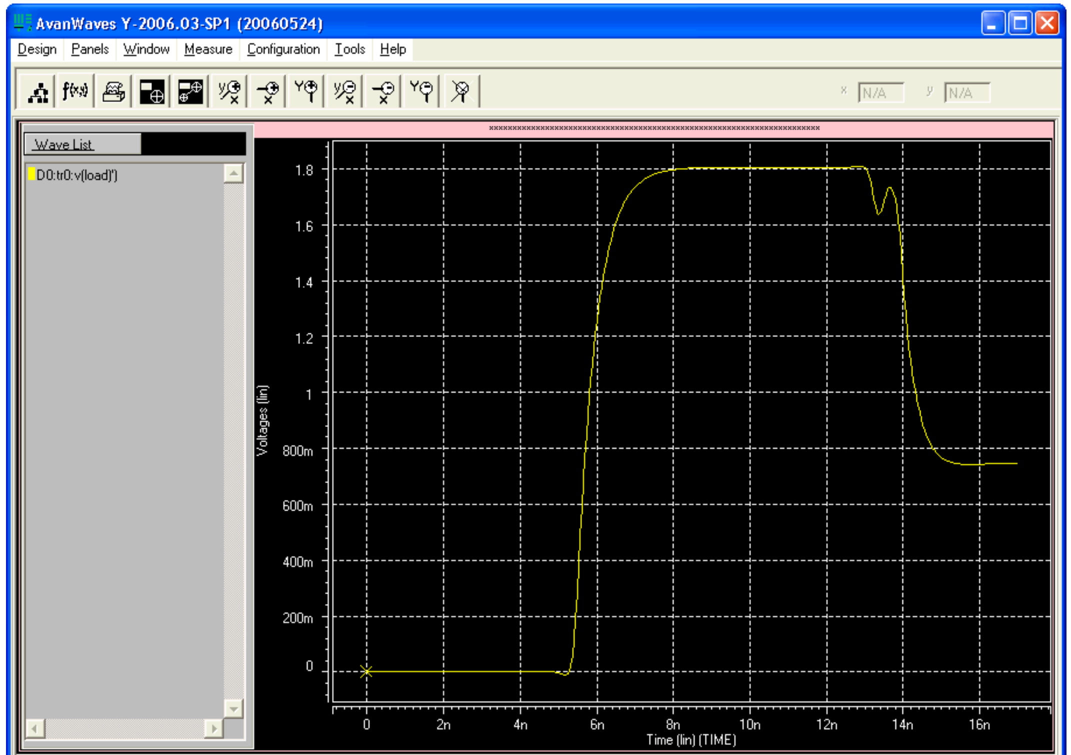
© March 2009 Altera Corporation

Figure 7–17. Example of Overshoot in the AvanWaves Waveform Viewer



If there is a discontinuity or any other anomalies at the destination as shown in the example in Figure 7–18, adjust the board description in the Quartus II Board Trace Model (for Stratix II, Stratix III, or Cyclone III devices) or in the generated HSPICE model files to change the termination scheme or adjust termination component values. After making these changes, regenerate the HSPICE files if necessary, and rerun the simulation to verify whether your adjustments solved the problem.

Figure 7–18. Example of Signal Integrity Anomaly in the AvanWaves Waveform Viewer



For more information about board-level signal integrity and to learn about ways to improve it with simple changes to your FPGA design, refer to the Altera Signal Integrity Center.

Sample Input for I/O HSPICE Simulation Deck

The following sections examine a typical HSPICE simulation spice deck for an I/O of type input. Each section presents the simulation file one block at a time.

Header Comment

The first block of an input simulation spice deck is the header comment. The purpose of this block is to provide an easily readable summary of how the simulation file has been automatically configured by the Quartus II software.

This block has two main components: The first component summarizes the I/O configuration relevant information such as device, speed grade, and so on. The second component specifies the exact test condition that the Quartus II software assumes for the given I/O standard. Example 7–6 shows a header comment block.

Example 7–6. Header Comment Block

```
* Quartus II HSPICE Writer I/O Simulation Deck*

* This spice simulation deck was automatically generated by
* Quartus for the following IO settings:
*
*  Device:       EP2S60F1020C3
*  Speed Grade:  C3
*  Pin:          AA4 (out96)
*  Bank:         IO Bank 6 (Row I/O)
*  I/O Standard: LVTTL, 12mA
*  OCT:          Off
*
* Quartus II's default I/O timing delays assume the following slow
* corner simulation conditions.
*
*  Specified Test Conditions For Quartus II Tco
*    Temperature:      85C (Slowest Temperature Corner)
*    Transistor Model: TT (Typical Transistor Corner)
*    Vccn:             3.135V (Vccn_min = Nominal - 5%)
*    Vccpd:            2.97V (Vccpd_min = Nominal - 10%)
*    Load:             No Load
*    Vtt:              1.5675V (Voltage reference is Vccn/2)
*
* Note: The I/O transistors are specified to operate at least as
*       fast as the TT transistor corner, actual production
*       devices can be as fast as the FF corner. Any simulations
*       for hold times should be conducted using the fast process
*       corner with the following simulation conditions.
*        Temperature:     0C (Fastest Commercial Temperature Corner **)
*        Transistor Model: FF (Fastest Transistor Corner)
*        Vccn:             1.98V (Vccn_hold = Nominal + 10%)
*        Vccpd:            3.63V (Vccpd_hold = Nominal + 10%)
*        Vtt:              0.95V (Vtt_hold = Vccn/2 - 40mV)
*        Vcc:              1.25V (Vcc_hold = Maximum Recommended)
*        Package Model:   Short-circuit from pad to pin (no parasitics)
*
* Warnings:
```

Simulation Conditions

The simulation conditions block loads the appropriate process corner models for the transistors. This condition is automatically set up for the slow timing corner and is modified only if other simulation corners are desired. Example 7–7 shows a simulation conditions block.

Example 7–7. Simulation Conditions Block

```
* Process Settings

.options brief
.inc 'sii_tt.inc' * TT process corner
```

Simulation Options

The simulation options block configures the simulation temperature and configures HSPICE with typical simulation options. Example 7–8 shows a simulation options block.

For a detailed description of these options, consult your *HSPICE* manual.

Example 7–8. Simulation Options Block

```
* Simulation Options

.options brief=0
.options badchr co=132 scale=1e-6 acct ingold=2 nomod dv=1.0
+        dcstep=1 absv=1e-3 absi=1e-8 probe csdf=2 accurate=1
+        converge=1
.temp 85
```

Constant Definition

The constant definition block of the simulation file instantiates the voltage sources that controls the configuration modes of the I/O buffer. Example 7–9 shows a constant definition block.

Example 7–9. Constant Definition Block

```
* Constant Definition

voeb       oeb       0     vc  * Set to 0 to enable buffer output
vopdrain   opdrain   0     0   * Set to vc to enable open drain
vrambh     rambh     0     0   * Set to vc to enable bus hold
vrpullup   rpullup   0     0   * Set to vc to enable weak pullup
vpcdp5     rpcdp5    0     rp5 * Set the IO standard
vpcdp4     rpcdp4    0     rp4
vpcdp3     rpcdp3    0     rp3
vpcdp2     rpcdp2    0     rp2
vpcdp1     rpcdp1    0     rp1
vpcdp0     rpcdp0    0     rp0
vpcdn4     rpcdn4    0     rn4
vpcdn3     rpcdn3    0     rn3
vpcdn2     rpcdn2    0     rn2
vpcdn1     rpcdn1    0     rn1
vpcdn0     rpcdn0    0     rn0
vdin din       0     0
```

Where:

- Voltage source `voeb` controls the output enable of the buffer and is set to *disabled* for inputs.
- `vopdrain` controls the open drain mode for the I/O.
- `vrambh` controls the bus hold circuitry in the I/O.
- `vrpullup` controls the weak pullup.
- The next 11 voltages sources control the I/O standard of the buffer and are configured through a later library call.
- `vdin` is not used on input pins because it is the data pin for the output buffer.

Buffer Netlist

The buffer netlist block (Example 7–10) of the simulation spice deck loads all the load models required for the corresponding input pin.

Example 7–10. Buffer Netlist Block

```
* IO Buffer Netlist

.include 'vio_buffer.inc'
```

Drive Strength

The drive strength block (Example 7–11) of the simulation SPICE deck loads the configuration bits necessary to configure the I/O into the proper I/O standard and drive strengths. Although these settings are not relevant to an input buffer, they are provided to allow the SPICE deck to be modifiable to support bidirectional simulations.

Example 7–11. Drive Strength Block

```
* Drive Strength Settings

.lib 'drive_select_hio.lib' 3p3ttl_12ma
```

I/O Buffer Instantiation

The I/O buffer instantiation block of the simulation SPICE deck instantiates the necessary power supplies and I/O model components that are necessary to simulate the given I/O.

Example 7–12 shows I/O buffer instantiation.

Example 7–12. I/O Buffer Instantiation

```
I/O Buffer Instantiation

* Supply Voltages Settings
.param vcn=3.135
.param vpd=2.97
.param vc=1.15

* Instantiate Power Supplies|
vvcc       vcc      0     vc     * FPGA core voltage

+ rpcdp5 rpcdp4 rpcdp3 rpcdp2 rpcdp1 rpcdp0
+ rpullup vccn vccpd vcpad0 vio_buf

* Internal Loading on Pad
* - No loading on this pad due to differential buffer/support
*   circuitry

* I/O Buffer Package Model
* - Single-ended I/O standard on a Row I/O
.lib 'lib/package.lib' hio
xpkg die pin hio_pkg
```

Board Trace and Termination

The board trace and termination block of the simulation SPICE deck is provided only as an example (shown in Example 7–13). Replace this block with your own board trace and termination models.

Example 7–13. Board Trace and Termination Block

```
* I/O Board Trace and Termination Description
* - Replace this with your board trace and termination description

wtline pin vssn load vssn N=1 L=1 RLGCMODEL=tlinemodel
.MODEL tlinemodel W MODELTYPE=RLGC N=1 Lo=7.13n Co=2.85p
Rterm2 load vssn 1x
```

Stimulus Model

The stimulus model block of the simulation spice deck is provided only as a place holder example (shown in Example 7–14). Replace this block with your own stimulus model. Options for this include an IBIS or HSPICE model, among others.

Example 7–14. Stimulus Model Block

```
* Sample source stimulus placeholder
* - Replace this with your I/O driver model

Vsource source 0 pulse(0 vcn 0s 0.4ns 0.4ns 8.5ns 17.4ns)
```

Simulation Analysis

The simulation analysis block (Example 7–15) of the simulation file is configured to measure the propagation delay from the source to the FPGA pin. Both the source and end point of the delay are referenced against the 50% V_{CCN} crossing point of the waveform.

Example 7–15. Simulation Analysis Block

```
* Simulation Analysis Setup

* Print out the voltage waveform at both the source and the pin
.print tran v(source)  v(pin)
.tran 0.020ns 17ns

* Measure the propagation delay from the source pin to the pin
* referenced against the 50% voltage threshold crossing point

.measure TRAN tpd_rise TRIG v(source) val='vcn*0.5' rise=1
+ TARG v(pin) val ='vcn*0.5' rise=1
.measure TRAN tpd_fall TRIG v(source) val='vcn*0.5' fall=1
+ TARG v(pin) val ='vcn*0.5' fall=1
```

Sample Output for I/O HSPICE Simulation Deck

The following sections examine a typical HSPICE simulation SPICE deck for an I/O-type output. Each section presents the simulation file one block at a time.

Header Comment

The first block of an output simulation SPICE deck is the header comment, as shown in Example 7–16. The purpose of this block is to provide a readable summary of how the simulation file has been automatically configured by the Quartus II software.

This block has two main components:

- The first component summarizes the I/O configuration relevant information such as device, speed grade, and so on.
- The second component specifies the exact test condition that the Quartus II software assumes when generating t_{CO} delay numbers. This information is used as part of the double-counting correction circuitry contained in the simulation file.

The SPICE decks are preconfigured to calculate the slow process corner delay but can also be used to simulate the fast process corner as well. The fast corner conditions are listed in the header under the notes section.

The final section of the header comment lists any warning messages that you must consider when you use the SPICE decks.

Example 7–16. Header Comment Block

```
* Quartus II HSPICE Writer I/O Simulation Deck
*
* This spice simulation deck was automatically generated by
* Quartus II for the following IO settings:
*
*  Device:       EP2S60F1020C3
*  Speed Grade:  C3
*  Pin:          AA4 (out96)
*  Bank:         IO Bank 6 (Row I/O)
*   I/O Standard: LVTTL, 12mA
*  OCT:          Off
*
* Quartus' default I/O timing delays assume the following slow
* corner simulation conditions.
*  Specified Test Conditions For Quartus II Tco
*    Temperature:      85C (Slowest Temperature Corner)
*    Transistor Model: TT (Typical Transistor Corner)
*    Vccn:             3.135V (Vccn_min = Nominal - 5%)
*    Vccpd:            2.97V (Vccpd_min = Nominal - 10%)
*    Load:             No Load
*    Vtt:              1.5675V (Voltage reference is Vccn/2)
* For C3 devices, the TT transistor corner provides an
* approximation for worst case timing. However, for functionality
* simulations, it is recommended that the SS corner be simulated
* as well.
*
* Note: The I/O transistors are specified to operate at least as
*       fast as the TT transistor corner, actual production
*       devices can be as fast as the FF corner. Any simulations
*       for hold times should be conducted using the fast process
*       corner with the following simulation conditions.
*         Temperature:      0C (Fastest Commercial Temperature Corner
**)
*         Transistor Model: FF (Fastest Transistor Corner)
*         Vccn:             1.98V (Vccn_hold = Nominal + 10%)
*         Vccpd:            3.63V (Vccpd_hold = Nominal + 10%)
*         Vtt:              0.95V (Vtt_hold = Vccn/2 - 40mV)
*         Vcc:              1.25V (Vcc_hold = Maximum Recommended)
*         Package Model:    Short-circuit from pad to pin
* Warnings:
```

Simulation Conditions

The simulation conditions block (Example 7–17) loads the appropriate process corner models for the transistors. This condition is automatically set up for the slow timing corner and must be modified only if other simulation corners are desired.

Two separate corners cannot be simulated at the same time. Instead, simulate the base case using the Quartus corner as one simulation and then perform a second simulation using the desired customer corner. The results of the two simulations can be manually added together.

 © March 2009 Altera Corporation

Example 7–17. Simulation Conditions Block

```
* Process Settings

.options brief
.inc ‘sii_tt.inc’ * typical-typical process corner
```

Simulation Options

The simulation options block (Example 7–18) configures the simulation temperature and configures HSPICE with typical simulation options.

For a detailed description of these options, consult your *HSPICE* manual.

Example 7–18. Simulation Options Block

```
* Simulation Options
.options brief=0
.options badchr co=132 scale=1e-6 acct ingold=2 nomod dv=1.0
+        dcstep=1 absv=1e-3 absi=1e-8 probe csdf=2 accurate=1
+        converge=1
.temp 85
```

Constraint Definition

The constant definition block (Example 7–19) of the output simulation SPICE deck instantiates the voltage sources that controls the configuration modes of the I/O buffer.

Example 7–19. Constant Definition Block

```
* Constant Definition

voeb        oeb       0     0 * Set to 0 to enable buffer output
vopdrain    opdrain   0     0 * Set to vc to enable open drain
vrambh      rambh     0     0 * Set to vc to enable bus hold
vrpullup    rpullup   0     0 * Set to vc to enable weak pullup
vpci        rpci      0     0 * Set to vc to enable pci mode
vpcdp4      rpcdp4    0     rp4  * These control bits set the IO standard
vpcdp3      rpcdp3    0     rp3
vpcdp2      rpcdp2    0     rp2
vpcdp1      rpcdp1    0     rp1
vpcdp0      rpcdp0    0     rp0
vpcdn4      rpcdn4    0     rn4
vpcdn3      rpcdn3    0     rn3
vpcdn2      rpcdn2    0     rn2
vpcdn1      rpcdn1    0     rn1
vpcdn0      rpcdn0    0     rn0
vdin        din       0     pulse(0 vc 0s 0.2ns 0.2ns 8.5ns 17.4ns)
```

Where:

- Voltage source `voeb` controls the output enable of the buffer.
- `vopdrain` controls the open drain mode for the I/O.
- `vrambh` controls the bus hold circuitry in the I/O.
- `vrpullup` controls the weak pullup.
- `vpci` controls the PCI clamp.
- The next ten voltage sources control the I/O standard of the buffer and are configured through a later library call. Stratix III and Cyclone III devices have more bits and so might have more voltage sources listed in the constant definition block. They also have slew rate and delay chain settings.
- `vdin` is connected to the data input of the I/O buffer.
- The edge rate of the input stimulus is automatically set to the correct value by the Quartus II software.

I/O Buffer Netlist

The I/O buffer netlist block (Example 7–20) loads all of the models required for the corresponding pin. These include a model for the I/O output buffer, as well as any loads that might be present on the pin.

Example 7–20. I/O Buffer Netlist Block

```
*IO Buffer Netlist

.include 'hio_buffer.inc'
.include 'lvds_input_load.inc'
.include 'lvds_oct_load.inc'
```

Drive Strength

The drive strength block (Example 7–21) of the simulation spice deck loads the configuration bits for configuring the I/O to the proper I/O standard and drive strength. These options are set by the HSPICE Writer tool and are not changed for expected use.

Example 7–21. Drive Strength Block

```
* Drive Strength Settings

.lib 'drive_select_hio.lib' 3p3ttl_12ma
```

Slew Rate and Delay Chain

Stratix III and Cyclone III devices have sections for configuring the slew rate and delay chain settings (Example 7–22).

Example 7–22. Slew Rate and Delay Chain Settings

```
* Programmable Output Delay Control Settings

.lib 'lib/output_delay_control.lib' no_delay

* Programmable Slew Rate Control Settings

.lib 'lib/slew_rate_control.lib' slow_slow
```

I/O Buffer Instantiation

The I/O buffer instantiation block (Example 7–23) of the output simulation spice deck instantiates the necessary power supplies and I/O model components that are necessary to simulate the given I/O.

Example 7–23. I/O Buffer Instantiation Block

```
* I/O Buffer Instantiation

* Supply Voltages Settings
.param vcn=3.135
.param vpd=2.97
.param vc=1.15

* Instantiate Power Supplies

* - This pad has an LVDS input buffer connected to it, along
*   with differential OCT circuitry. Both are disabled but
*   introduce loading on the pad that is modeled below.
xlvds_input_load die vss vccn lvds_input_load
xlvds_oct_load die vss vccpd vccn vcpad0 vccn lvds_oct_load

* I/O Buffer Package Model
* - Single-ended I/O standard on a Row I/O
.lib 'lib/package.lib' hio
xpkg die pin hio_pkg
```

Board and Trace Termination

The board trace and termination block (Example 7–24) of the simulation SPICE deck is provided only as an example. Replace this block with your specific board loading models.

Example 7–24. Board Trace and Termination Block

```
* I/O Board Trace And Termination Description
* - Replace this with your board trace and termination description

wtline pin vssn load vssn N=1 L=1 RLGCMODEL=tlinemodel
.MODEL tlinemodel W MODELTYPE=RLGC N=1 Lo=7.13n Co=2.85p
Rterm2 load vssn 1x
```

Double-Counting Compensation Circuitry

The double-counting compensation circuitry block (Example 7–25) of the simulation SPICE deck instantiates a second I/O buffer that is used to measure double-counting. The buffer is configured identically to the user I/O buffer but is connected to the Quartus II software test load. The simulated delay of this second buffer can be interpreted as the amount of double-counting between the Quartus II software and HSPICE Writer simulated results.

As the amount of double-counting is constant for a given I/O standard on a given pin, consider separating the double-counting circuitry from the simulation file. In doing so, you can perform any number of I/O simulations while referencing the delay only once. For more information about the double-counting problem, refer to "The Double Counting Problem in HSPICE Simulations" on page 7–18.

Example 7–25. Double-Counting Compensation Circuitry Block

```
* Double Counting Compensation Circuitry
*
* The following circuit is designed to calculate the amount of
* double counting between Quartus II and the HSPICE models. If
* you have not changed the default simulation temperature or
* transistor corner the double counting will be automatically
* compensated by this spice deck. In the event you wish to
* simulate an IO at a different temperature or transistor corner
* you will need to remove this section of code and manually
* account for double counting. A description of Altera's
* recommended procedure for this process can be found in the
* Quartus II HSPICE Writer AppNote.
*

* Supply Voltages Settings
.param vcn_tl=3.135
.param vpd_tl=2.97

* Test Load Constant Definition
vopdrain_tl   opdrain_tl   0     0
vrambh_tl     rambh_tl     0     0
vrpullup_tl   rpullup_tl   0     0

* Instantiate Power Supplies
vvccn_tl      vccn_tl      0     vcn_tl
vvssn_tl      vssn_tl      0     0
vvccpd_tl     vccpd_tl     0     vpd_tl

* Instantiate I/O Buffer
xhio_testload din oeb opdrain_tl die_tl rambh_tl
+ rpcdn4 rpcdn3 rpcdn2 rpcdn1 rpcdn0
+ rpcdp4 rpcdp3 rpcdp2 rpcdp1 rpcdp0
+ rpullup_tl vccn_tl vccpd_tl vcpad0_tl hio_buf

* Internal Loading on Pad
xlvds_input_testload die_tl vss vccn_tl lvds_input_load
xlvds_oct_testload die_tl vss vccpd_tl vccn_tl vcpad0_tl vccn_tl
lvds_oct_load

* I/O Buffer Package Model
* - Single-ended I/O standard on a Row I/O
.lib 'lib/package.lib' hio
xpkg die pin hio_pkg

* Default Altera Test Load
* - 3.3V LVTTL default test condition is an open load
```

Simulation Analysis

The simulation analysis block (Example 7–26) is set up to measure double-counting corrected delays. This is accomplished by measuring the uncompensated delay of the I/O buffer when connected to the user load, and when subtracting the simulated amount of double-counting from the test load I/O buffer.

Example 7–26. Simulation Analysis Block

```
*Simulation Analysis Setup

* Print out the voltage waveform at both the pin and far end load
.print tran v(pin) v(load)
.tran 0.020ns 17ns

* Measure the propagation delay to the load pin. This value will
* include some double counting with Quartus II's Tco
.measure TRAN tpd_uncomp_rise TRIG v(din) val='vc*0.5' rise=1
+ TARG v(load) val='vcn*0.5' rise=1
.measure TRAN tpd_uncomp_fall TRIG v(din) val='vc*0.5' fall=1
+ TARG v(load) val='vcn*0.5' fall=1

* The test load buffer can calculate the amount of double counting
.measure TRAN t_dblcnt_rise TRIG v(din) val='vc*0.5' rise=1
+ TARG v(pin_tl) val='vcn_tl*0.5' rise=1
.measure TRAN t_dblcnt_fall TRIG v(din) val='vc*0.5' fall=1
+ TARG v(pin_tl) val='vcn_tl*0.5' fall=1

* Calculate the true propagation delay by subtraction
.measure TRAN tpd_rise PARAM='tpd_uncomp_rise-t_dblcnt_rise'
.measure TRAN tpd_fall PARAM='tpd_uncomp_fall-t_dblcnt_fall'
```

Advanced Topics

The information in this section describes some of the more advanced topics and methods employed when setting up and running HSPICE simulation files.

PVT Simulations

The automatically generated HSPICE simulation files are set up to simulate the slow process corner using low voltage, high temperature, and slow transistors. To ensure a fully robust link, Altera recommends that you run simulations over all process corners.

To perform process, voltage, and temperature (PVT) simulations, manually modify the spice decks in a two step process:

1. Remove the double-counting compensation circuitry from the simulation file. This is required as the amount of double-counting is dependant upon how the Quartus II software calculates delays and is not based on which PVT corner is being simulated. By default, the Quartus II software provides timing numbers using the slow process corner.
2. Select the proper corner for the PVT simulation by setting the correct HSPICE temperature, changing the supply voltage sources, and loading the correct transistor models.

A more detailed description of HSPICE process corners can be found in the family-specific HSPICE model documentation. This document is available online with the HSPICE models as described in "Accessing HSPICE Simulation Kits" on page 7–18.

Hold Time Analysis

Altera recommends performing worst-case hold time analysis using the fast corner models, which use fast transistors, high voltage, and low temperature. This involves modifying the SPICE decks to select the correct temperature option, change the supply voltage sources, and load the correct fast transistor models. The values of these parameters are located in the header comment section of the corresponding simulation deck files.

For a truly worst-case analysis, combine the HSPICE Writer hold time analysis results with the Quartus II software fast timing model. This requires that you change the double-counting compensation circuitry in the simulations files to also simulate the fast process corners, as this is what the Quartus II software uses for the fast timing model.

This method of hold time analysis is recommended only for globally synchronous buses. Do not apply this method of hold-time analysis to source synchronous buses. This is because the source synchronous clocking scheme is designed to cancel out some of the PVT timing effects. If this is not taken into account, the timing results will not be accurate. Proper source synchronous timing analysis is beyond the scope of this document.

I/O Voltage Variations

Use each of the FPGA family datasheets to verify the recommended operating conditions for supply voltages. For current FPGA families, the maximum recommended voltage corresponds to the fast corner, while the minimum recommended voltage corresponds to the slow corner. These voltage recommendations are specified at the power pins of the FPGA and are not necessarily the same voltage that are seen by the I/O buffers due to package IR drops.

The automatically generated HSPICE simulation files model this IR effect pessimistically by including a 50-mV IR drop on the V_{CCPD} supply when a high drive strength standard is being used.

Correlation Report

Correlation reports for the HSPICE I/O models are located in the family-specific HSPICE I/O buffer simulation kits. Refer to "Accessing HSPICE Simulation Kits" on page 7–18 for additional information.

Conclusion

As FPGA devices are used in more high-speed applications, it becomes increasingly necessary to perform board-level signal integrity analysis simulations. You must run such simulations to ensure good signal integrity between the FPGA and any connected devices. The Quartus II software helps to simplify this process with the ability to automatically generate I/O buffer description models easily with the IBIS and HSPICE Writers. IBIS models can be integrated into a third-party signal integrity analysis workflow using a tool such as Mentor Graphics HyperLynx software,

generating quick and accurate simulation results. HSPICE decks include preconfigured simulations and only require descriptions of board routing and stimulus models to create highly accurate simulation results using Synopsys HSPICE. Either type of simulation helps prevent unnecessary board spins, increasing your productivity and decreasing your costs.

Document Revision History

Table 7–3 shows the revision history for this chapter.

Table 7–3. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Was volume 3, chapter 12 in the 8.1.0 release. ■ No change to content.	Updated for the Quartus II software version 9.0 release.
November 2008 v8.1.0	■ Changed to 8-1/2 x 11 page size. ■ Added information for Stratix III devices. ■ Input signals for Cyclone III devices are supported.	Updated for the Quartus II software version 8.1 release.
May 2008 v8.0.0	■ Updated "Introduction" on page 12–1. ■ Updated Figure 12–1. ■ Updated Figure 12–3. ■ Updated Figure 12–13. ■ Updated "Output File Generation" on page 12–6. ■ Updated "Simulation with HSPICE Models" on page 12–17. ■ Updated "Invoking HSPICE Writer from the Command Line" on page 12–22. ■ Added "Sample Input for I/O HSPICE Simulation Deck" on page 12–29. ■ Added "Sample Output for I/O HSPICE Simulation Deck" on page 12–33. ■ Updated "Correlation Report" on page 12–41. ■ Added hyperlinks to referenced documents and websites throughout the chapter. ■ Made minor editorial updates.	Updated for the Quartus II software version 8.0.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

8. Mentor Graphics PCB Design Tools Support

QII52015-9.0.0

Introduction

With today's large, high-pin-count and high-speed FPGA devices, good and correct printed circuit board (PCB) design practices are more essential than ever for ensuring correct system operation. Typically, the PCB design takes place concurrently with the design and programming of the FPGA. Signal and pin assignments are initially made by the FPGA or ASIC designer, and the board designer must correctly transfer these assignments to the symbols used in their system circuit schematics and board layout. As the board design progresses, pin reassignments may be needed to optimize the PCB layout. These reassignments must in turn be relayed back to the FPGA designer so that the new assignments can be processed through an updated placement and routing of the FPGA design.

Mentor Graphics® provides tools to support this type of design flow. This chapter discusses how the Quartus® II software interacts with the Mentor Graphics I/O Designer software and the DxDesigner software to provide a completely cyclical FPGA-to-board integration design workflow. This chapter covers the following topics:

- General design flow between the Quartus II software, the Mentor Graphics I/O Designer software, and the DxDesigner software
- Setting up the Quartus II software to create the design flow files
- Creating an I/O Designer database project to incorporate the Quartus II software signal and pin assignment data
- Updating signal and pin assignment changes between the I/O Designer software and the Quartus II software
- Generating symbols in the I/O Designer software
- Creating symbols in the DxDesigner software from the Quartus II software output files without the use of the I/O Designer software

This chapter is intended primarily for board design and layout engineers who want to start the FPGA board integration while the FPGA is still in the design phase. Optionally, the board designer can plan the FPGA pinout and routing requirements in the Mentor Graphics tools and pass the information back to the Quartus II software for place-and-route. In addition, part librarians benefit from learning how to take output from the Quartus II software and use it to create new library parts and symbols.

The procedures in this chapter require the following software:

- The Quartus II software version 5.1 or higher
- DxDesigner software version 2004 or higher

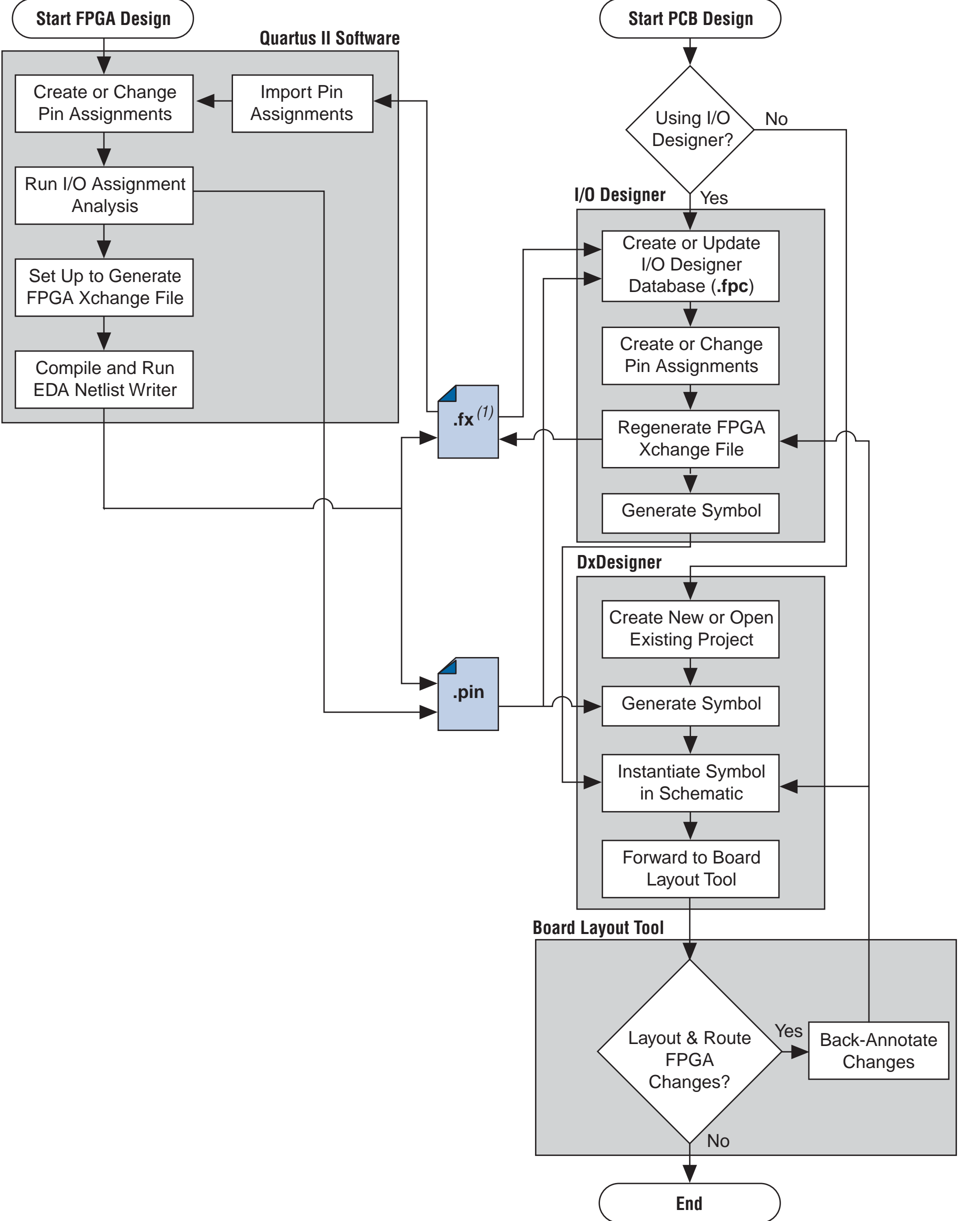
Mentor Graphics I/O Designer software is optional.

To obtain and license the Mentor Graphics tools and obtain product information, support, and training, go to the Mentor Graphics website at www.mentor.com.

FPGA-to-PCB Design Flow

In the examples in this section, you create a design flow integrating an Altera® FPGA design from the Quartus II software, and a circuit schematic in the DxDesigner software. Figure 8–1 shows the design flow with and without the I/O Designer software.

Figure 8–1. Design Flow with and without the I/O Designer Software



Note to Figure 8–1:

(1) The Quartus II software generates the FPGA Xchange file in the output directory you specify in the Board-Level Assignment Settings. However, the Quartus II software and the I/O Designer software can import pin assignments from an FPGA Xchange file located in any directory. Altera recommends that you work with a backup of the FPGA Xchange file to prevent overwriting existing assignments or importing invalid assignments.

The following tasks, which are described in this chapter, describe how to proceed through the design flow shown in Figure 8–1:

- Set up the board-level assignment settings to generate an FPGA Xchange file (**.fx**) for symbol generation in the Quartus II software
- Compile the design and generate the FPGA Xchange file and the Pin-Out file (**.pin**), which are located in the Quartus II project directory
- Create a board design using the DxDesigner software together with the I/O Designer software, which involves the following steps:
  - Create a new I/O Designer database based on the FPGA Xchange file and the Pin-Out file
  - Make adjustments to signal and pin assignments in the I/O Designer software
  - Regenerate the FPGA Xchange file in the I/O Designer software to reflect the I/O Designer software changes in the Quartus II software
  - Generate a single or fractured symbol for use in the DxDesigner software
  - Add the symbol to the **sym** directory of a DxDesigner project, or specify a new DxDesigner project with the new symbol
  - Instantiate the symbol in your DxDesigner schematic and export the design to the board layout tool
  - Back-annotate pin changes created in the board layout tool to the DxDesigner software and back to the I/O Designer software and the Quartus II software
- Create a board design using the DxDesigner software without the I/O Designer software, which involves the following steps:
  - Create a new DxBoardLink symbol using the Symbol Wizard and reference the Pin-Out file output from the Quartus II software in an existing DxDesigner project
  - Instantiate the symbol in your DxDesigner schematic and pass the design to a board layout tool

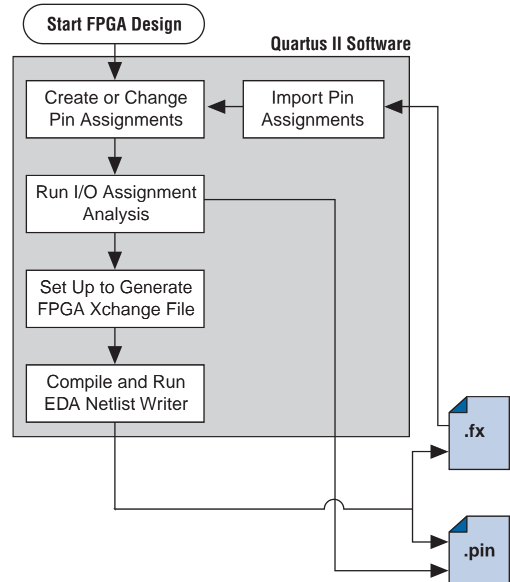
The I/O Designer software allows you to take advantage of the full FPGA symbol design, creation, editing, and back-annotation flow supported by Mentor Graphics tools.

Symbols can be updated with design changes at any point with or without the I/O Designer software. However, if symbols are changed in the DxDesigner software, the I/O Designer software does not see the changes. If you change symbols using the DxDesigner software, you must reimport the symbols into I/O Designer to avoid overwriting your symbol changes.

Setting Up the Quartus II Software

You can transfer pin and signal assignments from the Quartus II software to the Mentor Graphics tools by generating two output files, a Pin-Out file (**.pin**) and an FPGA Xchange file (**.fx**) (Figure 8–2).

Figure 8–2. Pin-Out Files and FPGA Xchange Files *(Note 1)*



Note to Figure 8–2:

(1) Refer to Figure 8–1 for the full design flow, which includes the I/O Designer software, the DxDesigner software, and the board layout tool flowchart details.

The two output files, the Pin-Out file and the FPGA Xchange file, are described in Table 8–1.

Table 8–1. Pin Assignment Output File Format Comparison

File Format	Description
Pin-Out file (**.pin**) *(1)*	An output file generated by the Quartus II Fitter. The file cannot be imported into the Quartus II software to change pin assignments. The file contains a complete list of the device pins including any unused I/O pins, and provides the following basic information fields for each assigned pin on a device: ■ Pin signal name/usage ■ Pin number ■ Signal direction ■ I/O standard ■ Voltage ■ I/O Bank ■ User or Fitter assigned
FPGA Xchange file (**.fx**) *(1)*,*(2)*	An input/output file generated by the Quartus II software and the I/O Designer software that can be imported and exported from both programs. Industry standard with room for future changes and additions. The FPGA Xchange file generated by the Quartus II software lists only assigned pins. The file provides the following advanced information fields for each pin on a device: ■ Pin number ■ I/O Bank ■ Signal name ■ Signal direction ■ I/O standard ■ Drive strength (mA) ■ Termination enabling ■ Slew rate ■ IOB Delay ■ Swap group ■ Differential pair type
	When generated by the I/O Designer software, all pins, including unused pins, are listed and the following fields are added: ■ Swap group ■ Differential pair type ■ Device pin name ■ Pin set ■ Pin set position ■ Pin set group ■ Super pin set group ■ Super pin set position

Notes to Table 8–1:

(1) For additional information about these file formats, refer to the Quartus II Help.

(2) For additional information about the information fields added by the Mentor Graphics software, refer to the Mentor Graphics website at www.mentor.com.

The I/O Designer software can also read from or update a Quartus II Settings File (**.qsf**). The Quartus II Settings File is used in the design flow in a similar manner to the FPGA Xchange file, but does not transfer pin swap group information between the I/O Designer software and the Quartus II software.

The **Quartus II Settings File** also contains additional important information about your project that is not used by the I/O Designer software. Because of this, Altera recommends that you use the FPGA Xchange file instead of the Quartus II Settings File for this design flow.

For more information about the Quartus II Settings File, refer to the *Quartus II Settings File Reference Manual*.

Generating Pin-Out Files

The Quartus II Fitter generates the Pin-Out file whenever you perform a full compilation or I/O Assignment Analysis on your design. The file is generated and placed in your design directory and your file is named <*project name*>**.pin**. The Mentor Graphics tools do not alter this file. The Quartus II software cannot import assignments from an existing Pin-Out file.

Generating FPGA Xchange Files

The FPGA Xchange file is not created automatically. To set up the Quartus II software to create the FPGA Xchange file, follow these steps:

1. Start the Quartus II software. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. Under **EDA Tool Settings**, click **Board-Level**. In the **Board-Level Symbol Format** list, choose **FPGA Xchange**.
3. Set the Output directory to the location where you want to save the file. The default output file path is <*project directory*>/symbols/fpgaxchange. Click **OK**.
4. On the Processing menu, point to **Start** and click **Start EDA Netlist Writer**.

The output directory you selected is created when you generate the FPGA Xchange file.

Both the Quartus II software and the I/O Designer software can export and import an FPGA Xchange file. It is therefore possible to overwrite the FPGA Xchange file and import incorrect assignments into one or both programs. To prevent this occurrence from happening, make a backup copy of the file before importing, and import the copy instead of the file generated by the Quartus II software. In addition, assignments in the Quartus II software can be protected by following the steps in "Protecting Assignments in the Quartus II Software" on page 8–18.

Creating a Backup Quartus II Settings File

To create a backup Quartus II Settings File, perform the following steps:

1. On the Assignments menu, click **Import Assignments**. The **Import Assignments** dialog box appears.

2. In the **Import Assignments** dialog box, browse to your project and turn on **Copy existing assignments into** <*project name*>**.qsf.bak**.
3. Click **OK**.

Following these steps automatically creates a backup Quartus II Settings File of your current pin assignments.

For more information about pin and signal assignment transfer, and files the Quartus II software can import and export, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

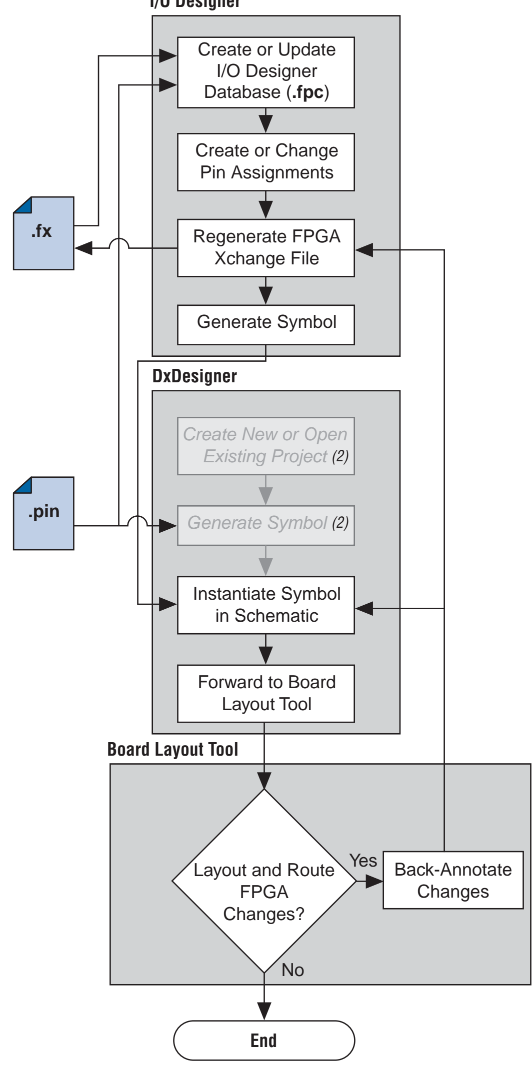
FPGA-to-Board Integration with the I/O Designer Software

The Mentor Graphics I/O Designer software allows you to integrate your FPGA and PCB designs. Pin and signal assignment changes can be made anywhere in the design flow, typically using either the Quartus II Pin Planner or the I/O Designer software. The I/O Designer software facilitates moving these changes, as well as synthesis, placement, and routing changes, between the Quartus II software, an external synthesis tool (if used), and a schematic capture tool such as the DxDesigner software.

This section describes how to use the I/O Designer software to transfer pin and signal assignment information to and from the Quartus II software with the FPGA Xchange file, and how to create symbols for the DxDesigner software.

Figure 8–3 shows the design flow using the I/O Designer software.

Figure 8–3. Design Flow Using the I/O Designer Software *(Note 1)*



Notes to Figure 8–3:

(1) Refer to Figure 8–1 for the full design flow including the Quartus II software flowchart details.

(2) These are DxDesigner software-specific steps in the design flow and are not part of the I/O Designer flow.

For more information about the I/O Designer software, and to obtain usage, support, and product updates, use the Help menu in the I/O Designer software or refer to the Mentor Graphics website at www.mentor.com.

I/O Designer Database Wizard

All I/O Designer project information is stored in an I/O Designer Database (**.fpc**) file. You can create a new database that incorporates the FPGA Xchange file and Pin-Out file information generated by the Quartus II software by using the I/O Designer Database Wizard. You can also create a new, empty database and manually add the assignment information. If there is no signal or pin assignment information currently available, you can create an empty database that contains only a selection of the target device. This is useful if you know the signals in your design and the pins you want to assign. You can transfer this information at a later time to the Quartus II software for place-and-route.

It is possible to create an I/O Designer database with only one type of file or the other. However, if only a Pin-Out file is used, any I/O assignment changes made in the I/O Designer software cannot be imported back into the Quartus II software without first generating an FPGA Xchange file. If only an FPGA Xchange file is used to create the I/O Designer database, the database may not contain a complete picture of all of the I/O assignment information available. The FPGA Xchange file generated by the Quartus II software only lists pins with assigned signals. Since the Pin-Out file lists all device pins—whether signals are assigned to them or not—its use, along with the FPGA Xchange file, produces the most complete set of information for creating the I/O Designer Database.

To create a new I/O Designer database using the Database Wizard, perform the following steps:

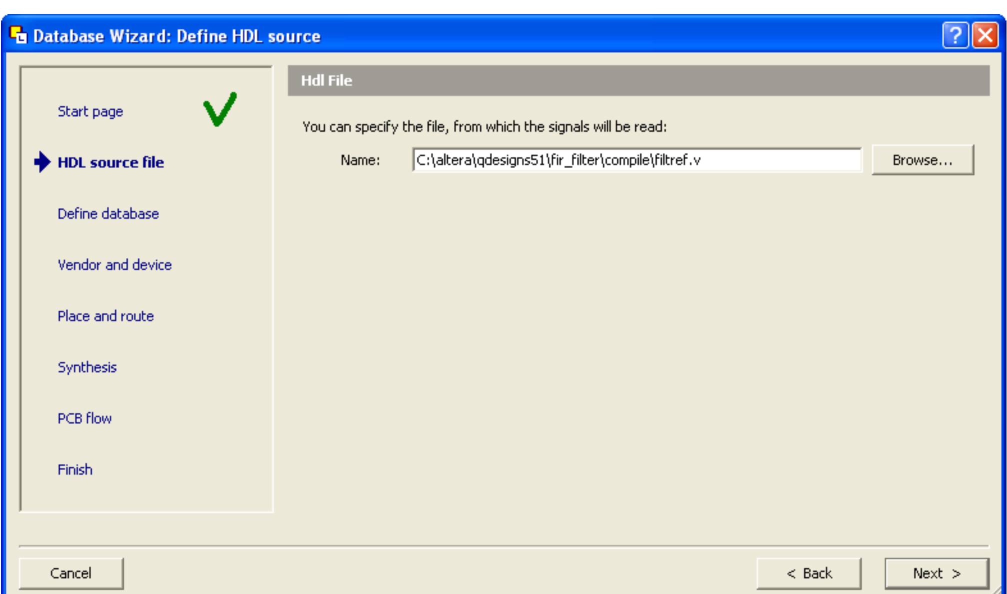
If you skip a step in this process, you can complete the skipped step later, filling in the appropriate information. To return to a skipped step, on the Properties menu, click **File**.

1. Start the I/O Designer software. The **Welcome to I/O Designer** dialog box appears. Select **Wizard to create new database** and click **OK**.

   If the **Welcome to I/O Designer** dialog box is not shown because it was disabled, you can access the Wizard through the menus. To access the Wizard, on the File menu, click **Database Wizard**.

2. Click **Next**. The **Define HDL source file** page opens (Figure 8–4).

Figure 8–4. Database Wizard HDL File Page



For more information about creating and using HDL files in the Quartus II software, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*, or refer to the I/O Designer Help.

If no HDL files are available, or if your signal and pin assignments are already contained in the FPGA Xchange file, you do not have to complete step 3 and can proceed to step 4.

3. If you have created a Verilog HDL or VHDL file in your Quartus II software design, you can enter a top-level Verilog HDL or VHDL file. Adding a file allows you to create functional blocks or get signal names from your design. All physical pin assignments must be created in I/O Designer if no FPGA Xchange file or Pin-Out file is used. Click **Next**. The Database Name page is shown.
4. In the Database Name window, enter your database file name. Click **Next**. The Database Location window is shown.
5. Enter a path to the new database or an existing one in the **Location** field, or browse to a database location. Click **Next**. The **FPGA flow** page is shown.
6. In the Vendor menu, click **Altera**.
7. In the Tool/Library menu, click **Quartus II 5.0**, or a later version of the Quartus II software.
8. Select the appropriate device family, device, package, and speed (if applicable), from the corresponding menus. Click **Next**. The **Place and route** page is shown.

The Quartus II software version selections in the Tool/Library menu may not reflect the version of the Quartus II software currently installed on your system even if you are using the most current version of the I/O Designer software. The version number selection in this window is used in the I/O Designer software to identify the devices that were available or obsolete in that particular version of the Quartus II software. If you are unsure of the version to select, use the most recent version listed in the menu. If the device you are targeting does not appear in the device menu after making this selection, the device may be new and not yet added to the I/O Designer software. For I/O Designer software updates, contact Mentor Graphics or refer to their website at www.mentor.com.

9. In the **FPGAX file name** field, type or browse to the backup copy of the FPGA Xchange file generated by the Quartus II software.
10. In the **Pin report file name** field, type or browse to the Pin-Out file generated by the Quartus II software. Click **Next**.

    In addition, you can select a Quartus II Settings File for update. The I/O Designer software can update the pin assignment information in the Quartus II Settings File without affecting any other information contained in the file.

You can select a Pin-Out file without selecting an FPGA Xchange file for import. The I/O Designer software does not generate a Pin-Out file. To transfer assignment information to the Quartus II software, select an additional file and file type. Altera recommends selecting an FPGA Xchange file in addition to a Pin-Out file for transferring all of the assignment information contained within both types of files.

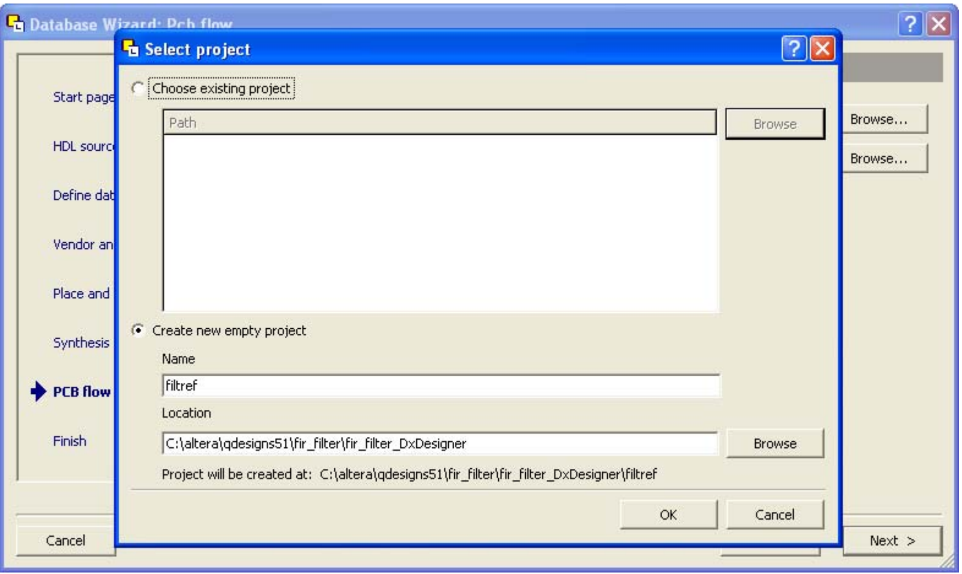
In some versions of the I/O Designer software, the standard file picker may incorrectly look for a Pin-Out file instead of an FPGA Xchange file. In this case, select **All Files (*.*)** from the **Save as type** list and select the file from the list.

11. The **Synthesis** page displays. On the **Synthesis** page, you can specify an external synthesis tool and a synthesis constraints file for use with the tool. If you do not use an external synthesis tool, click **Next**.

For more information about third-party synthesis tools, refer to *Volume 3: Verification* of the *Quartus II Handbook*.

12. On the **PCB Flow** page, you can select an existing schematic project or create a new project as a destination for symbol information.
    - To select an existing project, select **Choose existing project** and click **Browse** after the Project Path field. The **Select project** dialog box appears. Select the project.
    - To create a new project, in the **Select project** dialog box, select **Create new empty project**. Enter the project file name in the **Name** field and browse to the location where you want to save the file (Figure 8–5). Click **OK**.

Figure 8–5. Select Project Dialog Box

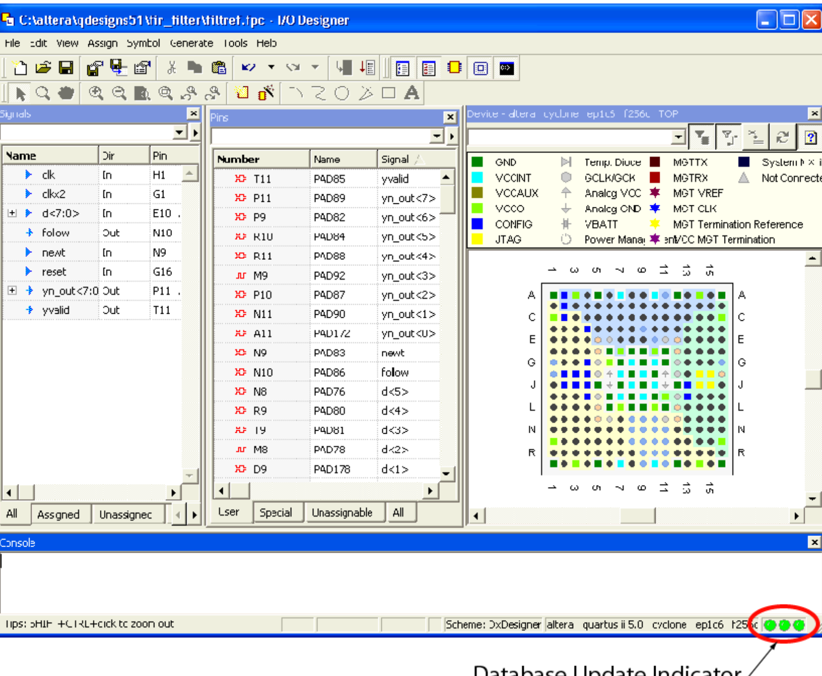


If you have not specified a design tool to which you can send symbol information in I/O Designer, click **Advanced** in the **PCB Flow** page and select your design tool. If the DxDesigner software is selected, you have the option of specifying a Hierarchical Occurrence Attributes (**.oat**) file to import into the I/O Designer software. Click **Next**, then click **Finish** to create the database.

In I/O Designer version 2005 or later, the Update Wizard (refer to Figure 8–9 on page 8–16) is shown when you finish creating the database using the database wizard. Use the Update Wizard to confirm creation of the I/O Designer database using the selected FPGA Xchange and Pin-Out files.

Use the I/O Designer software and your newly created database to make pin assignment changes, create pin swap groups, or adjust signal and pin properties in the I/O Designer GUI (Figure 8–6).

Figure 8–6. I/O Designer Main Window



For more information about using the I/O Designer software and the DxDesigner software, refer to the Mentor Graphics website at www.mentor.com or refer to the I/O Designer software or the DxDesigner Help.

Updating Pin Assignments from the Quartus II Software

As the design process continues, the FPGA designer may need to make changes to the logic design in the Quartus II software that place signals on different pins after the design is recompiled, or manually by using the Quartus II Pin Planner. These types of changes must be carried forward to the circuit schematic and board layout tools to ensure that signals are connected to the correct pins on the FPGA. Updating the FPGA Xchange file and the Pin-Out file in the Quartus II software facilitates this flow (Figure 8–7).

Figure 8–7. Updating the I/O Designer Pin Assignments in the Design Flow *(Note 1)*

Note to Figure 8–7:

(1) Refer to Figure 8–1 for the full design flow, which includes the Quartus II software, the DxDesigner software, and the board layout tool flowchart details.

To update the FPGA Xchange file and the Pin-Out file in the Quartus II software after making changes to the design, run a full compilation, or on the Start menu, point to Processing and click **Start EDA Netlist Writer**. The FPGA Xchange file in your selected output directory and the Pin-Out file in your project directory are updated. You must rerun the I/O Assignment Analyzer whenever you make I/O changes in the Quartus II software. To rerun the I/O Assignment Analyzer, on the Processing menu, click **Start Compilation**, or to run a full compilation, on the Processing menu, point to **Start** and click **Start I/O Assignment Analysis**.

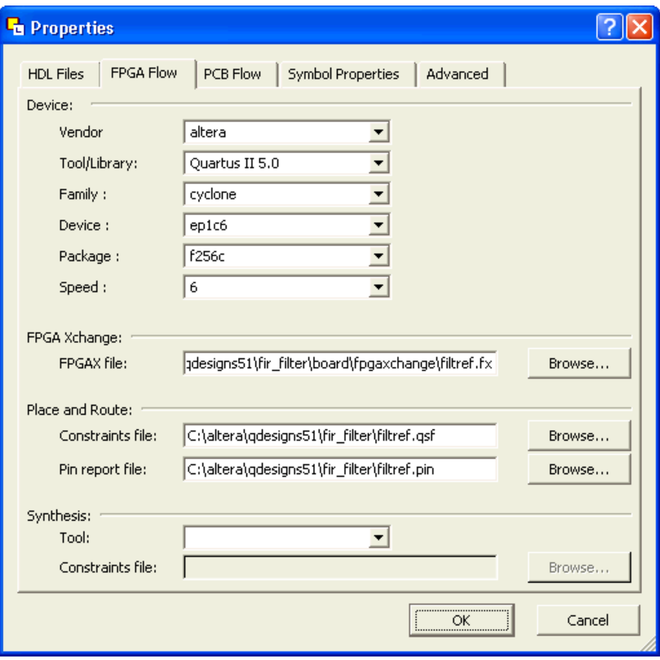
Refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook* for more information about setting up the FPGA Xchange file and running the I/O Assignment Analyzer.

If your I/O Designer database points to the FPGA Xchange file generated by the Quartus II software instead of a backup copy of the file, updating the file in the Quartus II software overwrites any changes made to the file by the I/O Designer software. If there are I/O Designer assignments in the FPGA Xchange file that you want to preserve, create a backup copy of the file before updating it in the Quartus II software, and verify that your I/O Designer database points to the backup copy. To point to the backup copy, perform the steps in the following section.

Whenever the FPGA Xchange file or the Pin-Out file is updated in the Quartus II software, the changes can be imported into the I/O Designer database. You must set up the locations for the files in the I/O Designer software.

1. To set up the file locations if they are not already set, on the File menu, click **Properties**. The project **Properties** dialog box appears (Figure 8–8).

Figure 8–8. Project Properties Dialog Box



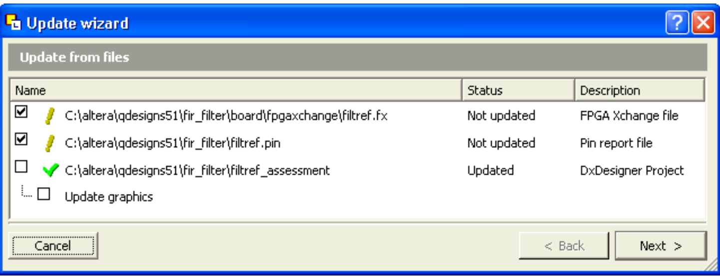
2. Under **FPGA Xchange**, click **Browse** to select the FPGA Xchange file name and file location.
3. To specify a Pin report file, under **Place and Route**, click **Browse** to select the Pin-Out file name and file location.

After you have set up these file locations, the I/O Designer software monitors these files for changes. If the FPGA Xchange file or Pin-Out file changes during the design flow, three indicators flash red in the lower right-hand corner of the I/O Designer main window (see Figure 8–6 on page 8–13). You can continue working or click on the indicators to open the I/O Designer Update Wizard. If you have made changes to your design in the Quartus II software that result in an updated FPGA Xchange file or Pin-Out file and the update indicators do not flash or you have previously canceled an indicated update, manually open the Update Wizard. To open the Wizard, on the File menu, click **Update**.

In versions of the I/O Designer software before version 2005, instead of using flashing indicators, the I/O Designer software displays a dialog box asking if you want to open the Update Wizard.

The I/O Designer Update Wizard lists the updated files associated with the database (Figure 8–9).

Figure 8–9. Update Wizard Dialog Box



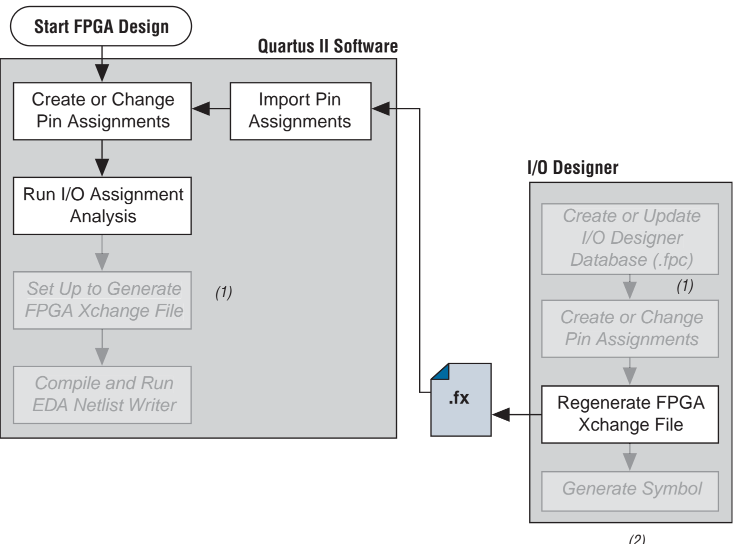
The paths to the updated files have yellow exclamation points and the **Status** column shows **Not updated**, indicating that the database has not yet been updated with the newer information contained in the files. A checkmark to the left of any updated file indicates that the file will update the database. Turn on any files you want to use to update the I/O Designer database, and click **Next**. If you are not satisfied with the database update, on the Edit menu, click **Undo**.

You can update the I/O Designer database using both the FPGA Xchange file and the Pin-Out file at the same time. Turning on both the FPGA Xchange file and the Pin-Out file for update causes the Update Wizard to provide options for using assignments from one file or the other exclusively or merging the assignments contained in both files into the I/O Designer database. Versions of the I/O Designer software older than version 2005 simply merge assignments contained in multiple files.

Sending Pin Assignment Changes to the Quartus II Software

In the same way that the FPGA designer can make adjustments that affect the PCB design, the board designer can make changes to optimize signal routing and layout that must be applied to the FPGA. The FPGA designer can take these required changes back into the Quartus II software to refit the logic to match the adjustments to the pinout. The I/O Designer software can accommodate this reverse flow as shown in Figure 8–10.

Figure 8–10. Updating the Quartus II Pin Assignments in the Reverse Design Flow



Notes to Figure 8–10:

(1) These are software-specific steps in the design flow and are not necessary for the reverse flow steps of the design.

(2) Refer to Figure 8–1 for the full design flow, which includes the complete I/O Designer software, the DxDesigner software, and the board layout tool flowchart details.

Pin assignment changes are made directly in the I/O Designer software, or the software automatically updates changes made in a board layout tool that are back-annotated to a schematic entry program such as the DxDesigner software. You must update the FPGA Xchange file to reflect these updates in the Quartus II software. To perform this update in the I/O Designer software, on the Generate menu, click **FPGA Xchange File**.

If your I/O Designer database points to the FPGA Xchange file generated by the Quartus II software instead of a backup copy, updating the file from the I/O Designer software overwrites any changes that may have been made to the file by the Quartus II software. If there are assignments from the Quartus II software in the file that you want to preserve, make a backup copy of the file before updating it in the I/O Designer software, and verify that your I/O Designer database points to the backup copy. To point to the backup copy, perform the steps in "Updating Pin Assignments from the Quartus II Software" on page 8–13.

After the FPGA Xchange file is updated, you must import it into the Quartus II software. To import the file, perform the following steps:

1. Start the Quartus II software and open your project.
2. On the Assignments menu, click **Import Assignments**.
3. In the File name box, click **Browse** and from the **Files of type** list, select **FPGA Xchange Files (*.fx)**.
4. Select the FPGA Xchange file and click **Open**.
5. Click **OK**.

Both the Quartus II software and the I/O Designer software can export and import an FPGA Xchange file. It is therefore possible to overwrite the FPGA Xchange file and import incorrect assignments into one or both programs. To prevent this occurrence from happening, make a backup copy of the file before importing, and import the copy instead of the file generated by the Quartus II software. In addition, assignments in the Quartus II software can be protected by following the steps in "Protecting Assignments in the Quartus II Software".

Protecting Assignments in the Quartus II Software

To protect assignments in the Quartus II software, perform the following steps:

1. Start the Quartus II software.
2. On the Assignments menu, click **Import Assignments**. The **Import Assignments** dialog box appears.
3. Turn on **Copy existing assignments into** <*project name*>**.qsf.bak before importing** before importing the FPGA Xchange file. This action automatically creates a backup Quartus II constraints file that contains all of your current pin assignments.

Generating Symbols for the DxDesigner Software

Along with circuit simulation, circuit board schematic creation is one of the first tasks required in the design of a new PCB. Schematics are required to understand how the PCB will work, and to generate a netlist that is passed to a board layout tool for board design and routing. The I/O Designer software provides the ability to create schematic symbols based on the FPGA design exported from the Quartus II software.

Most FPGA devices contain hundreds of pins, requiring large schematic symbols that may not fit on a single schematic page. Symbol designs in the I/O Designer software can be split or fractured into a number of functional blocks, allowing multiple part fractures on the same schematic page or across multiple pages. In the DxDesigner software, these part fractures are joined together with the use of the `HETERO` attribute.

The I/O Designer software can generate symbols for use in a number of Mentor Graphics schematic entry tools, and can import changes back-annotated by board layout tools to update the database and feed updates back to the Quartus II software using the FPGA Xchange file. This section discusses symbol creation specifically for the DxDesigner software.

Schematic symbols are created in the I/O Designer software in the following ways:

- Manually
- Using the I/O Symbol Wizard
- Importing previously created symbols from the DxDesigner software

The I/O Designer Symbol Wizard can be used as a design base that allows you to quickly create a symbol for manual editing at a later time. If you have already created symbols in a DxDesigner project and want to apply a different FPGA design to them, you can manually import these symbols from the DxDesigner project. To import the symbols, open the I/O Designer software, and on the File menu, click **Import Symbol**.

For more information about importing symbols from the DxDesigner software into an I/O Designer database, refer to the I/O Designer Help.

Symbols created in the I/O Designer software are either functional, physical (PCB), or a combination of functional and physical. A functional symbol is based on signals imported into the database, usually from Verilog HDL or VHDL files. No physical device pins must be associated with the signals to generate a functional symbol. This section focuses on board-level PCB symbols with signals directly mapped to physical device pins through assignments in either the Quartus II Pin Planner or in the I/O Designer database.

For information about manually creating symbols, importing symbols, and editing symbols in the I/O Designer software, as well as the different types of symbols the software can generate, refer to the I/O Designer Help.

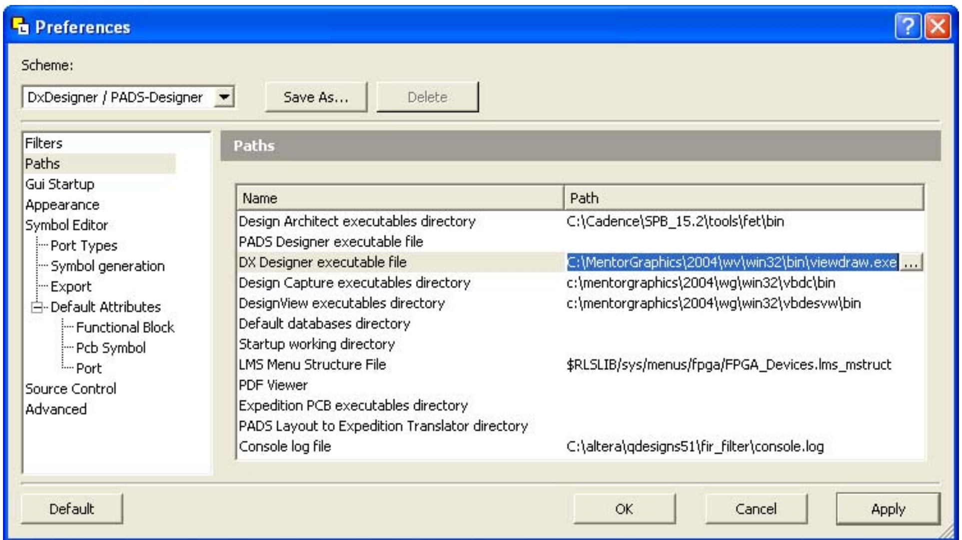
Setting Up the I/O Designer Software to Work with the DxDesigner Software

If you created your I/O Designer database using the Database Wizard, you may already be set up to export symbols to a DxDesigner project. To verify this, or to manually set up the I/O Designer software to work with the DxDesigner software, you must set the path to the DxDesigner executable, set the export type to DxDesigner, and set the path to a DxDesigner project directory.

To set these options, perform the following steps:

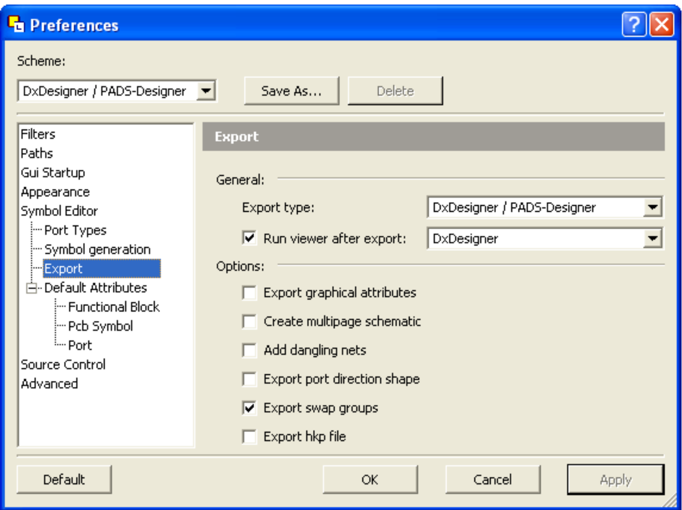
1. Start the I/O Designer software.
2. On the Tools menu, click **Preferences**. The **Preferences** dialog box appears.
3. Click **Paths**, double-click on the DxDesigner executable file path field, and click **Browse** to select the location of the DxDesigner application (Figure 8–11).
4. Click **Apply**.

Figure 8–11. Path Preferences Dialog Box



5. Click **Symbol Editor** and click **Export**. In the Export type menu, under **General**, select **DxDesigner/PADS-Designer** (Figure 8–12).
6. Click **Apply** and click **OK**.

Figure 8–12. Symbol Editor Export Preferences



7. On the File menu, click **Properties**. The project **Properties** dialog box appears.
8. Click the **PCB Flow** tab and click **Path to a DxDesigner project directory**.
9. Click **OK**.

If you did not create a new DxDesigner project in the Database Wizard and you do not already have a DxDesigner project, you must create a new database using the DxDesigner software, and point the I/O Designer software to this new project.

For information about creating and working with DxDesigner projects, refer to the DxDesigner Help.

Create Symbols with the Symbol Wizard

FPGA symbols based on Altera devices can be created, fractured, and edited using the I/O Designer Symbol Wizard. To create a symbol based on a selected Altera FPGA device:

1. Start the I/O Designer software.
2. Click **Symbol Wizard** in the toolbar, or on the Symbol menu, click **Symbol Wizard**. The **Symbol Wizard (1 of 6)** page is shown (Figure 8–13).

Figure 8–13. Symbol Wizard

3. On the first Symbol Wizard page, in the **Symbol name** field, enter the symbol name. The **DEVICE** and **PKG_TYPE** fields are populated with the device and package information automatically. Under **Symbol type**, click **PCB**. Under **Use signals**, click **All**.
4. Click **Next**. The **Symbol Wizard (2 of 6)** page is shown.

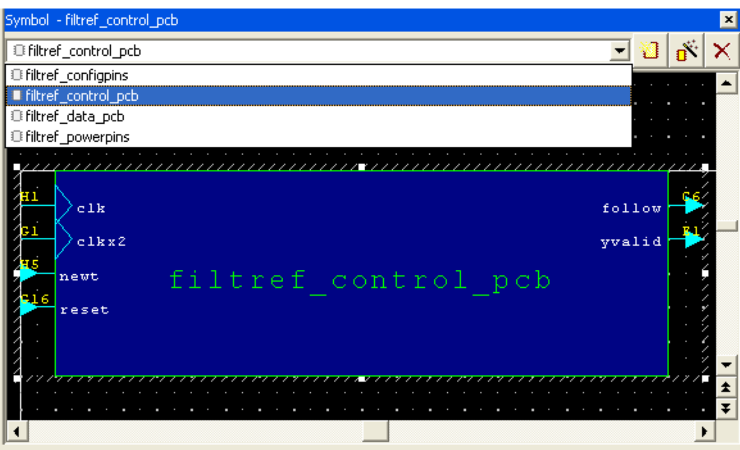
If the **DEVICE** and **PKG_TYPE** fields are blank or incorrect, cancel the Symbol Wizard and select the correct device information. On the File menu, click **Properties**. In the Properties window, click the **FPGA Flow** tab and enter the correct device information.

5. On page 2 of the Symbol Wizard, select fracturing options for your symbol. If you are using the Symbol Wizard to edit a previously created fractured symbol, you must turn on **Reuse existing fractures** so that your current fractures are not altered. Select other options on this page as appropriate for your symbol.
6. Click **Next**. The **Symbol Wizard (3 of 6)** page is shown.
7. Additional fracturing options are available on page 3 of the Symbol Wizard. After selecting the desired options, click **Next**. The **Symbol Wizard (4 of 6)** page is shown.
8. On page 4 of the Symbol Wizard, select the options for how the symbols will look. Select the desired options and click **Next**. The **Symbol Wizard (5 of 6)** page is shown.
9. On page 5 of the Symbol Wizard, define what information will be labeled for the entire symbol and for individual pins. Select the desired options and click **Next**. The **Symbol Wizard (6 of 6)** page is shown.

10. On the final page of the Symbol Wizard, add additional signals and pins that have not already been placed in the symbol. Click **Finish** when you complete your selections.

Your symbol is complete. You can view your symbol and any fractures you created using the Symbol Editor (Figure 8–14). You can edit parts of the symbol, delete fractures, or rerun the Symbol Wizard.

Figure 8–14. The I/O Designer Symbol Editor



If assignments in the I/O Designer database are updated, the symbols created in the I/O Designer software automatically reflect these changes. Assignment changes can be made within the I/O Designer software, with an updated FPGA Xchange file from the Quartus II software, or from a back-annotated change in your board layout tool.

Export Symbols to the DxDesigner Software

After you have completed your symbols, export the symbols to your DxDesigner project. To generate all the fractures of a symbol, on the Generate menu, click **All Symbols**. To generate a symbol for the currently displayed symbol in Symbol Editor, click **Current Symbol Only**. Each symbol in the database is saved as a separate file in the /sym directory in your DxDesigner project. The symbols can be instantiated in your DxDesigner schematics.

For more information about working with DxDesigner projects, refer to the DxDesigner Help.

Scripting Support

The I/O Designer software features a command line Tcl interpreter. All commands issued through the GUI in the I/O Designer software are translated into Tcl commands that are run by the tool. You can view the generated Tcl commands and run scripts, or enter individual commands in the I/O Designer Console window.

The following section includes commands that perform some of the operations described in this chapter.

If you want to change the FPGA Xchange file from which the I/O Designer software updates assignments, type the following command at an I/O Designer Tcl prompt:

```
set_fpga_xchange_file <file name>
```

After the FPGA Xchange file is specified, use the following command to update the I/O Designer database with assignment updates made in the Quartus II software:

```
update_from_fpga_xchange_file
```

Use the following command to update the FPGA Xchange file with changes made to the assignments in the I/O Designer software for transfer back into the Quartus II software:

```
generate_fpga_xchange_file
```

If you want to import assignment data from a Pin-Out file created by the Quartus II software, use the following command:

```
set_pin_report_file -quartus_pin <file name>
```

Run the I/O Designer Symbol Wizard with the following command:

```
symbolwizard
```

Set the DxDesigner project directory path where symbols are saved with the following command:

```
set_dx_designer_project -path <path>
```

For more information about Tcl scripting and Tcl scripting with the Quartus II software, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. For more information about the Tcl scripting capabilities of the I/O Designer software as well as a list of all the commands available, refer to the I/O Designer Help.

FPGA-to-Board Integration with the DxDesigner Software

The Mentor Graphics DxDesigner software is a design entry tool for schematic capture. You can use it to create flat circuit schematics for all types of PCB design. You can also use the DxDesigner software to create hierarchical schematics that facilitate design reuse and a team-based design. You can use the DxDesigner software in the design flow alone or in conjunction with the I/O Designer software. However, if you use the DxDesigner software without the I/O Designer software, the design flow is one-way, using only the Pin-Out file generated by the Quartus II software.

Signal and pin assignment changes can be made only in the Quartus II software and are reflected in updated symbols in a DxDesigner schematic. You cannot back-annotate changes made in a board layout tool or in a DxDesigner symbol to the Quartus II software. Figure 8–15 shows the design flow when the I/O Designer software is not used.

Figure 8–15. Design Flow Without the I/O Designer Software *(Note 1)*

DxDesigner
.pin
Create New or Open Existing Project
Generate Symbol
Instantiate in Schematic
Forward to Board Layout Tool

Note to Figure 8–15:

(1) Refer to Figure 8–1 for the full design flow, which includes the Quartus II software, the I/O Designer software, and the board layout tool flowchart details.

For more information about the DxDesigner software, including usage, support, training, and product updates, refer to the Mentor Graphics web page at www.mentor.com, or choose Schematic Design Help Topics in the DxDesigner Help.

DxDesigner Project Settings

New projects in the DxDesigner software are already set up to create FPGA symbols by default. However, for complete support and compatibility with the I/O Designer software, if it is used with the DxDesigner software, you should enable the DxBoardLink Flow options.

You can enable the DxBoardLink flow design configuration while creating a new DxDesigner project or after a project is created.

To enable the DxBoardLink flow design configuration when creating a new DxDesigner project, perform the following steps:

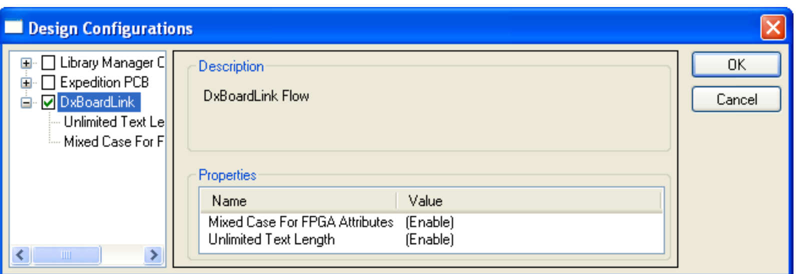
1. Start the DxDesigner software.
2. On the File menu, click **New** and click the **Project** tab. The **New** dialog box appears (Figure 8–16).

Figure 8–16. New Project Dialog Box

3. Click **More**. Turn on **DxBoardLink** (Figure 8–16).

To enable the DxBoardLink Flow design configuration in an existing project, click **Design Configurations** in the Design Configuration toolbar and turn on **DxBoardLink** (Figure 8–17).

Figure 8–17. DxBoardLink Design Configuration



DxDesigner Symbol Wizard

In addition to circuit simulation, circuit board schematic creation is one of the first tasks required in the design of a new PCB. Schematics are required to understand how the PCB will work, and to generate a netlist that is passed on to a board layout tool for board stackup design and routing.

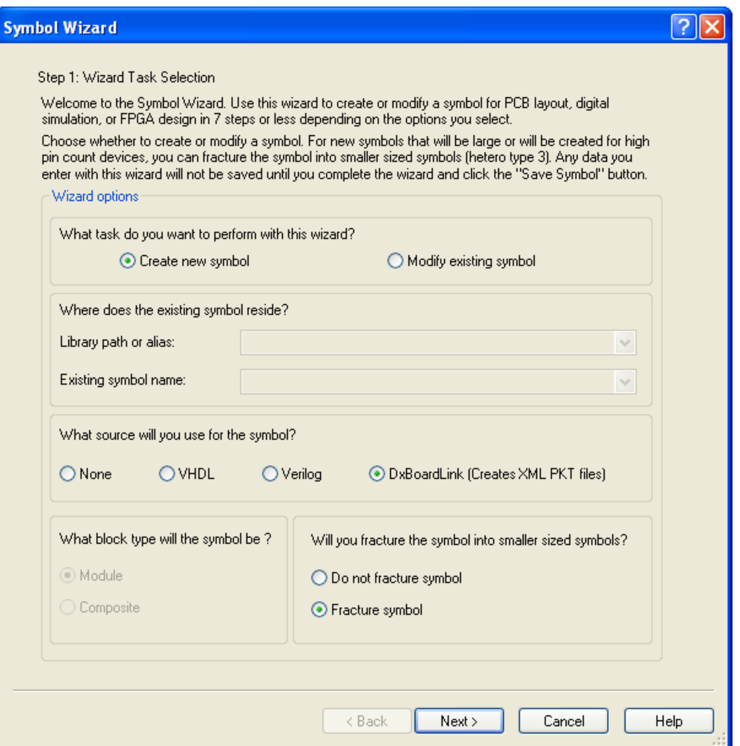
You can create schematic symbols using the DxDesigner software based on FPGA designs exported from the Quartus II software through the Pin-Out file for instantiation in DxDesigner schematic design files. Most FPGA devices are physically large with hundreds of pins, requiring large schematic symbols that may not fit on a single schematic page. You can split or fracture symbols created in the DxDesigner software into a number of functional blocks, allowing multiple part fractures on the same schematic page or across multiple pages. In the DxDesigner software, these part fractures are joined together with the use of the `HETERO` attribute.

You can create schematic symbols in the DxDesigner software manually or with the Symbol Wizard. The DxDesigner Symbol Wizard is similar to the I/O Designer Symbol Wizard, but with fewer fracturing options.

FPGA symbols based on Altera devices can be created, fractured, and edited using the DxDesigner Symbol Wizard. To start the Symbol Wizard, perform the following steps:

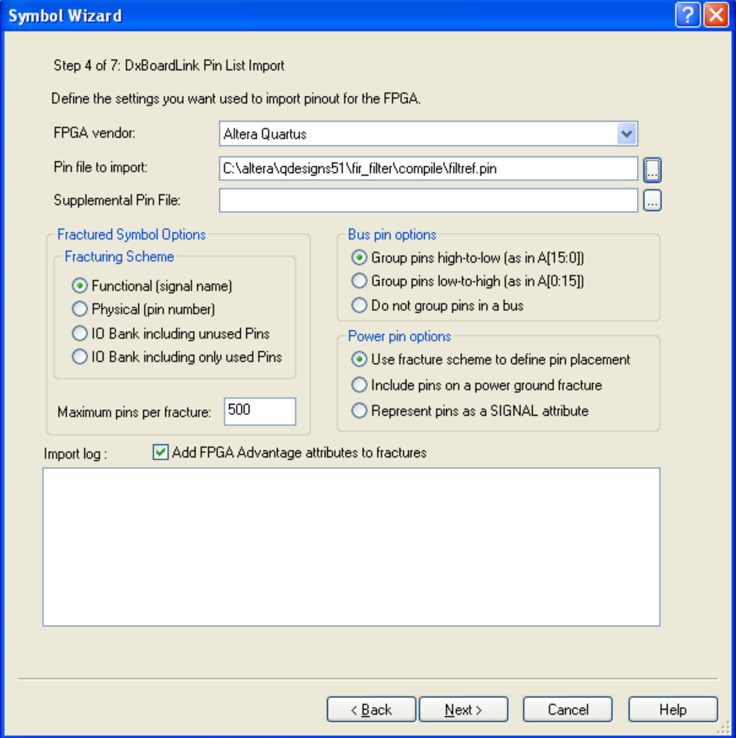
1. Start the DxDesigner software.
2. Click **Symbol Wizard** in the toolbar, or on the File menu, click **New**. The **New** window is shown. Click the **File** tab and create a new file of type **Symbol Wizard**.
3. Enter the new symbol name in the name field and click **OK**. The **Symbol Wizard** page is shown (Figure 8–18).

Figure 8–18. Wizard Task Selection



4. On the **Wizard Task Selection** page, choose to create a new symbol or modify an existing symbol. If you are modifying an existing symbol, specify the library path or alias, and select the existing symbol. If you are creating a new symbol, select DxBoardLink for the symbol source. The DxDesigner block type defaults to Module because the FPGA design does not have an underlying DxDesigner schematic. Define whether or not to fracture the symbol. After making your selections, click **Next**. The **New Symbol and Library Name** page is shown.
5. On the **New Symbol and Library Name** page, enter a name for the symbol, an overall part name for all of the symbol fractures, and a library name for the new library created for this symbol. By default, the part and library names are the same as the symbol name. Click **Next**. The **Symbol Parameters** page is shown.
6. On the **Symbol Parameters** page, decide how the generated symbol will look and how it will match up with the grid you have set in your DxDesigner project schematic. After making your selections, click **Next**. The **DxBoardLink Pin List Import** page is shown (Figure 8–19).

Figure 8–19. DxBoardLink Pin List Import



7. On the **DxBoardLink Pin List Import** page, in the **FPGA vendor** list, select **Altera Quartus**. In the Pin-Out file to import field, browse to and select the Pin-Out file from your Quartus II design project directory. Additionally, select choices from the Fracturing Scheme options, Bus pin options, and Power pin options. After you make your selections, click **Next**. The **Symbol Attributes** page is shown.
8. On the **Symbol Attributes** page, select to create or modify symbol attributes for use in the DxDesigner software. After you make your selections, click **Next**. The **Pin Settings** page is shown.

9. On the **Pin Settings** page, make any final adjustments to pin and label location and information. Each tabbed spreadsheet represents a fracture of your symbol. After you make your selections, click **Save Symbol**.

After you save the symbol, you can examine and place any fracture of the symbol in your schematic. When you are finished with the Symbol Wizard, all the fractures you created are saved as separate files in the library you specified or created in the **/sym** directory in your DxDesigner project. You can add the symbols to your schematics or you can edit the symbols manually or with the Symbol Wizard.

Symbols created in the DxDesigner software can be edited and updated with newer versions of the Pin-Out file generated by the Quartus II software. However, symbol fracturing is fixed, and the symbol cannot be fractured again. To create new fractures for your design, create a new symbol in the Symbol Wizard, and follow the steps in "DxDesigner Symbol Wizard" on page 8–25.

For more information about creating, editing, and instantiating component symbols in DxDesigner, choose Schematic Design Help Topics from the Help menu in the DxDesigner software.

Conclusion

Transferring a complex, high-pin-count FPGA design to a PCB for prototyping or manufacturing is a daunting process that can lead to errors in the PCB netlist or design, especially when multiple engineers are working on different parts of the project. The design workflow available when the Quartus II software is used in conjunction with the Mentor Graphics toolset assists the FPGA designer and the board designer in preventing errors and focusing their attention on the design.

9. Cadence PCB Design Tools Support

QII52014-9.0.0

Introduction

With today's large, high-pin-count and high-speed FPGA devices, good PCB design practices are more essential than ever to ensure the correct operation of your system. Typically, the PCB design takes place concurrently with the design and programming of the FPGA. Signal and pin assignments are initially made by the FPGA or ASIC designer, and it is up to the board designer to correctly transfer these assignments to the symbols used in their system circuit schematics and board layout. As the board design progresses, pin reassignments might be requested or required to optimize the layout. These reassignments must in turn be relayed to the FPGA designer so that the new assignments can be processed through the FPGA using updated place-and-route.

Cadence provides tools to support this type of design flow. This chapter addresses how the Quartus® II software interacts with the Cadence Allegro Design Entry HDL software and the Allegro Design Entry CIS (Component Information System) software (also known as OrCAD Capture CIS) to provide a complete FPGA-to-board integration design workflow. This chapter provides information about the following topics:

- Cadence tool description, history, and comparison
- The general design flow between the Quartus II software and the Cadence Allegro Design Entry HDL software and the Cadence Allegro Design Entry CIS software
- Generating schematic symbols from your FPGA design for use in the Cadence Allegro Design Entry HDL software
- Updating Design Entry HDL symbols when signal and pin assignment changes are made in the Quartus II software
- Creating schematic symbols in the Cadence Allegro Design Entry CIS software from your FPGA design
- Updating symbols in the Cadence Allegro Design Entry CIS software when signal and pin assignment changes are made in the Quartus II software
- Using Altera®-provided device libraries in the Cadence Allegro Design Entry CIS software

This chapter is intended primarily for board design and layout engineers who want to begin the FPGA board integration process while the FPGA is still in the design phase. In addition, part librarians benefit from learning how to take output from the Quartus II software and use it to create new library parts and symbols.

The instructions in this chapter require the following software:

- The Quartus II software version 5.1 or later
- The Cadence Allegro Design Entry HDL or the Cadence Allegro Design Entry CIS software version 15.2 or later
- If you are using the OrCAD Capture software, you must have version 10.3 or later (CIS is optional)

Because the Cadence Allegro Design Entry CIS software is based on OrCAD Capture, these programs are very similar. For this reason, this chapter refers to the Allegro Design Entry CIS software in directions; however, these directions also apply to OrCAD Capture unless otherwise noted.

To obtain and license the Cadence tools described in this chapter, and for product information, support, and training, refer to the Cadence website, www.cadence.com. For information about OrCAD Capture and the CIS option, refer to the Cadence website. For Cadence and OrCAD support and training, refer to the EMA Design Automation website, www.ema-eda.com.

Product Comparison

The design tools described in this chapter have similar functionality, but there are differences both in their use and where to access product information. Table 9–1 lists the products described in this chapter and provides information about changes, product information, and support.

Table 9–1. Cadence and OrCAD Product Comparison

	Cadence Allegro Design Entry HDL	Cadence Allegro Design Entry CIS	OrCAD Capture CIS
Former Name	Concept HDL Expert	Capture CIS Studio	—
History	More commonly known by its former name, Cadence renamed all board design tools in 2004 under the Allegro name.	Based directly on OrCAD Capture CIS, this tool is still developed by OrCAD but sold and marketed by Cadence. EMA provides support and training.	The basis for Design Entry CIS is still developed by OrCAD for continued use by existing OrCAD customers. EMA now provides support and training for all OrCAD products.
Vendor Design Flow	Cadence Allegro 600 series, formerly known as Expert Series, for high-end, high-speed design.	Cadence Allegro 200 series, formerly known as Studio Series, for small- to medium-level design.	—
Information and Support	www.cadence.com www.ema-eda.com	www.cadence.com www.ema-eda.com	www.cadence.com www.ema-eda.com

FPGA-to-PCB Design Flow

In the examples in this section, you create a design flow integrating an Altera FPGA design from the Quartus II software through a circuit schematic in the Allegro Design Entry HDL software (Figure 9–1) or the Allegro Design Entry CIS software (Figure 9–2).

Figure 9–1. Design Flow with the Allegro Design Entry HDL Software

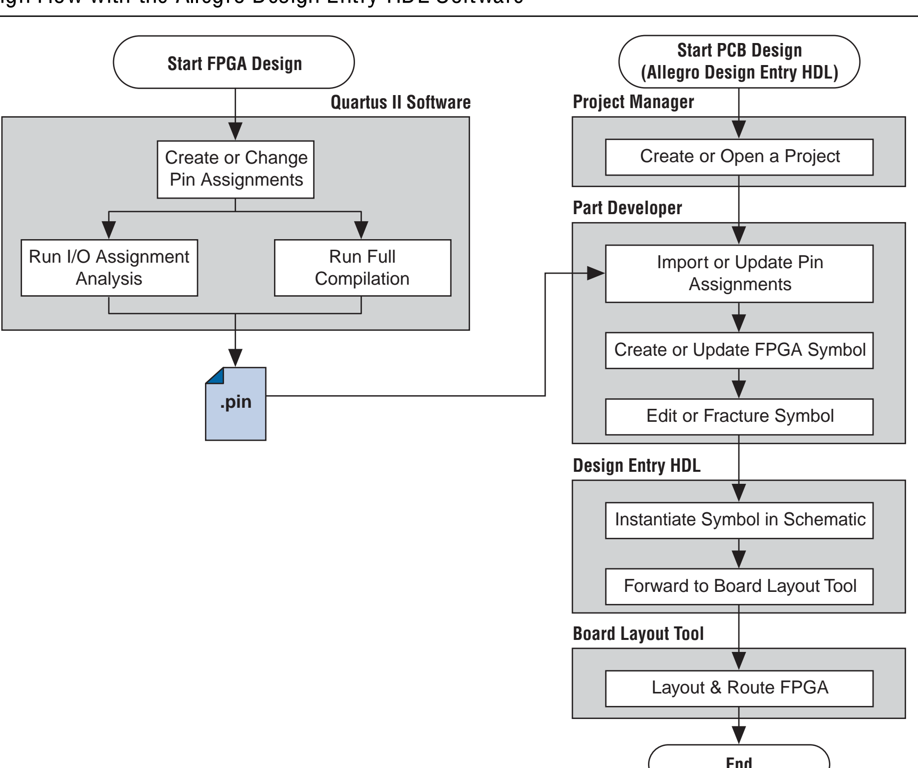

Figure 9–2. Design Flow with the Allegro Design Entry CIS Software

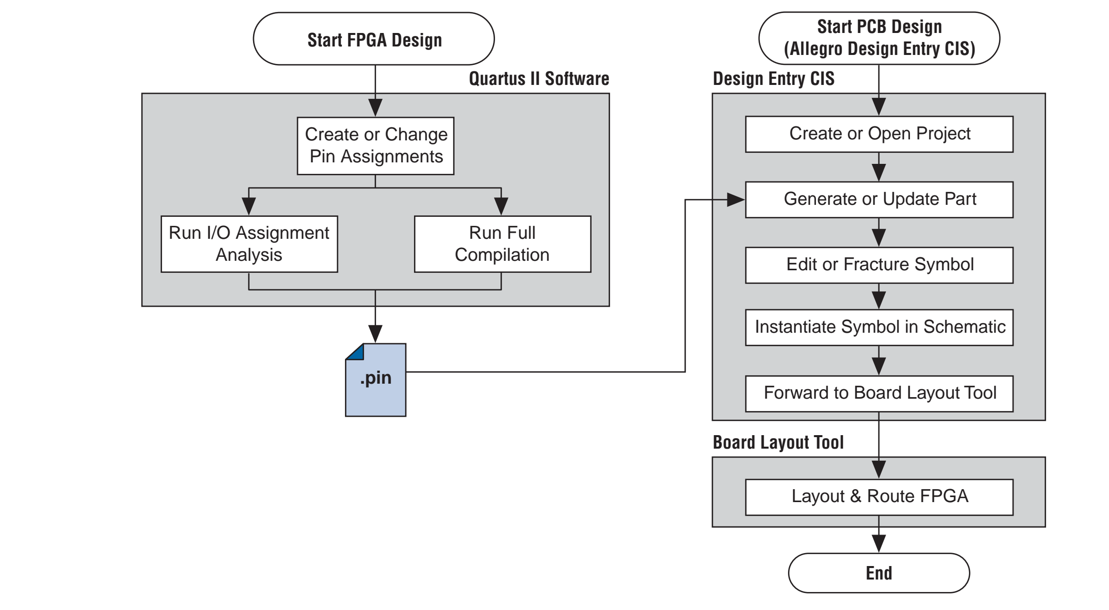


The basic steps in a complete design flow to integrate an Altera FPGA design starting in the Quartus II software through to a circuit schematic in Design Entry HDL or Design Entry CIS are as follows:

1. Start the Quartus II software.

2. In the Quartus II software, compile your design to generate a Pin-Out (**.pin**) file to transfer assignments to the Cadence tool.
3. If you are using the Cadence Allegro Design Entry HDL software for your schematic design:
   a. Open an existing project or create a new project in the Allegro Project Manager.
   b. Construct a new symbol or update an existing symbol using the Allegro PCB Librarian Part Developer.
   c. With the Part Developer, edit your symbol or fracture it into smaller parts, if desired.
   d. Instantiate the symbol in your Design Entry HDL software schematic and transfer the design to your board layout tool.
4. If you are using the Cadence Allegro Design Entry CIS software for your schematic design, perform the following steps:
   a. Generate a new part within an existing or new Allegro Design Entry CIS project, referencing the **.pin** file output from the Quartus II software. You can update an existing symbol with a new **.pin** file.
   b. Split the symbol into smaller parts as desired.
   c. Instantiate the symbol in your Design Entry CIS schematic and transfer the design to your board layout tool.

Figure 9–1 and Figure 9–2 show the possible design flows, depending on your tool choice. The Cadence PCB Librarian Expert license is required to use the PCB Librarian Part Developer to create FPGA symbols. You can update symbols with changes made to the FPGA design at any point using any of these tools.

Setting Up the Quartus II Software

You can transfer pin and signal assignments from the Quartus II software to the Cadence design tools by generating the Quartus II project **.pin** file. The **.pin** file is an output file generated by the Quartus II Fitter that contains pin assignment information. Use the Quartus II Pin Planner or Assignment Editor to set and change the assignments contained in the **.pin** file. This file cannot be used to import pin assignment changes into the Quartus II software. Use it only to transfer assignments for use with the Cadence design tools.

The **.pin** file lists all used and unused pins on your selected Altera device. It also provides the following basic information fields for each assigned pin on a device:

- Pin signal name and usage
- Pin number
- Signal direction
- I/O standard
- Voltage
- I/O bank
- User or Fitter-assigned

For information about using the Quartus II Pin Planner to create or change pin assignment details, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

Generating .pin Files

The Quartus II software automatically generates the **.pin** file when your FPGA design is fully compiled or when you start I/O Assignment Analysis. To start I/O Assignment Analysis, on the Processing menu, point to **Start** and click **Start I/O Assignment Analysis**. The file is output by the Quartus II Fitter. The file is generated and placed in your Quartus II design directory with the name <*project name*>**.pin**. The Cadence design tools do not generate or change this file.

For more information about pin and signal assignment transfer and the files that the Quartus II software can import and export, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook.*

FPGA-to-Board Integration with the Cadence Allegro Design Entry HDL Software

The Cadence Allegro Design Entry HDL software is Cadence's high-end schematic capture tool (part of the Cadence 600 series design flow). Use this software to create flat circuit schematics for all types of PCB design. The Cadence Allegro Design Entry HDL software can also create hierarchical schematics to facilitate design reuse and team-based design. With the Cadence Allegro Design Entry HDL software, the design flow from FPGA-to-board is one-way, using only the **.pin** file generated by the Quartus II software. Signal and pin assignment changes can only be made in the Quartus II software and are reflected in updated symbols in a Design Entry HDL project.

Routing or pin assignment changes made in a board layout tool or a Design Entry HDL symbol cannot be back-annotated to the Quartus II software.

Figure 9–1 shows the design flow with the Cadence Allegro Design Entry HDL software.

For more information about the Cadence Allegro Design Entry HDL software and the Part Developer, including licensing, support, usage, training, and product updates, refer to the Help in the software or to the Cadence website at www.cadence.com.

Symbol Creation

In addition to circuit simulation, circuit board schematic creation is one of the first tasks required in the design of a new PCB. Schematics are required to understand how the PCB works, and to generate a netlist that is passed on to a board layout tool for board design and routing. The Allegro PCB Librarian Part Developer provides the ability to create schematic symbols based on FPGA designs exported from the Quartus II software.

Create symbols for Design Entry HDL with the Allegro PCB Librarian Part Developer available in the Allegro Project Manager. The Part Developer is the recommended method for importing FPGA designs into the Cadence Allegro Design Entry HDL software.

You must have a PCB Librarian Expert license from Cadence to run the Part Developer. The Part Developer provides a graphical interface with many options for creating, editing, fracturing, and updating symbols. If you do not use the Part Developer, you must create and edit symbols manually in the Symbol Schematic View in the Cadence Allegro Design Entry HDL software.

If you do not have a PCB Librarian Expert license, you can still automatically create FPGA symbols using the programmable IC (PIC) design flow found in the Allegro Project Manager. For more information about using the PIC design flow, refer to the Help in the Cadence design tools, or go to the Cadence website at www.cadence.com.

Before you create a symbol from an FPGA design, you must open or create a Design Entry HDL design project. You can do this with the Allegro Project Manager, the main interface to all of the Cadence tools.

To open an existing design in the Allegro Project Manager, on the File menu, click **Open** and select the main design file for your project (found in your Allegro Design Entry HDL project directory and called <*project directory*>**.cpm**).

To create a new project, on the File menu, point to **New** and click **New Design**. The New Project wizard appears. Use the wizard to name your new project, set the file location, and define associated part libraries.

Allegro PCB Librarian Part Developer

Create, fracture, and edit schematic symbols for your FPGA designs in Altera devices using the Part Developer. Most FPGA devices are physically large with hundreds of pins, requiring large schematic symbols that might not fit on a single schematic page. Symbols designed in the Part Developer can be split or fractured into a number of functional blocks called slots, allowing multiple smaller part fractures to exist on the same schematic page or across multiple pages. Figure 9–3 highlights how the Part Developer fits into the design flow.

Figure 9–3. Part Developer in the Design Flow

(1) **Part Developer**

.pin

Import or Update Pin Assignments

Create or Update FPGA Symbol

Edit or Fracture Symbol

(2) *Design Entry HDL*

Instantiate Symbol in Schematic

Forward to Board Layout Tool

Board Layout Tool

Layout & Route FPGA

End

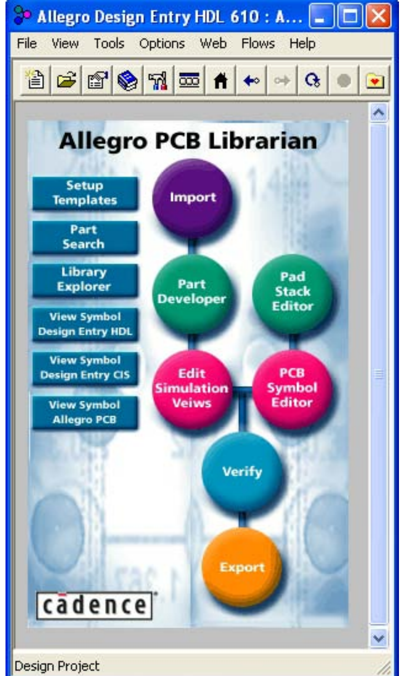
Notes to Figure 9–3:

(1) Refer to Figure 9–1 for the full design flow flowchart details.

(2) Grayed out steps are not part of the FPGA Symbol creation or update process.

Run the Part Developer from the Project Manager (Figure 9–4). To start the Part Developer in the Project Manager, on the Flows menu, click **Library Management**. Click **Part Developer** to start the tool.

Figure 9–4. Invoking the Part Developer from the Project Manager

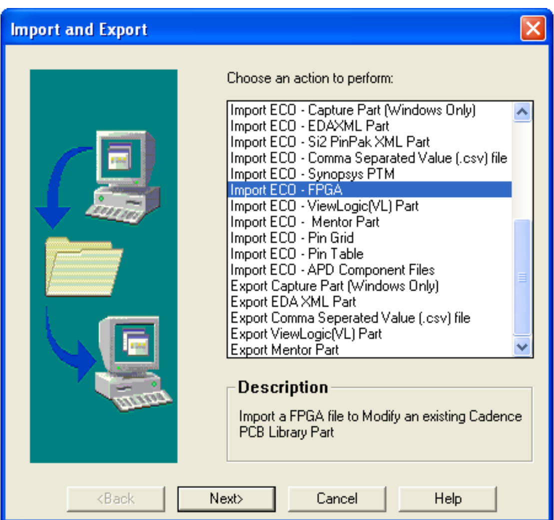


Import and Export Wizard

After you are in the Part Developer, you can use the Import and Export wizard to import your pin assignments from the Quartus II software. To access the wizard, perform the following steps:

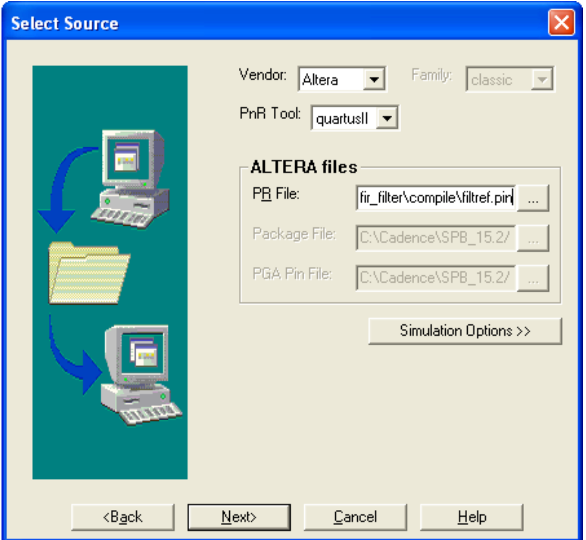
1. On the File menu, click **Import and Export**. The Import and Export wizard appears (Figure 9–5).

Figure 9–5. Import and Export Wizard



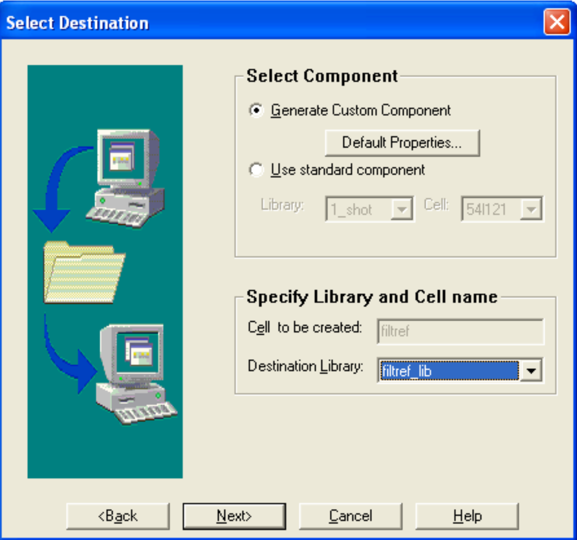
2. Select **Import ECO-FPGA**. Click **Next**. The **Select Source** dialog box appears (Figure 9–6).

Figure 9–6. Select Source Dialog Box



3. In the **Vendor** list, select **Altera.** In the **PnR Tool** list, select **quartusII**. To specify the **.pin** file in the **PR File** field, select the **.pin** file in your Quartus II project directory. Click **Simulation Options** if you want to select simulation input files. Click **Next**. The **Select Destination** dialog box appears (Figure 9–7).

Figure 9–7. Select Destination Dialog Box



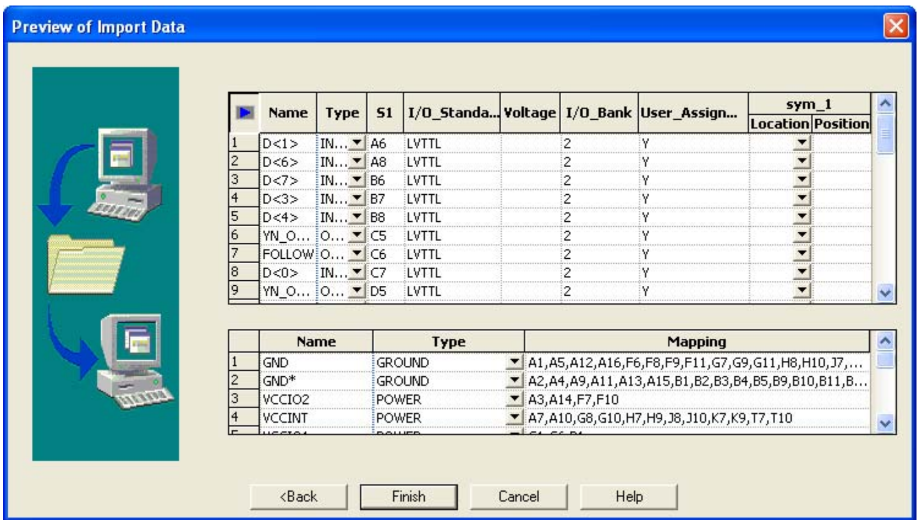
4. To create a new component in a library, click **Generate Custom Component**. To base your symbol on an existing component, click **Use standard component**.

You might want to do this if you previously created generic symbols for an FPGA device. You can place your pin and signal assignments from the Quartus II software on this symbol and reuse the symbol as a base any time you have a new FPGA design.

   In the **Library** list, select an existing library. You can now select from the cells contained in the selected library. Each cell represents all of the symbol versions and part fractures for that particular part. In the **Cell** list, select the existing cell to use as a base for your part.

5. In the **Destination Library** list, select a destination library for the component. Click **Next**. A preview of your import data appears (Figure 9–8).

Figure 9–8. Preview of Import Data Window



6. Review the assignments you are importing into the Part Developer based on the data in the **.pin** file. The location of each pin is not included in the information in this window, but inputs are placed on the left side of the created symbol, outputs on the right, power pins on the top, and ground pins on the bottom. Make any desired changes. When you have completed your changes, click **Finish** to create the symbol. The Part Developer main screen appears.

If the Part Developer is not set up to point to your PCB Librarian Expert license file, an error message displays in red at the bottom of the message text window of the Part Developer when you select the **Import and Export** command. To point to your PCB Librarian Expert license, on the File menu, click **Change Product** and select the correct product license.

For more information about licensing and obtaining licensing support, contact Cadence or refer to their website at www.cadence.com.

Edit and Fracture Symbol

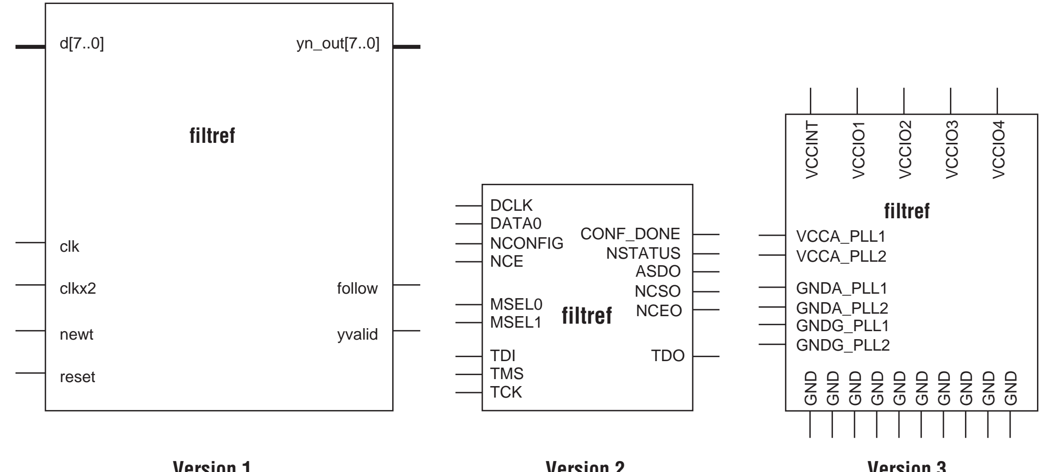
After you save your new symbol in the Part Developer software, you can edit the symbol graphics, fracture the symbol into multiple slots, and add or change package or symbol properties. These actions are available from the Part Developer main window.

The Part Developer Symbol Editor contains many graphical tools to edit the graphics of a particular symbol. Select the symbol in the cell hierarchy to edit the symbol graphics. The **Symbol Pins** tab appears. Edit the preview graphic of the symbol in the **Symbol Pins** tab.

Fracturing a Part Developer package into separate symbol slots is especially useful for FPGA designs. A single symbol for most FPGA packages might be too large for a single schematic page. Splitting the part into separate slots allows you to organize parts of the symbol by function, creating cleaner circuit schematics. For example, you could create one slot for an I/O symbol, a second slot for a JTAG symbol, and a third slot for a power/ground symbol.

Figure 9–9 shows a part fractured into separate slots.

Figure 9–9. Splitting a Symbol into Multiple Slots *(Note 1)*, *(2)*, *(3)*



Notes to Figure 9–9:

(1) Figure 9–9 represents a Cyclone device with JTAG or passive serial (PS) mode configuration option settings. Symbols created for other devices or other configuration modes might have different sets of configuration pins, but can be fractured in a similar manner.

(2) Symbol fractures are referred to in different ways in each of the tools described in this chapter. Refer to Table 9–2 for the specific tool naming conventions.

(3) The power/ground slot shows only a representation of power and ground pins. In actuality, the device contains a high number of power and ground pins.

While the Part Developer software refers to symbol fractures as slots, the other tools described in this chapter use different names to refer to symbol fractures. Table 9–2 lists the symbol fracture naming conventions for each of the tools addressed in this chapter.

Table 9–2. Symbol Fracture Naming

	Allegro PCB Librarian Part Developer Software	Allegro Design Entry HDL Software	Allegro Design Entry CIS Software
During symbol generation	Slots	—	Sections
During symbol schematic instantiation	—	Versions	Parts

To fracture a part into separate slots, or modify the slot locations of pins on parts that are already fractured in the Part Developer, perform the following steps:

1. Start the Cadence Allegro Design Project Manager.
2. On the Flows menu, click **Library Management**. The Library Management design flow appears. Click **Part Developer**. The Part Developer launches.
3. Click on the name of the package you want to change in the cell hierarchy. The **Package Pin** tab appears.

4. Click **Functions/Slots**. If you are not creating new slots but want to change the slot location of some pins, proceed to step 5. If you are creating new slots, click **Add**. A dialog box appears, allowing you to add extra symbol slots. Set the number of extra slots you want to add to the existing symbol, not the total number of desired slots for the part. Click **OK**.
5. Click **Distribute Pins**. Set the slot where each pin should reside. Use the checkboxes in each column to move pins from one slot to another. You can use the standard cut, copy, and paste keyboard commands on selected groups of checkboxes to move multiple pins from one slot to another. Click **OK**.
6. After distributing the pins, click the **Package Pin** tab and click **Generate Symbol(s)**. The **Generate Symbols** dialog box appears.
7. Select whether to create a new symbol or modify an existing symbol in each slot. Click **OK**.

The newly generated or modified slot symbols display as separate symbols in the cell hierarchy. Each of these symbols can be edited individually.

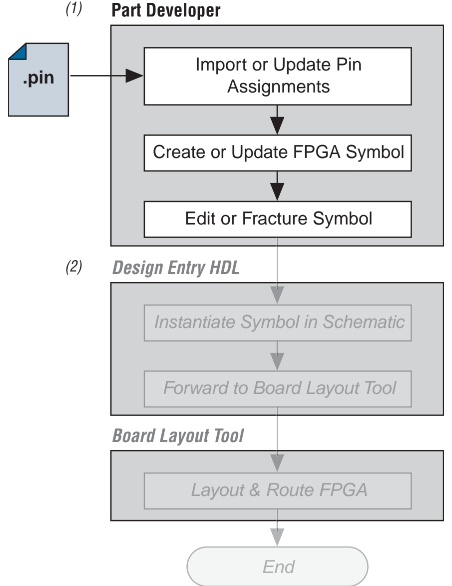
The Part Developer lets you remap pin assignments in the **Package Pin** tab of the main Part Developer window. If signals are remapped to different pins in the Part Developer, the changes are reflected only in regenerated symbols for use in your schematics. You cannot transfer pin assignment changes to the Quartus II software from the Part Developer, which creates a potential mismatch of the schematic symbols and assignments in the FPGA design. If pin assignment changes are necessary, make the changes in the Quartus II Pin Planner instead of the Part Developer, and update the symbol as described in the following sections.

For more information about creating, editing, and organizing component symbols with the Allegro PCB Librarian Part Developer, refer to the Part Developer Help.

Update FPGA Symbol

As the design process continues, you might have to make changes to the logic design in the Quartus II software, placing signals on different pins after the design is recompiled, or use the Quartus II Pin Planner to make changes manually. The board designer can request such changes to improve the board routing and layout. These types of changes must be carried forward to the circuit schematic and board layout tools to ensure signals are connected to the correct pins on the FPGA. Updating the **.pin** file in the Quartus II software facilitates this flow. Figure 9–10 shows this part of the design flow.

Figure 9–10. Updating the FPGA Symbol in the Design Flow



Notes to Figure 9–10:

(1) Refer to Figure 9–1 for the full design flow flowchart details.

(2) Grayed out steps are not part of the FPGA Symbol update process.

After the **.pin** file has been updated, perform the following steps to update the symbol using the Allegro PCB Librarian Part Developer:

1. On the File menu, click **Import and Export**. The Import and Export wizard appears.
2. In the list of actions to perform, select **Import ECO - FPGA**. Click **Next**. The **Select Source** dialog box appears.
3. Select the updated source of the FPGA assignment information. In the **Vendor** list, select **Altera**. In the **PnR Tool** list, select **quartusII**. In the **PR File** field, click **browse** to specify the updated **.pin** file in your Quartus II project directory. Click **Next**. The Select Destination window appears.
4. Select the source component and a destination cell for the updated symbol. To create a new component based on the updated pin assignment data, select **Generate Custom Component**. This replaces the cell listed under the **Specify Library and Cell** name header with a new, non-fractured cell. Any symbol edits or fractures are lost. You can preserve these edits by selecting **Use standard component and select the existing library and cell**. Select the destination library for the component and click **Next**. The **Preview of Import Data** dialog box appears.
5. Make any additional changes to your symbol. Click **Next**. A list of ECO messages displays summarizing what changes will be made to the cell. To accept the changes and update the cell, click **Finish**.
6. The main Part Developer window appears. You can edit, fracture, and generate the updated symbols as usual from this window.

If the Part Developer is not set up to point to your PCB Librarian Expert license file, an error message displays in red at the bottom of the message text window of the Part Developer when you select the **Import and Export** command. To point to your PCB Librarian Expert license, on the File menu, click **Change Product**, and select the correct product license. For more information about licensing and obtaining licensing support, contact Cadence or refer to their website at www.cadence.com.

Instantiating the Symbol in the Cadence Allegro Design Entry HDL Software

After the new symbol is saved in the Part Developer, perform the following steps to instantiate the symbol in your Design Entry HDL schematic:

1. In the Allegro Project Manager, switch to the board design flow.
2. On the Flows menu, click **Board Design**.
3. Click **Design Entry** to start the Design Entry HDL software.
4. To add the newly created symbol to your schematic, right-click in the main schematic window and choose **Add Component**, or on the Component menu, click **Add**. The **Add Component** dialog box appears.
5. Select the new symbol library location, and select the name of the cell you created from the list of cells.

The symbol is now “attached” to your cursor for placement in the schematic. If you fractured the symbol into slots, right-click the symbol and choose **Version** to select one of the slots for placement in the schematic.

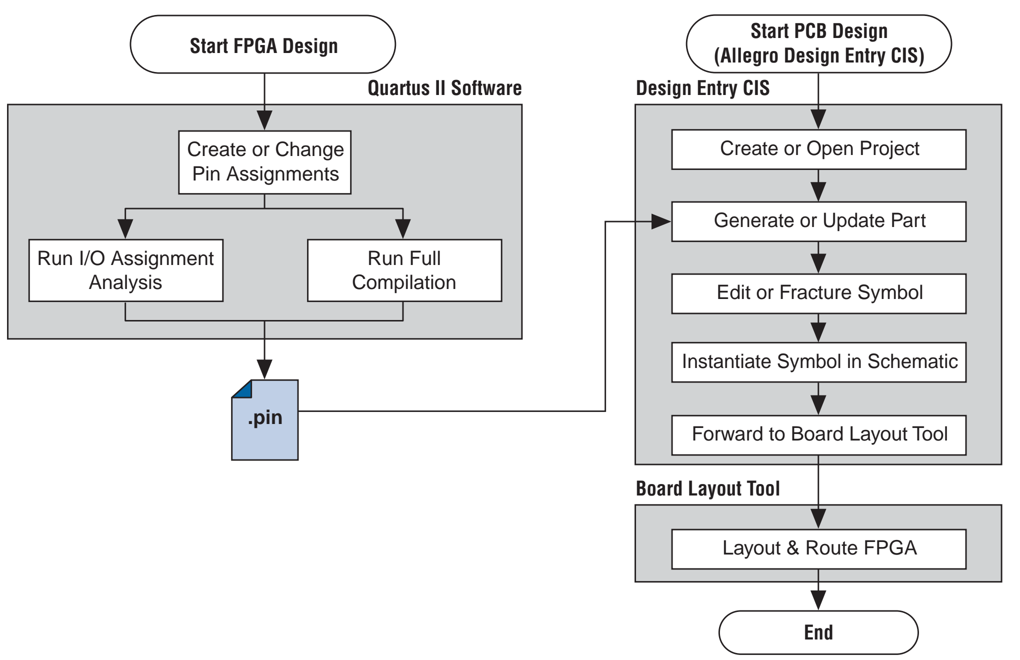
For more information about the Cadence Allegro Design Entry HDL software, including licensing, support, usage, training, and product updates, refer to the Help in the software or go to the Cadence website at www.cadence.com.

FPGA-to-Board Integration with Allegro Design Entry CIS

The Cadence Allegro Design Entry CIS software is Cadence’s mid-level schematic capture tool (part of the Cadence 200 series design flow based on OrCAD Capture CIS). Use this software to create flat circuit schematics for all types of PCB design. You can also create hierarchical schematics to facilitate design reuse and team-based design using this software. With the Cadence Allegro Design Entry CIS software, the design flow from FPGA-to-board is unidirectional using only the **.pin** file generated by the Quartus II software. Signal and pin assignment changes can only be made in the Quartus II software and are reflected in updated symbols in a Design Entry CIS schematic project.

Routing or pin assignment changes made in a board layout tool or a Design Entry CIS symbol cannot be back-annotated to the Quartus II software. Figure 9–11 shows the design flow with the Cadence Allegro Design Entry CIS software.

Figure 9–11. Design Flow with the Cadence Allegro Design Entry CIS Software



For more information about the Cadence Allegro Design Entry CIS software, including licensing, support, usage, training, and product updates, refer to the Help in the software, go to the Cadence website at www.cadence.com, or go to the EMA Design Automation website at www.ema-eda.com.

Allegro Design Entry CIS Project Creation

The Cadence Allegro Design Entry CIS software has built-in support for creating schematic symbols using pin assignment information imported from the Quartus II software.

If you have not already created a new project in the Cadence Allegro Design Entry CIS software, perform the following steps to create a new project:

1. On the File menu, point to **New** and click **Project.** The New Project wizard starts.

   When you create a new project, you can select the PC Board wizard, the Programmable Logic wizard, or a blank schematic.

2. Select the PC Board wizard to create a project where you can select which part libraries to use, or select a blank schematic.

The Programmable Logic wizard is used only to build an FPGA logic design in the Cadence Allegro Design Entry CIS software, which is unnecessary when using the Quartus II software.

No other special configuration for your project is required. Your new project is created in the specified location and initially consists of two files: the OrCAD Capture Project (**.opj**) file and the Schematic Design (**.dsn**) file.

Generate Part

After you create a new project or open an existing project in the Allegro Design Entry CIS software, you can generate a new schematic symbol based on your Quartus II FPGA design. You can also update an existing symbol if your **.pin** file has been updated in the Quartus II software. The Cadence Allegro Design Entry CIS software stores component symbols in OrCAD Library (**.olb**) files. When a symbol is placed in a library attached to a project, it is immediately available for instantiation in the project schematic.

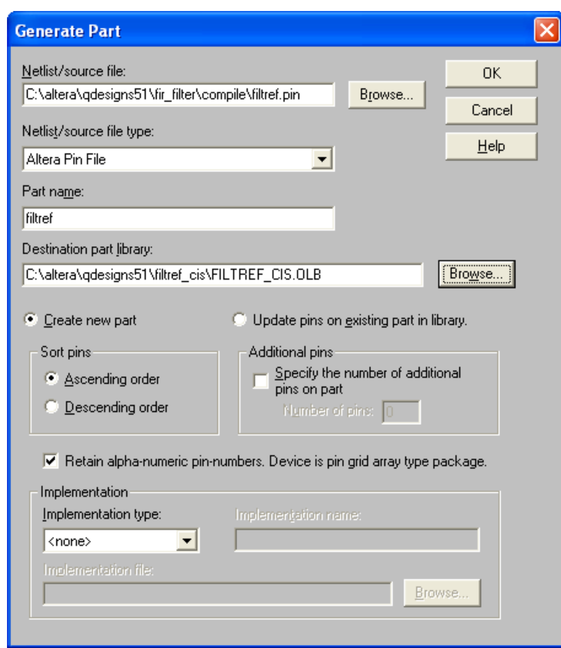
You can add symbols to an existing library or you can create a new library specifically for the symbols generated from your FPGA designs. To create a new library, perform the following steps:

1. On the File menu, point to **New** and click **Library** in the Cadence Allegro Design Entry CIS software to create a default library named **library1.olb**. This library appears in the **Library** folder in the Project Manager window of the Cadence Allegro Design Entry CIS software.
2. Right-click the new library and select **Save As** to specify a desired name and location for the library. The library file is not created until you save the new library.

You can now create a new symbol to represent your FPGA design in your schematic. To generate a schematic symbol, perform the following steps:

1. Start the Cadence Allegro Design Entry CIS software.
2. On the Tools menu, click **Generate Part**. The **Generate Part** dialog box appears (Figure 9–12).

Figure 9–12. Generate Part Dialog Box

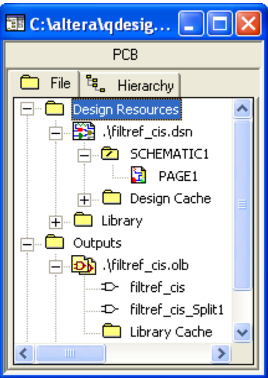


3. In the **Netlist/source file type** field, click **Browse** to specify the **.pin** file from your Quartus II design.

4. In the **Netlist/source file type** list, select **Altera Pin File**.
5. Enter the new part name.
6. Specify the **Destination part library** for the symbol. If you do not select an existing library for the part, a new library is created with a default name that matches the name of your Design Entry CIS project.
7. Select **Create new part** if you are creating a brand new symbol for this design. Select **Update pins on existing part in library** if you updated your **.pin** file in the Quartus II software and want to transfer any assignment changes to an existing symbol.
8. Select any other desired options and set **Implementation type** to **<none>**. The symbol is for a primitive library part based only on the **.pin** file and does not require a special implementation. Click **OK**.
9. Review the Undo warning and click **Yes** to complete the symbol generation.

The symbol is generated and placed in the selected library or in a new library found in the **Outputs** folder of the design in the Project Manager window (Figure 9–13). Double-click the name of the new symbol to see its graphical representation and edit it manually using the tools available in the Cadence Allegro Design Entry CIS software.

Figure 9–13. Project Manager Window



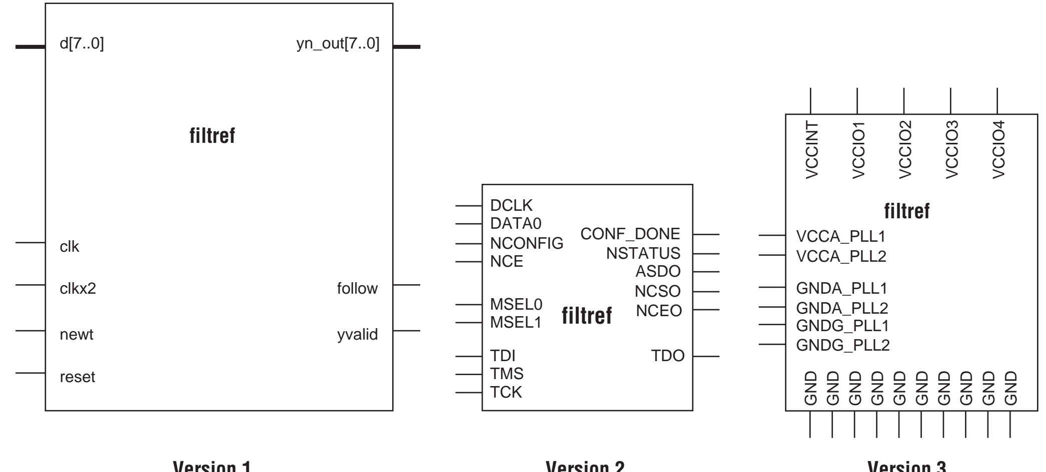
For more information about creating and editing symbols in the Allegro Design Entry CIS software, refer to the Help in the software.

Split Part

After a new symbol is saved in a project's library, you can fracture the symbol into multiple parts called sections. Fracturing a part into separate sections is especially useful for FPGA designs. A single symbol for most FPGA packages might be too large for a single schematic page. Splitting the part into separate sections allows you to organize parts of the symbol by function, creating cleaner circuit schematics. For example, you could create one slot for an I/O symbol, a second slot for a JTAG symbol, and a third slot for a power/ground symbol.

Figure 9–14 shows a part fractured into separate sections.

Figure 9–14. Splitting a Symbol into Multiple Sections *(Note 1)*, *(2)*, *(3)*



Notes to Figure 9–14:

(1) Figure 9–14 represents a Cyclone device with JTAG or passive serial (PS) mode configuration option settings. Symbols created for other devices or other configuration modes might have different sets of configuration pins, but can be fractured in a similar manner.

(2) Symbol fractures are referred to in different ways in each of the tools described in this chapter. Refer to Table 9–2 for the specific tool naming conventions.

(3) The power/ground section shows only a representation of power and ground pins. In actuality, the device contains a high number of power and ground pins.

While symbol generation in the Design Entry CIS software refers to symbol fractures as sections, the other tools described in this chapter use different names to refer to symbol fractures. Refer to Table 9–2 on page 9–11 for the symbol fracture naming conventions for each of the tools addressed in this chapter.

To split a part into sections, select the part in its library in the Project Manager window of Design Entry CIS. On the Tools menu, click **Split Part** or right-click the part and choose **Split Part**. The **Split Part Section Input Spreadsheet** appears (Figure 9–15).

Figure 9–15. Split Part Section Input Spreadsheet

	Number	Name	Type	Order	Length	User Assig	I/O Bank	Voltage	I/O Standard	Location	Section
1	H1	clk	Input	0	Line		1			Left	1
2	G1	clkx2	Input	1	Line		1			Left	1
3	K13	CONF_DONE	Passive	2	Line		3			Left	2
4	C7	d[0]	Input	3	Line		2			Left	1
5	A6	d[1]	Input	4	Line		2			Left	1
6	D7	d[2]	Input	5	Line		2			Left	1
7	B7	d[3]	Input	6	Line		2			Left	1
8	B8	d[4]	Input	7	Line		2			Left	1
9	M7	d[5]	Input	8	Line		4			Left	1
10	A8	d[6]	Input	9	Line		2			Left	1
11	B6	d[7]	Input	10	Line		2			Left	1
12	H2	DATA0	Input	11	Line		1			Left	2
13	K4	DCLK	Bidirectional	12	Line		1			Left	2
14	C6	follow	Output	13	Line		2			Right	1
15	J3	MSEL0	Passive	14	Line		1			Left	2
16	J2	MSEL1	Passive	15	Line		1			Left	2
17	J4	nCE	Passive	16	Line		1			Left	2
18	H4	nCEO	Passive	17	Line		1			Left	2
19	H3	nCONFIG	Passive	18	Line		1			Left	2
20	H5	newt	Input	19	Line		1			Left	1
21	J13	nSTATUS	Passive	20	Line		3			Left	2
22	G16	reset	Input	21	Line		3			Left	1

Each row in the spreadsheet represents a pin in the symbol. The spreadsheet column labeled **Section** indicates the section of the symbol to which each pin is assigned. By default, all pins in a new symbol are located in section 1. Change the values in this column to assign pins to different, new sections of the symbol. You can also specify the side of a section on which the pin will reside by changing the values in the **Location** column. When you are finished, click **Split**. A new symbol appears in the same library as the original with the name <*original part name*>**_Split1.**

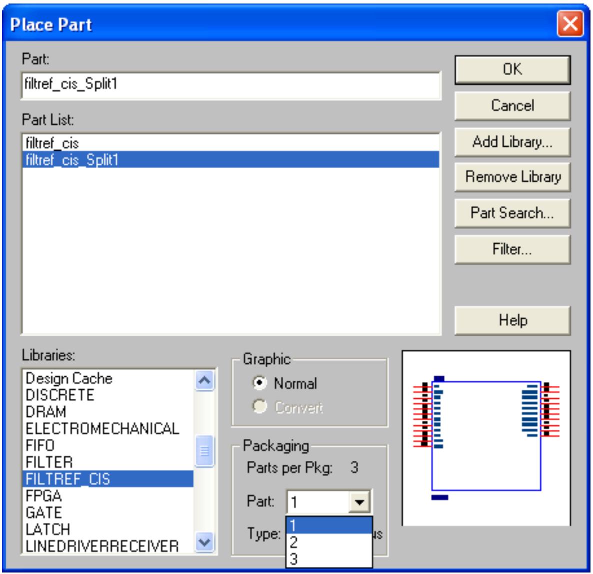
View and edit each section individually. To view the new sections of the part, double-click the part. The Part Symbol Editor window appears. The first section of the part is displayed for editing. On the View menu, click **Package** to view thumbnails of all the part sections. Double-click a thumbnail to edit that section of the symbol.

For more information about splitting parts into sections and editing symbol sections in the Cadence Allegro Design Entry CIS software, refer to the Help in the software.

Instantiate Symbol in Design Entry CIS Schematic

After a new symbol is saved in a library in your Design Entry CIS project, you can instantiate it on a page in your schematic. Open a schematic page in the Project Manager window of the Cadence Allegro Design Entry CIS software. On the schematic page, to add the newly created symbol to your schematic, on the Place menu, click **Part**. The **Place Part** dialog box appears (Figure 9–16).

Figure 9–16. Place Part Dialog Box



Select the new symbol library location and the newly created part name. If you select a part that is split into sections, you can select the section to place from the **Part** pop-up menu. Click **OK**. The symbol is now attached to your cursor for placement in the schematic. Click on the schematic page to place the symbol.

For more information about using the Cadence Allegro Design Entry CIS software, refer to the Help in the software.

Altera Libraries for Design Entry CIS

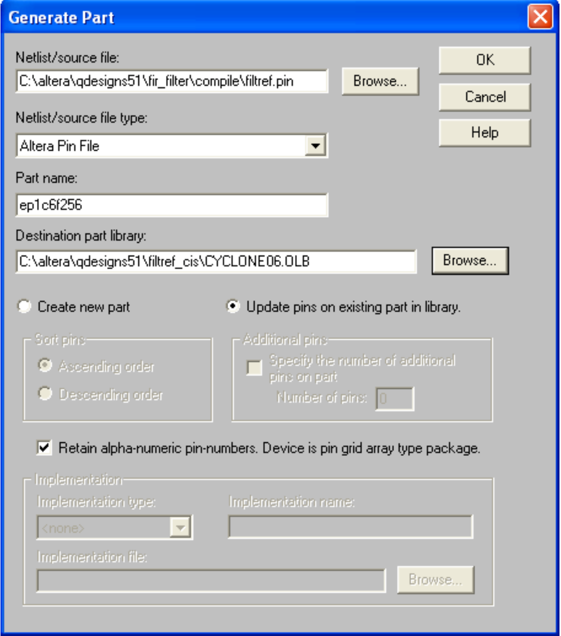
Altera provides downloadable **.olb** files for many of its device packages. You can add these libraries to your Design Entry CIS project and update the symbols with the pin assignments contained in the **.pin** file generated by the Quartus II software. This allows you to use the downloaded library symbols as a base for creating custom schematic symbols with your pin assignments that you can edit or fracture as desired. This can increase productivity by reducing the amount of time it takes to create and edit a new symbol.

To use the Altera-provided libraries with your Design Entry CIS project, perform the following steps:

1. Download the library of your target device from the Download Center page found through the Support page on the Altera website at www.altera.com.
2. Make a copy of the appropriate **.olb** file so that the original symbols are not altered. Place the copy in a convenient location, such as your Design Entry CIS project directory.
3. In the Project Manager window of the Cadence Allegro Design Entry CIS software, click once on the **Library** folder to select it. On the Edit menu, click **Project** or right-click the **Library** folder and choose **Add File** to select the copy of the downloaded **.olb** file and add it to your project. The new library is added to the list of part libraries for your project.

4. On the Tools menu, click **Generate Part.** The **Generate Part** dialog box appears (Figure 9–17).

Figure 9–17. Generate Part Dialog Box



5. In the **Netlist/source file** field, click **Browse** to specify the **.pin** file in your Quartus II design.
6. From the **Netlist/source file type** list, select **Altera Pin File**.
7. For **Part name**, enter the name of the target device the same as it appears in the downloaded library file. For example, if you are using a device from the **CYCLONE06.OLB** library, enter the part name to match one of the devices in this library such as `ep1c6f256`. You can rename the symbol later in the Project Manager window after the part is updated.
8. Set the **Destination part library** to the copy of the downloaded library you added to the project.
9. Select **Update pins on existing part in library**. Click **OK,** then click **Yes**.

The symbol is updated with your pin assignments. Double-click the symbol in the Project Manager window to view and edit the symbol. On the View menu, click **Package** if you want to view and edit other sections of the symbol. If the symbol in the downloaded library is already fractured into sections, as some of the larger packages are, you can edit each section but you cannot further fracture the part. Generate a new part without using the downloaded part library if you require additional sections.

For more information about creating, editing, and fracturing symbols in the Cadence Allegro Design Entry CIS software, refer to the Help in the software.

Conclusion

Transferring a complex, high-pin-count FPGA design to a PCB for prototyping or manufacturing is a daunting process that can lead to errors in the PCB netlist or design, especially when different engineers are working on different parts of the project. The design workflow available when the Quartus II software is used with tools from Cadence assists the FPGA designer and the board designer in preventing such errors and focusing all attention on the design.

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Chapter 9 was previously Chapter 7 in the 8.1 software release. ■ No change to content.	Updated for the Quartus II software version 9.0 release.
November 2008 v8.1.0	Changed to 8-1/2 x 11 page size.	Updated for the Quartus II software version 8.1 release.
May 2008 v8.0.0	Updated references.	Updated for the Quartus II software version 8.0.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

Section III. Area, Timing and Power Optimization

Introduction

Physical implementation can be an intimidating and challenging phase of the design process. This section introduces features in Altera's Quartus® II software that you can use to achieve the highest design performance when you design for programmable logic devices (PLDs), especially high density FPGAs. The Quartus II software provides a comprehensive environment for FPGA designs, delivering unmatched performance, efficiency, and ease-of-use.

In a typical design flow, you must synthesize your design with Quartus II integrated synthesis or a third-party tool, place and route your design with the Fitter, and use the TimeQuest static timing analyzer to ensure your design meets the timing requirements. With the PowerPlay Power Analyzer, you ensure the design's power consumption is within limits. If your design does not meet all of your constraints, reiterate this process either partially or completely (based on the specific situation).

Refer to "Further Reading" for more information on any particular feature.

Physical Implementation

Most optimization issues are about preserving previous results, reducing area, reducing critical path delay, reducing power consumption, and reducing runtime. The Quartus II software includes advisors to address each of these issues and helps you optimize your design. Run these advisors during physical implementation for advice about your specific design situation.

You can reduce the time spent on design iterations by following the recommended design practices for designing with Altera® devices. Design planning is critical for successful design timing implementation and closure.

Trade Offs and Limitations

Many optimization goals can conflict with one another, so you might be required to make trade offs between different goals. For example, one major trade-off during physical implementation is between resource usage and critical path timing, because certain techniques (such as logic duplication) can improve timing performance at the cost of increased area. Similarly, a change in power requirements can result in area and timing trade offs. For example, if you reduce the number of high-speed tiles available, or if you attempt to shorten high-power nets at the expense of critical path nets.

In addition, system cost and time-to-market considerations can affect the choice of the device. For example, a device with a higher speed grade or more clock networks can facilitate timing closure at the expense of higher power consumption and system cost.

Finally, not all designs can be realized in a hardware circuit with limited resources and given constraints. If you encounter resource limitation, timing constraints, or power constraints that cannot be resolved by the Fitter, you might have to consider rewriting parts of the HDL code.

Preserving Results and Enabling Teamwork

Some of the Quartus II Fitter algorithms are pseudo-random in nature, which means that small changes to the design can have a large impact on the final result. For example, a critical path delay can change by 10% or more because of seemingly insignificant changes. If you are close to meeting your timing objectives, you can use the Fitter algorithm to your advantage by changing the fitter seed, which changes the pseudo-random result of the Fitter.

Conversely, if you have trouble meeting timing on a portion of your design, you can partition the troublesome portion and prevent it from recompiling if an unrelated part of the design is changed. This feature, known as incremental compilation, can reduce the Fitter runtimes by up to 70% if the design is partitioned, such that only small portions require recompilation at any one time.

When you use incremental compilation, you can apply design optimization options to individual design partitions and preserve performance in other partitions by leaving them untouched. Many of the optimization techniques often result in longer compilation times, but by applying them only on specific partitions, you can reduce this impact and complete more iterations per day.

In addition, by physically floorplanning your partitions with LogicLock, you can enable team-based flows and allow multiple people to work on different portions of the design.

Reducing Area

By default, the Quartus II Fitter might spread out a design to meet the set timing constraints. If you prefer to optimize your design to use the smallest area, you can change this behavior. If you require more area savings, you can enable certain physical synthesis options to modify your netlist to create more area-efficient implementation, but at the cost of increased runtime and decreased performance.

Reducing Critical Path Delay

To meet complex timing requirements involving multiple clocks, routing resources, and area constraints, the Quartus II software offers a close interaction between synthesis, timing analysis, floorplan editing, and place-and-route processes.

By default, the Quartus II Fitter tries to meet specified timing requirements and stops trying once the requirements are met. Therefore, using realistic constraints is important to successfully close timing. If you under-constrain your design, you are likely to get sub-optimal results. By contrast, if you over-constrain your design, the Fitter might over-optimize non-critical paths at the expense of true critical paths. In addition, you might incur an increased area penalty. Compilation time might increase because of excessively tight constraints.

If your resource use is very high, the Quartus II Fitter might have trouble finding a legal placement. In such circumstances, the Fitter automatically modifies some of its settings to try to trade off performance for area.

The Quartus II Fitter offers a number of advanced options that can help in improving the performance of your design when you properly set constraints. Use the Timing Optimization Advisor to determine which options are best suited for your design.

If you use incremental compilation, you can help resolve inter-partition timing requirements by locking down the results for each partition at a time or by guiding the placement of the partitions with LogicLock regions. You might be able to improve the timing on such paths by placing the partitions optimally to reduce the length of critical paths. Once your inter-partition timing requirements are met, use incremental compilation to preserve the results and work on partitions that have not met timing requirements.

In high-density FPGAs, routing accounts for a major part of critical path timing. Because of this, duplicating or retiming logic can allow the Fitter to shorten critical paths. The Quartus II software offers push-button netlist optimizations and physical synthesis options that can improve design performance at the expense of considerable increases of compilation time and area. Turn on only those options that help you keep reasonable compilation times. Alternately, you can modify your HDL to manually duplicate or retime logic.

Reduce Power Consumption

The Quartus II software has features that help reduce design power dissipation. The PowerPlay power optimization options control the power-driven compilation settings for Synthesis and Fitter.

Reducing Runtime

Many Fitter settings influence compilation time. Most of the default settings in the Quartus II software are set for reduced compilation time. You can modify these settings based on your project requirements.

The Quartus II software supports parallel compilation in computers with multiple processors. This can reduce compilation times by up to 15% while giving the identical result as serial compilation.

You can also reduce compilation time with your iterations by using incremental compilation. Use incremental compilation when you want to change parts of your design, while keeping most of the remaining logic unchanged.

Using Quartus II Tools

Design Analysis

The Quartus II software provides tools that help with a visual representation of your design. You can use the RTL Viewer to see a schematic representation of your design before behavioral simulation, synthesis, and place-and-route. The Technology Map Viewer provides a schematic representation of the design implementation in the selected device architecture after synthesis and place-and-route. It can also include timing information.

With incremental compilation, the Design Partition Planner and the Chip Planner allow you to partition and layout your design at a higher level. In addition, you can perform many different tasks with the Chip Planner, including: making floorplan assignments, implementing engineering change orders (ECOs), and performing power analysis. Also, you can analyze your design and achieve a faster timing closure with the Chip Planner. The Chip Planner provides physical timing estimates, critical path display, and routing congestion view to help guide placement for optimal performance.

Advisors

The Quartus II software includes several advisors to help you optimize your design. You can save time by following the recommendations in the timing optimization advisor, the area optimization advisor, and the power optimization advisor. These advisors give recommendations based on your project settings and your design constraints.

Design Space Explorer

Use the Design Space Explorer (DSE) to find optimum settings in the Quartus II software. DSE automatically tries different combinations of netlist optimizations and advanced Quartus II software compiler settings, and reports the best settings for your design. You can try different seeds with the DSE if you are fairly close to meeting timing requirements. Finally, the DSE can run the different compilations on multiple computers at once, which shortens the timing closure process.

Further Reading

This section includes the following chapters:

- Chapter 10, Area and Timing Optimization
- Chapter 11, Power Optimization
- Chapter 12, Analyzing and Optimizing the Design Floorplan
- Chapter 13, Netlist Optimizations and Physical Synthesis
- Chapter 14, Design Space Explorer

Other supporting documents in volume 1 of the Quartus II Handbook are:

- *Design Planning with the Quartus II Software*
- *Quartus II Incremental Compilation for Hierarchical and Team-Based Designs*
- *Design Recommendations for Altera Devices and the Quartus II Design Assistant*
- *Recommended HDL Coding Styles*
- *Section IV. Engineering Change Management*

10. Area and Timing Optimization

QII52005-9.0.0

Introduction

Good optimization techniques are essential for achieving the highest possible quality of results when designing for programmable logic devices (PLDs). The optimization features available in the Quartus® II software are designed to allow you to meet design requirements by applying these techniques at multiple points in the design process.

This chapter explains techniques to reduce resource usage, improve timing performance, and reduce compilation times when designing for Altera® devices. It also explains how and when to use some of the features described in other chapters of the *Quartus II Handbook*. This introduction describes the various stages in a design optimization process, and points you to the appropriate sections in the chapter for area, timing, or compilation time optimization.

Topics in this chapter include:

- "Initial Compilation: Required Settings" on page 10–3
- "Initial Compilation: Optional Settings" on page 10–6
- "Design Analysis" on page 10–11
- "Resource Utilization Optimization Techniques (LUT-Based Devices)" on page 10–19
- "Timing Optimization Techniques (LUT-Based Devices)" on page 10–32
- "Resource Utilization Optimization Techniques (Macrocell-Based CPLDs)" on page 10–55
- "Timing Optimization Techniques (Macrocell-Based CPLDs)" on page 10–60
- "Compilation-Time Optimization Techniques" on page 10–64
- "Other Optimization Resources" on page 10–70
- "Scripting Support" on page 10–71

The application of these techniques varies from design to design. Applying each technique does not always improve design results. Settings and options in the Quartus II software have default values that generally provide the best trade-off between compilation time, resource utilization, and timing performance. You can adjust these settings to determine whether other settings provide better results for your design.

When using advanced optimization settings and tools, it is important to benchmark their effect on your quality of results and to use them only if they improve results for your design.

Use the optimization flow described in this chapter to explore various compiler settings and determine the techniques that provide the best results.

Optimizing Your Design

The first stage in the optimization process is to perform an initial compilation to view the quality of results for your design. "Initial Compilation: Required Settings" on page 10–3 provides guidelines on some of the settings and assignments that are recommended for your initial compilation. "Initial Compilation: Optional Settings" on page 10–6 describes settings that you might have to turn on based on your design requirements. "Design Analysis" on page 10–11 explains how to analyze the compilation results.

You can use incremental compilation as part of the optimization process. Incremental compilation can be used as a tool for timing preservation that aids in timing closure, as well as compilation time reduction; however, it can cause a slight increase in resource utilization.

For more details about incremental compilation with the Quartus II software, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

After you have analyzed the compilation results, perform the optimization stages in the recommended order, as described in this chapter.

For LUT-based devices (FPGAs, MAX® II series of devices), perform optimizations in the following order:

1. If your design does not fit, refer to "Resource Utilization Optimization Techniques (LUT-Based Devices)" on page 10–19 before trying to optimize I/O timing or register-to-register timing.
2. If your design does not meet the required I/O timing performance, refer to "I/O Timing Optimization Techniques (LUT-Based Devices)" on page 10–73 before trying to optimize register-to-register timing.
3. If your design does not meet the required slack on any of the clock domains in the design, refer to "Register-to-Register Timing Optimization Techniques (LUT-Based Devices)" on page 10–40.

For macrocell-based devices (MAX 7000 and MAX 3000 CPLDs), perform optimizations in the following order:

1. If your design does not fit, refer to "Resource Utilization Optimization Techniques (Macrocell-Based CPLDs)" on page 10–55 before trying to optimize I/O timing or register-to-register timing.
2. If your timing performance requirements are not met, refer to "Timing Optimization Techniques (Macrocell-Based CPLDs)" on page 10–60.
3. For device-independent techniques to reduce compilation time, refer to "Compilation-Time Optimization Techniques" on page 10–64.

You can use all these techniques in the GUI or with Tcl commands. For more information about scripting techniques, refer to "Scripting Support" on page 10–71.

Initial Compilation: Required Settings

This section describes the basic assignments and settings for your initial compilation. Ensure that you check all the following suggested compilation assignments before compiling the design in the Quartus II software. Significantly different compilation results can occur depending on the assignments you have set.

The following settings are required:

- "Device Settings"
- "I/O Assignments"
- "Timing Requirement Settings" on page 10–4
- "Device Migration Settings" on page 10–5
- "Partitions and Floorplan Assignments for Incremental Compilation" on page 10–6

Device Settings

Assigning a specific device determines the timing model that the Quartus II software uses during compilation. Choose the correct speed grade to obtain accurate results and the best optimization. The device size and the package determine the device pin-out and how many resources are available in the device.

To choose the target device, on the Assignments menu, click **Device**.

In a Tcl script, use the following command to set the device:

```
set_global_assignment -name DEVICE <device> ↵
```

I/O Assignments

The I/O standards and drive strengths specified for a design affect I/O timing. Specify I/O assignments so that the Quartus II software uses accurate I/O timing delays in timing analysis and Fitter optimizations.

The Quartus II software can choose pin locations automatically for best quality of results. If your pin locations are not fixed due to PCB layout requirements, leave pin locations unconstrained to achieve the best results. If your pin locations are already fixed, make pin assignments to constrain the compilation appropriately. "Resource Utilization Optimization Techniques (Macrocell-Based CPLDs)" on page 10–55 includes recommendations for making pin assignments that can have a larger effect on your quality of results in smaller macrocell-based architectures.

Use the Assignment Editor and Pin Planner to assign I/O standards and pin locations.

For more information about I/O standards and pin constraints, refer to the appropriate device handbook. For information about planning and checking I/O assignments, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*. For information about using the Assignment Editor, refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook*.

Timing Requirement Settings

Using comprehensive timing requirement settings is an important step for achieving the optimal quality of results, for the following reasons:

- Correct timing assignments allow the software to work hardest to optimize the performance of the timing-critical parts of the design and make trade-offs for performance. This optimization can also save area or power utilization in non-critical parts of the design.
- If enabled, the Quartus II software performs physical synthesis optimizations based on timing requirements (refer to "Physical Synthesis Optimizations" on page 10–41 for more information).
- Depending on the **Fitter Effort** setting, the Quartus II Fitter can reduce runtime considerably if your timing requirements are being met. For a full description of the different effort levels, refer to "Fitter Effort Setting" on page 10–10.

As a general rule, do not over-constrain the software by applying timing requirements that are higher than your design requirements. Use your real design requirements to get the best results. Power utilization might also be larger in an over-constrained design when the software balances power and performance during compilation.

Both the Classic and TimeQuest Timing Analyzers check your design against the timing assignments. The compilation report and timing analysis reporting commands show whether timing requirements are met and provide detailed timing information about paths that violate timing requirements.

To make clock and timing assignments for the Quartus II TimeQuest Timing Analyzer, create a Synopsys Design Constraint (**.sdc**) file that contains all of your constraints. You can also create constraints in the TimeQuest GUI. Use the `write_sdc` command, or, in the TimeQuest Timing Analyzer, on the Constraints menu, click **Write SDC File** to write your constraints to an **.sdc** file. You can add an **.sdc** file to your project on the **TimeQuest Timing Analyzer** page under **Timing Analysis Settings**.

To make clock assignments for the Quartus II Classic Timing Analyzer, on the Assignments menu, click the **Timing Analysis Settings**. Select the **Classic Timing Analyzer Settings** page. Use the **Delay requirements**, **Minimum delay requirements**, and **Clock Settings** boxes to make global settings, or to apply settings to individual clocks, click **Individual Clocks** (recommended for multiple-clock designs). Create the clock setting and apply it to the appropriate clock node in the design. The Timing Wizard can also step you through the process of making individual clock constraints for the Quartus II Classic Timing Analyzer. To run the Timing Wizard, on the Assignments menu, click **Timing Wizard**.

The Classic Timing Analyzer is not supported for designs using some of the newer Altera device families.

© March 2009 Altera Corporation

Ensure that every clock signal has an accurate clock setting assignment. If clocks come from a common oscillator, they can be considered related. Ensure that all related or derived clocks are set up correctly in the assignments. All I/O pins that require I/O timing optimization must have settings. You should also specify minimum timing constraints as applicable. If there is more than one clock or there are different I/O requirements for different pins, make multiple clock settings and individual I/O assignments instead of using the global settings.

Make any complex timing assignments required in the design, including any cut-timing and multicycle path assignments. Common situations for these types of assignments include reset or static control signals, cases in which it is not important how long it takes a signal to reach a destination, and paths that can operate in more than one clock cycle. These assignments allow the Quartus II software to make appropriate trade-offs between timing paths and can enable the Compiler to improve timing performance in other parts of the design.

For more information about timing assignments and timing analysis, refer to the *Quartus II TimeQuest Timing Analyzer* and *Quartus II Classic Timing Analyzer* chapters in volume 3 of the *Quartus II Handbook*. For more information on how to specify multicycle exceptions in the TimeQuest Timing Analyzer, refer to *AN 481: Applying Multicycle Exceptions in the TimeQuest Timing Analyzer*.

Timing Constraint Check—Report Unconstrained Paths

To ensure that all constraints or assignments have been applied to design nodes, you can report all unconstrained paths in your design.

While using the Quartus II TimeQuest Timing Analyzer, you can report all the unconstrained paths in your design with the Report Unconstrained Paths command (`report_ucp`) in the Task pane.

If you are using the Quartus II Classic Timing Analyzer, perform the following steps:

1. On the Assignments menu, click **Timing Analysis Settings**. The **Settings** dialog box appears.
2. Under **Timing Analysis Settings**, select **Classic Timing Analyzer Settings**.
3. Click **More Settings**. The **More Timing Settings** dialog box appears.
4. From the **Existing option settings** list, select **Report Unconstrained Paths**. From the **Setting** list, select **On**.

Device Migration Settings

If you anticipate a change to the target device later in the design cycle, either because of changes in the design or other considerations, plan for it at the beginning of your design cycle. Whenever you select a target device in **Settings** dialog box, you can also list any other compatible devices you can migrate to by clicking on the **Migration Devices** button on the **Device** page. If you plan to move your design to a HardCopy® device, make sure to select the device from the list under the **Companion device** tab on the **Device** page.

Selecting the migration device and companion device early in the design cycle helps you to minimize changes to the design at a later stage.

Partitions and Floorplan Assignments for Incremental Compilation

The Quartus II incremental compilation feature enables hierarchical and team-based design flows in which you compile parts of your design while other parts of the design remain unchanged, or import parts of your design from separate Quartus II projects.

Using the incremental compilation methodology with a good partitioning of the design can often help to achieve timing closure. Creating LogicLock™ regions and using incremental compilation can help you achieve timing closure block by block, and preserve the timing performance between iterations, which helps achieve timing closure for the entire design.

Using incremental compilation also helps reduce compilation times. For information about using the incremental compilation feature to reduce your compilation time, refer to "Incremental Compilation" on page 10–64.

If you want to take advantage of this feature for a team-based design flow to reduce your compilation times, or to improve the timing performance of your design during iterative compilation runs, make meaningful design partitions as well as create a floorplan for your design partitions. Assignments can negatively affect a design's quality of results if you do not follow Altera's recommendations. Good assignments can improve your quality of results.

If you plan to use incremental compilation, you must create a floorplan for your design. If you are not using incremental compilation, this step is optional.

For guidelines about how to create partition and floorplan assignments for your design, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Initial Compilation: Optional Settings

This section describes the settings that are optional, but that can help to compile your design. You can selectively set all the optional settings that help to improve performance (if required) and reduce compilation time. These settings vary between designs and there is no standard set that applies to all designs. Significantly different compilation results can occur depending on the assignments you have set.

The following settings are optional:

- "Design Assistant" on page 10–7
- "Smart Compilation Setting" on page 10–7
- "Early Timing Estimation" on page 10–7
- "Optimize Hold Timing" on page 10–8
- "Asynchronous Control Signal Recovery/Removal Analysis" on page 10–9
- "Limit to One Fitting Attempt" on page 10–9

Design Assistant

You can run the Design Assistant to analyze the post-fitting results of your design during a full compilation. The Design Assistant checks rules related to areas such as gated clocks, reset signals, asynchronous design practices, and signal race conditions. This is especially useful during the early stages of your design, so that you can work on any areas of concern in your design before proceeding with design optimization.

On the Assignments menu, click **Settings**. In the **Category** list, select **Design Assistant** and turn on **Run Design Assistant during compilation**.

You can also specify which rules you want the Design Assistant to apply when analyzing and generating messages for a design.

For more information about the rules in the Design Assistant, refer to the *Design Recommendations for Altera Devices and the Quartus II Design Assistant* chapter in volume 1 of the *Quartus II Handbook*.

Smart Compilation Setting

Smart compilation can reduce compilation time by skipping compiler stages that are not required to recompile the design. This is especially useful when you perform multiple compilation iterations during the optimization phase of the design process. However, smart compilation uses more disk space. To turn on smart compilation, on the Assignments menu, click **Settings**. In the **Category** list, select **Compilation Process Settings** and turn on **Use smart compilation**.

This feature skips entire compiler stages (such as Analysis and Synthesis) when they are not required. This feature is different from incremental compilation, which you can use to compile parts of your design while preserving results for unchanged parts. For information about using the incremental compilation feature to reduce your compilation time, refer to "Incremental Compilation" on page 10–64.

Early Timing Estimation

The Quartus II software provides an Early Timing Estimation feature that estimates your design's timing results before the software performs full placement and routing. On the Processing menu, point to **Start**, and click **Start Early Timing Estimate** to generate initial compilation results after you have run analysis and synthesis. When you want a quick estimate of a design's performance before proceeding with further design or synthesis tasks, this command can save significant compilation time. Using this feature provides a timing estimate up to 45× faster than running a full compilation, though the fit is not fully optimized or routed. Therefore, the timing report is only an estimate. On average, the estimated delays are within 11% of those achieved by a full compilation compared to the final timing results.

You can specify what type of delay estimates to use with this feature. On the Assignments menu, click **Settings**. In the **Category** list, select **Compilation Process Settings**, and select **Early Timing Estimate**. On the **Early Timing Estimate** page, the following options are available:

- The **Realistic** option, which is the default, generates delay estimates that are likely to be close to the results of a full compilation.

- The **Optimistic** option uses delay estimates that are lower than those likely to be achieved by a full compilation, which results in an optimistic performance estimate.
- The **Pessimistic** option uses delay estimates that are higher than those likely to be achieved by a full compilation, which results in a pessimistic performance estimate.

All three options offer the same reduction in compilation time.

You can use the Chip Planner or the Timing Closure Floorplan (for older devices) to view the placement estimate created by this feature to identify critical paths in the design. Then, if necessary, you can add or modify floorplan constraints such as LogicLock regions, or make other changes to the design. You can then rerun the Early Timing Estimator to quickly assess the impact of any floorplan assignments or logic changes, enabling you to try different design variations and find the best solution.

Optimize Hold Timing

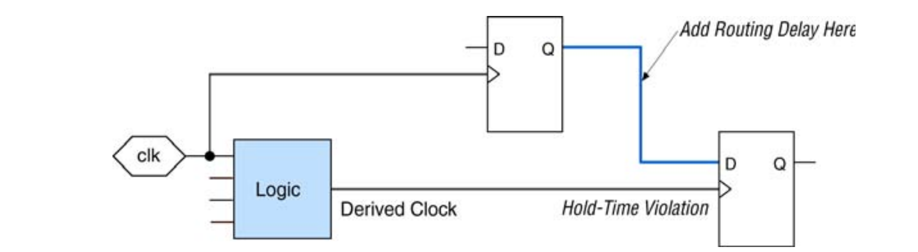
The **Optimize Hold Timing** option directs the Quartus II software to optimize minimum delay timing constraints. This option is available only for the Arria® GX, Stratix®, Cyclone®, MAX II series of devices, and HardCopy III and HardCopy II ASICs. By default, the Quartus II software optimizes hold timings for all paths for designs using newer devices such as Arria II GX, Arria GX, Stratix III, Stratix IV, and Cyclone III devices. By default, the Quartus II software optimizes hold timings only for I/O paths and minimum TPD paths for older devices.

When you turn on **Optimize Hold Timing**, the Quartus II software adds delay to paths to guarantee that the minimum delay requirements are satisfied. In the **Fitter Settings** panel, if you choose **I/O Paths and Minimum TPD Paths** (the default choice for older devices such as Cyclone II and Stratix II family of devices if you turn on **Optimize Hold Timing**), the Fitter works to meet the following criteria:

- Hold times (t_H) from device input pins to registers
- Minimum delays from I/O pins to I/O registers or from I/O registers to I/O pins
- Minimum clock-to-out time (t_{CO}) from registers to output pins

If you select **All Paths**, the Fitter also works to meet hold requirements from registers to registers, as in Figure 10–1, where a derived clock generated with logic causes a hold time problem on another register. However, if your design has internal hold time violations between registers, Altera recommends that you correct the problems by making changes to your design, such as using a clock enable signal instead of a derived or gated clock.

Figure 10–1. Optimize Hold Timing Option Fixing an Internal Hold Time Violation



For design practices that can help eliminate internal hold time violations, refer to the *Design Recommendations for Altera Devices and the Quartus II Design Assistant* chapter in volume 1 of the *Quartus II Handbook*.

Asynchronous Control Signal Recovery/Removal Analysis

This option determines whether you want the software to analyze the results of recovery, and removal checks for paths that end at an asynchronous clear, preset, or load signal of a register. Recovery time is the minimum length of time an asynchronous control signal, for example, clear and preset, must be stable before the active clock edge. Removal time is the minimum time an asynchronous control signal must be stable after the active clock edge. Recovery and removal requirements are similar to setup and hold time requirements, respectively.

When using TimeQuest for timing analysis, Recovery/Removal analysis and optimization are always performed during placement and routing. You can use the `create_timing_summary` Tcl command to report the recovery and removal analysis. The slack for Removal/Recovery is determined in a similar way to Setup and Hold checks.

When using the Quartus II Classic Timing Analyzer for timing analysis, Recovery/Removal analysis is turned off by default. Turning on the option adds additional constraints during placement and routing, which can increase compilation time and reduce performance. If this analysis is required, on the Assignments menu, click **Settings**. In the **Category** list, select **Timing Requirements & Options**, then click **More Settings**. Turn on **Enable Recovery/Removal analysis**. By running the Recovery/Removal analysis, you can make sure that no timing failures are related to the asynchronous control signals in your design.

For more details about Recovery/Removal analysis with the TimeQuest Timing Analyzer, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

For designs containing FIFOs, Altera recommends turning on Recovery/Removal analysis. Recovery/Removal analysis helps to analyze corner-case conditions to achieve better functional coverage.

Limit to One Fitting Attempt

A design might fail to fit for several reasons, such as logic overuse or illegal assignments. For most of these failures, the Quartus II software informs you of the problem. However, if the design uses too much routing, the Quartus II software makes up to two additional attempts to fit your design, each time trying harder than the last to reduce routing resource utilization. Each of these fit attempts takes significantly longer than the previous attempt.

However, for large designs, you might not wish to wait for all three attempts, and would rather receive an error message earlier. This would allow you to take corrective action sooner. To get an early error indication, turn on **Limit to one fitting attempt** from the **Fitter Settings** page. When you choose this setting for your design, the Quartus II software quits with an error message after the first failed fitting attempt.

Refer to “Routing” on page 10–29 for instructions about how to lower the design’s routing utilization, so your design can be made to fit into the target device if it fails to fit due to the lack of routing resources.

Optimize Multi-Corner Timing

Historically, FPGA timing analysis has been performed using only worst-case delays, which are described in the slow corner timing model. However, due to process variation and changes in the operating conditions, delays on some paths can be significantly smaller than those in the slow corner timing model. This can result in hold time violations on those paths, and in rare cases, additional setup time violations.

By default, the Fitter optimizes constraints using only the slow corner timing model. You can turn on the **Optimize multi-corner timing** option to instruct the Fitter to also optimize constraints using the fast corner timing model and operating conditions, as well as the slow corner timing model and operating conditions to avoid the possible timing violations described above. By optimizing for both fast and slow process corners, you can create a design implementation that is more robust across process, temperature, and voltage variations. This option is available only for Arria GX, Stratix, Cyclone, and MAX II series of devices.

To turn on the **Optimize fast-corner timing** option, on the Assignments menu, click **Settings**. In the **Category** list, select **Fitter Settings** and turn on **Optimize fast-corner timing**. Using the two different timing models can be important to account for process, voltage, and temperature variations for each device. Turning this option on increases compilation time by approximately 10%.

For designs with external memory interfaces such as DDR and QDR, Altera recommends that you turn on the **Optimize fast-corner timing** setting.

Fitter Effort Setting

To set the Fitter effort, on the Assignments menu, click **Settings**. In the **Category** list, select **Fitter Settings**. The **Fitter effort** settings are **Auto Fit**, **Standard Fit**, and **Fast Fit**. The default setting depends on the device family specified.

Auto Fit

The **Auto Fit** option (available for Arria GX, Stratix, Cyclone, and MAX II series of devices) focuses the full Fitter effort on those aspects of the design that require further optimization. **Auto Fit** can significantly reduce compilation time relative to **Standard Fit** if your design has some easy-to-meet timing requirements, low routing resource utilization, or both. However, those designs that require full optimization generally receive the same effort as is achieved by selecting **Standard Fit**. **Auto Fit** is the default Fitter effort setting for all devices for which this option is available.

If you want the Fitter to attempt to exceed the timing requirements by a certain margin instead of simply meeting them, specify a minimum slack in the **Desired worst case slack** box.

Specifying a minimum slack does not guarantee that the Fitter achieves the slack requirement; it only guarantees that the Fitter applies full optimization unless the target slack is exceeded.

In some designs with multiple clocks, it might be possible to improve the timing performance on one clock domain while reducing the performance on other clock domains by over-constraining the most important clock. If you use this technique, ensure that any performance improvements that you see are real gains by performing a sweep over multiple seeds. For more information, refer to "Fitter Seed" on page 10–47.

Over-constraining the clock for which you require maximum slack, while using the **Auto Fit** option, increases the chances that the Fitter is able to meet this requirement.

The **Auto Fit** option also causes the Quartus II Fitter to optimize for shorter compilation times instead of maximum performance if the design includes no timing assignments. For designs with no timing assignments, the resulting f_{MAX} is, on average, 10% lower than that achieved using the **Standard Fit** option. If your design has aggressive timing requirements or is hard to route, the placement does not stop early and the compilation time is the same as using the **Standard Fit** option. For designs with no timing requirements or easily achieved timing requirements, you can achieve an average compilation time reduction of 40% by using the **Auto Fit** option.

The **Auto Fit** option might increase the number of routing wires used. This can lead to an increase in the dynamic power when compared to using the **Standard Fit** option, unless the **Extra effort** option in the **PowerPlay power optimization** list is also enabled. When you turn on **Extra effort**, **Auto Fit** continues to optimize for reduction of wire usage even after meeting the register-to-register requirement. There is no adverse effect on the dynamic power consumption. If dynamic power consumption is a concern, select **Extra effort** in both the **Analysis & Synthesis Settings** and the **Fitter Settings** pages.

For more details, refer to the "Power Driven Compilation" section in the *Power Optimization* chapter in volume 2 of the *Quartus II Handbook*.

Standard Fit

Use the **Standard Fit** option to exceed specified timing requirements and achieve the best possible timing results and lowest routing resource utilization for your design. However, this setting usually increases compilation time relative to **Auto Fit**, because it applies full optimization, regardless of the design requirement.

Fast Fit

The **Fast Fit** option reduces the amount of optimization effort for each algorithm employed during fitting. This option reduces the compilation time by about 50%, resulting in a fit that has, on average, 10% lower f_{MAX} than that achieved using the **Standard Fit** setting.

Design Analysis

The initial compilation establishes whether the design achieves a successful fit and meets the specified performance. This section describes how to analyze your design results in the Quartus II software. After design analysis, proceed to optimization as described in "Optimizing Your Design" on page 10–2.

Error and Warning Messages

After your initial compilation, it is important to evaluate all error and warning messages to see if any design or setting changes are required. If required, make these changes and recompile the design before proceeding with design optimization.

To suppress messages that you have evaluated and that can be ignored, right-click on the message in the Messages window and click **Suppress**.

For more information about message suppression, refer to the "Message Suppression" section in the *Managing Quartus II Projects* chapter in volume 2 of the *Quartus II Handbook*.

Ignored Timing Assignments

You can use the **Ignored Timings Assignments** page in the Compilation Report to view any assignments that were ignored by the Quartus II Classic Timing Analyzer during the previous compilation. The Quartus II Classic Timing Analyzer ignores assignments that are invalid, conflict with other assignments, or become obsolete through the use of other assignments. If any assignments are ignored, analyze why they were ignored. If necessary, correct the assignments and recompile the design before proceeding with design optimization.

If you are using TimeQuest for timing analysis, you can list any ignored constraints by clicking **Report Ignored Constraints** in the Reports menu in the TimeQuest GUI or by using the following command to generate a listing of ignored timing constraints:

```
report_sdc -ignored -panel_name "Ignored Constraints" ↵
```

For more information about the `report_sdc` command and its options, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Resource Utilization

Determining device utilization is important regardless of whether a successful fit is achieved. If your compilation results in a no-fit error, resource utilization information is important for analyzing the fitting problems in your design. If your fitting is successful, review the resource utilization information to determine whether the future addition of extra logic or other design changes can introduce fitting difficulties.

To determine resource usage, refer to the **Flow Summary** section of the Compilation Report. This section reports how many resources are used, including pins, memory bits, digital signal processing (DSP) block 9-bit elements (for Arria GX, Stratix, and Stratix II devices) or 18-bit elements (for Arria II GX, Stratix IV and Stratix III devices), and phase-locked loops (PLLs). The **Flow Summary** indicates whether the design exceeds the available device resources. More detailed information is available by viewing the reports under **Resource Section** in the **Fitter** section of the Compilation Report.

For Arria II GX, Arria GX, Stratix IV, Stratix III, and Stratix II devices, a device with low utilization does not have the lowest adaptive logic module (ALM) utilization possible. For these devices, the Fitter uses adaptive look-up tables (ALUTs) in different ALMs—even when the logic can be placed within one ALM—to achieve the best timing and routability results. In achieving these results, the Fitter can spread

logic throughout the device. As the device fills up, the Fitter automatically searches for logic functions with common inputs to place in one ALM. The number of partnered ALUTs and packed registers also increases. Therefore, a design that is reported as close to 100% full might still have space for extra logic if logic and registers can be packed together more aggressively.

If resource usage is reported as less than 100% and a successful fit cannot be achieved, either there are not enough routing resources or some assignments are illegal. In either case, a message appears in the **Processing** tab of the Messages window describing the problem.

If the Fitter finishes faster than the Fitter runs on similar designs, a resource might be over-utilized or there might be an illegal assignment. If the Quartus II software seems to run for an excessively long time compared to runs on similar designs, a legal placement or route probably cannot be found. Look for errors and warnings that indicate these types of problems.

Refer to "Limit to One Fitting Attempt" on page 10–9 for more information about how to get a quick error message on hard-to-fit designs.

You can use the Chip Planner or the Timing Closure Floorplan (for older devices) to find areas of the device that have routing congestion.

For details about using the Chip Planner and the Timing Closure Floorplan tools, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

I/O Timing (Including t_{PD})

The Quartus II TimeQuest Timing Analyzer supports the Synopsys Design Constraints (SDC) format for constraining your design. When using TimeQuest for timing analysis, use the `set_input_delay` constraint to specify the data arrival time at an input port with respect to a given clock. For output ports, use the `set_output_delay` command with respect to a given clock. You can use the `report_timing` Tcl command to generate the required I/O timing reports.

If you are using the Quartus II Classic Timing Analyzer, from the Compilation Report, select **Timing Analyzer** to determine whether or not I/O timing has been met. The t_{SU}, t_H, and t_{CO} reports list the I/O paths, together with the required timing number if you have specified a timing requirement, the actual timing number for the timing as reported by the Quartus II software, and the slack (the difference between your requirement and the actual number). If you have any point-to-point propagation delay (t_{PD}) assignments, the t_{PD} report lists the corresponding paths.

The I/O paths that do not meet the required timing performance are reported as having negative slack and are displayed in red. In cases when you do not make an explicit I/O timing assignment to an I/O pin, the Quartus II timing analysis software still reports the **Actual** number, which is the timing number that must be met for that timing parameter when the device runs in your system.

To analyze the reasons why your timing requirements were not met, right-click an entry in the report and click **List Paths**. A message listing the paths appears in the **System** tab of the Messages window. To expand a selection, click the "+" icon at the beginning of the line (Figure 10–2). This is a good method to determine where the greatest delay is located along the path.

The List Paths report lists the slack time and how that slack time was calculated. By expanding the various entries, you can see the incremental delay through each node in the path as well as the total delay. The incremental delay is the sum of the interconnect delay (`IC`) and the cell delay (`CELL`) through the logic.

Figure 10–2. I/O Slack Report

```
Info: Slack time is -184 ps for clock "clk" between source pin "newt" and destination register "taps:inst|xn[3]~reg0"
  Info: + tsu requirement for source pin and destination register is 0.615 ns
  Info: - tsu from clock to input pin is 0.799 ns
    Info: + Longest pin to register delay is 3.853 ns
      Info: 1: + IC(0.000 ns) + CELL(1.490 ns) = 1.490 ns; Loc. = PIN_M8; Fanout = 34; PIN Node = 'newt'
      Info: 2: + IC(1.961 ns) + CELL(0.402 ns) = 3.853 ns; Loc. = IOC_X0_Y20_N1; Fanout = 1; REG Node = 'taps:inst|xn[3]~reg0'
      Info: Total cell delay = 1.892 ns ( 49.10 % )
      Info: Total interconnect delay = 1.961 ns ( 50.90 % )
    Info: + Micro setup delay of destination is 0.096 ns
    Info: - Shortest clock path from clock "clk" to destination register is 3.150 ns
System  Processing
```

To analyze I/O timing, right-click on an I/O entry in the report, point to **Locate**, and click **Locate in Chip Planner** or **Timing Closure Floorplan** (for older devices) to highlight the I/O path on the floorplan. Negative slack indicates paths that failed to meet their timing requirements. Other options allow you to see all the intermediate nodes (combinational logic cells) on a path and the delay for each level of logic, or to see the fan-in and fan-out of a selected node.

For more information about how timing numbers are calculated, refer to the *Quartus II Classic Timing Analyzer* chapter or the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Register-to-Register Timing

This section contains the following sections:

- "Timing Analysis with the TimeQuest Timing Analyzer"
- "Tips for Analyzing Failing Paths"
- "Tips for Analyzing Failing Clock Paths that Cross Clock Domains"

Timing Analysis with the TimeQuest Timing Analyzer

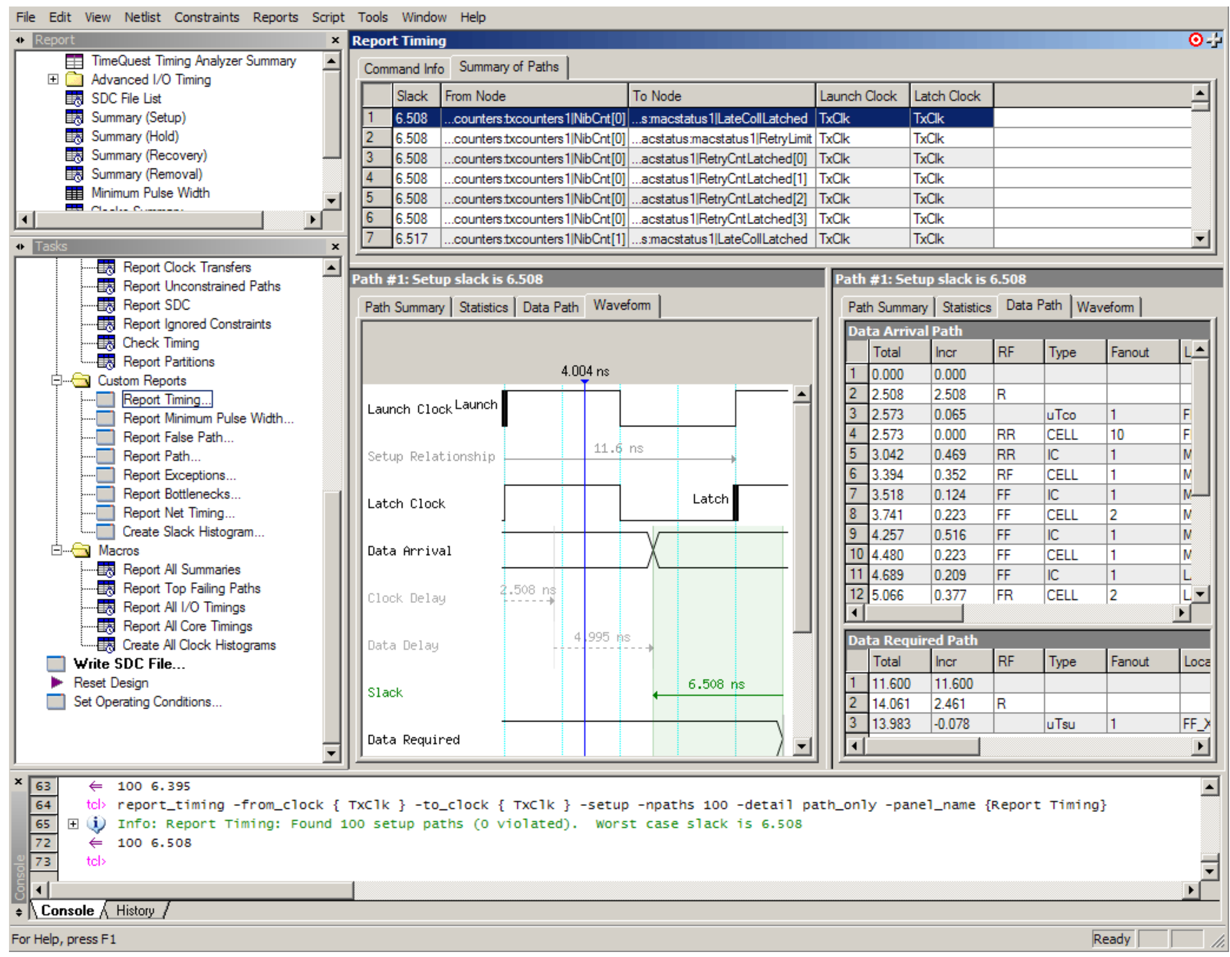
If you are using the TimeQuest Timing Analyzer, you should analyze all valid register-to-register paths by using appropriate constraints. Use the `report_timing` command to generate the required timing reports for any register-to-register path. Your design meets timing requirements when you do not have negative slack on any register-to-register path on any of the clock domains.

All paths that do not meet the timing requirement are shown with a negative slack and appear in red color in the TimeQuest Timing Analyzer GUI.

When you select a path listed in the TimeQuest report timing panel, the corresponding Path Summary that indicates the source and destination registers, the complete data path that indicates various nodes in the path, and the waveforms of relevant signals are displayed (Figure 10–3). You can locate a selected path in the Chip Planner or the Technology Map Viewer by using the right-click menu. You can use this to analyze your failing paths or timing critical paths. Similarly, if you know that a path is not a valid path, you can set it to be a false path using the right-click menu.

To see the path details of any selected path, click on the **Data Path** tab in the path details pane that appears. This displays the details of the Data Arrival Path, as well as the Data Required Path. For a graphical view of the information, click on the **Waveform** tab.

Figure 10–3. TimeQuest Timing Analyzer GUI



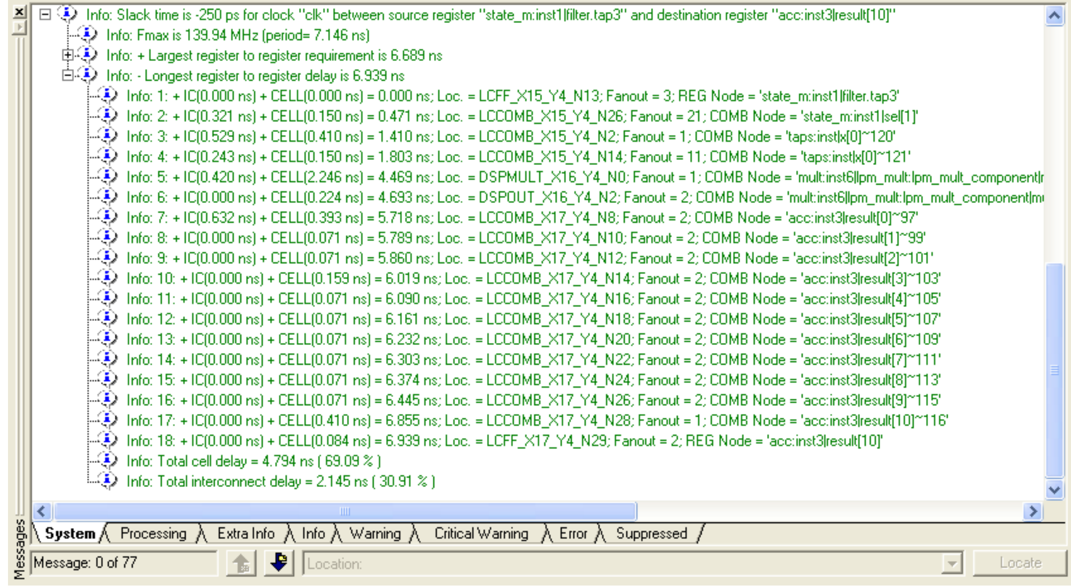
Timing Analysis with the Classic Timing Analyzer

If you are using the Quartus II Classic Timing Analyzer, in the Compilation Report window, use the **Timing Analyzer** section to determine whether register-to-register timing requirements are met. The **Clock Setup** folder displays figures for the actual register-to-register for each clock and the slack delays as reported by the Quartus II software. The paths that do not meet timing requirements are shown with a negative slack and appear in red.

To determine why your timing requirements were not met, right-click on an entry in the report and click **List Paths**. A message listing the paths appears in the **System** tab of the Messages window. The expanded report for the path appears (Figure 10–4). Click the "+" icon at the beginning of the line. Use this method to determine where the greatest delay is located along the path.

The List Paths report shows the slack time and how that slack time was calculated. By expanding the various entries, you can see the incremental delay through each node in the path as well as the total delay. The incremental delay is the sum of the interconnect delay (`IC`) and the cell delay (`CELL`) through the logic.

Figure 10–4. f_{MAX} Slack Report



To visually analyze register-to-register timing paths, right-click on a path, point to **Locate**, and click **Locate in Chip Planner**. For older devices, such as APEX™ series devices, ACEX®, FLEX® 10K, and MAX 7000 devices, click **Locate in Timing Closure Floorplan** to perform this analysis. The Chip Planner or Timing Closure Floorplan appears with the path highlighted. Use the **Critical Path Settings** to select which failing paths to show. To turn critical paths on or off, use the **Show Critical Paths** command.

For more information about how timing analysis results are calculated, refer to the *Quartus II Classic Timing Analyzer* and the *Quartus II TimeQuest Timing Analyzer* chapters in volume 3 of the *Quartus II Handbook*.

You also can see the logic in a particular path by cross-probing to the RTL Viewer or Technology Map Viewer. These viewers allow you to see a gate-level or technology-mapped representation of your design netlist. To locate a timing path in one of the viewers, right-click on a path in the report, point to **Locate**, and click **Locate in RTL Viewer** or **Locate in Technology Map Viewer**. When you locate a timing path in the Technology Map Viewer, the annotated schematic displays the same delay information that is shown when you use the **List Paths** command.

For more information about the netlist viewers, refer to the *Analyzing Designs with Quartus II Netlist Viewers* chapter in volume 1 of the *Quartus II Handbook*.

Tips for Analyzing Failing Paths

When you are analyzing clock path failures, focus on improving the paths that show the worst slack. The Fitter works hardest on paths with the least slack. If you fix these paths, the Fitter might be able to improve the other failing timing paths in the design.

Check for particular nodes that appear in many failing paths. Look for paths that have common source registers, destination registers, or common intermediate combinational nodes. In some cases, the registers might not be identical, but are part of the same bus. In the timing analysis report panels, clicking on the **From** or **To** column headings can be helpful to sort the paths by the source or destination registers. Clicking first on **From**, then on **To**, uses the registers in the **To** column as the primary sort and **From** as the secondary sort. If you see common nodes, these nodes indicate areas of your design that might be improved through source code changes or Quartus II optimization settings. Constraining the placement for just one of the paths might decrease the timing performance for other paths by moving the common node further away in the device.

Tips for Analyzing Failing Clock Paths that Cross Clock Domains

When analyzing clock path failures, check whether these paths cross between two clock domains. This is the case if the **From Clock** and **To Clock** in the timing analysis report are different. There can also be paths that involve a different clock in the middle of the path, even if the source and destination register clock are the same. To analyze these paths in more detail, right-click on the entry in the report and click **List Paths**.

Expand the **List Paths** entry in the Messages window and analyze the largest register-to-register requirement. Evaluate the setup relationship between the source and destination (launch edge and latch edge) to determine if that is reducing the available setup time. For example, the path can start at a rising edge and end at a falling edge, which reduces the setup relationship by one half clock cycle.

Check if the PLL phase shift is reducing the setup requirement. You might be able to adjust this using PLL parameters and settings.

Check if the PLL compensation delay is reducing the setup relationship. If you are using the Quartus II Classic Timing Analyzer, you can direct the software to analyze this delay as clock skew by enabling Clock Latency analysis. On the Assignments menu, click **Timing Analysis Settings**. In the **Category** list, select **Classic Timing Analyzer Settings** and click **More Settings**. In the **Name** list, select **Enable Clock Latency**. In the **Setting** list, select **On**. Typically, you must enable this option if your design results in timing violations for paths that pass between PLL clock domains. The Quartus II TimeQuest Timing Analyzer performs this analysis by default.

Paths that cross clock domains are generally protected with synchronization logic (for example, FIFOs or double-data synchronization registers) to allow asynchronous interaction between the two clock domains. In such cases, you can ignore the timing paths between registers in the two clock domains while running timing analysis, even if the clocks are related.

The Fitter attempts to optimize all failing timing paths. If there are paths that can be ignored for optimization and timing analysis, but the paths do not have constraints that instruct the Fitter to ignore them, the Fitter tries to optimize those paths as well. In some cases, optimizing unnecessary paths can prevent the Fitter from meeting the timing requirements on timing paths that are critical to the design. It is beneficial to specify all paths that can be ignored, so that the Fitter can put more effort into the paths that must meet their timing requirements instead of optimizing paths that can be ignored.

For more details about how to ignore timing paths that cross clock domains, refer to the *Quartus II Classic Timing Analyzer* chapter or the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the Quartus II handbook.

Evaluate the clock skew between the source clock and the destination clock to determine if that is reducing the available setup time. You can check the shortest and longest clock path reports to see what is causing the clock skew. Avoid using combinational logic in clock paths because it contributes to clock skew. Differences in the logic or in its routing between the source and destination can cause clock skew problems and result in warnings during compilation.

Global Routing Resources

Global routing resources are designed to distribute high-fan-out, low-skew signals (such as clocks) without consuming regular routing resources. Depending on the device, these resources can span the entire chip, or some smaller portion, such as a quadrant. The Quartus II software attempts to assign signals to global routing resources automatically, but you might be able to make more suitable assignments manually.

Refer to the relevant device handbook for details about the number and types of global routing resources available.

Check the global signal utilization in your design to ensure that appropriate signals have been placed on global routing resources. In the Compilation Report, open the Fitter report and click the **Resource Section**. Analyze the Global & Other Fast Signals and Non-Global High Fan-out Signals reports to determine whether any changes are required.

You might be able to reduce clock skew for high fan-out signals by placing them on global routing resources. Conversely, you can reduce the insertion delay of low fan-out signals by removing them from global routing resources. Doing so can improve clock enable timing and control signal recovery/removal timing, but increases clock skew. You can also use the **Global Signal** setting in the Assignment Editor to control global routing resources.

Compilation Time

In long compilations, most of the time is spent in the Analysis & Synthesis and Fitter modules. Analysis & Synthesis includes synthesis netlist optimizations, if you have turned on that option. The Fitter includes two steps, placement and routing, and also includes physical synthesis if you turned on that option. The **Flow Elapsed Time** section of the Compilation Report shows how much time is spent running the Analysis & Synthesis and Fitter modules. The Fitter Messages report in the **Fitter** section of the Compilation Report shows the specific time that was spent in placement and how much time was spent in routing.

Placement is the process of finding optimum locations for the logic in your design. Routing is the process of connecting the nets between the logic in your design. There are many possible placements for the logic in a design, and finding better placements typically takes more compilation time. Good logic placement allows you to more easily meet your timing requirements and makes the design easier to route.

The applicable messages are indicated as shown in the following example, with each time component in two-digit format:

```
Info: Fitter placement operations ending: elapsed time = <days:hours:mins:secs>
Info: Fitter routing operations ending: elapsed time = <days:hours:mins:secs>
```

Days are not shown if the time is less than one day.

While the Fitter is running (including Placement and Routing), hourly info messages similar to the following message are displayed every hour to indicate Fitter operations are progressing normally.

```
Info: Placement optimizations have been running for x hour(s)
```

In this case, x indicates the number of hours the process has run.

Resource Utilization Optimization Techniques (LUT-Based Devices)

After design analysis, the next stage of design optimization is to improve resource utilization. Complete this stage before proceeding to I/O timing optimization or register-to-register timing optimization. Ensure that you have already set the basic constraints described in "Initial Compilation: Required Settings" on page 10–3 before proceeding with the resource utilization optimizations discussed in this section. If a design does not fit into a specified device, use the techniques in this section to achieve a successful fit. After you optimize resource utilization and your design fits in the desired target device, optimize I/O timing as described in "I/O Timing Optimization Techniques (LUT-Based Devices)" on page 10–73. These tips are valid for all FPGA families and the MAX II family of CPLDs.

Using the Resource Optimization Advisor

The Resource Optimization Advisor provides guidance in determining settings that optimize the resource usage. To run the Resource Optimization Advisor, on the Tools menu, point to **Advisors**, and click **Resource Optimization Advisor**.

The Resource Optimization Advisor provides step-by-step advice about how to optimize the resource usage (logic element, memory block, DSP block, I/O, and routing) of your design. Some of the recommendations in these categories might contradict each other. Altera recommends evaluating the options, and choosing the settings that best suit your requirements.

Resolving Resource Utilization Issues Summary

Resource utilization issues can be divided into the following three categories:

- Issues relating to I/O pin utilization or placement, including dedicated I/O blocks such as PLLs or LVDS transceivers (refer to "I/O Pin Utilization or Placement").
- Issues relating to logic utilization or placement, including logic cells containing registers and look-up tables as well as dedicated logic, such as memory blocks and DSP blocks (refer to "Logic Utilization or Placement" on page 10–21).
- Issues relating to routing (refer to "Routing" on page 10–29).

I/O Pin Utilization or Placement

Use the suggestions in the following sections to help you resolve I/O resource problems.

Use I/O Assignment Analysis

On the Processing menu, point to **Start** and click **Start I/O Assignment Analysis** to help with pin placement. The **Start I/O Assignment Analysis** command allows you to check your I/O assignments early in the design process. You can use this command to check the legality of pin assignments before, during, or after compilation of your design. If design files are available, you can use this command to accomplish more thorough legality checks on your design's I/O pins and surrounding logic. These checks include proper reference voltage pin usage, valid pin location assignments, and acceptable mixed I/O standards.

Common issues with I/O placement relate to the fact that differential standards have specific pin pairings, and certain I/O standards might be supported only on certain I/O banks.

If your compilation or I/O assignment analysis results in specific errors relating to I/O pins, follow the recommendations in the error message. Right-click on the message in the Messages window and click **Help** to open the Quartus II Help topic for this message.

Modify Pin Assignments or Choose a Larger Package

If a design that has pin assignments fails to fit, compile the design without the pin assignments to determine whether a fit is possible for the design in the specified device and package. You can use this approach if a Quartus II error message indicates fitting problems due to pin assignments.

If the design fits when all pin assignments are ignored or when several pin assignments are ignored or moved, you might have to modify the pin assignments for the design or choose a larger package.

If the design fails to fit because insufficient I/Os are available, a successful fit can often be obtained by using a larger device package (which can be the same device density) that has more available user I/O pins.

For more information about I/O assignment analysis, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

Logic Utilization or Placement

Use the suggestions in the following subsections to help you resolve logic resource problems, including logic cells containing registers and lookup tables (LUTs), as well as dedicated logic such as memory blocks and DSP blocks.

Optimize Synthesis for Area, Not Speed

If your design fails to fit because it uses too much logic, resynthesize the design to improve the area utilization. First, ensure that you have set your device and timing constraints correctly in your synthesis tool. Particularly when the area utilization of the design is a concern, ensure that you do not over-constrain the timing requirements for the design. Synthesis tools generally try to meet the specified requirements, which can result in higher device resource usage if the constraints are too aggressive.

If resource utilization is an important concern, some synthesis tools offer an easy way to optimize for area instead of speed. If you are using Quartus II integrated synthesis, choose **Balanced** or **Area** for the **Optimization Technique**. You can also specify this logic option for specific modules in your design with the Assignment Editor in cases where you want to reduce area using the **Area** setting (potentially at the expense of register-to-register timing performance) while leaving the default **Optimization Technique** setting at **Balanced** (for the best trade-off between area and speed for certain device families) or **Speed**. You can also use the **Speed Optimization Technique for Clock Domains** logic option to specify that all combinational logic in or between the specified clock domain(s) is optimized for speed.

In some synthesis tools, not specifying an f_{MAX} requirement can result in less resource utilization.

In the Quartus II software, the **Balanced** setting typically produces utilization results that are very similar to those produced by the **Area** setting, with better performance results. The **Area** setting can give better results in some unusual cases.

For information about setting timing requirements and synthesis options in Quartus II integrated synthesis and other synthesis tools, refer to the appropriate chapter in *Section III. Synthesis* in volume 1 of the *Quartus II Handbook*, or your synthesis software’s documentation.

The Quartus II software provides additional attributes and options that can help improve the quality of your synthesis results.

Restructure Multiplexers

Multiplexers form a large portion of the logic utilization in many FPGA designs. By optimizing your multiplexed logic, you can achieve a more efficient implementation in your Altera device.

The Quartus II software provides the **Restructure Multiplexers** logic option, which can extract and optimize buses of multiplexers during synthesis. This option is available on the **Analysis & Synthesis Settings** page of the **Settings** dialog box and is useful if your design contains buses of fragmented multiplexers. This option restructures multiplexers more efficiently for area, allowing the design to implement multiplexers with a reduced number of logic elements (LEs) or ALMs. Using the **Restructure Multiplexers** logic option can reduce your design's register-to-register timing performance. This option is turned on automatically when you set the Quartus II Analysis & Synthesis **Optimization Technique** option to **Area** or **Balanced**. To change the default setting, on the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**, and click the appropriate option from the **Restructure Multiplexers** list to set the option globally.

For design guidelines to achieve optimal resource utilization for multiplexer designs, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*. For more information about the **Restructure Multiplexers** option in the Quartus II software, refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*.

Perform WYSIWYG Resynthesis with Balanced or Area Setting

If you use another EDA synthesis tool and want to determine if the Quartus II software can remap the circuit to use fewer LEs or ALMs, follow these steps:

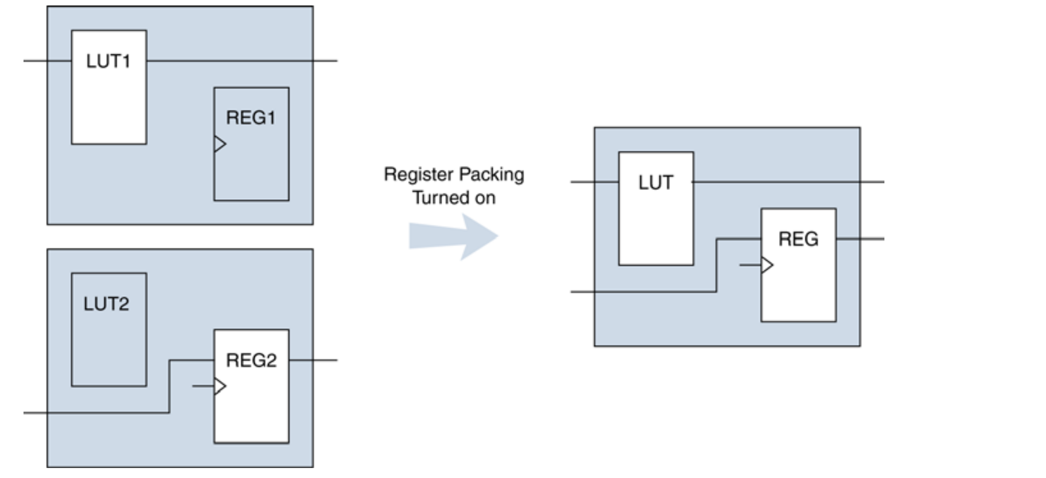
1. On the Assignments menu, click **Settings**.
2. In the **Category** list, select **Analysis & Synthesis Settings**. The **Analysis & Synthesis Settings** page appears.
3. Turn on **Perform WYSIWYG primitive resynthesis (using optimization techniques specified in Analysis & Synthesis settings)**. Or, on the Assignments menu, click **Assignment Editor**, and set the **Perform WYSIWYG Primitive Resynthesis** logic option for a specific module in your design.
4. On the same page, choose **Balanced** or **Area** under **Optimization Technique**. Or, on the Assignments menu, click **Assignment Editor**. Set the **Optimization Technique** to **Balanced** or **Area** for a specific module in your design.
5. Recompile the design.

The **Balanced** setting typically produces utilization results that are very similar to the **Area** setting with better performance results. The **Area** setting can give better results in some unusual cases. Performing WYSIWYG resynthesis for area in this way typically reduces register-to-register timing performance.

Use Register Packing

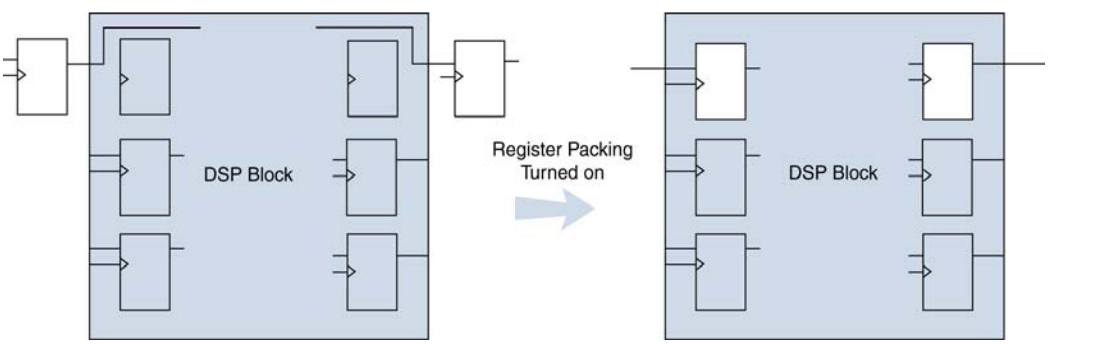
The **Auto Packed Registers** option implements the functions of two cells into one logic cell by combining the register of one cell in which only the register is used with the LUT of another cell in which only the LUT is used. Figure 10–5 shows register packing and the gain of one logic cell in the design.

Figure 10–5. Register Packing



Registers can also be packed into DSP blocks (Figure 10–6).

Figure 10–6. Register Packing in DSP Blocks



The following list shows the most common cases in which register packing helps to optimize a design:

- A LUT can be implemented in the same cell as an unrelated register with a single data input
- A LUT can be implemented in the same cell as the register that is fed by the LUT
- A LUT can be implemented in the same cell as the register that feeds the LUT
- A register can be packed into a RAM block
- A register can be packed into a DSP block
- A register can be packed into an I/O Element (IOE)

The following options are available for register packing (for certain device families):

- **Off**—Does not pack registers
- **Normal**—Packs registers when this is not expected to hurt timing results
- **Minimize Area**—Aggressively packs registers to reduce area

- **Minimize Area with Chains**—Aggressively packs registers to reduce area. This option packs registers with carry chains. It also converts registers into register cascade chains and packs them with other logic to reduce area. This option is available only for Arria GX, Stratix, Cyclone, and MAX II series of devices.
- **Auto**—This is the default setting for register packing. This setting tells the Fitter to attempt to achieve the best performance while maintaining a fit for the design in the specified device. The Fitter combines all combinational (LUT) and sequential (register) functions that benefit circuit speed. In addition, more aggressive combinations of unrelated combinational and sequential functions are performed to the extent required to reduce the area of the design to achieve a fit in the specified device. This option is available only for Arria GX, Stratix, and Cyclone series of devices.
- **Sparse**—In this mode, the combinational (LUT) and sequential (register) functions are combined such that the combined logic has either a combinational output or a sequential output, but not both. This mode is available only for Arria II GX, Arria GX, Stratix III, Stratix II, Cyclone III, and Cyclone II devices. This option results in a higher logic array block (LAB) usage, but might give you better timing performance because of reduced routing congestion.
- **Sparse Auto**—In this mode, the Quartus II Fitter starts with sparse mode packing, and then attempts to achieve best performance while maintaining a fit for the specified device. Later optimizations are carried out in a way similar to the **Auto** mode. This mode is available only for Arria II GX, Arria GX, Stratix IV, Stratix III, Stratix II, Cyclone III, and Cyclone II devices.

Turning on register packing decreases the number of LEs or ALMs in the design, but could also decrease performance in some cases. On the Assignments menu, click **Settings**. In the **Category** list, select **Fitter Settings**, and then click **More Settings. Turn on Auto Packed Registers** to turn on register packing.

The area reduction and performance results with register packing can vary greatly depending on the design.

The **Auto** setting performs more aggressive register packing as required, so the typical results vary depending on the device resource utilization.

Remove Fitter Constraints

A design with conflicting constraints or constraints that are difficult to meet might not fit in the targeted device. This can occur when the location or LogicLock assignments are too strict and not enough routing resources are available on the device.

In this case, use the **Routing Congestion** view in the Chip Planner or Timing Closure Floorplan (for older devices) to locate routing problems in the floorplan, then remove any location or LogicLock region assignments in that area. If your design still does not fit, the design is over-constrained. To correct the problem, remove all location and LogicLock assignments and run successive compilations, incrementally constraining the design before each compilation. You can delete specific location assignments in the Assignment Editor, the Chip Planner, or the Timing Closure Floorplan. To remove LogicLock assignments in the Chip Planner (or in the Timing Closure Floorplan), in the LogicLock Regions Window, or on the Assignments menu, click **Remove Assignments.** Turn on the assignment categories you want to remove from the design in the **Available assignment categories** list.

For more information about the **Routing Congestion** view in the Chip Planner and the Timing Closure Floorplan, refer to *Analyzing and Optimizing the Design Floorplan* in volume 2 of the *Quartus II Handbook*. Also refer to the Quartus II Help.

Change State Machine Encoding

State machines can be encoded using various techniques. Using binary or gray code encoding typically results in fewer state registers than one-hot encoding, which requires one register for every state bit. If your design contains state machines, changing the state machine encoding to one that uses the minimal number of registers might reduce resource utilization. The effect of state machine encoding varies depending on the way your design is structured.

If your design does not manually encode the state bits, you can specify the state machine encoding in your synthesis tool. When using Quartus II integrated synthesis, on the Assignments menu, click **Settings**. In the **Category** list, select A**nalysis & Synthesis Settings** and turn on **Minimal Bits for State Machine Processing**. You also can specify this logic option for specific modules or state machines in your design with the Assignment Editor.

You can also use the following Tcl command in scripts to modify the state machine encoding.

```
set_global_assignment -name state_machine_processing <value>
```

In this case, <*value*> can be `AUTO`, `ONE-HOT`, `MINIMAL BITS`, or `USER-ENCODE`.

Flatten the Hierarchy During Synthesis

Synthesis tools typically provide the option of preserving hierarchical boundaries, which can be useful for verification or other purposes. However, optimizing across hierarchical boundaries allows the synthesis tool to perform the most logic minimization, which can reduce area. Therefore, to achieve the best results, flatten your design hierarchy whenever possible. If you are using Quartus II integrated synthesis, ensure that the **Preserve Hierarchical Boundary** logic option is turned off, that is, make sure that you have not turned on the option in the Assignment Editor or with Tcl assignments. If you are using Quartus II incremental compilation, you cannot flatten your design across design partitions. Incremental compilation always preserves the hierarchical boundaries between design partitions. Follow Altera's recommendations for design partitioning, such as registering partition boundaries to reduce the effect of cross-boundary optimizations.

For more information about using incremental compilation and recommendations for design partitioning, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Retarget Memory Blocks

If the design fails to fit because it runs out of device memory resources, your design might require a certain type of memory the device does not have. For example, a design that requires two M-RAM blocks can be targeted to a Stratix EP1S10 device, which has only one M-RAM block. You might be able to obtain a fit by building one of the memories with a different size memory block, such as an M4K memory block.

If the memory block was created with the MegaWizard™ Plug-In Manager, open the MegaWizard Plug-In Manager and edit the RAM block type so it targets a new memory block size.

ROM and RAM memory blocks can also be inferred from your HDL code, and your synthesis software can place large shift registers into memory blocks by inferring the ALTSHIFT_TAPS megafunction. This inference can be turned off in your synthesis tool to cause the memory to be placed in logic instead of in memory blocks. To disable inference when using Quartus II integrated synthesis, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Analysis & Synthesis**. The **Analysis & Synthesis** page appears.
3. Turn off the **Auto RAM Replacement**, **Auto ROM Replacement**, or **Auto Shift Register Replacement** logic option as appropriate for your project. Or, disable the option for a specific entity in the Assignment Editor.

Depending on your synthesis tool, you can also set the RAM block type for inferred memory blocks. In Quartus II integrated synthesis, set the **ramstyle** attribute to the desired memory type for the inferred RAM blocks, or set the option to **logic** to implement the memory block in standard logic instead of a memory block.

Consider the resource utilization by hierarchy in the report file, and determine whether there is an unusually high register count in any of the modules. Some coding styles can prevent the Quartus II software from inferring RAM blocks from the source code because of their architectural implementation and forces the software to implement the logic in flipflops. As an example, a function such as an asynchronous reset on a register bank might make it incompatible with the RAM blocks in the device architecture, so that the register bank is implemented in flipflops. It is often possible to move a large register bank into RAM by slight modification of associated logic.

For more information about memory inference control in other synthesis tools, refer to the appropriate chapter in *Section III. Synthesis* in volume 1 of the *Quartus II Handbook*, or your synthesis software's documentation. For more information about coding styles and HDL examples that ensure memory inference, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

Use Physical Synthesis Options to Reduce Area

The physical synthesis options for fitting can help you decrease the resource usage; additional optimizations for fitting are available. When you enable these settings for physical synthesis for fitting, the Quartus II software makes placement-specific changes to the netlist that reduce resource utilization for a specific Altera device.

The compilation time might increase considerably when you use physical synthesis options.

With the Quartus II software, you can apply physical synthesis options to specific instances, which can reduce the impact on compilation time. Physical synthesis instance assignments allow you to enable physical synthesis algorithms for specific portions of their design.

If you want the performance gain from physical synthesis, but do not want a specific hierarchy of the design to be modified, you can selectively disable physical synthesis for that hierarchy. Likewise, if you do not want to run physical synthesis for most parts of the design, but require the algorithms for a specific module in the design, you can enable physical synthesis for a single module.

The following physical synthesis optimizations for fitting are available:

- Physical synthesis for combinational logic
- Map logic into memory

On the Assignments menu, click **Settings**. In the **Category** list, expand **Compilation Process Settings** and select **Physical Synthesis Optimization**. The **Physical Synthesis Optimization** page appears. Under **Optimize for fitting**, turn on the options to enable physical synthesis optimizations during fitting. You can also specify the physical synthesis effort, which sets the level of physical synthesis optimization that you want the Quartus II software to perform.

The **Perform physical synthesis for combinational logic** option allows the Quartus II Fitter to resynthesize the combinational logic in a design to reduce the resource utilization to help achieve a fit.

The **Perform logic to memory mapping** option allows the Quartus II Fitter to automatically map logic into unused memory blocks during fitting, reducing the number of logic elements required to implement the design.

To apply physical synthesis assignments for fitting on a per instance basis, use the Quartus II Assignment Editor. The following assignments are available as instance assignments for fitting:

- **Perform physical synthesis for combinational logic**
- **Perform logic to memory mapping**

In the Assignment Editor, indicate the module instance you want to apply the setting in the **To** tab. Select the required physical synthesis assignment in the Assignment **Name** tab. In the **Value** tab, select **ON**. In the **Enabled** tab, select **Yes**.

Retarget or Balance DSP Blocks

A design might not fit because it requires too many DSP blocks. All DSP block functions can be implemented with logic cells, so you can retarget some of the DSP blocks to logic to obtain a fit.

If the DSP function was created with the MegaWizard Plug-In Manager, open the MegaWizard Plug-In Manager and edit the function so it targets logic cells instead of DSP blocks. The Quartus II software uses the `DEDICATED_MULTIPLIER_CIRCUITRY` megafunction parameter to control the implementation.

DSP blocks also can be inferred from your HDL code for multipliers, multiply-adders, and multiply-accumulators. This inference can be turned off in your synthesis tool. When you are using Quartus II integrated synthesis, you can disable inference by turning off the **Auto DSP Block Replacement** logic option for your whole project. On the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**, and turn off **Auto DSP Block Replacement**. Alternatively, you can disable the option for a specific block with the Assignment Editor.

For more information about disabling DSP block inference in other synthesis tools, refer to the appropriate chapter in *Section III. Synthesis* in volume 1 of the *Quartus II Handbook*, or your synthesis software's documentation.

The Quartus II software also offers the **DSP Block Balancing** logic option, which implements DSP block elements in logic cells or in different DSP block modes. The default **Auto** setting allows DSP block balancing to convert the DSP block slices automatically as appropriate to minimize the area and maximize the speed of the design. You can use other settings for a specific node or entity, or on a project-wide basis, to control how the Quartus II software converts DSP functions into logic cells and DSP blocks. Using any value other than **Auto** or **Off** overrides the `DEDICATED_MULTIPLIER_CIRCUITRY` parameter used in megafunction variations.

For more details about the Quartus II logic options described in this section, refer to the Quartus II Help.

Optimize Source Code

If your design does not fit because of logic utilization, and the methods described in the preceding sections do not sufficiently improve the resource utilization of the design, modify the design at the source to achieve the desired results. You can often improve logic significantly by making design-specific changes to your source code. This is typically the most effective technique for improving the quality of your results.

If your design does not fit into available LEs or ALMs, but you have unused memory or DSP blocks, check to see if you have code blocks in your design that describe memory or DSP functions that are not being inferred and placed in dedicated logic. You might be able to modify your source code to allow these functions to be placed into dedicated memory or DSP resources in the target device.

Ensure that your state machines are recognized as state machine logic and optimized appropriately in your synthesis tool. State machines that are recognized are generally optimized better than if the synthesis tool treats them as generic logic. In the Quartus II software, you can check for the State Machine report under **Analysis & Synthesis** in the Compilation Report. This report provides details, including the state encoding for each state machine that was recognized during compilation. If your state machine is not being recognized, you might have to change your source code to enable it to be recognized.

For coding style guidelines, including examples of HDL code for inferring memory and DSP functions, refer to the "Instantiating Altera Megafunctions" and the "Inferring Altera Megafunctions" sections of the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*. For guidelines and sample HDL code for state machines, refer to the "General Coding Guidelines" section of the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

Use a Larger Device

If a successful fit cannot be achieved because of a shortage of LEs or ALMs, memory, or DSP blocks, you might require a larger device.

Routing

Use the suggestions in the following subsections to help you resolve routing resource problems.

Set Auto Register Packing to Sparse or Sparse Auto

This option is useful for reducing LE or ALM count in a design. This option is available for Arria GX, Cyclone, and Stratix series of devices. On the Assignments menu, click **Settings**. The **Settings** dialog box appears. In the **Category** list, select **Fitter Settings**. Click **More Settings**. Under **Option**, in the **Name** list, select **Auto Packed Registers**. In the **Settings** list, select the **Sparse** or **Sparse Auto** from the list.

When you select **Sparse**, the Fitter combines functions to improve the performance of many designs. When you select **Sparse Auto**, the Fitter attempts to achieve the highest performance with the possibility of increasing the area, but without exceeding the logic capacity of the device. These options might help improve the routing because they do not aggressively pack registers.

Selecting the default **Auto** setting can help routing in many designs. However, for some dense designs, the Fitter attempts to combine additional logic to reduce the area of the design to achieve the best performance. It does this by fitting the design within the best area of the selected device. Therefore, the Fitter can turn on the more aggressive minimize area with the chains option, making it more difficult to route the design.

As an alternative, select **Normal**, and then increase the aggressiveness of register packing to reduce LE/ALM count if the design does not fit.

When you choose a register packing setting to perform more aggressive register packing than the **Auto** setting, the extra register packing can affect the routability of the design as an unintended result. The **Minimize the area with chains** setting restricts placement and reduces routability significantly more than using the **Minimize Area** setting. For more information about register packing, refer to "Use Register Packing" on page 10–22.

Set Fitter Aggressive Routability Optimizations to Always

If routing resources are resulting in no-fit errors, use this option to reduce routing wire utilization. On the Assignments menu, click **Settings**. In the **Category** list, select **Fitter Settings**. Click **More Settings**. In the **More Fitter Settings** dialog box, set **Fitter Aggressive Routability Optimizations** to **Always** and click **OK**.

If there is a significant imbalance between placement and routing time (during the first fitting attempt), it might be because of high wire utilization. By turning on this option, you might be able to reduce your compilation time.

On average, in Arria GX and Stratix II devices, this option saves approximately 3% wire utilization but can reduce performance by approximately 1%. In Stratix III devices, this option saves approximately 6% wire utilization, at the same time reducing the performance by approximately 3%. In Cyclone III devices, using this option saves approximately 4.5% wire utilization while reducing the performance by about 4%.

These optimizations are used automatically when the Fitter performs more than one fitting attempt, but turning the option on increases the optimization effort on the first fitting attempt. This option also ensures that the Quartus II software uses maximum optimization to reduce routability, even if the Fitter Effort is set to **Auto Fit**.

Increase Placement Effort Multiplier

Increasing the placement effort can improve the routability of the design, allowing the software to route a design that otherwise requires too many routing resources. On the Assignments menu, click **Settings**. In the **Category** list, select **Fitter Settings**. Click **More Settings**. In the **More Fitter Settings** dialog box, increase the value of the **Placement Effort Multiplier** to increase placement effort. The default value is 1.0. Legal values must be greater than 0 and can be non-integer values. Numbers less than 1 reduce the placement effort and might affect placement quality. Higher numbers increase compilation time but can improve placement quality. For example, a value of 4 increases fitting time by approximately 2 to 4 times but can increase the quality of results. Increasing the placement effort multiplier does not tend to improve timing optimization unless the design also has very high routing resource usage.

Increased effort is used automatically when the Fitter performs more than one fitting attempt. Setting a multiplier higher than one (before compilation) increases the optimization effort on the first fitting attempt. The second and third fitting loops increase the Placement Effort Multiplier to 4 and then to 16. These loops result in increased compilation times, with possible improvement in the quality of placement.

You can modify the Placement Effort Multiplier using the following Tcl command:

```
set_global_assignment -name PLACEMENT_EFFORT_MULTIPLIER <value> ↵
```

<value> can be any positive, non-zero number.

Increase Router Effort Multiplier

The Router Effort Multiplier controls how quickly the router tries to find a valid solution. The default value is 1.0 and legal values must be greater than 0. Numbers higher than 1 (as high as 3 is generally reasonable) can improve routing quality at the expense of run-time on difficult-to-route circuits. Numbers closer to 0 (for example, 0.1) can reduce router runtime, but usually reduce routing quality slightly. Experimental evidence shows that a multiplier of 3.0 reduces overall wire usage by about 2%. There is usually no gain in performance beyond a multiplier value of 3.

You can set the Router Effort Multiplier to a value higher than the default value for difficult-to-route designs. To set the Router Effort Multiplier, on the Assignments menu, click **Settings**, and then click **Fitter Settings**. Click the **More Settings** button. From the options available, select **Router Effort Multiplier** and edit the value in the dialog box that appears.

You can modify the Router Effort Multiplier by the following Tcl command. *<value>* can be any positive, non-zero number.

```
set_global_assignment -name ROUTER_EFFORT_MULTIPLIER  <value> ↵
```

Remove Fitter Constraints

A design with conflicting constraints or constraints that are difficult to meet may not fit the targeted device. This can occur when location or LogicLock assignments are too strict and there are not enough routing resources.

In this case, use the **Routing Congestion** view in the Chip Planner or the Timing Closure Floorplan (for older devices) to locate routing problems in the floorplan, then remove all location and LogicLock region assignments from that area. If your design still does not fit, the design is over-constrained. To correct the problem, remove all location and LogicLock assignments and run successive compilations, incrementally constraining the design before each compilation. You can delete specific location assignments in the Assignment Editor, the Chip Planner, or Timing Closure Floorplan (for supported devices). Remove LogicLock assignments in the Chip Planner (or in the Timing Closure Floorplan), in the LogicLock Regions Window, or on the Assignments menu, click **Remove Assignments**. Turn on the assignment categories you want to remove from the design in the **Available assignment categories** list.

For more information about the **Routing Congestion** view in the Chip Planner or the Timing Closure Floorplan, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*. You can also refer to the Quartus II Help.

Optimize Synthesis for Area, Not Speed

In some cases, resynthesizing the design to improve the area utilization can also improve the routability of the design. First, ensure that you have set your device and timing constraints correctly in your synthesis tool. Ensure that you do not over-constrain the timing requirements for the design, particularly when the area utilization of the design is a concern. Synthesis tools generally try to meet the specified requirements, which can result in higher device resource usage if the constraints are too aggressive.

If resource utilization is important to improving the routing results in your design, some synthesis tools offer an easy way to optimize for area instead of speed. If you are using Quartus II integrated synthesis, on the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**, and choose **Balanced** or **Area** under **Optimization Technique**.

You can also specify this logic option for specific modules in your design with the Assignment Editor in cases where you want to reduce area using the **Area** setting (potentially at the expense of register-to-register timing performance). You can apply the setting to specific modules while leaving the default **Optimization Technique** setting at **Balanced** (for the best trade-off between area and speed for certain device families) or **Speed**. You can also use the **Speed Optimization Technique for Clock Domains** logic option to specify that all combinational logic in or between the specified clock domain(s) is optimized for speed.

In the Quartus II software, the **Balanced** setting typically produces utilization results that are very similar to those obtained with the **Area** setting, with better performance results. The **Area** setting can yield better results in some unusual cases.

In some synthesis tools, not specifying an f_{MAX} requirement can result in less resource utilization, which can improve routability.

For information about setting timing requirements and synthesis options in Quartus II integrated synthesis and other synthesis tools, refer to the appropriate chapter in *Section III. Synthesis* in volume 1 of the *Quartus II Handbook*, or your synthesis software's documentation.

Optimize Source Code

If your design does not fit because of routing problems and the methods described in the preceding sections do not sufficiently improve the routability of the design, modify the design at the source to achieve the desired results. You can often improve results significantly by making design-specific changes to your source code, such as duplicating logic or changing the connections between blocks that require significant routing resources.

Use a Larger Device

If a successful fit cannot be achieved because of a shortage of routing resources, you might require a larger device.

Timing Optimization Techniques (LUT-Based Devices)

This section contains guidelines if your design does not meet its timing requirements.

Timing Optimization Advisor

The Timing Optimization Advisor guides you in making settings that optimize your design to meet your timing requirements. To run the Timing Optimization Advisor, on the Tools menu, point to **Advisors**, and click on **Timing Optimization Advisor**. This advisor describes many of the suggestions made in this section.

When you open the Timing Optimization Advisor after compilation, you find recommendations to improve the timing performance of your design. Some of the recommendations in these advisors can contradict each other. Altera recommends evaluating these options and choosing the settings that best suit the given requirements.

Metastability Analysis and Optimization Techniques

Metastability problems can occur when a signal is transferred between circuitry in unrelated or asynchronous clock domains, because the designer cannot guarantee that the signal will meet its setup and hold time requirements. The mean time between failure (MTBF) is an estimate of the average time between instances when metastability could cause a design failure.

For more information about metastability and MTBF, refer to the *Understanding Metastability in FPGAs* white paper.

You can use the Quartus II software to analyze the average MTBF due to metastability when a design synchronizes asynchronous signals, and optimize the design to improve the MTBF. These metastability features are supported only for designs constrained with the TimeQuest Timing Analyzer, and for select device families.

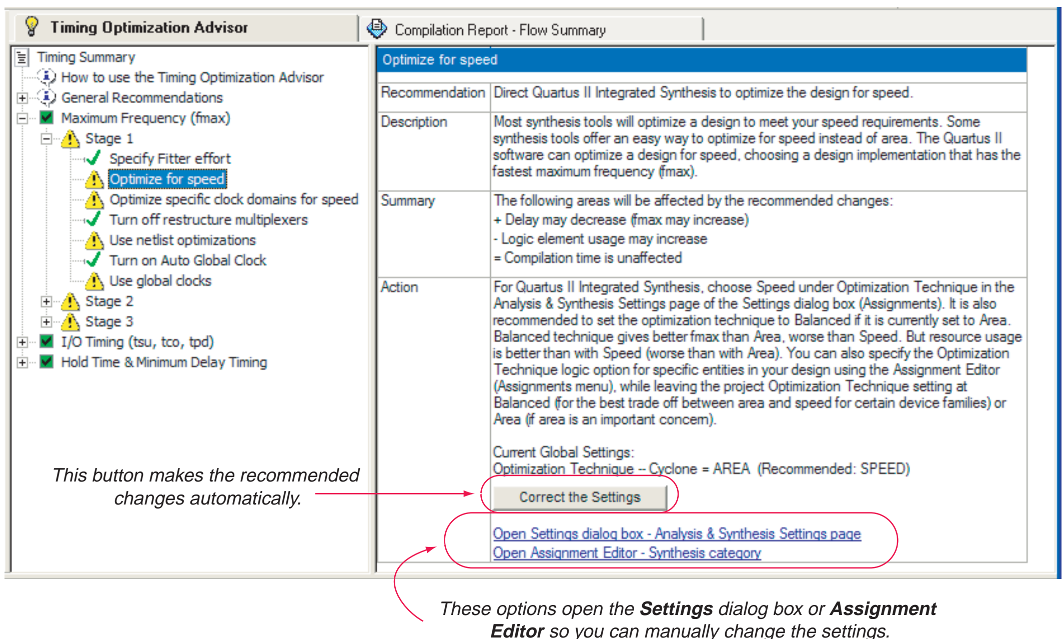
If the MTBF of your design is low, refer to the Metastability Optimization section in the Timing Optimization Advisor, which suggests various settings that can help optimize your design in terms of metastability.

For details about the metastability features in the Quartus II software, refer to the *Managing Metastability with the Quartus II Software* chapter in the *Quartus II Handbook*. This chapter describes how to enable metastability analysis and identify the register synchronization chains in your design, provides details about metastability reports, and provides additional guidelines for managing metastability.

I/O Timing Optimization

The example in Figure 10–7 shows the Timing Optimization Advisor after compiling a design that meets its frequency requirements, but requires setting changes to improve the timing.

Figure 10–7. Timing Optimization Advisor



When you expand one of the categories in the Advisor, such as **Maximum Frequency (fmax)** or **I/O Timing (tsu, tco, tpd)**, the recommendations are divided into stages. The stages show the order in which you should apply the recommended settings. The first stage contains the options that are easiest to change, make the least drastic changes to your design optimization, and have the least effect on compilation time. Icons indicate whether each recommended setting has been made in the current project. In Figure 10–7, the checkmark icons in the list of recommendations for Stage 1 indicate recommendations that are already implemented. The warning icons indicate recommendations that are not followed for this compilation. The information icons indicate general suggestions. For these entries, the advisor does not report whether these recommendations were followed, but instead explains how you can achieve better performance. Refer to the “How to use” page in the Advisor for a legend that provides more information for each icon.

There is a link from each recommendation to the appropriate location in the Quartus II user interface where you can change the settings. For example, consider the **Synthesis Netlist Optimizations** page of the **Settings** dialog box or the **Global Signals category** in the Assignment Editor. This approach provides the most control over which settings are made and helps you learn about the settings in the software. In some cases, you can also use the **Correct the Settings** button to automatically make the suggested change to global settings.

For some entries in the advisor, a button appears that allows you to further analyze your design and gives you more information. The advisor provides a table with the clocks in the design and indicates whether they have been assigned a timing constraint.

The next stage of design optimization focuses on I/O timing. Ensure that you have made the appropriate assignments as described in "Initial Compilation: Required Settings" on page 10–3, and that the resource utilization is satisfactory before proceeding with I/O timing optimization. The suggestions given in this section are applicable to all Altera FPGA families and to the MAX II family of CPLDs.

Because changes to the I/O paths affect the internal register-to-register timing, complete this stage before proceeding to the register-to-register timing optimization stage as described in the "Register-to-Register Timing Optimization Techniques (LUT-Based Devices)" on page 10–40.

The options presented in this section address how to improve I/O timing, including the setup delay (t_{SU}), hold time (t_H), and clock-to-output (t_{CO}) parameters.

Improving Setup and Clock-to-Output Times Summary

Table 10–1 shows the recommended order in which to use techniques to reduce t_{SU} and t_{CO} times. Check marks indicate which timing parameters are affected by each technique. Reducing t_{SU} times increases hold (t_H) times.

Table 10–1. Improving Setup and Clock-to-Output Times *(Note 1)* (Part 1 of 2)

Technique	Affects t_{SU}	Affects t_{CO}
Ensure that the appropriate constraints are set for the failing I/Os (page 10–3)	✓	✓
Use timing-driven compilation for I/O (page 10–36)	✓	✓
Use fast input register (page 10–36)	✓	—
Use fast output register, fast output enable register, and fast OCT register (page 10–36)	—	✓
Decrease the value of **Input Delay from Pin to Input Register** or set **Decrease Input Delay to Input Register = ON** (page 10–37)	✓	—
Decrease the value of **Input Delay from Pin to Internal Cells**, or set **Decrease Input Delay to Internal Cells = ON** (page 10–37)	✓	—
Decrease the value of **Delay from Output Register to Output Pin**, or set **Increase Delay to Output Pin = OFF** (page 10–37)	—	✓
Increase the value of **Input Delay from Dual-Purpose Clock Pin to Fan-Out Destinations** (page 10–39)	✓	—
Use PLLs to shift clock edges (page 10–39)	✓	✓
Use the Fast Regional Clock (page 10–40)	—	✓
For MAX II series of devices, set **Guarantee I/O paths** to zero, **Hold Time at Fast Timing Corner** to **OFF**, or when t_{SU} and t_{PD} constraints permit (page 10–40)	✓	—

Table 10–1. Improving Setup and Clock-to-Output Times *(Note 1)* (Part 2 of 2)

Technique	Affects t_{SU}	Affects t_{CO}
Increase the value of **Delay to output enable pin** or set **Increase delay to output enable pin** (page 10–39)	—	✓

Note to Table 10–1:

(1) These options may not apply to all device families.

Timing-Driven Compilation

To perform IOC timing optimization using the **Optimize IOC Register Placement For Timing** option, perform the following steps:

1. On the Assignments menu, click **Settings**.
2. In the **Category** list, select **Fitter Settings** and click **More Settings**.
3. In the **More Fitter Settings** dialog box, under **Existing options settings**, select **Optimize IOC Register Placement for Timing.**

This option moves registers into I/O elements if required to meet t_{SU} or t_{CO} assignments, duplicating the register if necessary (as in the case in which a register fans out to multiple output locations). This option is turned on by default and is a global setting. The option does not apply to MAX II series of devices because they do not contain I/O registers.

For APEX 20KE and APEX 20KC devices, if the I/O register is not available, the Fitter tries to move the register into the LAB adjacent to the I/O element.

The **Optimize IOC Register Placement for Timing** option affects only pins that have a t_{SU} or t_{CO} requirement. Using the I/O register is possible only if the register directly feeds a pin or is fed directly by a pin. This setting does not affect registers with any of the following characteristics:

- Have combinational logic between the register and the pin
- Are part of a carry or cascade chain
- Have an overriding location assignment
- Use the synchronous load or asynchronous clear ports of APEX 20K and APEX II devices
- Are input registers that use the synchronous load port and the value is not 1 (in device families where the port is available, other than APEX 20K, APEX II, and FLEX 6000 devices)
- Use the asynchronous load port and the value is not 1 (in device families where the port is available)

Registers with the characteristics listed are optimized using the regular Quartus II Fitter optimizations.

Fast Input, Output, and Output Enable Registers

You can place individual registers in I/O cells manually by making fast I/O assignments with the Assignment Editor. For an input register, use the **Fast Input Register** option; for an output register, use the **Fast Output Register** option; and for an output enable register, use the **Fast Output Enable Register** option. Stratix II devices also support the **Fast OCT (on-chip termination) Register** option. In the MAX II series of devices, which have no I/O registers, these assignments lock the register into the LAB adjacent to the I/O pin if there is a pin location assignment for that I/O pin.

If the fast I/O setting is on, the register is always placed in the I/O element. If the fast I/O setting is off, the register is never placed in the I/O element. This is true even if the **Optimize IOC Register Placement for Timing** option is turned on. If there is no fast I/O assignment, the Quartus II software determines whether to place registers in I/O elements if the **Optimize IOC Register Placement for Timing** option is turned on.

The four fast I/O options (**Fast Input Register**, **Fast Output Register**, **Fast Output Enable Register**, and **Fast OCT Register**) also can be used to override the location of a register that is in a LogicLock region, and force it into an I/O cell. If this assignment is applied to a register that feeds multiple pins, the register is duplicated and placed in all relevant I/O elements. In MAX II series of devices, the register is duplicated and placed in each distinct LAB location that is next to an I/O pin with a pin location assignment.

Programmable Delays

Various programmable delay options can be used to minimize the t_{SU} and t_{CO} times. For Arria GX, Stratix, and Cyclone series devices, and MAX II series of devices, the Quartus II software automatically adjusts the applicable programmable delays to help meet timing requirements. For APEX series devices, the default values are set to avoid any hold time problems. Programmable delays are advanced options that you should use only after you compile a project, check the I/O timing, and determine that the timing is unsatisfactory. For detailed information about the effect of these options, refer to the device family handbook or data sheet.

After you have made a programmable delay assignment and compiled the design, you can view the value of every delay chain for every I/O pin in the **Delay Chain Summary** section of the Compilation Report.

You can assign programmable delay options to supported nodes with the Assignment Editor. You can also view and modify the delay chain setting for the target device with the Chip Planner and Resource Property Editor. When you use the Resource Property Editor to make changes after performing a full compilation, recompiling the entire design is not necessary; you can save changes directly to the netlist. Because these changes are made directly to the netlist, the changes are not made again automatically when you recompile the design. The change management features allow you to reapply the changes on subsequent compilations.

Though the programmable delays in newer devices like Arria II GX, Stratix IV, and Stratix III are user-controllable, Altera recommends their use for advanced users only. However, the Quartus II software might use the programmable delays internally during the Fitter phase.

For more details about Stratix III programmable delays, refer to the *Stratix III Device Handbook* and *AN 474: Implementing Stratix III Programmable I/O Delay Settings in the Quartus II Software*. For more information about using the Chip Planner and Resource Property Editor, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

Table 10–2 summarizes the programmable delays available for Altera devices.

Table 10–2. Programmable Delays for Altera Devices (Part 1 of 3)

Programmable Delay	Description	I/O Timing Impact	Devices
Decrease input delay to input register	Decreases propagation delay from an input pin to the data input of the input register in the I/O cell associated with the pin. Applied to an input/bidirectional pin or register it feeds.	Decreases t_{SU} Increases t_H	■ Stratix ■ Stratix GX ■ Cyclone ■ MAX 7000B ■ APEX II ■ APEX 20KE ■ APEX 20KC
Input delay from pin to input register	Sets propagation delay from an input pin to the data input of the input register implemented in the I/O cell associated with the pin. Applied to an input/bidirectional pin.	Changes t_{SU} Changes t_H	■ Arria GX ■ Stratix II ■ Stratix II GX ■ Cyclone III ■ Cyclone II
Decrease input delay to internal cells	Decreases the propagation delay from an input or bidirectional pin to logic cells and embedded cells in the device. Applied to an input/bidirectional pin or register it feeds.	Decreases t_{SU} Increases t_H	■ Stratix ■ Stratix GX ■ Cyclone ■ APEX II ■ APEX 20KE ■ APEX 20KC ■ ACEX 1K ■ FLEX 10K ■ FLEX 6000
Input delay from pin to internal cells	Sets the propagation delay from an input or bidirectional pin to logic and embedded cells in the device. Applied to an input or bidirectional pin.	Changes t_{SU} Changes t_H	■ Stratix II ■ Stratix II GX ■ Cyclone III ■ Cyclone II ■ HardCopy II ■ MAX IIE and MAX IIZ

Table 10–2. Programmable Delays for Altera Devices (Part 2 of 3)

Programmable Delay	Description	I/O Timing Impact	Devices
Decrease input delay to output register	Decreases the propagation delay from the interior of the device to an output register in an I/O cell. Applied to an input/bidirectional pin or register it feeds.	Decreases t_{PD}	■ Arria GX ■ Stratix ■ Stratix GX ■ APEX II ■ APEX 20KE ■ APEX 20KC
Increase delay to output enable pin	Increases the propagation delay through the tri-state output to the pin. The signal can either come from internal logic or the output enable register in an I/O cell. Applied to an output/bidirectional pin or register feeding it.	Increases t_{CO}	■ Stratix ■ Stratix GX ■ APEX II
Delay to output enable pin	Sets the propagation delay to an output enable pin from internal logic or the output enable register implemented in an I/O cell.	Changes t_{CO}	■ Arria GX ■ Stratix II ■ Stratix II GX ■ Cyclone III
Increase delay to output pin	Increases the propagation delay to the output or bidirectional pin from internal logic or the output register in an I/O cell. Applied to output/bidirectional pin or register feeding it.	Increases t_{CO}	■ Stratix ■ Stratix GX ■ Cyclone ■ APEX II ■ APEX 20KE ■ APEX 20KC
Delay from output register to output pin	Sets the propagation delay to the output or bidirectional pin from the output register implemented in an I/O cell. This option is off by default.	Changes t_{CO}	■ Arria GX ■ Stratix II ■ Stratix II GX ■ Cyclone III ■ Cyclone II
Increase input clock enable delay	Increases the propagation delay from the interior of the device to the clock enable input of an I/O input register.	—	■ Stratix ■ Stratix GX ■ APEX II ■ APEX 20KE ■ APEX 20KC
Input delay from dual purpose clock pin to fan-out destinations	Sets the propagation delay from a dual-purpose clock pin to its fan-out destinations that are routed on the global clock network. Applied to an input or bidirectional dual-purpose clock pin.	—	■ Cyclone III ■ Cyclone II

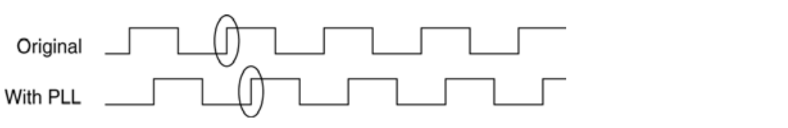
Table 10–2. Programmable Delays for Altera Devices (Part 3 of 3)

Programmable Delay	Description	I/O Timing Impact	Devices
Increase output clock enable delay	Increases the propagation delay from the interior of the device to the clock enable input of the I/O output register and output enable register.	—	■ Stratix ■ Stratix GX ■ APEX II ■ APEX 20KE ■ APEX 20KC
Increase output enable clock enable delay	Increases the propagation delay from the interior of the device to the clock enable input of an output enable register.	—	■ Stratix ■ Stratix GX
Increase t_{ZX} delay to output pin	Used for zero bus-turnaround (ZBT) by increasing the propagation delay of the falling edge of the output enable signal.	Increases t_{CO}	■ Stratix ■ Stratix GX ■ APEX II

Use PLLs to Shift Clock Edges

Using a PLL typically improves I/O timing automatically. If the timing requirements are still not met, most devices allow the PLL output to be phase shifted to change the I/O timing. Shifting the clock backwards gives a better t_{CO} at the expense of t_{SU}, while shifting it forward gives a better t_{SU} at the expense of t_{CO} and t_H. Refer to Figure 10–8. This technique can be used only in devices that offer PLLs with the phase shift option.

Figure 10–8. Shift Clock Edges Forward to Improve t_{SU} at the Expense of t_{CO}



You can achieve the same type of effect in certain devices using the programmable delay called **Input Delay from Dual Purpose Clock Pin to Fan-Out Destinations**, described in Table 10–2.

Use Fast Regional Clock Networks and Regional Clocks Networks

Altera devices have a variety of hierarchical clock structures available within them. These include dedicated global clock networks (GCLKs), regional clock networks (RCLKs), fast regional clock networks (FCLK) and periphery clock networks (PCLKs). The available resources differ between various Altera device families. Refer to the appropriate device handbook to get the number of various clocking resources available in your target device.

In general, fast regional clocks have less delay to I/O elements than regional and global clocks, and are used for high fan-out control signals. Regional clocks on the other hand provide the lowest clock delay and skew for logic contained in a single quadrant. Placing clocks on these low-skew and low-delay clock nets provides better t_{CO} performance.

Change How Hold Times are Optimized for MAX II Devices

For MAX II series of devices, you can use the **Guarantee I/O paths have zero hold time at Fast Timing Corner** option to control how hold time is optimized by the Quartus II software. On the Assignments menu, click **Settings**. In the **Category** list, select **Fitter Settings**. Click **More Settings.** In the **More Fitter Settings** dialog box, set the option globally. Or, on the Assignments menu, click **Assignment Editor** to set this option for specific I/Os.

The option controls whether the Fitter uses timing-driven compilation to optimize a design to achieve a zero hold time for I/Os that feed globally clocked registers at the fast (best-case) timing corner, even in the absence of any user timing assignments. When this option is set to **On** (default), the Fitter guarantees zero hold time (t_H) for I/Os feeding globally clocked registers at the fast timing corner, at the expense of possibly violating t_{SU} or t_{PD} timing constraints. When this option is set to **When tsu and tpd constraints permit**, the Fitter achieves zero hold time for I/Os feeding globally clocked registers at the fast timing corner only when t_{SU} or t_{PD} timing constraints are not violated. When this option is set to **Off**, designs are optimized to meet user timing assignments only.

By setting this option to **Off** or **When tsu and tpd constraints permit**, you improve t_{SU} at the expense of t_H.

Register-to-Register Timing Optimization Techniques (LUT-Based Devices)

The next stage of design optimization is to improve register-to-register (f_{MAX}) timing. There are a number of options available if the performance requirements are not achieved after compilation.

Note that the coding style affects the performance of your design to a greater extent than to other changes in settings. Always evaluate your code and make sure to use synchronous design practices. For more details, refer to the handbook chapter on design practices and coding guidelines.

When using the Quartus II TimeQuest Timing Analyzer, register-to-register timing optimization is the same as maximizing the slack on the clock domains in your domain. You can use the techniques described in this section to improve the slack on different timing paths in your design.

Before optimizing your design, you should understand the structure of your design as well as the type of logic affected by each optimization. An optimization can decrease performance if the optimization does not benefit your logic structure.

Improving Register-to-Register Timing Summary

The choice of options and settings to improve the timing margin (slack) or to improve register-to-register timing depends on the failing paths in the design. To achieve the results that best approximate your performance requirements, apply the following techniques and compile the design after each step:

1. Ensure that your timing assignments are complete. For details, refer to "Timing Requirement Settings" on page 10–4.

2. Ensure that you have reviewed all warning messages from your initial compilation and check for ignored timing assignments. Refer to "Design Analysis" on page 10–11 for details and fix any of these problems before proceeding with optimization.
3. Apply netlist synthesis optimization options and physical synthesis.
4. Try multiple different Fitter seeds (page 10–47). You can omit this step if a large number of critical paths are failing, or if the paths are failing badly.
5. Apply the following synthesis options to optimize for speed:
   - Optimize Synthesis for Speed, Not Area (page 10–44)
   - Flatten the Hierarchy During Synthesis (page 10–45)
   - Set the Synthesis Effort to High (page 10–45)
   - Change State Machine Encoding (page 10–45)
   - Duplicate Logic for Fan-Out Control (page 10–45)
   - Prevent Shift Register Inference (page 10–46)
   - Use Other Synthesis Options Available in Your Synthesis Tool (page 10–46)
6. Make LogicLock assignments (page 10–49) to control placement.
7. Make design source code modifications to fix areas of the design that are still failing timing requirements by significant amounts (page 10–48).
8. Make location assignments, or as a last resort, perform manual placement by back-annotating the design (page 10–51).

You can use the Design Space Explorer (DSE) to automate the process of running several different compilations with different settings. For more information, refer to the *Design Space Explorer* chapter in volume 2 of the *Quartus II Handbook*.

If these techniques do not achieve performance requirements, additional design source code modifications might be required (page 10–48).

Physical Synthesis Optimizations

The Quartus II software offers physical synthesis optimizations that can help improve the performance of many designs regardless of the synthesis tool used. Physical synthesis optimizations can be applied both during synthesis and during fitting.

Physical synthesis optimizations that occur during the synthesis stage of the Quartus II compilation operate either on the output from another EDA synthesis tool or as an intermediate step in Quartus II integrated synthesis. These optimizations make changes to the synthesis netlist to improve either area or speed, depending on your selected optimization technique.

To view and modify the synthesis netlist optimization options, on the Assignments menu, click **Settings**. In the **Category** list, expand **Compilation Process Settings** and select **Physical Synthesis Optimizations**.

If you use a third-party EDA synthesis tool and want to determine if the Quartus II software can remap the circuit to improve performance, you can use the **Perform WYSIWYG Primitive Resynthesis** option. This option directs the Quartus II software to unmap the LEs in an atom netlist to logic gates and then map the gates back to Altera-specific primitives. Using Altera-specific primitives enables the Fitter to remap the circuits using architecture-specific techniques.

To turn on the **Perform WYSIWYG Primitive Resynthesis** option, on the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings** and check the box for **Perform WYSIWYG Primitive Resynthesis**.

The Quartus II technology mapper optimizes the design for **Speed**, **Area**, or **Balanced**, according to the setting of the **Optimization Technique** option. To change this setting, on the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**, and choose **Speed** or **Balanced** under **Optimization Technique**.

The physical synthesis optimizations occur during the Fitter stage of the Quartus II compilation. Physical synthesis optimizations make placement-specific changes to the netlist that improve speed performance results for a specific Altera device.

The following physical synthesis optimizations are available during the Fitter stage for improving performance:

- Physical synthesis for combinational logic
- Automatic asynchronous signal pipelining
- Physical synthesis for registers
  - Register duplication
  - Register retiming

You can apply physical synthesis options on specific instances if you want the performance gain from physical synthesis only on parts of your design.

To view and modify the **Physical Synthesis Optimizations**: On the Assignments menu, click **Settings**. In the **Category** list, select **Fitter Settings**, and specify the physical synthesis optimization options on the **Physical Synthesis Optimizations** page. You can also specify the **Physical synthesis effort**, which sets the level of physical synthesis optimization that you want the Quartus II software to perform.

The **Perform physical synthesis for combinational logic** option allows the Quartus II Fitter to resynthesize the combinational logic in a design to reduce delay along the critical path and improve design performance.

The **Perform automatic asynchronous signal pipelining** option allows the Quartus II Fitter to insert pipeline stages for asynchronous clear and asynchronous load signals automatically during fitting to increase circuit performance. You can use this option if asynchronous control signal recovery and removal times do not meet your requirements. The option improves performance for designs in which asynchronous signals in very fast clock domains cannot be distributed across the chip quickly enough (because of long global network delays).

To apply physical synthesis assignments for fitting on a per instance basis, use the Quartus II Assignment Editor. The following assignments are available as instance assignments:

- Perform physical synthesis for combinational logic
- Perform register duplication for performance
- Perform register retiming for performance
- Perform automatic asynchronous signal pipelining

In the Assignment Editor, indicate the module instance you want to apply to the specific physical synthesis setting in the **To** tab. Select the required physical synthesis assignment in the **Assignment Name** tab. In the **Value** tab, select **ON**. In the **Enabled** tab, select **Yes**.

The **Perform automatic asynchronous signal pipelining** option adds registers to nets driving the asynchronous clear or asynchronous load ports of registers. This adds register delays (and latency) to the reset, adding the same number of register delays for each destination using the reset. Therefore, the option should be used only when adding latency to reset signals does not violate any design requirements. This option also prevents the promotion of signals to use global routing resources.

The **Perform register duplication** physical synthesis option allows the Quartus II software to duplicate registers based on Fitter placement information to improve design performance. The Fitter can also duplicate combinational logic when this option is enabled.

The **Perform register retiming** physical synthesis option allows the Quartus II software to move registers across combinational logic to balance timing. This option applies to registers and combinational logic that have already been placed into logic cells.

You can perform physical synthesis during the fitter stage to improve the fitting results as well.

The Quartus II software performs the optimizations that help achieve a better fit when you turn on the **Perform physical synthesis for combinational logic** option.

The Fitter performs physical synthesis optimizations on logic and registers, allowing the mapping of logic and registers into unused memory blocks in the device to achieve a fit, when you turn on the **Perform logic to memory mapping** option.

For more information and detailed descriptions of these netlist optimization options, refer to the *Netlist Optimizations and Physical Synthesis* chapter in volume 2 of the *Quartus II Handbook*.

Because performance results are design-dependent, try the physical synthesis options in different combinations until you achieve the best results. Generally, turning on all the options gives the best results but significantly increases compilation time. The following information provides typical benchmark results on different designs with varying amounts of logic using synthesis netlists from leading third-party synthesis tools and compiled with Quartus II software. These results use the default **Balanced** setting for the Optimization Technique for WYSIWYG resynthesis. Changing the setting to **Speed** or **Area** can affect your results.

Using WYSIWIG primitive resynthesis can reduce area by about 8% in about 60% of designs, with an average improvement in f_{MAX} of about 3% and a maximum improvement in f_{MAX} of about 6%. By using other physical synthesis options for combinational logic and registers, you might be able to increase the f_{MAX} between 10% to 20% (depending on the physical synthesis effort level selected) in about 80% of the designs.

Compilation time might increase considerably when you use high physical synthesis effort levels, sometimes as much as 4×. The optimizations are design dependent, and some designs might not produce much improvement with physical synthesis.

Turn Off Extra-Effort Power Optimization Settings

If PowerPlay power optimization settings are set to **Extra Effort**, your design performance can be affected. If improving timing performance is more important than reducing power use, set the PowerPlay power optimization setting to **Normal**.

To change the PowerPlay power optimization level, on the Assignments menu, choose **Settings**. The **Setting** dialog box appears. From the **Category** list, select **Analysis & Synthesis Settings**. From the pull-down menu, select the appropriate level of PowerPlay power optimization level.

For more information about reducing power use, refer to the *Power Optimization* chapter in volume 2 of the *Quartus II Handbook*.

Optimize Synthesis for Speed, Not Area

The manner in which the design is synthesized has a large impact on design performance. Design performance varies depending on the way the design is coded, the synthesis tool used, and the options specified when synthesizing. Change your synthesis options if a large number of paths are failing, or if specific paths are failing badly and have many levels of logic.

Set your device and timing constraints in your synthesis tool. Synthesis tools are timing-driven and optimized to meet specified timing requirements. If you do not specify target frequency, some synthesis tools optimize for area.

Some synthesis tools offer an easy way to instruct the tool to focus on speed instead of area.

For Quartus II integrated synthesis, on the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**, and specify **Speed** as the **Optimization Technique** option. You can also specify this logic option for specific modules in your design with the Assignment Editor while leaving the default **Optimization Technique** setting at **Balanced** (for the best trade-off between area and speed for certain device families) or **Area** (if area is an important concern). You can also use the **Speed Optimization Technique for Clock Domains** option to specify that all combinational logic in or between the specified clock domain(s) is optimized for speed.

To achieve best performance with push-button compilation, follow the recommendations in the following sections for other synthesis settings. You can use the DSE to experiment with different Quartus II synthesis options to optimize your design for the best performance.

For information about setting timing requirements and synthesis options in Quartus II integrated synthesis and third-party synthesis tools, refer to the appropriate chapter in *Section III. Synthesis* in volume 1 of the *Quartus II Handbook*, or refer to your synthesis software documentation.

Flatten the Hierarchy During Synthesis

Synthesis tools typically let you preserve hierarchical boundaries, which can be useful for verification or other purposes. However, the best optimization results generally occur when the synthesis tool optimizes across hierarchical boundaries, because doing so often allows the synthesis tool to perform the most logic minimization, which can improve performance. Whenever possible, flatten your design hierarchy to achieve the best results. If you are using Quartus II integrated synthesis, ensure that the **Preserve Hierarchical Boundary** option is turned off. If you are using Quartus II incremental compilation, you cannot flatten your design across design partitions. Incremental compilation always preserves the hierarchical boundaries between design partitions. Follow Altera's recommendations for design partitioning such as registering partition boundaries to reduce the effect of cross-boundary optimizations.

For more information about using incremental compilation and recommendations for design partitioning, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Set the Synthesis Effort to High

Some synthesis tools offer varying synthesis effort levels to trade off compilation time with synthesis results. Set the synthesis effort to high to achieve best results when applicable.

Change State Machine Encoding

State machines can be encoded using various techniques. One-hot encoding, which uses one register for every state bit, usually provides the best performance. If your design contains state machines, changing the state machine encoding to one-hot can improve performance at the cost of area.

If your design does not manually encode the state bits, you can select the state machine encoding chosen in your synthesis tool. In Quartus II integrated synthesis, on the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**, and for **State Machine Processing**, choose **One-Hot**. You also can specify this logic option for specific modules or state machines in your design with the Assignment Editor.

In some cases (especially in Stratix II and Stratix III devices), encoding styles other than the default offer better performance. Experiment with different encoding styles to see what effect the style has on your resource utilization and timing performance.

Duplicate Logic for Fan-Out Control

Duplicating logic or registers can help improve timing in cases where moving a register in a failing timing path to reduce routing delay creates other failing paths, or where there are timing problems due to the fan-out of the registers. Most often, timing failures occur not because of the high Fan-Out registers, but because of the location of those registers. Duplicating registers, where source and destination registers are physically close, can help improve slack on critical paths.

Many synthesis tools support options or attributes that specify the maximum fan-out of a register. When using Quartus II integrated synthesis, you can set the **Maximum Fan-Out** logic option in the Assignment Editor to control the number of destinations for a node so that the fan-out count does not exceed a specified value. You can also use the `maxfan` attribute in your HDL code. The software duplicates the node as required to achieve the specified maximum fan-out.

Logic duplication using **Maximum Fan-Out** assignments normally increases resource utilization and can potentially increase compilation time, depending on the placement and the total resource usage within the selected device. The improvement in timing performance that results because of **Maximum Fan-Out** assignments is very design-specific.

If you are using **Maximum Fan-Out** assignments, Altera recommends benchmarking your design with and without these assignments to evaluate whether they give the expected improvement in timing performance. Use the assignments only when you get improved results.

You can manually duplicate registers in the Quartus II software regardless of the synthesis tool used. To duplicate a register, apply the **Manual Logic Duplication** option to the register with the Assignment Editor.

The **Manual Logic Duplication** option also accepts wildcards. This is an easy and powerful duplication technique that you can use without editing your source code. For example, you can use this technique to make a duplicate of a large fan-out node for all of its destinations in a certain design hierarchy, such as `hierarchy_A`. To apply such an assignment in the Assignment Editor, make an entry such as the one shown in Table 10–3.

Table 10–3. Duplicating Logic in the Assignment Editor

From	To	Assignment Name	Value
`My_high_fanout_node`	`*hierarchy_A*`	Manual Logic Duplication	`high_fanout_to_A`

For more information about the manual logic duplication option, refer to the Quartus II Help.

Prevent Shift Register Inference

In some cases, turning off the inference of shift registers increases performance. Doing so forces the software to use logic cells to implement the shift register instead of implementing the registers in memory blocks using the ALTSHIFT_TAPS megafunction. If you implement shift registers in logic cells instead of memory, logic utilization is increased.

Use Other Synthesis Options Available in Your Synthesis Tool

With your synthesis tool, experiment with the following options if they are available:

- Turn on register balancing or retiming
- Turn on register pipelining
- Turn off resource sharing

These options can increase performance. They typically increase the resource utilization of your design.

Fitter Seed

The Fitter seed affects the initial placement configuration of the design. Changing the seed value changes the Fitter results because the fitting results change whenever there is a change in the initial conditions. Because each seed value results in a somewhat different fit, you can experiment with several different seeds to attempt to obtain better fitting results and timing performance.

When there are changes in your design, there is some random variation in performance between compilations. This variation is inherent in placement and routing algorithms—there are too many possibilities to try them all and get the absolute best result, so the initial conditions change the compilation result.

Any design change that directly or indirectly affects the Fitter has the same type of random effect as changing the seed value. This includes any change in source files, **Analysis & Synthesis Settings**, **Fitter Settings**, or **Timing Analyzer Settings**. The same effect can appear if you use a different computer processor type or different operating system because different systems can change the way floating point numbers are calculated in the Fitter.

If a change in optimization settings slightly affects the register-to-register timing or number of failing paths, you can't always be certain that your change caused the improvement or degradation, or whether it could be due to random effects in the Fitter. If your design is still changing, running a seed sweep (compiling your design with multiple seeds) determines whether the average result has improved after an optimization change and whether a setting that increases compilation time has benefits worth the increased time (such as setting the **Physical Synthesis Effort** to **Extra**). The sweep also shows the amount of random variation you should expect for your design.

If your design is finalized, you can compile your design with different seeds to obtain one optimal result. However, if you subsequently make any changes to your design, you will likely have to perform seed sweep again.

On the Assignments menu, select **Fitter Settings** to control the initial placement with the Seed. You can use the DSE to perform a seed sweep easily.

You can use the following Tcl command from a script to specify a Fitter seed:

```
set_global_assignment -name SEED <value> ↵
```

For more information about compiling with different seeds using the DSE script, refer to the *Design Space Explorer* chapter in volume 2 of the *Quartus II Handbook*.

Set Maximum Router Timing Optimization Level

To improve routability in designs where the router did not pick up the optimal routing lines, set the **Router Timing Optimization Level** to **Maximum**. This setting determines how aggressively the router tries to meet timing requirements. Setting this option to **Maximum** can increase design speed slightly at the cost of increased compilation time. Setting this option to **Minimum** can reduce compilation time at the cost of slightly reduced design speed. The default value is **Normal**.

To modify the **Router Timing Optimization Level**, on the Assignments menu, click **Settings**. The **Settings** dialog box appears. In the **Category** list, click **Fitter Settings**. Click on the **More Settings** tab. From the available settings, select **Router Timing Optimization Level** and choose the required setting from the list.

Enable Beneficial Skew Optimization

The Quartus II Fitter intentionally inserts some small delays on global clock networks to improve performance on designs that target Arria II GX, Stratix IV, Stratix III, and Cyclone III devices. This is called beneficial skew optimization and is enabled by default for devices that support this feature.The value of skew introduced depends on the device family and the speed grade of the chosen device. For example, when this option is turned on for a Stratix III device (-2 speed grade), a skew value of approximately 150 ps is introduced if the inclusion improves the timing performance of your design. If you are targeting a Cyclone III device (-6 speed grade), the delay value introduced is approximately 350 ps. For Arria II GX and Stratix IV devices, an approximate skew of 100 ps could be introduced. To enable the **Beneficial Skew Optimization** option, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Fitter Settings**. The **Fitter Settings** page appears.
3. Click **More Settings**. The **More Fitter Settings** dialog box appears.
4. Under **Options**, in the **Name** list, select **Enable Beneficial Skew Optimization**. In the **Setting** list, select **On**.
5. Click **OK**.
6. In the **Settings** dialog box, click **OK**.

When you turn on **Enable Beneficial Skew Optimization** globally, you can disable skew insertion on a particular clock or destination by using an instance level `ENABLE_BENEFICIAL_SKEW_OPTIMIZATION` assignment.

When you want to use **Enable Beneficial Skew Optimization**, you must also set the **Optimize hold timing** option to **All paths** (in the **Fitter Settings** page of the **Settings** dialog box). If you turn on **Enable Beneficial Skew Optimization**, the fitter overrides the setting of **Optimize hold timing** if it is not set to **All paths**, and displays an info message describing the change.

Optimize Source Code

If the methods described in the preceding sections do not sufficiently improve timing of the design, modify your design files to achieve the desired results. Try restructuring the design to use pipelining or more efficient coding techniques. In many cases, optimizing the design’s source code can have a very significant effect on your design performance. In fact, optimizing your source code is typically the most effective technique for improving the quality of your results, and is often a better choice than using LogicLock or location assignments.

If the critical path in your design involves memory or DSP functions, check whether you have code blocks in your design that describe memory or functions that are not being inferred and placed in dedicated logic. You might be able to modify your source code to cause these functions to be placed into high-performance dedicated memory or resources in the target device.

Ensure that your state machines are recognized as state machine logic and optimized appropriately in your synthesis tool. State machines that are recognized are generally optimized better than if the synthesis tool treats them as generic logic. In the Quartus II software, you can check for the State Machine report under **Analysis & Synthesis** in the Compilation Report. This report provides details, including the state encoding for each state machine that was recognized during compilation. If your state machine is not being recognized, you might have to change your source code to enable it to be recognized.

For coding style guidelines including examples of HDL code for inferring memory, functions, guidelines, and sample HDL code for state machines, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

LogicLock Assignments

Using LogicLock assignments to improve timing performance is only recommended for older Altera devices, such as the APEX 20K family. For designs using these devices, you can make LogicLock assignments for based nodes optimization, design hierarchy, or critical paths. This method can be used if a large number of paths are failing, and recoding the design does not seem to be necessary. LogicLock assignments can help if routing delays form a large portion of your critical path delay, and placing logic closer together in the device improves the routing delay.

Improving fitting results with LogicLock assignments, especially for larger devices, such as the Stratix and Arria GX series of devices can be difficult. The LogicLock feature is intended to be used for performance preservation and to floorplan your design. Therefore, LogicLock assignments do not always improve the performance of the design. In many cases, you cannot improve upon results from the Fitter by making location assignments.

If there are existing LogicLock assignments in your design, remove the assignments if your design methodology permits it. Recompile the design to see if the assignments are making the performance worse.

When making LogicLock assignments, it is important to consider how much flexibility to give the Fitter. LogicLock assignments provide more flexibility than hard location assignments. Assignments that are more flexible require higher Fitter effort, but reduce the chance of design over-constraint. The following types of LogicLock assignments are available, listed in the order of decreasing flexibility:

- Auto size, floating location regions
- Fixed size, floating location regions
- Fixed size, locked location regions

For more information about using LogicLock regions, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

To determine what to put into a LogicLock region, refer to the timing analysis results and analyze the critical paths in the Chip Planner (Timing Closure Floorplan for older devices). The register-to-register timing paths in the Timing Analyzer section of the Compilation Report helps you recognize patterns.

The following sections describe cases in which LogicLock regions can help to optimize a design.

Hierarchy Assignments

For a design with the hierarchy shown in Figure 10–9, which has failing paths in the timing analysis results similar to those shown in Table 10–4, mod_A is probably a problem module. In this case, a good strategy to fix the failing paths is to place the mod_A hierarchy block in a LogicLock region so that all the nodes are closer together in the floorplan.

Figure 10–9. Design Hierarchy

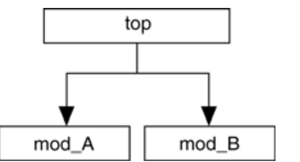


Table 10–4 shows the failing paths connecting two regions together within mod_A listed in the timing analysis report.

Table 10–4. Failing Paths in a Module Listed in Timing Analysis

From	To
|mod_A|reg1	|mod_A|reg9
|mod_A|reg3	|mod_A|reg5
|mod_A|reg4	|mod_A|reg6
|mod_A|reg7	|mod_A|reg10
|mod_A|reg0	|mod_A|reg2

Hierarchical LogicLock regions are also important if you are using an incremental compilation flow. Each design partition for incremental compilation should be placed in a separate LogicLock region to reduce conflicts and ensure good quality of results as the design develops. You can use auto size and floating location regions to find a good design floorplan, but you should fix the size and placement to achieve the best results in future compilations.

For more information about using incremental compilation and recommendations for creating a design floorplan using LogicLock regions, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* and *Best Practices for Incremental Compilation and Floorplan Assignments* chapters in volume 1 of the *Quartus II Handbook*, and *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

Path Assignments

If you see a pattern such as the one shown in Figure 10–10 and Table 10–5, it often indicates paths with a common problem. In this case, a path-based assignment can be made from all d_reg registers to all memaddr registers. You can make a path-based assignment to place all source registers, destination registers, and the nodes between them in a LogicLock region with the wildcard characters “*” and “?.”

You also can explicitly place the nodes of a critical path in a LogicLock region. However, using this method instead of path assignments can result in alternate paths between the source and destination registers becoming critical paths.

Figure 10–10. Failing Paths in Timing Analysis

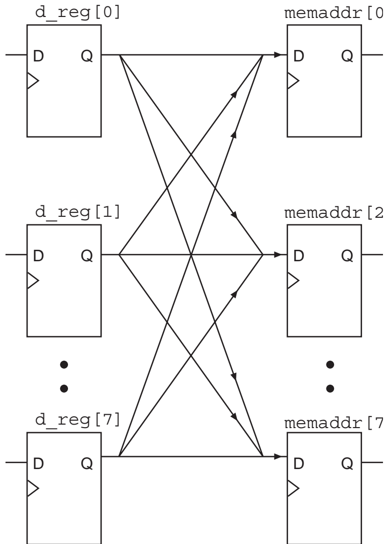

Table 10–5 shows the failing paths listed in the timing analysis report.

Table 10–5. Failing Paths in Timing Analysis

From	To
|d_reg[1]	|memaddr[5]
|d_reg[1]	|memaddr[6]
|d_reg[1]	|memaddr[7]
|d_reg[2]	|memaddr[0]
|d_reg[2]	|memaddr[1]

For more information about path-based LogicLock assignments, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

Location Assignments and Back-Annotation

If a small number of paths are failing to meet their timing requirements, you can use hard location assignments to optimize placement. Location assignments are less flexible for the Quartus II Fitter than LogicLock assignments. In some cases, when you are very familiar with your design, you can enter location constraints in a way that produces better results.

Improving fitting results, especially for larger devices, such as the Stratix and Arria GX series of devices, can be difficult. Location assignments do not always improve the performance of the design. In many cases, you cannot improve upon the results from the Fitter by making location assignments.

The following commonly used location assignments are listed in the order of decreasing flexibility:

- Custom regions
- Back-annotated LAB location assignments
- Back-annotated LE or ALM location assignments

Custom Regions

A custom region is a rectangular region containing user-assigned nodes, which are constrained in the region's boundaries. If any portion of a block in the device floorplan overlaps a custom region, such as an M-RAM block, it is considered to be entirely in that region.

Custom regions are hard location assignments that cannot be overridden and are very similar to fixed-size, locked-location, LogicLock regions. Custom regions are commonly used when logic must be constrained to a specific portion of the device.

Back-Annotation and Manual Placement

Assigning the location of nodes in a design to the locations to which they were assigned during the last compilation is called "back-annotation." When nodes are locked to their assigned locations in a back-annotated design, you can manually move specific nodes without affecting other back-annotated nodes. The process of manually moving and reassigning specific nodes is called manual placement.

Back-annotation is very restrictive to the compiler, so you should back-annotate only when the design has been finalized and no further changes are expected. Assignments can become invalid if the design is changed. Combinational nodes often change names when a design is resynthesized, even if they are unrelated to the logic that was changed.

Moving nodes manually can be very difficult for large devices. In many cases, you cannot improve upon the Fitter's results. Illegal or unroutable location constraints can cause "no fit" errors. Before making location assignments, determine whether to back-annotate to lock down the assigned locations of all nodes in the design. When you are using a hierarchical design flow, you can lock down node locations in one LogicLock region only, while other node locations are left floating in a fixed LogicLock region. By implementing a hierarchical approach, you can use the LogicLock design methodology to reduce the dependence of logic blocks on other logic blocks in the device.

Consistent node names are required to perform back-annotation. If you use Quartus II integrated synthesis or any Quartus II optimizations, such as the WYSIWYG primitive resynthesis netlist optimization or any physical synthesis optimizations, you must create an atom netlist before you back-annotate to lock down the placement of any nodes. This creates consistent node names.

Physical synthesis optimizations are placement-specific as well as design-specific. Unless you back-annotate the design before recompilation, the physical synthesis results can differ. This happens because the atom netlist creates different placement results. By back-annotating the design, the design source and the atom netlist use the same placement when the design is recompiled. When you use an atom netlist and you want to maintain the same placement results as a previous compilation, use LogicLock regions and back-annotate the placement of all nodes in the design. Not back-annotating the design can result in the design source and the atom netlist having different placement results and therefore different synthesis results.

For more information about creating atom netlists for your design, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

When you back-annotate a design, you can choose whether to assign the nodes either to LABs (this is preferred because of increased flexibility) or LEs/ALMs. You also can choose to back-annotate routing to further restrict the Fitter and force a specific routing within the device.

Using back-annotated routing with physical synthesis optimizations can result in a routing failure.

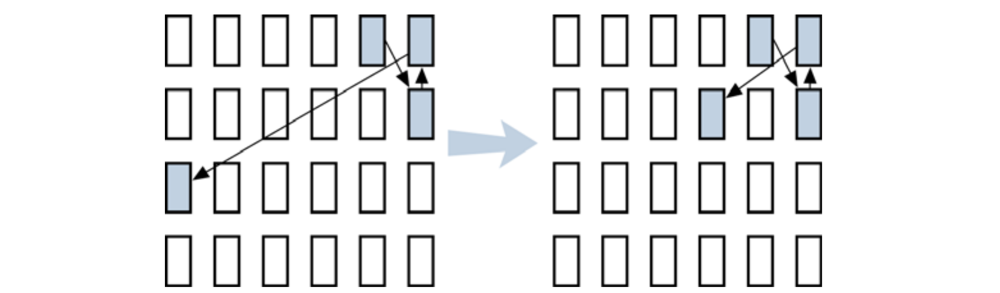
For more information about back-annotating routing, refer to the Quartus II Help.

When performing manual placement at a detailed level, Altera recommends that you move LABs, not logic cells (LEs or ALMs). The Quartus II software places nodes that share the same control signals in appropriate LABs. Successful placement and routing is more difficult when you move individual logic cells. This is because LEs with different control signals that are put into the same LAB might not have any unused control signals available, and the design might not fit.

In general, when you are performing manual placement and routing, fix all I/O paths first, because often fewer options are available to meet I/O timing. After I/O timing is met, focus on manually placing register-to-register timing paths. This strategy is consistent with the methodology outlined in this chapter.

The best way to meet performance is to move nodes closer together. For a critical path such as the one shown in Figure 10–11, moving the destination node closer to the other nodes reduces the delay and helps meet your timing requirements.

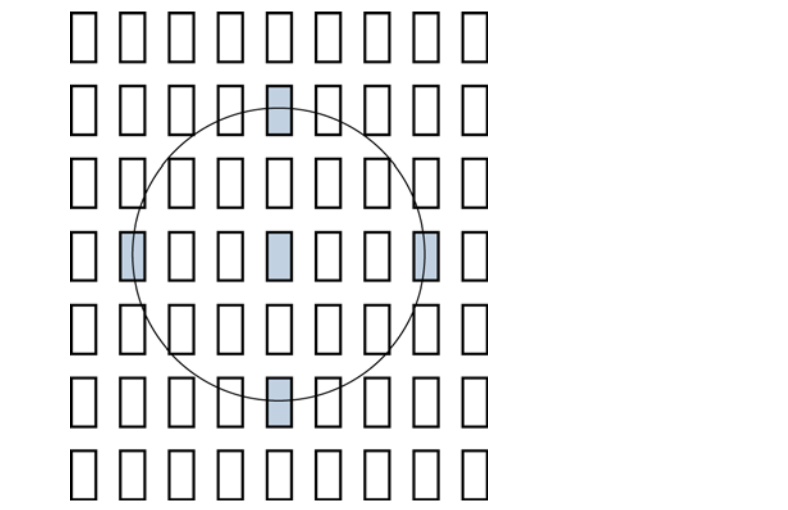
Figure 10–11. Reducing Delay of Critical Path



Optimizing Placement for Stratix, Stratix II, Arria GX, and Cyclone II Devices

In the Arria GX, Stratix, and Cyclone series of devices, the row interconnect delay is slightly faster than the column interconnect delay. Therefore, when placing nodes, optimal placement is typically an ellipse around the source or destination node. In Figure 10–12, if the source is located in the center, any of the shaded LABs should give approximately the same delay.

Figure 10–12. Possible Optimal Placement Ellipse



In addition, you should avoid crossing any M-RAM memory blocks for node-to-node routing, because routing paths across M-RAM blocks requires using R24 or C16 routing lines.

The Quartus II software calculates the interconnect delay based on different electrical characteristics of each individual wire, such as the length, fan-out, distribution of the parasitic loading on the wire, and so forth.

To determine the actual delays to and from a resource, use the **Show Physical Timing Estimate** feature in the Chip Planner.

For more information about using the Chip Planner or the Timing Closure Floorplan, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

Optimizing Placement for Cyclone Devices

In Cyclone devices, the row and column interconnect delays are similar; therefore, when placing nodes, optimal placement is typically a circle around the source or destination node.

Try to avoid long routes across the device. Long routes require more than one routing line to cross the Cyclone device.

Optimizing Placement for APEX II and APEX 20KE/C Devices

For the APEX II and APEX 20KE/C device families, the delay for paths is reduced by placing the source and destination nodes in the same geographical resource location. The following device resources are listed in order from fastest to slowest:

- LAB
- MegaLAB structure
- MegaLAB column
- Row

For example, if the nodes cannot be placed in the same MegaLAB structure to reduce the delay, place them in the same MegaLAB column. For the actual delays to and from resources, use the **Show Physical Timing Estimate** feature in the Timing Closure Floorplan.

Resource Utilization Optimization Techniques (Macrocell-Based CPLDs)

The following recommendations help you take advantage of the macrocell-based architecture in the MAX 7000 and MAX 3000 device families to yield maximum speed, reliability, and device resource utilization while minimizing fitting difficulties.

After design analysis, the first stage of design optimization is to improve resource utilization. Complete this stage before proceeding to timing optimization. First, ensure that you have set the basic constraints described in "Initial Compilation: Required Settings" on page 10–3. If your design is not fitting into a specified device, use the techniques in this section to achieve a successful fit.

Use Dedicated Inputs for Global Control Signals

MAX 7000 and MAX 3000 devices have four dedicated inputs that can be used for global register control. Because the global register control signals can bypass the logic cell array and directly feed registers, product terms can be preserved for primary logic. Also, because each signal has a dedicated path into the LAB, global signals also can bypass logic and data path interconnect resources.

Because the dedicated input pins are designed for high fan-out control signals and provide low skew, you should always assign global signals (such as clock, clear, and output enable) to the dedicated input pins.

You can use logic-generated control signals for global control signals instead of dedicated inputs. However, the following list shows the disadvantages of using logic-generated control signals:

- More resources are required (logic cells, interconnect).
- More data skew is introduced.
- If the logic-generated control signals have high fan-out, the design can be more difficult to fit.

By default, the Quartus II software uses dedicated inputs for global control signals automatically. You can assign control signals to dedicated input pins in one of the following ways:

- In the Assignment Editor, choose one of the two following methods:
  - Assign pins to dedicated pin locations.
  - Assign a **Global Signal** setting to the pins.

- On the Assignments menu, click **Settings**. On the **Analysis & Synthesis Settings** page, in the **Auto Global Options** section, in the **Category** list, select **Register Control Signals**.
- Insert a `GLOBAL` primitive after the pins.
- If you have already assigned pins for the design in the MAX+PLUS® II software, on the Assignments menu, click **Import Assignments**.

Reserve Device Resources

Because pin and logic option assignments can be necessary for board layout and performance requirements, and because full utilization of the device resources can increase the difficulty of fitting the design, Altera recommends that you leave 10% of the device's logic cells and 5% of the I/O pins unused to accommodate future design modifications. Following the Altera-recommended device resource reservation guidelines for macrocell-based CPLDs increases the chance that the Quartus II software can fit the design during recompilation after changes or assignments have been made.

Pin Assignment Guidelines and Procedures

Sometimes user-specified pin assignments are necessary for board layout. This section discusses pin assignment guidelines and procedures.

To minimize fitting issues with pin assignments, follow these guidelines:

- Assign speed-critical control signals to dedicated inputs.
- Assign output enables to appropriate locations.
- Estimate fan-in to assign output pins to the appropriate LAB.
- Assign output pins that require parallel expanders to macrocells numbered 4 to 16.

Altera recommends that you allow the Quartus II software to choose pin assignments automatically when possible. You can use the Quartus II Pin Advisor feature (accessible from the Tools menu) for pin connection guidelines. For more information about the Pin Advisor, refer to Quartus II Help.

Control Signal Pin Assignments

Assign speed-critical control signals to dedicated input pins. Every MAX 7000 and MAX 3000 device has four dedicated input pins (`GCLK1`, `OE2/GCLK2`, `OE1`, and `GCLRn`). You can assign clocks to global clock dedicated inputs (`GCLK1` and `OE2/GCLK2`), clear to the global clear dedicated input (`GCLRn`), and speed-critical output enable to global OE dedicated inputs (`OE1` and `OE2/GCLK2`).

Output Enable Pin Assignments

Occasionally, because the total number of required output enable pins is more than the dedicated input pins, output enable signals must be assigned to I/O pins.

To minimize possible fitting errors when assigning the output enable pins for MAX 7000 and MAX 3000 devices, refer to **Pin-Out Files for Altera Devices** on the Altera website (www.altera.com).

Estimate Fan-In When Assigning Output Pins

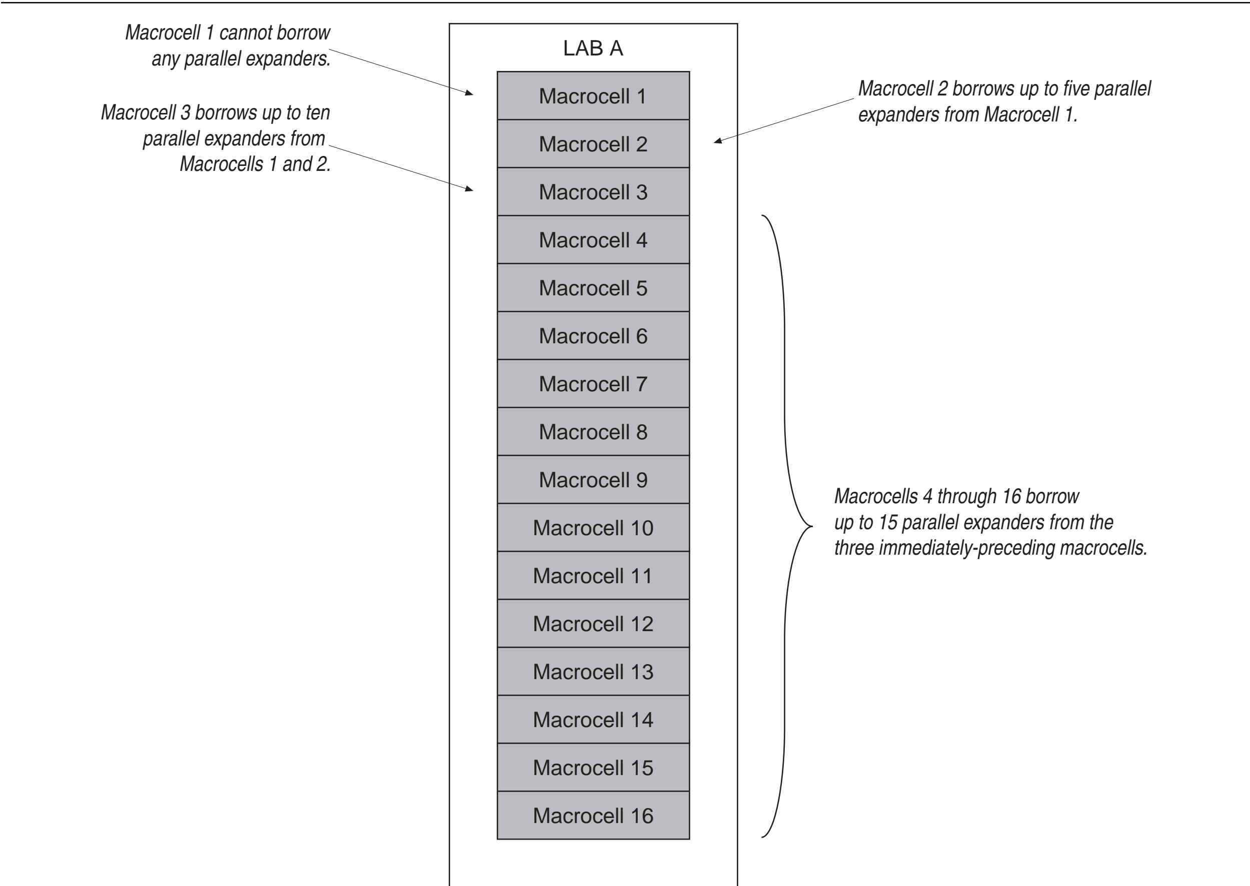
Macrocells with high fan-in can cause more placement problems for the Quartus II Fitter than those with low fan-in. The maximum fan-in per LAB should not exceed 36 in MAX 7000 and MAX 3000 devices. Therefore, estimate the fan-in of logic (such as an *x*-input AND gate) that feeds each output pin. If the total fan-in of logic that feeds each output pin in the same LAB exceeds 36, compilation can fail. To save resources and prevent compilation errors, avoid assigning pins that have high fan-in.

Outputs Using Parallel Expander Pin Assignments

Figure 10–13 illustrates how parallel expanders are used within a LAB. MAX 7000 and MAX 3000 devices contain chains that can lend or borrow parallel expanders. The Quartus II Fitter places macrocells in a location that allows them to lend and borrow parallel expanders appropriately.

As shown in Figure 10–13, only macrocells 2 through 16 can borrow parallel expanders. Therefore, assign output pins that might require parallel expanders to pins adjacent to macrocells 4 through 16. Altera recommends using macrocells 4 through 16 because they can borrow the largest number of parallel expanders.

Figure 10–13. LAB Macrocells and Parallel Expander Associations



Resolving Resource Utilization Problems

Two common Quartus II compilation fitting issues cause errors: excessive macrocell usage and lack of routing resources. Macrocell usage errors occur when the total number of macrocells in the design exceed the available macrocells in the device. Routing errors occur when the available routing resources are insufficient to implement the design. Check the Message window for the compilation results.

Messages in the Messages window are also copied in the Report Files. Right-click on a message and click **Help** for more information.

Resolving Macrocell Usage Issues

Occasionally, a design requires more macrocell resources than are available in the selected device, which results in the design not fitting. The following list provides tips for resolving macrocell usage issues as well as tips to minimize the number of macrocells used.

- On the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**, and turn off **Auto Parallel Expanders**. If the design's clock frequency (f_{MAX}) is not an important design requirement, turn off parallel expanders for all or part of the project. The design usually requires more macrocells if parallel expanders are turned on.
- Change **Optimization Technique** from **Speed** to **Area**. Selecting **Area** instructs the compiler to give preference to area utilization rather than speed (f_{MAX}). On the Assignments menu, click **Settings**. In the **Category** list, change the **Optimization Technique** option in the **Analysis & Synthesis Settings** page.
- Use D-type flipflops instead of latches. Altera recommends that you always use D-type flipflops instead of latches in your design because D-type flipflops can reduce the macrocell fan-in, and thus reduce macrocell usage. The Quartus II software uses extra logic to implement latches in MAX 7000 and MAX 3000 designs because MAX 7000 and MAX 3000 macrocells contain D-type flipflops instead of latches.
- Use asynchronous clear and preset instead of synchronous clear and preset. To reduce the product term usage, use asynchronous clear and preset in your design whenever possible. Using other control signals such as synchronous clear produces macrocells and pins with higher fan-out.

After following the suggestions in this section, if your project still does not fit the targeted device, consider using a larger device. When upgrading to a different density, the vertical package-migration feature of the MAX 7000 and MAX 3000 device families allows pin assignments to be maintained.

Resolving Routing Issues

Routing is another resource that can cause design fitting issues. For example, if the total fan-in into a LAB exceeds the maximum allowed, a no-fit error can occur during compilation. If your design does not fit the targeted device because of routing issues, consider the following suggestions.

- Use dedicated inputs/global signals for high fan-out signals. The dedicated inputs in MAX 7000 and MAX 3000 devices are designed for speed-critical and high fan-out signals. Always assign high fan-out signals to dedicated inputs/global signals.
- Change the **Optimization Technique** option from **Speed** to **Area**. This option can resolve routing resource and macrocell usage issues. Refer to "Resolving Macrocell Usage Issues" on page 10–58.
- Reduce the fan-in per cell. If you are not limited by the number of macrocells used in the design, you can use the **Fan-in per cell (%)** option to reduce the fan-in per cell. The allowable values are 20–100%; the default value is 100%. Reducing the fan-in can reduce localized routing congestion but increase the macrocell count. You can set this logic option in the Assignment Editor or under **More Settings** in the **Analysis & Synthesis Settings** page of the **Settings** dialog box.
- On the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**, and turn off **Auto Parallel Expanders**. By turning off the parallel expanders, you give the Quartus II software more fitting flexibility for each macrocell, allowing macrocells to be relocated. For example, each macrocell (previously grouped together in the same LAB) can be moved to a different LAB to reduce routing constraints.
- Insert logic cells. Inserting logic cells reduces fan-in and shared expanders used per macrocell, increasing routability. By default, the Quartus II software automatically inserts logic cells when necessary. Otherwise, **Auto Logic Cell** can be disabled as follows. On the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**. Under More **Settings**, turn off **Auto Logic Cell Insertion**. Refer to "Using LCELL Buffers to Reduce Required Resources" for more information.
- Change pin assignments. If you want to discard your pin assignments, you can let the Quartus II Fitter ignore some or all of the assignments.

If you prefer reassigning pins to increase routing efficiency, refer to "Pin Assignment Guidelines and Procedures" on page 10–56.

Using LCELL Buffers to Reduce Required Resources

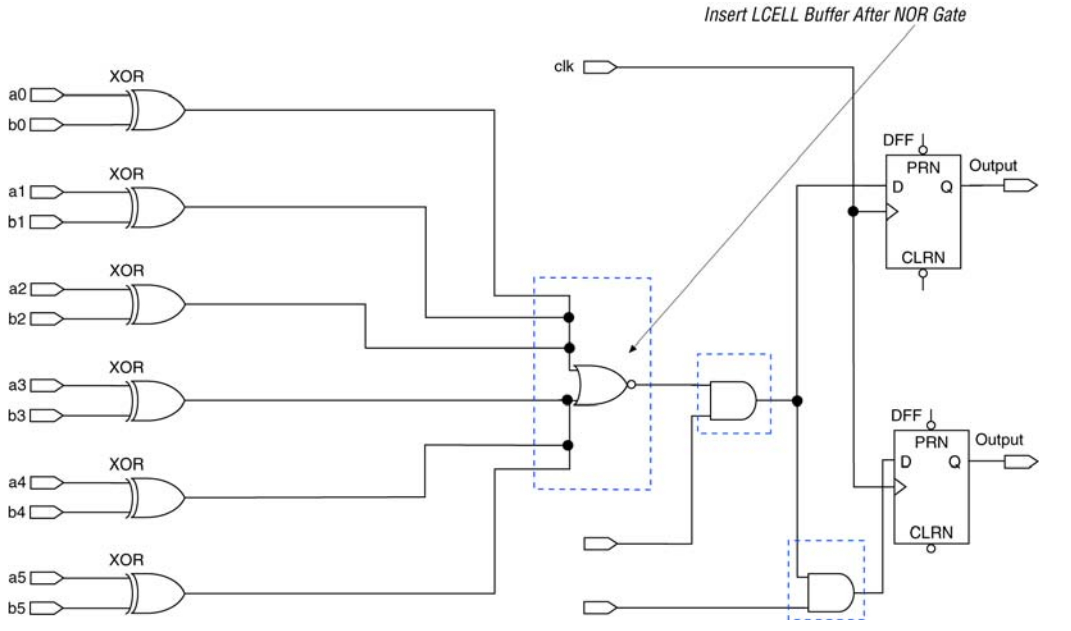
Complex logic, such as multilevel XOR gates, are often implemented with more than one macrocell. When this occurs, the Quartus II software automatically allocates shareable expanders—or additional macrocells (called synthesized logic cells)—to supplement the logic resources that are available in a single macrocell. You can also break down complex logic by inserting logic cells in the project to reduce the average fan-in and the total number of shareable expanders required. Manually inserting logic cells can provide greater control over speed-critical paths.

Instead of using the Quartus II software's **Auto Logic Cell Insertion** option, you can manually insert logic cells. However, Altera recommends that you use the **Auto Logic Cell Insertion** option unless you know which part of the design is causing the congestion.

A good location to manually insert LCELL buffers is where a single complex logic expression feeds multiple destinations in your design. You can insert an LCELL buffer just after the complex expression; the Quartus II Fitter extracts this complex expression and places it in a separate logic cell. Rather than duplicate all the logic for each destination, the Quartus II software feeds the single output from the logic cell to all destinations.

To reduce fan-in and prevent no-fit compilations caused by routing resource issues, insert an LCELL buffer after a NOR gate (Figure 10–14). The design in Figure 10–14 was compiled for a MAX 7000AE device. Without the LCELL buffer, the design requires two macrocells and eight shareable expanders, and the average fan-in is 14.5 macrocells. However, with the LCELL buffer, the design requires three macrocells and eight shareable expanders, and the average fan-in is just 6.33 macrocells.

Figure 10–14. Reducing the Average Fan-In by Inserting LCELL Buffers



Timing Optimization Techniques (Macrocell-Based CPLDs)

After resource optimization, design optimization focuses on timing. Ensure that you have made the appropriate assignments as described in "Initial Compilation: Required Settings" on page 10–3, and that the resource utilization is satisfactory before proceeding with timing optimization.

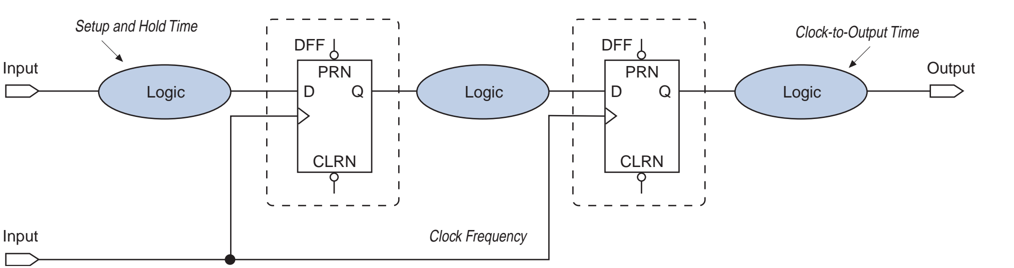
Maintaining system performance at or above certain timing requirements is an important goal of circuit designs. The following five timing parameters are primarily responsible for a design's performance:

- Setup time (t_{SU})—the propagation time for input data signals
- Hold time (t_H)—the propagation time for input data signals
- Clock-to-output time (t_{CO})—the propagation time for output signals
- Pin-to-pin delays (t_{PD})—the time required for a signal from an input pin to propagate through combinational logic and appear at an external output pin

- Maximum clock frequency (f_{MAX})—the internal register-to-register performance

This section provides guidelines to improve the timing if the timing requirements are not met. Figure 10–15 shows the parts of the design that determine the t_{SU}, t_H, t_{CO}, t_{PD}, and f_{MAX} timing parameters.

Figure 10–15. Main Timing Parameters that Determine the System's Performance



Timing results for t_{SU}, t_H, t_{CO}, t_{PD}, and f_{MAX} are found in the Compilation Report for the Quartus II Classic Timing Analyzer, as discussed in "Design Analysis" on page 10–11.

When you are analyzing a design to improve performance, be sure to consider the two major contributors to long delay paths:

- Excessive levels of logic
- Excessive loading (high fan-out)

When a MAX 7000 or MAX 3000 device signal drives more than one LAB, the programmable interconnect array (PIA) delay increases by 0.1 ns per additional LAB fan-out. Therefore, to minimize the added delay, concentrate the destination macrocells into fewer LABs, minimizing the number of LABs that are driven. The main cause of long delays in circuit design is excessive levels of logic.

Improving Setup Time

Sometimes the t_{SU} timing reported by the Quartus II Fitter does not meet your timing requirements. To improve the t_{SU} timing, refer to the following guidelines:

- Turn on the **Fast Input Register** option using the Assignment Editor. The **Fast Input Register** option allows input pins to directly drive macrocell registers via the fast-input path, thus minimizing the pin-to-register delay. This option is useful when a pin drives a D-type flipflop and there is no combinational logic between the pin and the register.
- Reduce the amount of logic between the input and the register. Excessive logic between the input pin and register causes more delays. To improve setup time, Altera recommends that you reduce the amount of logic between the input pin and the register whenever possible.
- Reduce fan-out. The delay from input pins to macrocell registers increases when the fan-out of the pins increases. To improve the setup time, minimize the fan-out.

Improving Clock-to-Output Time

To improve a design's clock-to-output time, minimize the register-to-output-pin delay. To improve the t_{CO} timing, refer to the following guidelines:

- Use the global clock. In addition to minimizing the delay from a register to an output pin, minimizing the delay from the clock pin to the register can also improve t_{CO} timing. Always use the global clock for low-skew and speed-critical signals.
- Reduce the amount of logic between the register and output pin. Excessive logic between the register and the output pin causes more delay. Always minimize the amount of logic between the register and output pin for faster clock-to-output time.

Table 10–6 shows the timing results for an EPM7064AETC100-4 device when a combination of the **Fast Input Register** option, global clock, and minimal logic is used. When the **Fast Input Register** option is turned on, the t_{SU} timing is improved (t_{SU} decreases from 1.6 ns to 1.3 ns and from 2.8 ns to 2.5 ns). The t_{CO} timing is improved when the global clock is used for low-skew and speed-critical signals (t_{CO} decreases from 4.3 ns to 3.1 ns). However, if there is additional logic used between the input pin and the register or the register and the output pin, the t_{SU} and t_{CO} delays increase.

Table 10–6. EPM7064AETC100-4 Device Timing Results

Number of Registers	t_{SU} (ns)	t_H (ns)	t_{CO} (ns)	Global Clock Used	Fast Input Register Option	D Input Location	Q Output Location	Additional Logic Between:	
								D Input Location & Register	Register & Q Output Location
1	1.3	1.2	4.3	—	On	LAB A	LAB A	—	—
1	1.6	0.3	4.3	—	Off	LAB A	LAB A	—	—
1	2.5	0	3.1	✓	On	LAB A	LAB A	—	—
1	2.8	0	3.1	✓	Off	LAB A	LAB A	—	—
1	3.6	0	3.1	✓	Off	LAB A	LAB A	✓	—
1	2.8	0	7.0	✓	Off	LAB D	LAB A	—	✓
16 with the same D and clock inputs	2.8	0	All 6.2	✓	Off	LAB D	LAB A, B	—	—
32 with the same D and clock inputs	2.8	0	All 6.4	✓	Off	LAB C	LAB A, B, C	—	—

Improving Propagation Delay (t_{PD})

Achieving fast propagation delay (t_{PD}) timing is required in many system designs. However, if there are long delay paths through complex logic, achieving fast propagation delays can be difficult. To improve your design's t_{PD}, refer to the following guidelines.

- On the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**, and turn on **Auto Parallel Expanders**. Turning on the parallel expanders for individual nodes or sub-designs can increase the performance of complex logic functions. However, if the project's pin or logic cell assignments use parallel expanders placed physically together with macrocells (which can reduce routability), parallel expanders can cause the Quartus II Fitter to have difficulties

finding and optimizing a fit. Additionally, the number of macrocells required to implement the design increases and results in a no-fit error during compilation if the device resources are limited. For more information about turning on the **Auto Parallel Expanders** option, refer to "Resolving Macrocell Usage Issues" on page 10–58.

- Set the **Optimization Technique** to **Speed**. By default, the Quartus II software sets the **Optimization Technique** option to **Speed** for MAX 7000 and MAX 3000 devices. Reset the **Optimization Technique** option to **Speed** only if you previously set it to **Area**. On the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**, and turn on **Speed** under **Optimization Technique**.

Improving Maximum Frequency (f_{MAX})

Maintaining the system clock at or above a certain frequency is a major goal in circuit design. For example, if you have a fully synchronous system that must run at 100 MHz, the longest delay path from the output of any register to the inputs of the registers it feeds must be less than 10 ns. Maintaining the system clock speed can be difficult if there are long delay paths through complex logic. Altera recommends that you perform the following guidelines to improve your design's clock speed (f_{MAX}).

- On the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings** and turn on **Auto Parallel Expanders**. Turning on the parallel expanders for individual nodes or subdesigns can increase the performance of complex logic functions. However, if the project's pin or logic cell assignments use parallel expanders placed physically together with macrocells (which can reduce routability), parallel expanders can cause the Quartus II compiler to have difficulties finding and optimizing a fit. Additionally, the number of macrocells required to implement the design also increases and can result in a no-fit error during compilation if the device's resources are limited. For more information about using the **Auto Parallel Expanders** option, refer to "Resolving Macrocell Usage Issues" on page 10–58.
- Use global signals or dedicated inputs. Altera MAX 7000 and MAX 3000 devices have dedicated inputs that provide low skew and high speed for high fan-out signals. Minimize the number of control signals in the design and use the dedicated inputs to implement them.
- Set the **Optimization Technique** to **Speed**. By default, the Quartus II software sets the **Optimization Technique** option to **Speed** for MAX 7000 and MAX 3000 devices. Reset the **Optimization Technique** option to **Speed** only if you have previously set it to **Area**. You can reset the **Optimization Technique** option. In the **Category** list, choose **Analysis & Synthesis Settings**, and turn on **Speed** under **Optimization Technique**.
- Pipeline the design. Pipelining, which increases clock frequency (f_{MAX}), refers to dividing large blocks of combinational logic by inserting registers.

Optimizing Source Code—Pipelining for Complex Register Logic

If the methods described in the preceding sections do not sufficiently improve your results, modify the design at the source to achieve the desired results. Using a pipelining technique consumes device resources, but it also lowers the propagation delay between registers, allowing you to maintain high system clock speed.

Compilation-Time Optimization Techniques

If reducing the compilation time of your design is important, use the techniques in this section. Be aware that reducing compilation time with some of these techniques can reduce the overall quality of results. A Compilation Time Advisor is also available in the Quartus II software, which helps you to reduce the compilation time. You can run the Compilation Time Advisor on the Tools menu by pointing to **Advisors** and clicking **Compilation Time Advisor**. You can find all the compilation time optimizing techniques described in this section in the Compilation Time Advisor as well.

If you open the Compilation Time Advisor after compilation, it displays recommendations on settings that can reduce the compilation time. Some of the recommendations from different advisors can contradict each other; Altera recommends evaluating the options, and choosing the settings that best suit your design requirements.

Incremental Compilation

The incremental compilation feature can speed up design iteration time by an average of 60% when making changes to the design and helps you reach design timing closure more efficiently. Using incremental compilation allows you to organize your design into logical and physical partitions for design synthesis and fitting. Design iterations can be made dramatically faster by recompiling only a particular design partition and merging results with previous compilation results from other partitions. You can also use physical synthesis optimization techniques for specific design partitions while leaving other modules untouched to preserve performance.

If you are using a third-party synthesis tool, you can create separate atom netlist files for parts of your design that you already have synthesized and optimized so that you update only the parts of the design that change.

Regardless of your synthesis tool, you can use full incremental compilation along with LogicLock regions to preserve your placement and routing results for unchanged partitions while working on other partitions. This ability provides the most reduction in compilation time and run-time memory usage because neither synthesis nor fitting is performed for unchanged partitions in the design.

You can also perform a bottom-up compilation in which parts of the design are compiled completely independently in separate Quartus II projects, and then exported into the top-level design. This flow is useful in team-based designs or when incorporating third-party IP.

For information about the full incremental compilation flow in the Quartus II software, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*. For information about creating multiple netlist files in third-party tools for use with incremental compilation, refer to the appropriate chapter in *Section III. Synthesis* in volume 1 of the *Quartus II Handbook*.

Use Multiple Processors for Parallel Compilation

The Quartus II software can run some algorithms in parallel to take advantage of multiple processors and reduce compilation time when more than one processor is available to compile the design. Parallel compilation is turned on by default in the Quartus II software and the software can detect if multiple processors are available in a computer used for compiling your design. You can also specify the maximum number of processors that the software can use if you want to reserve some of the available processors for other tasks. The Quartus II software supports up to four processors. The software does not necessarily use all the processors that you specify during a given compilation, but it never uses more than the specified number of processors. This allows you to work on other tasks on your computer without it becoming slow or less responsive. However, for interactive tasks such as word processing, it is typically not necessary to restrict the number of processors in this manner.

By allowing the Quartus II software to use two processors, you might be able to reduce the compilation time by up to 10% on systems with two processing cores and by up to 15% on systems with four cores. With certain design flows in which timing analysis runs alone, using multiple processors can reduce the time required for timing analysis by an average of 12% when using two processors. This reduction can reach an average of 15% when using four processors.

The actual reduction in compilation time depends on the design and on the specific settings used for compilation. For example, compilations with fast-corner optimization turned on benefit more from using multiple processors than do compilations that do not use fast-corner optimization. The runtime requirement is not reduced for some other compilation goals, such as Analysis and Synthesis. The Fitter (`quartus_fit`), the Classic Timing Analyzer (`quartus_tan`), and the TimeQuest Timing Analyzer (`quartus_sta`) stages in the compilation might benefit from the use of multiple processors. The average number of processors used for these stages is shown in the Compilation Report, on the **Flow Elapsed Time** panel. A more detailed breakdown of processor usage is also shown in the Parallel Compilation panel of the appropriate report, such as the Fit report. This panel is only displayed if parallel compilation is enabled.

This feature is available for Arria GX, Stratix, Cyclone, and MAX II series of devices.

Do not consider processors with Intel Hyper-Threading to be more than one processor. If you have a single processor with Intel Hyper-Threading enabled, you should set the number of processors to one. Altera recommends that you do not use the Intel Hyper-Threading feature for Quartus II compilations, as it can increase runtimes.

Many factors can impact the performance of parallel compilation. For detailed information and instructions that can help improve the performance of this feature, refer to the solution to the problem "How can I improve the compilation time performance of the parallel compilation feature in the Quartus II software?" on the Altera website, www.altera.com.

The Quartus II software can detect the number of processors available on a computer and use all the processors (up to 4) to reduce compilation time. You can also control the number of processors used during a compilation on a per user basis by performing the following steps:

1. On the Tools menu, click **Options**. The **Options** dialog box appears.
2. In the **Category** list, select **Processing**. The **Processing** page appears.
3. Under **Parallel compilation**, select **Use all available processors** or specify the **Maximum processors allowed** for compilation.

These settings are applicable to all projects unless you override it with other local project-specific settings.

To control the number of processors used during compilation for a specific project, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Compilation Process Settings**. The **Compilation Process Settings** page appears.
3. Under **Parallel compilation**, choose **Use global parallel compilation setting** if you want a global setting for parallel compilation. If you want a different option for this project, select the **Use all available processors** which utilizes all processors. If you do not want to run the compilation on all available processors, choose the **Maximum processors allowed** and type in the number of processors to be used for compilation. The default value for the number of processors is `1`.

Using multiple processors does not affect the quality of the fit. For a given Fitter seed on a specific design, the fit is exactly the same, regardless of whether the Quartus II software uses one processor or multiple processors. The only difference between such compilations using a different number of processors is the compilation time.

You can also set the number of processors available for Quartus II compilation using the following Tcl command in your script.

```
set_global_assignment -name NUM_PARALLEL_PROCESSORS <value> ↵
```

In this case, <*value*> is an integer from `1` to `4`.

If you want the Quartus II software to detect the number of processors and use all of them for running the compilation, use the following Tcl command in your script:

```
set_global_assignment -name NUM_PARALLEL_PROCESSORS ALL ↵
```

Reduce Synthesis Time and Synthesis Netlist Optimization Time

You can reduce synthesis time by reducing your use of netlist optimizations and by using incremental compilation. Use incremental compilation (with Netlist Type set to **Post-Synthesis**) to reduce the synthesis time, without affecting the Fitter time. For more ideas about reducing synthesis time in third-party EDA synthesis tools, refer to your synthesis software's documentation.

Synthesis Netlist Optimizations

You can use Quartus II integrated synthesis to synthesize and optimize HDL designs, and you can use synthesis netlist optimizations to optimize netlists that were synthesized by third-party EDA software. Using these netlist optimizations can cause the Analysis and Synthesis module to take much longer to run. Look at the Analysis and Synthesis messages to find out how much time these optimizations take. The compilation time spent in Analysis and Synthesis is typically small compared to the compilation time spent in the Fitter.

If your design meets your performance requirements without synthesis netlist optimizations, turn off the optimizations to save time. If you require synthesis netlist optimizations to meet performance, you can optimize parts of your design hierarchy separately to reduce the overall time spent in analysis and synthesis.

Check Early Timing Estimation before Fitting

The Quartus II software can provide an estimate of your timing results after synthesis, before the design is fully processed by the Fitter. In cases where you want a quick estimate of your design results before proceeding with further design or synthesis tasks, this feature can save you significant compilation time. For more information, refer to "Early Timing Estimation" on page 10–7.

After you perform analysis and synthesis in the Quartus II software, on the Processing menu, point to **Start**, and click **Start Early Timing Estimate**.

Reduce Placement Time

The time required to place a design depends on two factors: the number of ways the logic in the design can be placed in the device and the settings that control how hard the placer works to find a good placement. You can reduce the placement time in two ways:

- Change the settings for the placement algorithm
- Use incremental compilation to preserve the placement for parts of the design

Sometimes there is a trade-off between placement time and routing time. Routing time can increase if the placer does not run long enough to find a good placement. When you reduce placement time, make sure that it does not increase routing time and negate the overall time reduction.

Fitter Effort Setting

Standard fit takes the most runtime and usually does not yield a better result than **Auto Fit**. To switch from **Standard** to **Auto Fit**, on the Assignments menu, click **Settings**. In the **Category** list, select **Fitter Settings**, and use the **Fitter effort** setting to shorten runtime by changing the effort level to **Auto Fit**. If you are certain that your design has only easy-to-meet timing constraints, you can select **Fast Fit** for an even greater runtime saving.

Placement Effort Multiplier Settings

You can control the amount of time the Fitter spends in placement by reducing one aspect of placement effort with the **Placement Effort Multiplier** option. On the Assignments menu, click **Settings**. Select **Fitter Settings**, and click **More Settings**. Under **Existing Option Settings**, select **Placement Effort Multiplier**. The default is `1.0`. Legal values must be greater than 0 and can be non-integer values. Numbers between 0 and 1 can reduce fitting time, but also can reduce placement quality and design performance. Numbers higher than 1 increase placement time and placement quality, but can reduce routing time for designs with routing congestion. For example, a value of 4 increases placement time by approximately 2 to 4 times, but might result in better placement, which can result in reduced routing time.

Final Placement Optimization Levels

The **Final Placement Optimization Level** option specifies whether the Fitter performs final placement optimizations. This can be set to **Always**, **Never**, and **Automatically**. Performing optimizations can improve register-to-register timing and fitting, but might require longer compilation times. The default setting of **Automatically** can be used with the **Auto Fit** Fitter Effort Level (also the default) to let the Fitter decide whether these optimizations should run based on the routability and timing requirements of the design.

Setting the **Final Placement Optimization Level** to **Never** often reduces your compilation time, but typically affects routability negatively and reduces timing performance.

To change the **Final Placement Optimization Level**, on the Assignments menu, choose **Settings**. The **Settings** dialog box appears. From the **Category** list, select **Fitter Settings**. Click the **More Settings** button. Select **Final Placement Optimization Level**, and then from the list, select the required setting.

Physical Synthesis Effort Settings

You can use the physical synthesis options to optimize your post-synthesis netlist and improve your timing performance. These options, which affect placement, can significantly increase compilation time.

If your design meets your performance requirements without physical synthesis options, turn them off to save time. You also can use the **Physical synthesis effort** setting on the **Physical Synthesis Optimizations** page under **Fitter Settings** in the **Category** list to reduce the amount of extra compilation time that these optimizations use. The **Fast** setting directs the Quartus II software to use a lower level of physical synthesis optimization that, compared to the normal level, can cause a smaller increase in compilation time. However, the lower level of optimization can result in a smaller increase in design performance.

Limit to One Fitting Attempt

This option causes the software to quit after one fitting attempt option, instead of repeating placement and routing with increased effort.

From the Assignments menu, select **Settings**. On the **Fitter Settings** page, turn on **Limit to one fitting attempt**.

For more details about this option, refer to "Limit to One Fitting Attempt" on page 10–9.

Preserving Placement, Incremental Compilation, and LogicLock Regions

Preserving information about previous placements can make future placements take less time. The incremental compilation provides an easy-to-use methodology for preserving placement results. For more information, refer to "Incremental Compilation" on page 10–64 and the references listed in the section.

Reduce Routing Time

The time required to route a design depends on three factors: the device architecture, the placement of the design in the device, and the connectivity between different parts of the design. Typically, the routing time is not a significant amount of the compilation time. If your design takes a long time to route, perform one or more of the following actions:

- Check for routing congestion
- Let the placer run longer to find a more routable placement
- Use incremental compilation to preserve routing information for parts of your design

Identify Routing Congestion in the Chip Planner

To identify areas of congested routing in your design, open the Chip Planner. On the Tools menu, click **Chip Planner**. To view the routing congestion in the Chip Planner, click the Layers icon located next to the Task menu. Under **Background Color Map**, select the **Routing Utilization**. Routing resource usage above 90% indicates routing congestion. You can change the connections in your design to reduce routing congestion. If the area with routing congestion is in a LogicLock region or between LogicLock regions, change or remove the LogicLock regions and recompile the design. If the routing time remains the same, the time is a characteristic of the design and the placement. If the routing time decreases, consider changing the size, location, or contents of LogicLock regions to reduce congestion and decrease routing time.

For information about identifying areas of congested routing using the Chip Planner tool, refer to the "Viewing Routing Congestion" subsection in the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

Identify Routing Congestion in the Timing Closure Floorplan for Legacy Devices

If the device in your design is not supported by the Chip Planner, you must use the Timing Closure Floorplan tool to identify areas of congested routing in your design. To open the Timing Closure Floorplan, on the Assignments menu, click **Timing Closure Floorplan,** and turn on **Show Routing Congestion**. This feature is available only when you choose the **Field View** on the View menu. Routing resource usage above 90% indicates routing congestion. You can change the connections in your design to reduce routing congestion. If the area with routing congestion is in a LogicLock region or between LogicLock regions, change or remove the LogicLock regions and recompile the design. If the routing time remains the same, the time is a characteristic of the design and the placement. If the routing time decreases, consider changing the size, location, or contents of LogicLock regions to reduce congestion and decrease routing time.

Placement Effort Multiplier Setting

Some designs might be difficult to route and take a long time to route because the placement is less than optimal. In such cases, you can increase the Placement Effort Multiplier to get a better placement. This might increase the placement time, but it can reduce the routing time, and even overall compilation time in some cases.

Preserve Routing Incremental Compilation and LogicLock Regions

Preserving information about the previous routing results for part of the design can make future routing efforts take less time. The use of LogicLock regions with incremental compilation provides an easy-to-use methodology that preserves placement and routing results. For more information, refer to "Incremental Compilation" on page 10–64 and the references listed in the section.

Setting Process Priority

It might be necessary to reduce the computing resources allocated to the Quartus II compilation at the expense of increased compilation time. It can be convenient to reduce the resource allocation to the Quartus II compilation with single processor machines if you also have to run other tasks at the same time.

To run a Quartus II compilation at a reduced process priority, perform the following steps:

1. On the Tools menu, click **Options**. The **Options** dialog box appears.
2. In the **Category** list, under **General**, select **Processing**. The **Processing** page appears.
3. Turn on **Run design processing at a lower priority (recommended for single processor machines)**.

When you turn on this option, it is applied to all future compilations.

Using this option can increase your compilation time.

Other Optimization Resources

The Quartus II software has additional resources to help you optimize your design for resource, performance, compilation time, and power.

Design Space Explorer

The DSE automates the process of running multiple compilations with different settings. You can use the DSE to try the techniques described in this chapter. The DSE utility helps automate the process of finding the best set of options for your design. The DSE explores the design space by applying various optimization techniques and analyzing the results.

For more information, refer to the *Design Space Explorer* chapter in volume 2 of the *Quartus II Handbook*.

Other Optimization Advisors

The Quartus II software has a Power Optimization Advisor to provide guidance for reducing power consumption. In addition, the Incremental Compilation Advisor provides suggestions to improve your quality of results when partitioning your design for a hierarchical or team-based design flow using the Quartus II incremental compilation feature.

For more information about using the Power Optimization Advisor, refer to the *Power Optimization* chapter in volume 2 of the *Quartus II Handbook*. Fore more information about using the Incremental Compilation Advisor, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II command-line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ↵
```

The *Quartus II Scripting Reference Manual* includes the same information in PDF form.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. Refer to the *Quartus II Settings File Reference Manual* for information about all settings and constraints in the Quartus II software. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

You can specify many of the options described in this section either in an instance, or at a global level, or both.

Use the following Tcl command to make a global assignment:

```
set_global_assignment -name <.qsf variable name> <value> ↵
```

Use the following Tcl command to make an instance assignment:

```
set_instance_assignment -name <.qsf variable name> <value> \
-to <instance name> ↵
```

If the *<value>* field includes spaces (for example, “Standard Fit”), the value must be enclosed by straight double quotation marks.

Initial Compilation Settings

The Quartus II Settings File (**.qsf**) variable name is used in the Tcl assignment to make the setting along with the appropriate value. The **Type** column indicates whether the setting is supported as a global setting, an instance setting, or both.

This chapter refers to timing settings and analysis in the Quartus II Classic Timing Analyzer. For equivalent settings and analysis in the Quartus II TimeQuest Timing Analyzer, refer to the *Quartus II TimeQuest Timing Analyzer* or the *Switching to the Quartus II TimeQuest Timing Analyzer* chapters in volume 3 of the *Quartus II Handbook*.

Table 10–7 lists the **.qsf** file variable name and applicable values for the settings discussed in "Initial Compilation: Required Settings" on page 10–3. Table 10–8 shows the list of advanced compilation settings.

Table 10–7. Initial Compilation Settings

Setting Name	.qsf File Variable Name	Values	Type
Device Setting	DEVICE	<*device part number*>	Global
Use Smart Compilation	SPEED_DISK_USAGE_TRADEOFF	SMART, NORMAL	Global
Optimize IOC Register Placement For Timing	OPTIMIZE_IOC_REGISTER_PLACEMENT_FOR_TIMING	ON, OFF	Global
Optimize Hold Timing	OPTIMIZE_HOLD_TIMING	OFF, IO PATHS AND MINIMUM TPD PATHS, ALL PATHS	Global
Fitter Effort	FITTER_EFFORT	STANDARD FIT, FAST FIT, AUTO FIT	Global

Table 10–8. Advanced Compilation Settings

Setting Name	.qsf File Variable Name	Values	Type
Router Effort Multiplier	ROUTER_EFFORT_MULTIPLIER	Any positive, non-zero value	Global
Router Timing Optimization level	ROUTER_TIMING_OPTIMIZATION_LEVEL	NORMAL, MINIMUM, MAXIMUM	Global
Final Placement Optimization	FINAL_PLACEMENT_OPTIMIZATION	ALWAYS, AUTOMATICALLY, NEVER	Global

Resource Utilization Optimization Techniques (LUT-Based Devices)

Table 10–9 lists the **.qsf** file variable name and applicable values for the settings discussed in "Resource Utilization Optimization Techniques (LUT-Based Devices)" on page 10–19. The **.qsf** file variable name is used in the Tcl assignment to make the setting along with the appropriate value. The **Type** column indicates whether the setting is supported as a global setting, an instance setting, or both.

Table 10–9. Resource Utilization Optimization Settings (Part 1 of 2)

Setting Name	.qsf File Variable Name	Values	Type
Auto Packed Registers *(1)*	AUTO_PACKED_REGISTERS_<*device family name*>	OFF, NORMAL, MINIMIZE AREA, MINIMIZE AREA WITH CHAINS, AUTO	Global, Instance
Perform WYSIWYG Primitive Resynthesis	ADV_NETLIST_OPT_SYNTH_WYSIWYG_REMAP	ON, OFF	Global, Instance

Table 10–9. Resource Utilization Optimization Settings (Part 2 of 2)

Setting Name	.qsf File Variable Name	Values	Type
Physical Synthesis for Combinational Logic for Reducing Area	PHYSICAL_SYNTHESIS_COMBO_LOGIC_FOR_AREA	ON, OFF	Global, Instance
Physical Synthesis for Mapping Logic to Memory	PHYSICAL_SYNTHESIS_MAP_LOGIC_TO_MEMORY_FOR AREA	ON, OFF	Global, Instance
Optimization Technique	<*device family name*>_OPTIMIZATION_TECHNIQUE	AREA, SPEED, BALANCED	Global, Instance
Speed Optimization Technique for Clock Domains	SYNTH_CRITICAL_CLOCK	ON, OFF	Instance
State Machine Encoding	STATE_MACHINE_PROCESSING	AUTO, ONE-HOT, MINIMAL BITS, USER-ENCODE	Global, Instance
Preserve Hierarchy	PRESERVE_HIERARCHICAL_BOUNDARY	OFF, RELAXED, FIRM	Instance
Auto RAM Replacement	AUTO_RAM_RECOGNITION	ON, OFF	Global, Instance
Auto ROM Replacement	AUTO_ROM_RECOGNITION	ON, OFF	Global, Instance
Auto Shift Register Replacement	AUTO_SHIFT_REGISTER_RECOGNITION	ON, OFF	Global, Instance
Auto Block Replacement	AUTO_DSP_RECOGNITION	ON, OFF	Global, Instance
Number of Processors for Parallel Compilation	NUM_PARALLEL_PROCESSORS	Integer between 1 and 4 inclusive, or ALL	Global

Note to Table 10–9:

(1) Allowed values for this setting depend on the device family that is selected.

I/O Timing Optimization Techniques (LUT-Based Devices)

Table 10–10 lists the **.qsf** file variable name and applicable values for the settings discussed in "I/O Timing Optimization Techniques (LUT-Based Devices)" on page 10–73. The **.qsf** file variable name is used in the Tcl assignment to make the setting along with the appropriate value. The **Type** column indicates whether the setting is supported as a global setting, an instance setting, or both.

Table 10–10. I/O Timing Optimization Settings

Setting Name	.qsf File Variable Name	Values	Type
Optimize IOC Register Placement For Timing	OPTIMIZE_IOC_REGISTER_PLACEMENT_FOR_TIMING	ON, OFF	Global
Fast Input Register	FAST_INPUT_REGISTER	ON, OFF	Instance
Fast Output Register	FAST_OUTPUT_REGISTER	ON, OFF	Instance
Fast Output Enable Register	FAST_OUTPUT_ENABLE_REGISTER	ON, OFF	Instance
Fast OCT Register	FAST_OCT_REGISTER	ON, OFF	Instance

Register-to-Register Timing Optimization Techniques (LUT-Based Devices)

Table 10–11 lists the **.qsf** file variable name and applicable values for the settings discussed in "Register-to-Register Timing Optimization Techniques (LUT-Based Devices)" on page 10–40. The **.qsf** file variable name is used in the Tcl assignment to make the setting along with the appropriate value. The **Type** column indicates whether the setting is supported as a global setting, an instance setting, or both.

Table 10–11. Register-to-Register Timing Optimization Settings

Setting Name	.qsf File Variable Name	Values	Type
Perform WYSIWYG Primitive Resynthesis	ADV_NETLIST_OPT_SYNTH_WYSIWYG_REMAP	ON, OFF	Global, Instance
Perform Physical Synthesis for Combinational Logic	PHYSICAL_SYNTHESIS_COMBO_LOGIC	ON, OFF	Global, Instance
Perform Register Duplication	PHYSICAL_SYNTHESIS_REGISTER_DUPLICATION	ON, OFF	Global, Instance
Perform Register Retiming	PHYSICAL_SYNTHESIS_REGISTER_RETIMING	ON, OFF	Global, Instance
Perform Automatic Asynchronous Signal Pipelining	PHYSICAL_SYNTHESIS_ASYNCHRONOUS_SIGNAL_PIPELINING	ON, OFF	Global, Instance
Physical Synthesis Effort	PHYSICAL_SYNTHESIS_EFFORT	NORMAL, EXTRA, FAST	Global
Fitter Seed	SEED	<*integer*>	Global
Maximum Fan-Out	MAX_FANOUT	<*integer*>	Instance
Manual Logic Duplication	DUPLICATE_ATOM	<*node name*>	Instance
Optimize Power during Synthesis	OPTIMIZE_POWER_DURING_SYNTHESIS	NORMAL, OFF EXTRA_EFFORT	Global
Optimize Power during Fitting	OPTIMIZE_POWER_DURING_FITTING	NORMAL, OFF EXTRA_EFFORT	Global

Duplicate Logic for Fan-Out Control

The manual logic duplication option accepts wildcards. This is an easy and powerful duplication technique that you can use without editing your source code. You can use this technique, for example, to make a duplicate of a large fan-out node for all of its destinations in a certain design hierarchy, such as `hierarchy_A`. To make such an assignment with Tcl, use a command similar to Example 10–1.

Example 10–1. Duplication Technique

```
set_instance_assignment -name DUPLICATE_ATOM high_fanout_to_A -from \
high_fanout_node -to *hierarchy_A*
```

Conclusion

Using the recommended techniques described in this chapter can help you close timing quickly on complex designs, reduce iterations by providing more intelligent and better linkage between analysis and assignment tools, and balance multiple design constraints including multiple clocks, routing resources, and area constraints.

The Quartus II software provides many features to achieve optimal results. Follow the techniques presented in this chapter to efficiently optimize a design for area or timing performance, or to reduce compilation time.

Date and Document Version	Changes Made	Summary of Changes
November 2008 v8.1.0	■ Changed document to 8½” × 11” page size. ■ Updated the following sections: →“Optimizing Your Design” on page 10–2 →“Timing Requirement Settings” on page 10–4 →“Optimize Hold Timing” on page 10–8 →“Limit to One Fitting Attempt” on page 10–9 →“Auto Fit” on page 10–10 →“Fast Fit” on page 10–11 →“Ignored Timing Assignments” on page 10–12 →“I/O Timing (Including tPD)” on page 10–13 →“Register-to-Register Timing” on page 10–14 →“Timing Analysis with the TimeQuest Timing Analyzer” on page 10–14 →“Use I/O Assignment Analysis” on page 10–20 →“Flatten the Hierarchy During Synthesis” on page 10–25 →“Retarget Memory Blocks” on page 10–25 →“Use Physical Synthesis Options to Reduce Area” on page 10–26 →“Increase Placement Effort Multiplier” on page 10–30 →“Metastability Analysis and Optimization Techniques” on page 10–32 →“Synthesis Netlist Optimizations and Physical Synthesis Optimizations” on page 10–43 →“Incremental Compilation” on page 10–65 →“Use Multiple Processors for Parallel Compilation” on page 10–66 ■ Updated Table 10–9 on page 10–73 and Table 10–11 on page 10–75.	Updated for the Quartus II 8.1 software release.
May 2008 v8.0.0	■ Updated links ■ Updated Other Optimization Resources] ■ Updated Setting Process Priority ■ Updated Location Assignment and Back-Annotation ■ Updated Fitter Effort Setting ■ Updated Synthesis Netlist Optimizations and Physical Synthesis Optimizations ■ Updated Fast Fit ■ Added Metastability Analysis ■ Added Enable Beneficial Skew Optimization and Analyze Your Design for Metastability ■ Removed figures from “Optimizing Source Code—Pipelining for Complex Register Logic ■ Updated Table 8-5	Changes made to this chapter reflect the software changes made in version 8.0. Removed support for Mercury devices. Added information for Stratix IV devices.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

11. Power Optimization

QII52016-9.0.0

Introduction

The Quartus® II software offers power-driven compilation to fully optimize device power consumption. Power-driven compilation focuses on reducing your design's total power consumption using power-driven synthesis and power-driven place-and-route. This chapter describes the power-driven compilation feature and flow in detail, as well as low power design techniques that can further reduce power consumption in your design. The techniques primarily target Arria® GX, Stratix® and Cyclone® series of devices, and HardCopy® II devices. These devices utilize a low-k dielectric material that dramatically reduces dynamic power and improves performance. The latest Stratix device families include new, more efficient, logic structures called adaptive logic modules (ALMs) that obtain maximum performance while minimizing power consumption. Cyclone device families offer the optimal blend of high performance and low power in a low-cost FPGA.

For more information about Stratix IV and Stratix III device architecture, refer to the *Stratix IV Device Handbook* and *Stratix III Device Handbook*, respectively.

Altera provides the Quartus II PowerPlay Power Analyzer to aid you during the design process by delivering fast and accurate estimations of power consumption. You can minimize power consumption, while taking advantage of the industry's leading FPGA performance, by using the tools and techniques described in this chapter.

For more information about the PowerPlay Power Analyzer, refer to the *PowerPlay Power Analysis* chapter in volume 3 of the *Quartus II Handbook*.

Total FPGA power consumption is comprised of I/O power, core static power, and core dynamic power. This chapter focuses on design optimization options and techniques that help reduce core dynamic power and I/O power. In addition to these techniques, there are additional power optimization techniques available for Stratix IV and Stratix III devices. These techniques include:

- Selectable Core Voltage (available only for Stratix III devices)
- Programmable Power Technology
- Device Speed Grade Selection

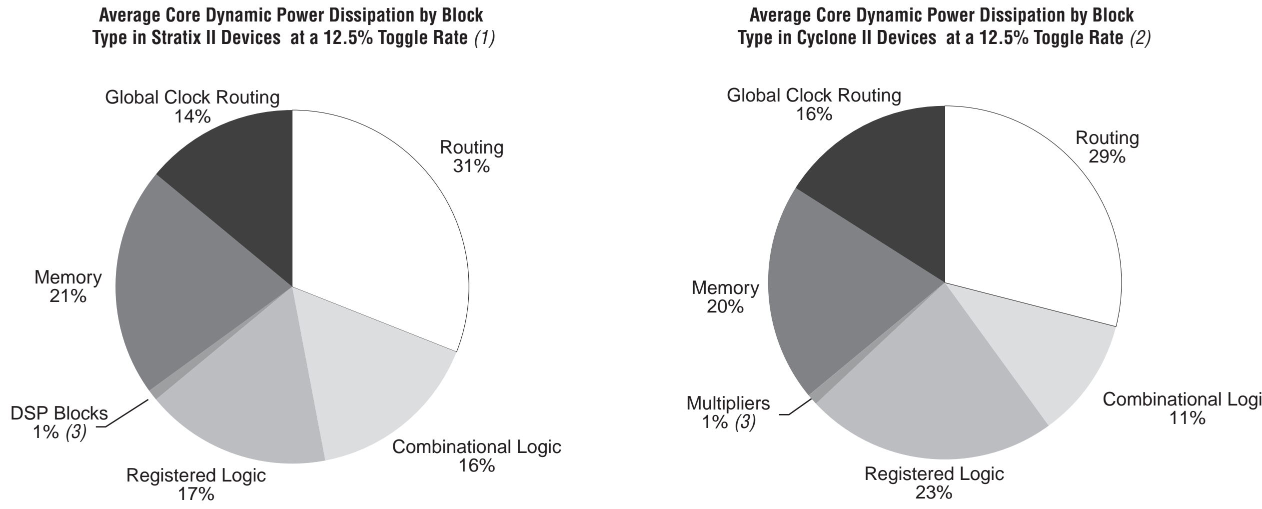
For more information about power optimization techniques available for Stratix III devices, refer to *AN 437: Power Optimization in Stratix III FPGAs*. For more information about power optimization techniques available for Stratix IV devices, refer to *AN 514: Power Optimization in Stratix IV FPGAs*.

Power Dissipation

This section describes the sources of power dissipation in Stratix II and Cyclone II devices. You can refine techniques that reduce power consumption in your design by understanding the sources of power dissipation.

Figure 11–1 shows the power dissipation of Stratix III and Cyclone III devices in different designs. All designs were analyzed at a fixed clock rate of 100 MHz and exhibited varied logic resource utilization across available resources.

Figure 11–1. Average Core Dynamic Power Dissipation



Notes to Figure 11–1:

(1) 103 different designs were used to obtain these results.
(2) 96 different designs were used to obtain these results.
(3) In designs using DSP blocks, DSPs consumed 5% of core dynamic power.

As shown in Figure 11–1, a significant amount of the total power is dissipated in routing for both Stratix III and Cyclone III devices, with the remaining power dissipated in logic, clock, and RAM blocks.

In Stratix and Cyclone device families, a series of column and row interconnect wires of varying lengths provide signal interconnections between logic array blocks (LABs), memory block structures, and digital signal processing (DSP) blocks or multiplier blocks. These interconnects dissipate the largest component of device power.

FPGA combinational logic is another source of power consumption. The basic building block of logic in the latest Stratix series devices is the ALM, and in Cyclone III and Cyclone II devices, it is the logic element (LE).

For more information about ALMs and LEs in Stratix IV, Stratix III, Stratix II, Cyclone III, and Cyclone II devices, refer to the respective device handbook.

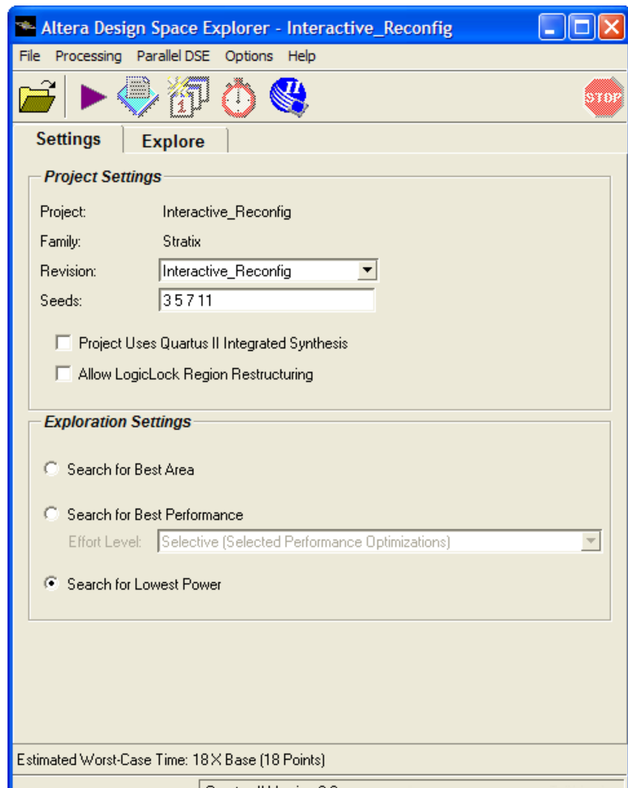
Memory and clock resources are other major consumers of power in FPGAs. Stratix II devices feature the TriMatrix memory architecture. TriMatrix memory includes 512-bit M512 blocks, 4-Kbit M4K blocks, and 512-Kbit M-RAM blocks, which are configurable to support many features. Stratix IV and Stratix III TriMatrix on-chip memory is an enhancement based upon the Stratix II FPGA TriMatrix memory and includes three sizes of memory blocks: MLAB blocks, M9K blocks, and M144K blocks. Cyclone II devices have 4-Kbit M4K memory blocks and Cyclone III devices have 9-Kbit M9K memory blocks.

Design Space Explorer

The Design Space Explorer (DSE) is a simple, easy-to-use, design optimization utility that is included in the Quartus II software. The DSE explores and reports optimal Quartus II software options for your design, targeting either power optimization, design performance, or area utilization improvements. You can use the DSE to implement the techniques described in this chapter.

Figure 11–2 shows the DSE user interface. The **Settings** tab is divided into **Project Settings** and **Exploration Settings**.

Figure 11–2. Design Space Explorer User Interface



The **Search for Lowest Power** option, under **Exploration Settings**, uses a predefined exploration space that targets overall design power improvements. This setting focuses on applying different options that specifically reduce total design thermal power. You can also set the **Optimization Goal** option for your design using the **Advanced** tab in the DSE window. You can select your design optimization goal, such as optimize for power, from the list of available settings in the **Optimization Goal** list. The DSE then uses the selection from the **Optimization Goal** list, along with the **Search for Lowest Power** selection, to determine the best compilation results.

By default, the Quartus II PowerPlay Power Analyzer is run for every exploration performed by the DSE when the **Search for Lowest Power** option is selected. This helps you debug your design and determine trade-offs between power requirements and performance optimization.

For more information about the DSE, refer to the *Design Space Explorer* chapter in volume 2 of the *Quartus II Handbook*.

Power-Driven Compilation

The standard Quartus II compilation flow consists of Analysis and Synthesis, Fitter, Assembler, and Timing Analysis. Power-driven compilation takes place at the analysis and synthesis and Fitter levels. Power-driven compilation settings are divided in the **PowerPlay power optimization** list on the **Analysis & Synthesis Settings** page, and **PowerPlay power optimization** on the **Fitter Settings** page. The following section describes these power optimization options at the analysis and synthesis and Fitter levels.

Power-Driven Synthesis

Synthesis netlist optimization occurs during the synthesis stage of the compilation flow. The optimization technique makes changes to the synthesis netlist to optimize your design according to the selection of area, speed, or power optimization. This section describes power optimization techniques at the synthesis level.

The **Analysis & Synthesis Settings** page allows you to specify logic synthesis options. The **PowerPlay power optimization** option is available for the Arria GX, Stratix and Cyclone families of devices, and MAX® II devices (Figure 11–3).

To perform power optimization at the synthesis level in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Analysis & Synthesis**. The **Analysis & Synthesis** page appears.
3. In the **PowerPlay power optimization** list, select your preferred setting. This option determines how aggressively Analysis and Synthesis optimizes the design for power.

Figure 11–3. Analysis & Synthesis Settings Page

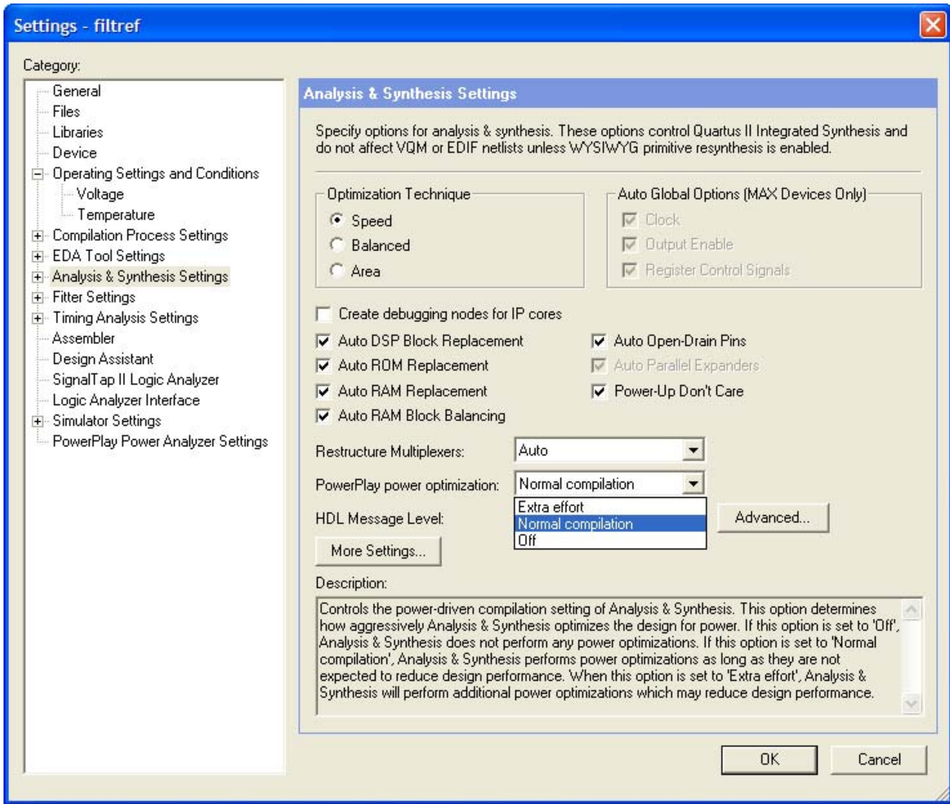


Table 11–1 shows the settings in the **PowerPlay power optimization** list. You can apply these settings on a project or entity level.

Table 11–1. Optimize Power During Synthesis Options

Settings	Description
Off	No netlist, placement, or routing optimizations are performed to minimize power.
Normal compilation (Default)	Low compute effort algorithms are applied to minimize power through netlist optimizations as long as they are not expected to reduce design performance.
Extra effort	High compute effort algorithms are applied to minimize power through netlist optimizations. Max performance might be impacted.

The **Normal compilation** setting is turned on by default. This setting performs memory optimization and power-aware logic mapping during synthesis.

Memory blocks can represent a large fraction of total design dynamic power as described in "Reducing Memory Power Consumption" on page 11–14. Minimizing the number of memory blocks accessed during each clock cycle can significantly reduce memory power. Memory optimization involves effective movement of user-defined read/write enable signals to associated read-and-write clock enable signals for all memory types (Figure 11–4).

Figure 11–4. Memory Transformation

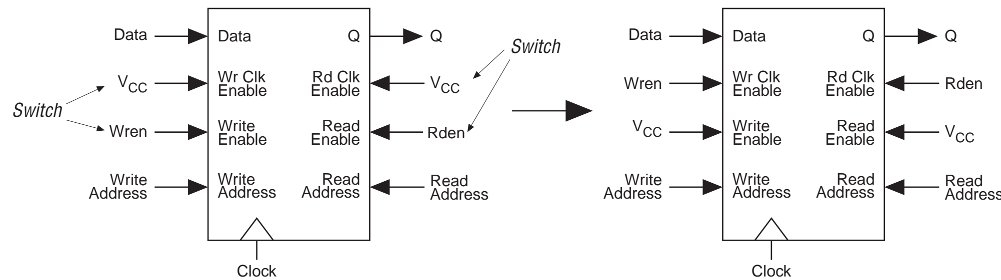

Figure 11–4 shows a default implementation of a simple dual-port memory block in which write-clock enable and read-clock enable signals are connected to V_{CC}, making both read-and-write memory ports active during each clock cycle. Memory transformation effectively moves the read-enable and write-enable signals to the respective read-clock enable and write-clock enable signals. By using this technique, memory ports are shut down when they are not accessed. This significantly reduces your design's memory power consumption. For more information about clock enable signals, refer to "Reducing Memory Power Consumption" on page 11–14. For Stratix IV and Stratix III devices, the memory transformation takes place at the Fitter level by selecting the **Normal compilation** settings for the power optimization option.

In Stratix III and Cyclone III devices, the specified read-during-write behavior can significantly impact the power of single-port and bidirectional dual-port RAMs. It is best to set the read-during-write parameter to "Don't care" (at the HDL level), as it allows an optimization whereby the `read-enable` signal can be set to the inversion of the existing `write-enable` signal (if one exists). This allows the core of the RAM to shut down (that is, not toggle), which saves a significant amount of power.

The other type of power optimization that takes place with the **Normal compilation** setting is power-aware logic mapping. The power-aware logic mapping reduces power by rearranging the logic during synthesis to eliminate nets with high toggle rates.

The **Extra effort** setting performs the functions of the **Normal compilation** setting and other memory optimizations to further reduce memory power by shutting down memory blocks that are not accessed. This level of memory optimization can require extra logic, which can reduce design performance.

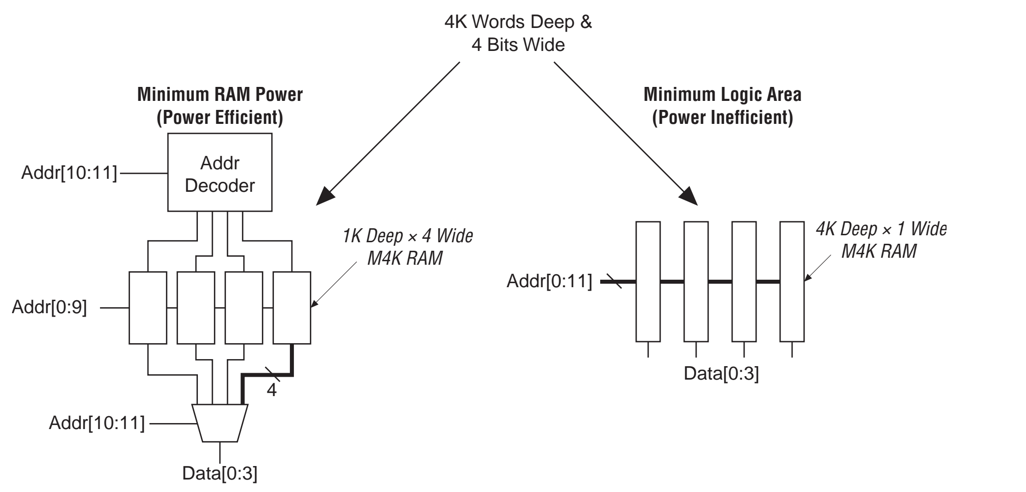
The **Extra effort** setting also performs power-aware memory balancing. Power-aware memory balancing automatically chooses the best memory configuration for your memory implementation and provides optimal power saving by determining the number of memory blocks, decoder, and multiplexer circuits required. If you have not previously specified target-embedded memory blocks for your design's memory functions, the power-aware balancer automatically selects them during memory implementation.

Figure 11–5 shows an example of a 4K × 4 (4K deep and 4 bits wide) memory implementation in two different configurations using M4K memory blocks available in Stratix II devices. The minimum logic area implementation uses M4K blocks configured as 4K × 1. This implementation is the default in the Quartus II software because it has the minimum logic area (0 logic cells) and the highest speed. However,

all four M4K blocks are active on each memory access in this implementation, which increases RAM power. The minimum RAM power implementation is created by selecting **Extra effort** in the **PowerPlay power optimization** list. This implementation automatically uses four M4K blocks configured as 1K × 4 for optimal power saving. An address decoder is implemented by the RAM megafunction to select which of the four M4K blocks should be activated on a given cycle, based on the state of the top two user address bits. The RAM megafunction automatically implements a multiplexer to feed the downstream logic by choosing the appropriate M4K output. This implementation reduces RAM power because only one M4K block is active on any cycle, but it requires extra logic cells, costing logic area and potentially impacting design performance.

There is a trade-off between power saved by accessing fewer memories and power consumed by the extra decoder and multiplexor logic. The Quartus II software automatically balances the power savings against the costs to choose the lowest power configuration for each logical RAM. The benchmark data shows that the power-driven synthesis can reduce memory power consumption by as much as 60% in Stratix devices.

Figure 11–5. 4K × 4 Memory Implementation Using Multiple M4K Blocks



Memory optimization options can also be controlled by the `Low_Power_Mode` parameter in the **Default Parameters** page of the **Settings** dialog box. The settings for this parameter are **None**, **Auto**, and **ALL**. **None** corresponds to the **Off** setting in the **PowerPlay power optimization** list. **Auto** corresponds to the **Normal compilation** setting and **ALL** corresponds to the **Extra effort** setting, respectively. You can apply PowerPlay power optimization either on a compiler basis or on individual entities. The `Low_Power_Mode` parameter always takes precedence over the **Optimize Power for Synthesis** option for power optimization on memory.

You can also set the MAXIMUM_DEPTH parameter manually to configure the memory for low power optimization. This technique is the same as the power-aware memory balancer, but it is manual rather than automatic like the **Extra effort** setting in the **PowerPlay power optimization** list. You can set the MAXIMUM_DEPTH parameter for memory modules manually in the megafunction instantiation or in the MegaWizard™ Plug-In Manager for power optimization as described in "Reducing Memory Power Consumption" on page 11–14. The MAXIMUM_DEPTH parameter always takes precedence over the **Optimize Power for Synthesis** options for power optimization on memory optimization.

Power-Driven Fitter

The **Fitter Settings** page enables you to specify options for fitting (Figure 11–6). The **PowerPlay power optimization** option is available for Arria GX, Stratix IV, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, and MAX II devices.

To perform power optimization at the Fitter level, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Fitter Settings**. The **Fitter Settings** page appears.
3. In the **PowerPlay power optimization** list, select your preferred setting. This option determines how aggressively the Fitter optimizes the design for power.

Figure 11–6. Fitter Settings Page

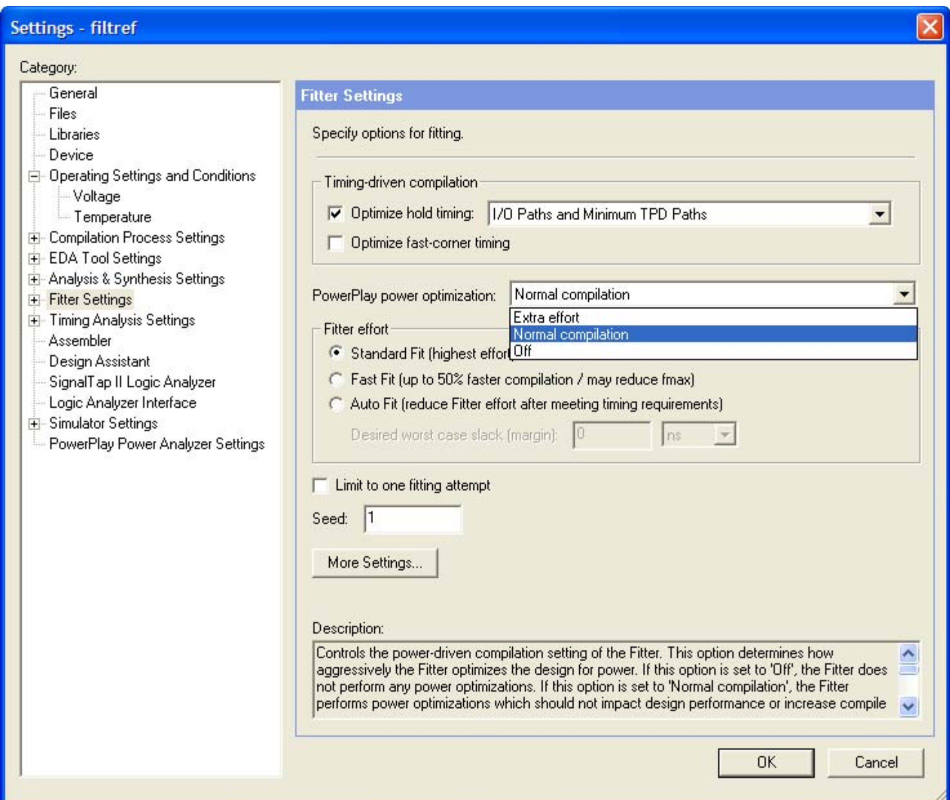


Table 11–2 lists the settings in the **PowerPlay power optimization** list. These settings can only be applied on a project-wide basis. The **Extra effort** setting for the Fitter requires extensive effort to optimize the design for power and can increase the compilation time.

Table 11–2. Power-Driven Fitter Option

Settings	Description
Off	No netlist, placement, or routing optimizations are performed to minimize power.
Normal compilation (Default)	Low compute effort algorithms are applied to minimize power through placement and routing optimizations as long as they are not expected to reduce design performance.
Extra effort	High compute effort algorithms are applied to minimize power through placement and routing optimizations. Max performance might be impacted.

The **Normal compilation** setting is selected by default and performs DSP optimization by creating power-efficient DSP block configurations for your DSP functions. For Stratix III devices, this setting, which is based on timing constraints entered for the design, enables the Programmable Power Technology to configure tiles as high-speed mode or low-power mode. Programmable Power Technology is always turned **ON** even when the **OFF** setting is selected for the **Fitter PowerPlay power optimization** option. Tiles are the combination of LAB and MLAB pairs (including the adjacent routing associated with LAB and MLAB), which can be configured to operate in high-speed or low-power mode. This level of power optimization does not have any affect on the fitting, timing results, or compile time. Also, for Stratix III devices, this setting enables the memory transformation as described in "Power-Driven Synthesis" on page 11–4.

For more information about Stratix III power optimization, refer to *AN 437: Power Optimization in Stratix III FPGAs*. For more information about Stratix IV power optimization, refer to *AN 514: Power Optimization in Stratix IV FPGAs*.

The **Extra effort** setting performs the functions of the **Normal compilation** setting and other place-and-route optimizations during fitting to fully optimize the design for power. The Fitter applies an extra effort to minimize power even after timing requirements have been met by effectively moving the logic closer during placement to localize high-toggling nets, and using routes with low capacitance. However, this effort can increase the compilation time.

The **Extra effort** setting uses a Signal Activity File (**.saf**) or Verilog Value Change Dump File (**.vcd**) that guides the Fitter to fully optimize the design for power, based on the signal activity of the design. The best power optimization during fitting results from using the most accurate signal activity information. Signal activities from full post-fit netlist (timing) simulation provide the highest accuracy because all node activities reflect the actual design behavior, provided that supplied input vectors are representative of typical design operation. If you do not have a **.saf** file (from simulation or other source), the Quartus II software uses assignments, clock assignments, and vectorless estimation values (PowerPlay Power Analyzer Tool settings) to estimate the signal activities. This information is used to optimize your design for power during fitting. The benchmark data shows that the power-driven Fitter technique can reduce power consumption by as much as 19% in Stratix devices.

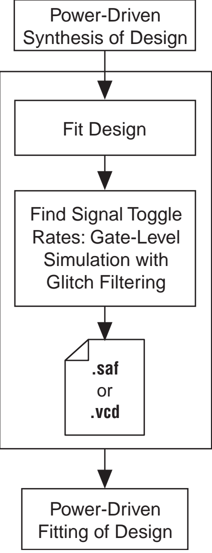
Only the **Extra effort** setting in the **PowerPlay power optimization** list for the Fitter option uses the signal activities (from **.vcd** or **.saf** file) during fitting. The settings made in the **PowerPlay Power Analyzer Settings** page in the **Settings** dialog box are used to calculate the signal activity of your design.

For more information about **.saf** and **.vcd** files, and how to create them, refer to the *PowerPlay Power Analysis* chapter in volume 3 of the *Quartus II Handbook*.

Recommended Flow for Power-Driven Compilation

Figure 11–7 shows the recommended design flow to fully optimize your design for power during compilation. This flow utilizes the power-driven synthesis and power-driven Fitter options. On average, you can reduce core dynamic power by 16% with the extra effort synthesis and extra effort fitting settings, as compared to the **Off** settings in both synthesis and Fitter options for power-driven compilation.

Figure 11–7. Recommended Flow for Power-Driven Compilation



Area-Driven Synthesis

Using area optimization rather than timing or delay optimization during synthesis saves power because you use fewer logic blocks. Using less logic usually means less switching activity. The Quartus II integrated synthesis tool provides **Speed**, **Balanced**, or **Area** for the **Optimization Technique** option. You can also specify this logic option for specific modules in your design with the Assignment Editor in cases where you want to reduce area using the **Area** setting (potentially at the expense of register-to-register timing performance) while leaving the default **Optimization Technique** setting at **Balanced** (for the best trade-off between area and speed for certain device families). The **Speed Optimization Technique** can increase the resource usage of your design if the constraints are too aggressive, and can also result in increased power consumption.

The benchmark data shows that the area-driven technique can reduce power consumption by as much as 31% in Stratix devices and as much as 15% in Cyclone devices.

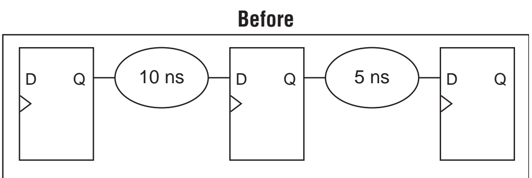
Gate-Level Register Retiming

You can also use gate-level register retiming to reduce circuit switching activity. Retiming shuffles registers across combinational blocks without changing design functionality. The **Perform gate-level register retiming** option in the Quartus II software enables the movement of registers across combinational logic to balance timing, allowing the software to trade off the delay between timing critical and non-critical timing paths.

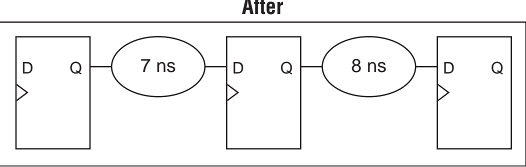
Retiming uses fewer registers than pipelining. Figure 11–8 shows an example of gate-level register retiming, where the 10 ns critical delay is reduced by moving the register relative to the combinational logic, resulting in the reduction of data depth and switching activity.

Figure 11–8. Gate-Level Register Retiming

Before



After



Gate-level register retiming makes changes at the gate level. If you are using an atom netlist from a third-party synthesis tool, you must also select the **Perform WYSIWYG primitive resynthesis** option to undo the atom primitives to gates mapping (so that register retiming can be performed), and then to remap gates to Altera® primitives. When using the Quartus II integrated synthesis, retiming occurs during synthesis before the design is mapped to Altera primitives. The benchmark data shows that the combination of WYSIWYG remapping and gate-level register retiming techniques can reduce power consumption by as much as 6% in Stratix devices and as much as 21% in Cyclone devices.

For more information about register retiming, refer to the *Netlist Optimizations and Physical Synthesis* chapter in volume 2 of the *Quartus II Handbook*.

Design Guidelines

Several low-power design techniques can reduce power consumption when applied during FPGA design implementation. This section provides detailed design techniques for Stratix III, Stratix II, Cyclone III, and Cyclone II devices that affect overall design power. The results of these techniques might be different from design to design.

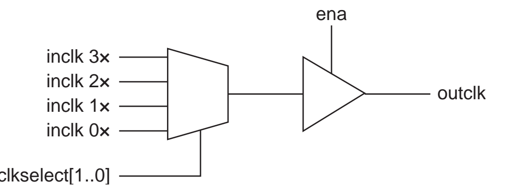
Clock Power Management

Clocks represent a significant portion of dynamic power consumption due to their high switching activity and long paths. Figure 11–1 on page 11–2 shows a 14% average contribution to power consumption for global clock routing in Stratix III devices and 17% in Cyclone III devices. Actual clock-related power consumption is higher than this because the power consumed by local clock distribution within logic, memory, and DSP or multiplier blocks is included in the power consumption for the respective blocks.

Clock routing power is automatically optimized by the Quartus II software, which only enables those portions of the clock network that are required to feed downstream registers. Power can be further reduced by gating clocks when they are not required. It is possible to build clock-gating logic, but this approach is not recommended because it is difficult to generate a glitch-free clock in FPGAs using ALMs or LEs.

Arria GX, Stratix IV, Stratix III, Stratix II, Cyclone III, and Cyclone II devices use clock control blocks that include an enable signal. A clock control block is a clock buffer that lets you dynamically enable or disable the clock network and dynamically switch between multiple sources to drive the clock network. You can use the Quartus II MegaWizard Plug-In Manager to create this clock control block with the ALTCLKCTRL megafunction. Arria GX, Stratix IV, Stratix III, Stratix II, Cyclone III, and Cyclone II devices provide clock control blocks for global clock networks. In addition, Stratix IV, Stratix III and Stratix II devices have clock control blocks for regional clock networks. The dynamic clock enable feature lets internal logic control the clock network. When a clock network is powered down, all the logic fed by that clock network does not toggle, thereby reducing the overall power consumption of the device. Figure 11–9 shows a 4-input clock control block diagram.

Figure 11–9. Clock Control Block Diagram

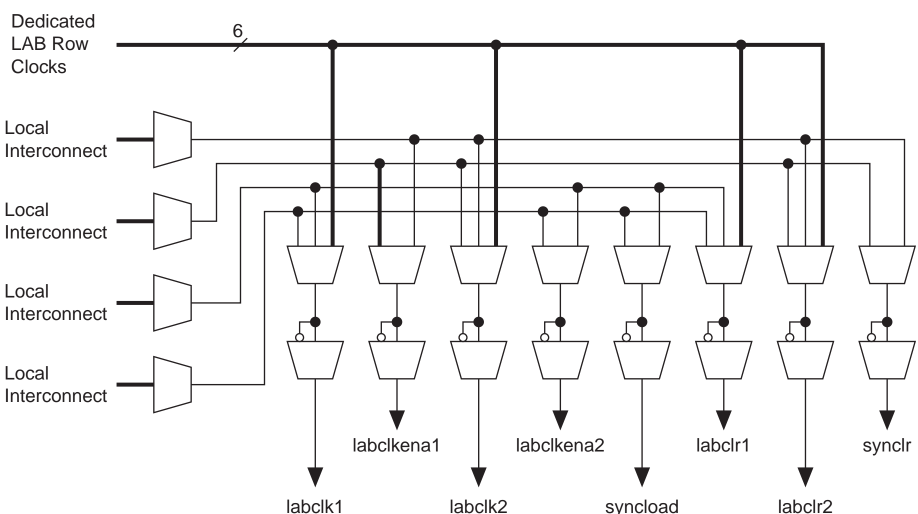


The enable signal is applied to the clock signal before being distributed to global routing. Therefore, the enable signal can either have a significant timing slack (at least as large as the global routing delay) or it can reduce the f_{MAX} of the clock signal.

For more information about using clock control blocks, refer to the *Clock Control Block Megafunction User Guide (ALTCLKCTRL)*.

Another contributor to clock power consumption is the LAB clock that distributes a clock to the registers within a LAB. LAB clock power can be the dominant contributor to overall clock power. For example, in Cyclone III and Cyclone II devices, each LAB can use two clocks and two clock enable signals, as shown in Figure 11–10. Each LAB's clock signal and clock enable signal are linked. For example, an LE in a particular LAB using the `labclk1` signal also uses the `labclkena1` signal.

Figure 11–10. LAB-Wide Control Signals



To reduce LAB-wide clock power consumption without disabling the entire clock tree, use the LAB-wide clock enable to gate the LAB-wide clock. The Quartus II software automatically promotes register-level clock enable signals to the LAB-level. All registers within an LAB that share a common clock and clock enable are controlled by a shared gated clock. To take advantage of these clock enables, use a clock enable construct in the relevant HDL code for the registered logic.

LAB-Wide Clock Enable Example

The VHDL code in Example 11–1 makes use of a LAB-wide clock enable. This clock-gating logic is automatically turned into an LAB-level clock enable signal.

Example 11–1.

```
IF clk'event AND clock = '1' THEN
    IF logic_is_enabled = '1' THEN
        reg <= value;
    ELSE
        reg <= reg;
    END IF;
END IF;
```

For more information about LAB-wide control signals, refer to the *Stratix II Architecture*, *Cyclone III Device Family Overview*, or *Cyclone II Architecture* chapters in the respective device handbook.

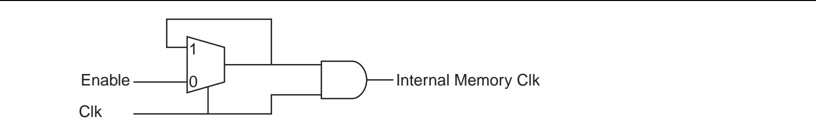
Reducing Memory Power Consumption

The memory blocks in FPGA devices can represent a large fraction of typical core dynamic power. Memory represents 21% of the core dynamic power in a typical Stratix III device design and 20% in a Cyclone III device design. Memory blocks are unlike most other blocks in the device because most of their power is tied to the clock rate, and is insensitive to the toggle rate on the data and address lines.

When a memory block is clocked, there is a sequence of timed events that occur within the block to execute a read or write. The circuitry controlled by the clock consumes the same amount of power regardless of whether or not the address or data has changed from one cycle to the next. Thus, the toggle rate of input data and the address bus have no impact on memory power consumption.

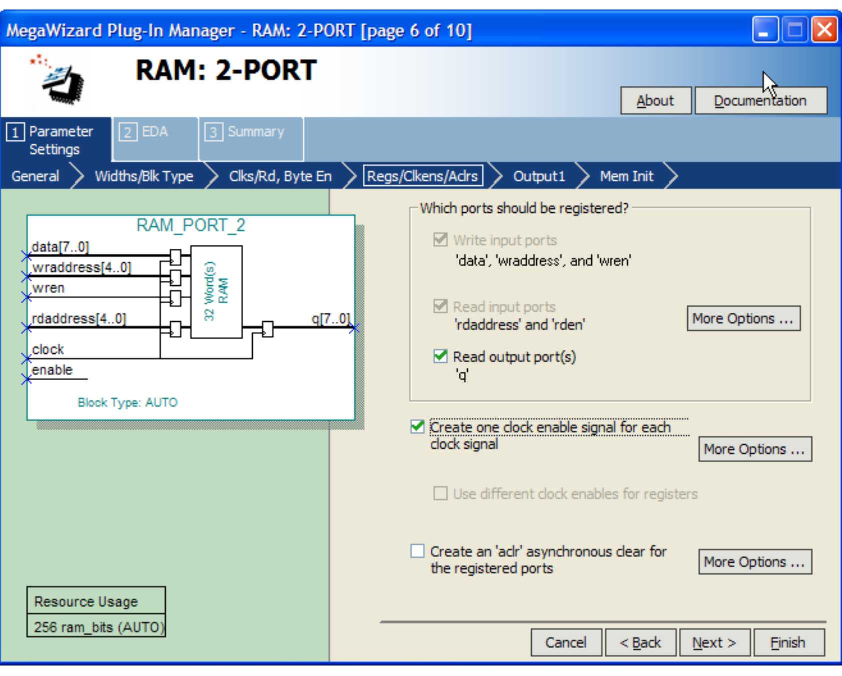
The key to reducing memory power consumption is to reduce the number of memory clocking events. You can achieve this through clock network-wide gating described in "Clock Power Management" on page 11–12, or on a per-memory basis through use of the clock enable signals on the memory ports. Figure 11–11 shows the logical view of the internal clock of the memory block. Use the appropriate enable signals on the memory to make use of the clock enable signal instead of gating the clock.

Figure 11–11. Memory Clock Enable Signal



Using the clock enable signal enables the memory only when necessary and shuts it down for the rest of the time, reducing the overall memory power consumption. You can use the MegaWizard Plug-In Manager to create these enable signals by selecting the **Clock enable signal** option for the appropriate port when generating the memory block function (Figure 11–12).

Figure 11–12. MegaWizard Plug-In Manager RAM 2-Port Clock Enable Signal Selectable Option

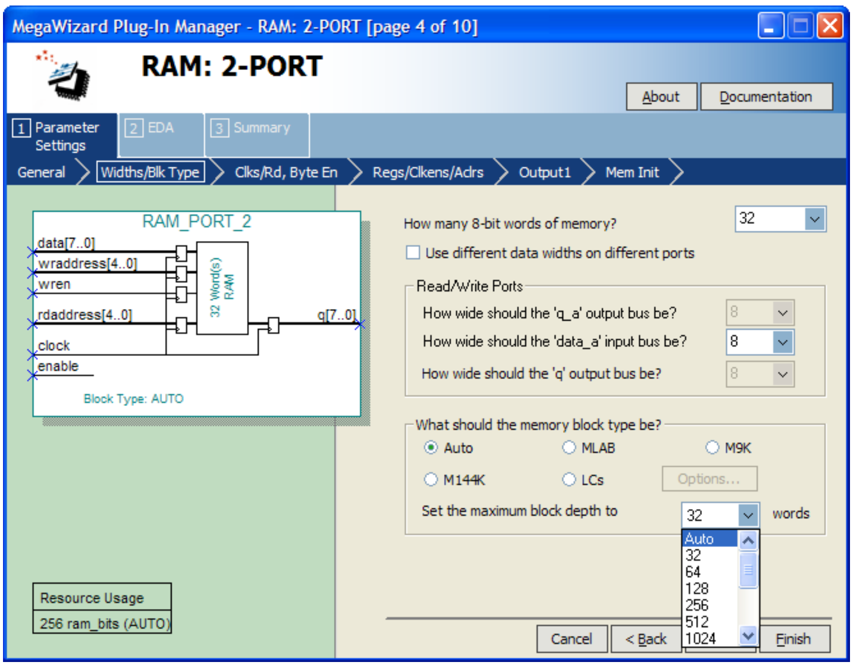


For example, consider a design that contains a 32-bit-wide M4K memory block in ROM mode that is running at 200 MHz. Assuming that the output of this block is only required approximately every four cycles, this memory block will consume 8.45 mW of dynamic power according to the demands of the downstream logic. By adding a small amount of control logic to generate a read clock enable signal for the memory block only on the relevant cycles, the power can be cut 75% to 2.15 mW.

You can also use the `MAXIMUM_DEPTH` parameter in your memory megafunction to save power in Stratix IV, Stratix III, Stratix II, Cyclone III, and Cyclone II devices; however, this approach might increase the number of LEs required to implement the memory and affect design performance.

You can set the `MAXIMUM_DEPTH` parameter for memory modules manually in the megafunction instantiation or in the MegaWizard Plug-In Manager (Figure 11–13). The Quartus II software automatically chooses the best design memory configuration for optimal power, as described in "Power-Driven Compilation" on page 11–4.

Figure 11–13. MegaWizard Plug-In Manager RAM 2-Port Maximum Depth Selectable Option



Memory Power Reduction Example

Table 11–3 shows power usage measurements for a 4K × 36 simple dual-port memory implemented using multiple M4K blocks in a Stratix II EP2S15 device. For each implementation, the M4K blocks are configured with a different memory depth.

Table 11–3. 4K × 36 Simple Dual-Port Memory Implemented Using Multiple M4K Blocks

M4K Configuration	Number of M4K Blocks	ALUTs
4K × 1 (Default setting)	36	0
2K × 2	36	40
1K × 4	36	62
512 × 9	32	143
256 × 18	32	302
128 × 36	32	633

Figure 11–14 shows the amount of power saved using the `MAXIMUM_DEPTH` parameter. For all implementations, a user-provided read enable signal is present to indicate when read data is required. Using this power-saving technique can reduce power consumption by as much as 60%.

Figure 11–14. Power Savings Using the MAXIMUM_DEPTH Parameter

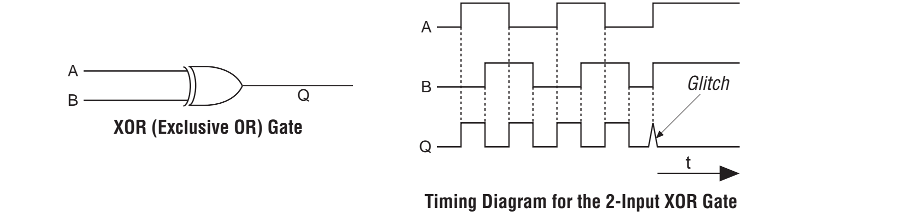
As the memory depth becomes more shallow, memory dynamic power decreases because unaddressed M4K blocks can be shut off using a decoded combination of address bits and the read enable signal. For a 128-deep memory block, power used by the extra LEs starts to outweigh the power gain achieved by using a more shallow memory block depth. The power consumption of the memory blocks and associated LEs depends on the memory configuration.

Pipelining and Retiming

Designs with many glitches consume more power because of faster switching activity. Glitches cause unnecessary and unpredictable temporary logic switches at the output of combinational logic. A glitch usually occurs when there is a mismatch in input signal timing leading to unequal propagation delay.

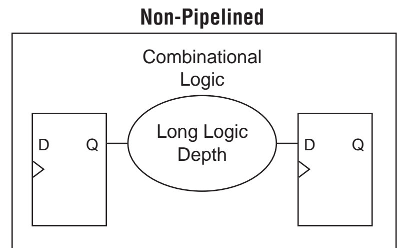
For example, consider an input change on one input of a 2-input XOR gate from `1` to `0`, followed a few moments later by an input change from `0` to `1` on the other input. For a moment, both inputs become `1` (high) during the state transition, resulting in `0` (low) at the output of the XOR gate. Subsequently, when the second input transition takes place, the XOR gate output becomes `1` (high). During signal transition, a glitch is produced before the output becomes stable, as shown in Figure 11–15. This glitch can propagate to subsequent logic and create unnecessary switching activity, increasing power consumption. Circuits with many XOR functions, such as arithmetic circuits or cyclic redundancy check (CRC) circuits, tend to have many glitches if there are several levels of combinational logic between registers.

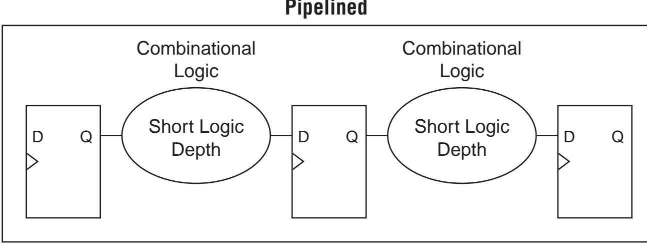
Figure 11–15. XOR Gate Showing Glitch at the Output



Pipelining can reduce design glitches by inserting flipflops into long combinational paths. Flipflops do not allow glitches to propagate through combinational paths. Therefore, a pipelined circuit tends to have less glitching. Pipelining has the additional benefit of generally allowing higher clock speed operations, although it does increase the latency of a circuit (in terms of the number of clock cycles to a first result). Figure 11–16 shows an example where pipelining is applied to break up a long combinational path.

Figure 11–16. Pipelining Example





Pipelining is very effective for glitch-prone arithmetic systems because it reduces switching activity, resulting in reduced power dissipation in combinational logic. Additionally, pipelining allows higher-speed operation by reducing logic-level numbers between registers. The disadvantage of this technique is that if there are not many glitches in your design, pipelining can increase power consumption by adding unnecessary registers. Pipelining can also increase resource utilization. The benchmark data shows that pipelining can reduce dynamic power consumption by as much as 31% in Stratix devices and as much as 30% in Cyclone devices.

Architectural Optimization

You can use design-level architectural optimization by taking advantage of specific device architecture features. These features include dedicated memory and DSP or multiplier blocks available in FPGA devices to perform memory or arithmetic-related functions. You can use these blocks in place of LUTs to reduce power consumption. For example, you can build large shift registers from RAM-based FIFO buffers instead of building the shift registers from the LE registers.

The Stratix device family allows you to efficiently target small, medium, and large memories with the TriMatrix memory architecture. Each TriMatrix memory block is optimized for a specific function. The M512 memory blocks available in Stratix II devices are useful for implementing small FIFO buffers, DSP, and clock domain transfer applications. M512 memory blocks are more power-efficient than the distributed memory structures in some competing FPGAs. The M4K memory blocks are used to implement buffers for a wide variety of applications, including processor code storage, large look-up table implementation, and large memory applications. The M-RAM blocks are useful in applications where a large volume of data must be stored on-chip. Effective utilization of these memory blocks can have a significant impact on power reduction in your design.

The latest Stratix and Cyclone device families have configurable M9K memory blocks that provide various memory functions such as RAM, FIFO buffers, and ROM.

For more information about using DSP and memory blocks efficiently, refer to the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*.

I/O Power Guidelines

Non-terminated I/O standards such as LVTTL and LVCMOS have a rail-to-rail output swing. The voltage difference between logic-high and logic-low signals at the output pin is equal to the V_{CCIO} supply voltage. If the capacitive loading at the output pin is known, the dynamic power consumed in the I/O buffer can be calculated as shown in Equation 11–1:

Equation 11–1.

$$P = 0.5 \times F \times C \times V^2$$

In this equation, *F* is the output transition frequency and *C* is the total load capacitance being switched. *V* is equal to V_{CCIO} supply voltage. Because of the quadratic dependence on V_{CCIO}, lower voltage standards consume significantly less dynamic power. In addition, lower pin capacitance is an important factor in considering I/O power consumption. Hardware and simulation data show that Stratix II device I/O pins have half the pin capacitance of the nearest competing FPGA. Cyclone II devices exhibit 20% less I/O power consumption than competitive, low-cost, 90 nm FPGAs.

Transistor-to-transistor logic (TTL) I/O buffers consume very little static power. As a result, the total power consumed by a LVTTL or LVCMOS output is highly dependent on load and switching frequency.

When using resistively terminated I/O standards like SSTL and HSTL, the output load voltage swings by a small amount around some bias point. The same dynamic power equation is used, where *V* is the actual load voltage swing. Because this is much smaller than V_{CCIO}, dynamic power is lower than for non-terminated I/O under similar conditions. These resistively terminated I/O standards dissipate significant static (frequency-independent) power, because the I/O buffer is constantly driving current into the resistive termination network. However, the lower dynamic power of these I/O standards means they often have lower total power than LVCMOS or LVTTL for high-frequency applications. Use the lowest drive strength I/O setting that meets your speed and waveform requirements to minimize I/O power when using resistively terminated standards.

You can save a small amount of static power by connecting unused I/O banks to the lowest possible V_{CCIO} voltage of 1.2 V.

Table 11–4 shows the total supply and thermal power consumed by outputs using different I/O standards for Stratix II devices. The numbers are for an I/O pin transmitting random data clocked at 200 MHz with a 10 pF capacitive load.

Table 11–4. I/O Power for Different I/O Standards in Stratix II Devices (Part 1 of 2)

Standard	Total Supply Current Drawn from V_{CCIO} Supply (mA)	Total On-Chip Thermal Power Dissipation (mW)
3.3-V LVTTL	2.42	9.87
2.5-V LVCMOS	1.9	6.69

Table 11–4. I/O Power for Different I/O Standards in Stratix II Devices (Part 2 of 2)

Standard	Total Supply Current Drawn from V_{CCIO} Supply (mA)	Total On-Chip Thermal Power Dissipation (mW)
1.8-V LVCMOS	1.34	4.18
1.5-V LVCMOS	1.18	3.58
3.3-V PCI	2.47	10.23
SSTL-2 class I	6.07	4.42
SSTL-2 class II	10.72	5.1
SSTL-18 class I	5.33	3.28
SSTL-18 class II	8.56	4.06
HSTL-15 class I	6.06	3.49
HSTL-15 class II	11.08	4.87
HSTL-18 class I	6.87	4.09
HSTL-18 class II	12.33	5.82

For this configuration, non-terminated standards generally use less power, but this is not always the case. If the frequency or the capacitive load is increased, the power consumed by non-terminated outputs increases faster than the power of terminated outputs.

For more information about I/O Standards, refer to the *Selectable I/O Standards in Stratix II Devices and Stratix II GX Devices* chapter in volume 2 of the *Stratix II Device Handbook* or the *Selectable I/O Standards in Cyclone II Devices* chapter in the *Cyclone II Device Handbook* or the *Cyclone III Device Handbook.*

When calculating I/O power, the PowerPlay Power Analyzer uses the default capacitive load set for the I/O standard in the **Capacitive Loading** tab of the **Device & Pin Options** dialog box. For Stratix II, if **Enable Advanced I/O Timing** is turned on, I/O power is measured using an equivalent load calculated as the sum of the near capacitance, the transmission line distributed capacitance, and the far-end capacitance as defined in the **Board Trace Model** tab of the **Device & Pin Options** dialog box or the Board Trace Model view in the Pin Planner. Any other components defined in the board trace model are not taken into account for the power measurement.

For Stratix IV, Stratix III, and Cyclone III devices, advanced I/O power, which uses the full board trace model, is always used.

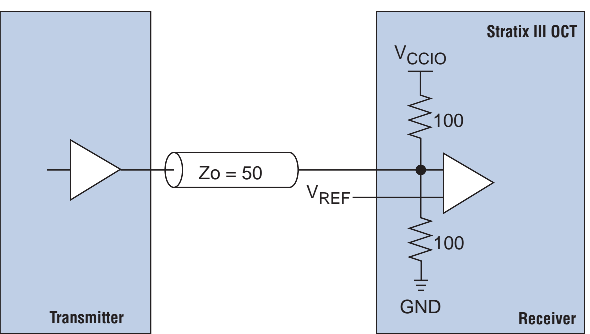
For information about using Advanced I/O Timing and configuring a board trace model, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

Dynamically-Controlled On-Chip Terminations

Stratix IV and Stratix III FPGAs offer dynamic on-chip termination (OCT). Dynamic OCT enables series termination (RS) and parallel termination (RT) to dynamically turn on/off during the data transfer. This feature is especially useful when Stratix IV and Stratix III FPGAs are used with external memory interfaces, such as interfacing with DDR memories.

Compared to conventional termination, dynamic OCT reduces power consumption significantly as it eliminates the constant DC power consumed by parallel termination when transmitting data. Parallel termination is extremely useful for applications that interface with external memories where I/O standards, such as HSTL and SSTL, are used. Parallel termination supports dynamic OCT, which is useful for bidirectional interfaces (see Figure 11–17).

Figure 11–17. Stratix III On-Chip Parallel Termination



The following is an example of power saving for a DDR3 interface using on-chip parallel termination.

The static current consumed by parallel OCT is equal to the V_{CCIO} voltage divided by 100 Ω . For DDR3 interfaces that use SSTL-15, the static current is 1.5 V / 100 Ω = 15 mA per pin. Therefore, the static power is 1.5 V ×15 mA = 22.5 mW. For an interface with 72 DQ and 18 DQS pins, the static power is 90 pins × 22.5 mW = 2.025 W. Dynamic parallel OCT disables parallel termination during write operations, so if writing occurs 50% of the time, the power saved by dynamic parallel OCT is 50% × 2.025 W = 1.0125 W.

For more information about dynamic OCT in Stratix IV and Stratix III devices, refer to the *Stratix III Device I/O Features* chapter in the *Stratix III Device Handbook* and the *Stratix IV Device I/O Features* chapter in the *Stratix IV Device Handbook*, respectively.

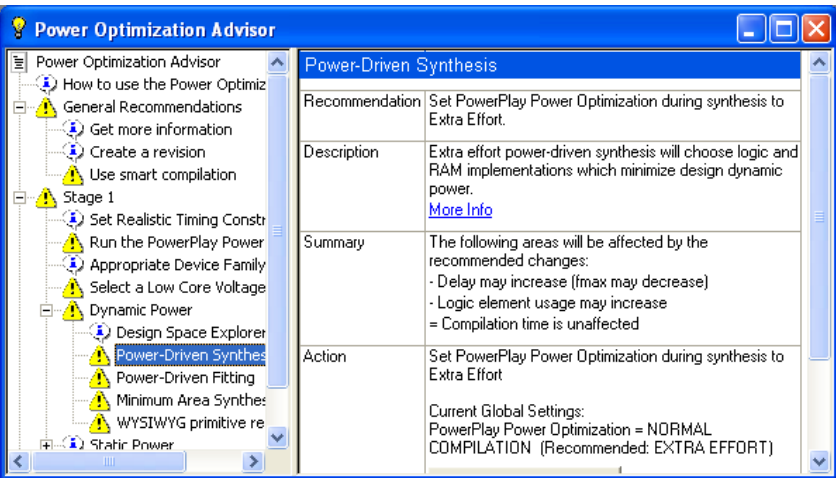
Power Optimization Advisor

The Quartus II software includes the Power Optimization Advisor, which provides specific power optimization advice and recommendations based on the current design project settings and assignments. The advisor covers many of the suggestions listed in this chapter. The following example shows how to reduce your design power with the Power Optimization Advisor.

Power Optimization Advisor Example

After compiling your design, run the PowerPlay Power Analyzer to determine your design power and to see where power is dissipated in your design. Based on this information, you can run the Power Optimization Advisor to implement recommendations that can reduce design power. Figure 11–18 shows the Power Optimization Advisor after compiling a design that is not fully optimized for power.

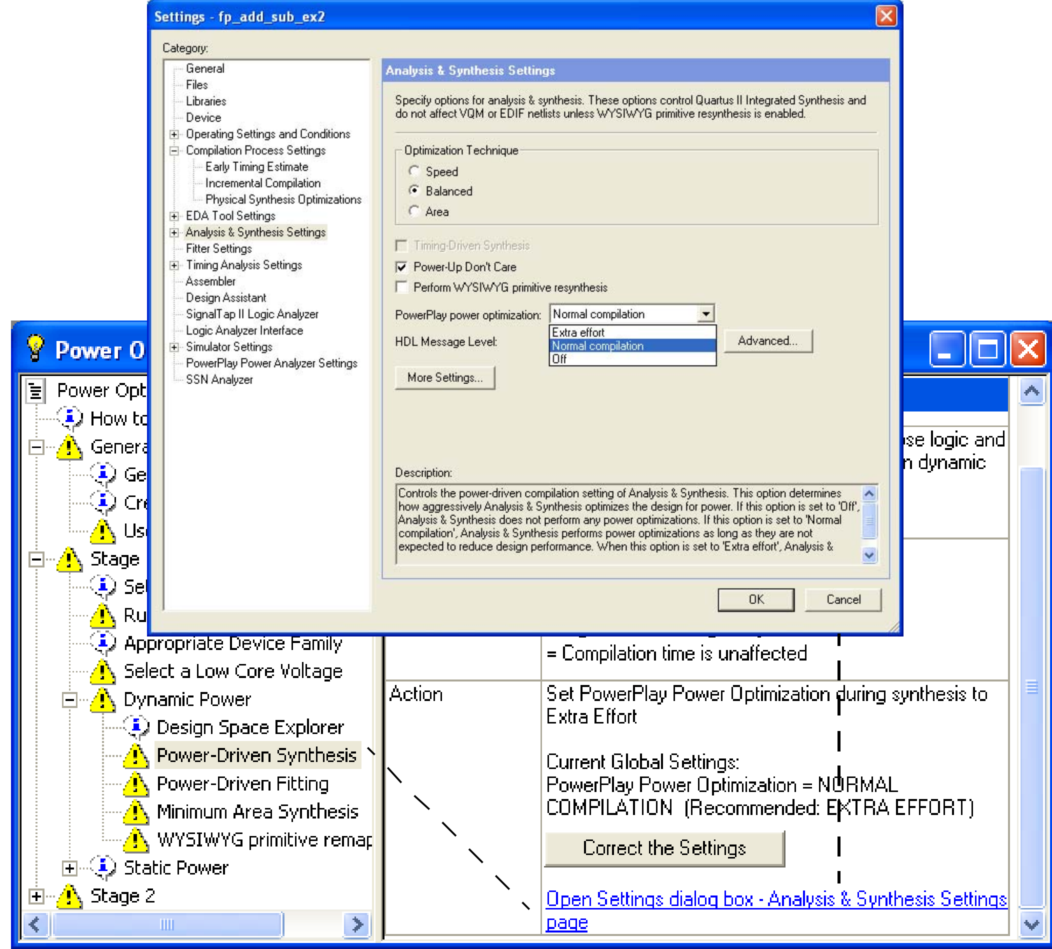
Figure 11–18. Power Optimization Advisor



The Power Optimization Advisor shows the recommendations that can reduce power in your design. The recommendations are split into stages to show the order in which you should apply the recommended settings. The first stage shows mostly CAS setting options that are easy to implement and highly effective in reducing design power. An icon indicates whether each recommended setting is made in the current project. In Figure 11–18, the checkmark icon for Stage 1 shows the recommendations that are already implemented. The warning icons indicate recommendations that are not followed for this compilation. The information icon shows the general suggestions. Each recommendation includes the description, summary of the affect of the recommendation, and the action required to make the appropriate setting.

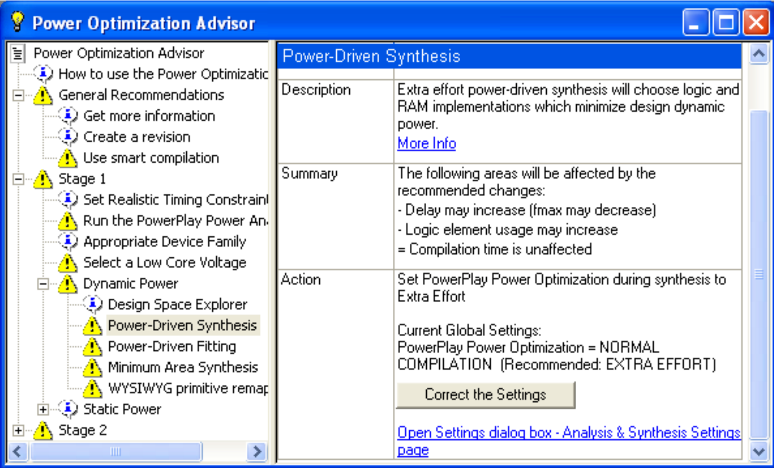
There is a link from each recommendation to the appropriate location in the Quartus II user interface where you can change the setting, such as the **Power-Driven Synthesis** setting. You can change the **Power-Driven Synthesis** setting by clicking **Open Settings dialog box - Analysis & Synthesis Settings page** (Figure 11–19). The **Settings** dialog box is shown with the **Analysis & Synthesis Settings** page selected, where you can change the **PowerPlay power optimization** settings.

Figure 11–19. Analysis & Synthesis Settings Page



After making the recommended changes, recompile your design. The Power Optimization Advisor indicates with green checkmarks that the recommendations were implemented successfully (Figure 11–20). You can use the PowerPlay Power Analyzer to verify your design power results.

Figure 11–20. Implementation of Power Optimization Advisor Recommendations



The recommendations listed in Stage 2 generally involve design changes, rather than CAD settings changes as in Stage 1. You can use these recommendations to further reduce your design power consumption. Altera recommends that you implement Stage 1 recommendations first, then the Stage 2 recommendations.

Conclusion

The combination of a smaller process technology, the use of low-k dielectric material, and reduced supply voltage significantly reduces dynamic power consumption in the latest FPGAs. To further reduce your dynamic power, use the design recommendations presented in this chapter to optimize resource utilization and minimize power consumption.

Document Revision History

Table 11–5 shows the revision history for this chapter.

Table 11–5. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Was chapter 9 in the 8.1.0 release. ■ Updated for the Quartus II software release. ■ Added benchmark results. ■ Removed several sections. ■ Updated Figure 11–1, Figure 11–18, Figure 11–19, and Figure 11–20.	Updated for the Quartus II 9.0 software release.
November 2008 v8.1.0	■ Changed to 8½” × 11” page size. ■ Changed references to altsyncram to RAM. ■ Minor editorial updates	Updated for the Quartus II 8.1 software release.
May 2008 v8.0.0	■ Updated Table 9–1 and 9–9. ■ Updated “Architectural Optimization” on page 9–22 ■ Added “Dynamically-Controlled On-Chip Terminations” on page 9–26 ■ Updated “Referenced Documents” on page 9–29 ■ Updated references	Added support for Stratix IV devices.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

12. Analyzing and Optimizing the Design Floorplan

QII52006-9.0.0

Introduction

As FPGA designs grow larger and larger in density, analyzing the design for performance, routing congestion, and logic placement to meet the design requirements becomes critical.

You can use the Chip Planner tool in the Quartus® II software to perform design analysis and create a design floorplan. With some of the older device families, you must use the Timing Closure Floorplan in the Quartus II software to analyze the device floorplan.

This chapter discusses how to analyze the design floorplan with both the Chip Planner and the Timing Closure Floorplan. It also shows you how to create LogicLock™ regions in the design floorplan and how to use the LogicLock design methodology as a performance preservation tool for older device families.

You can use the Design Partition Planner along with the Chip Planner to floorplan your design. For more information, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* and the *Best Practices for Incremental Compilation Partition and Floorplan Assignments* chapters in volume 1 of the *Quartus II Handbook*.

This chapter includes the following topics:

- "Chip Planner Overview" on page 12–2
- "LogicLock Regions" on page 12–6
- "Using LogicLock Regions in the Chip Planner" on page 12–18
- "Design Floorplan Analysis Using the Chip Planner" on page 12–19
- "Design Analysis Using the Timing Closure Floorplan" on page 12–40
- "Using LogicLock Methodology for Older Device Families" on page 12–52
- "Scripting Support" on page 12–57

To view and create assignments for a design floorplan in supported devices, use the Chip Planner. To make I/O assignments, use the Pin Planner tool.

For more information about the Pin Planner tool, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

Table 12–1 lists the device families supported by the Chip Planner and the Timing Closure Floorplan.

This chapter describes how to use the Chip Planner and the Timing Closure Floorplan (for devices not supported by the Chip Planner) for design analysis.

Chip Planner Overview

The Chip Planner provides a visual display of chip resources. It can show logic placement, LogicLock regions, relative resource usage, detailed routing information, fan-in and fan-out connections between nodes, timing paths between registers, and delay estimates for paths. With the Chip Planner, you can view critical path information, physical timing estimates, and routing congestion.

You can also perform assignment changes with the Chip Planner, such as creating and deleting resource assignments, and post-compilation changes like creating, moving, and deleting logic cells and I/O atoms. By using the Chip Planner in conjunction with the Resource Property Editor, you can change connections between resources and make post-compilation changes to the properties of logic cells, I/O elements, PLLs, and RAM and digital signal processing (DSP) blocks. With the Chip Planner, you can view and create assignments for a design floorplan, perform power and design analyses, and implement ECOs in a single tool.

For details about how to implement ECOs in your design using the Chip Planner in the Quartus II software, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

Starting the Chip Planner

To start the Chip Planner, on the Tools menu, click **Chip Planner (Floorplan & Chip Editor)**. The following methods can also be used to start the Chip Planner:

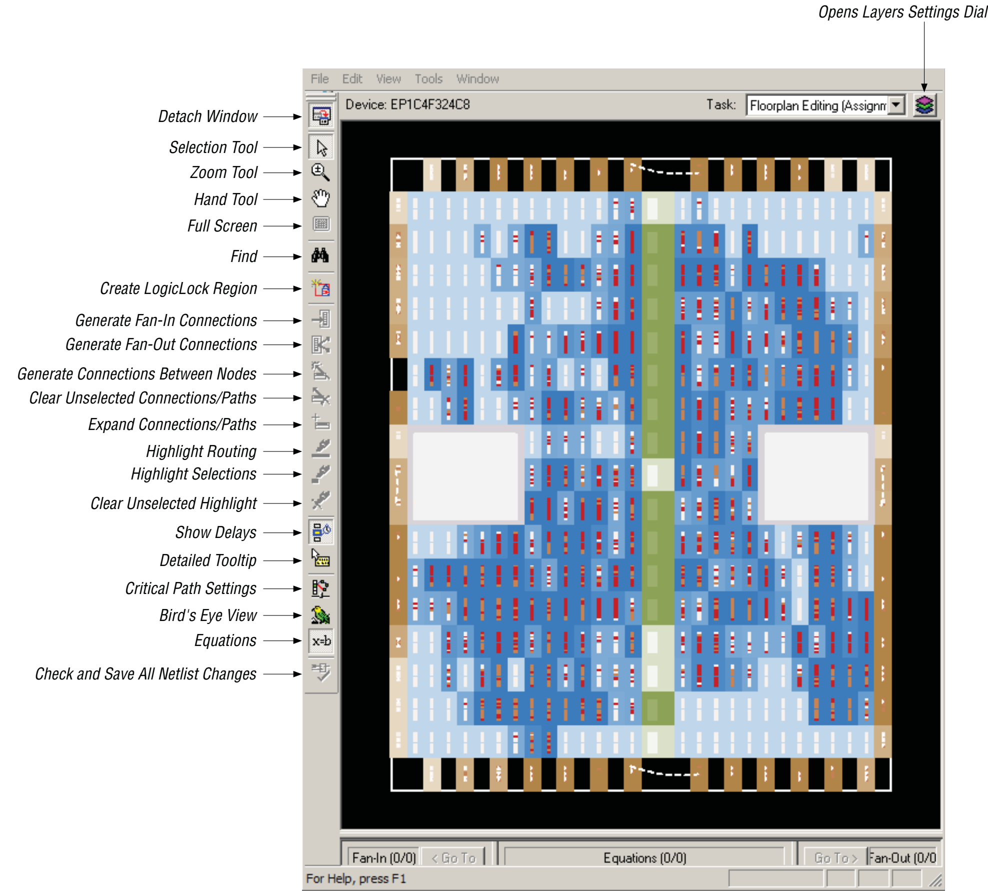
- Click the Chip Planner icon on the Quartus II software toolbar
- Use the right-click menu from the following sources and use the Locate menu:
  - Design Partition Planner
  - Compilation Report
  - LogicLock Regions window
  - Technology Map Viewer
  - Project Navigator window
  - RTL source code
  - Node Finder
  - Simulation Report
  - RTL Viewer
  - Report Timing panel of the TimeQuest Timing Analyzer

If the device in your project is not supported by the Chip Planner and you attempt to start the Chip Planner, the following message appears: `Can't display Chip Planner: the current device family is unsupported.` Use the Timing Closure Floorplan for these devices.

The Chip Planner Toolbar

The Chip Planner gives you powerful capabilities for design analysis with a user-friendly GUI. Many functions within the Chip Planner can be selected or performed from the menu items or by clicking the icons on the toolbar. Figure 12–1 shows an example of the Chip Planner toolbar and provides descriptions for commonly used icons available from the Chip Planner toolbar.

Figure 12–1. Chip Planner Toolbar



You can customize the icons present on the Chip Planner toolbar by clicking **Customize Chip Planner** on the Tools menu (if the Chip Planner window is attached), or by clicking **Customize** on the Tools menu (if the Chip Planner window is detached).

Chip Planner Tasks and Layers

The Chip Planner has predefined tasks that enable you to quickly implement ECO changes or manipulate assignments for the floorplan of the device. To select a task, click on the task name in the Task menu. The predefined tasks in the Chip Planner are:

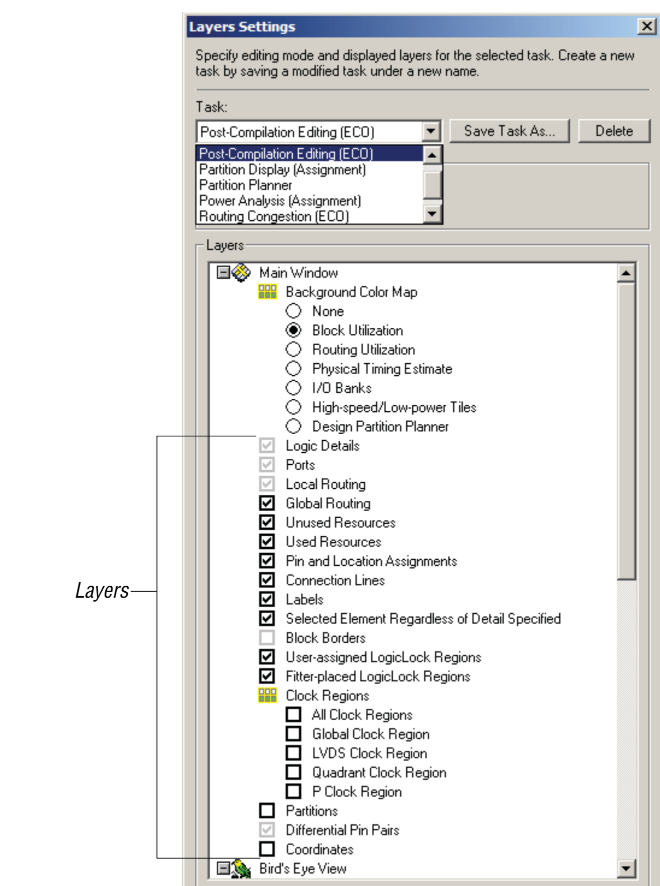
- **Floorplan Editing (Assignment)**
- **Post-Compilation Editing (ECO)**
- **Partition Display (Assignment)**
- **Partition Planner**
- **Routing Congestion (ECO)**
- **Clock Regions (Assignment)**—available for Stratix IV, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, and HardCopy II devices only

- **Power Analysis (Assignment)—**available for Stratix IV and Stratix III devices only

In the Chip Planner, layers allow you to specify the graphic elements that are displayed for a given task. You can turn off the display of specific graphic elements to increase the window refresh speed and reduce visual clutter when viewing complex designs. The **Background Color Map** can indicate the **Block Utilization**, **Routing Utilization**, **Physical Timing Estimate**, **I/O Banks**, or the High speed-Low power Tiles. When you select **Design Partition Planner** in the **Background Color Map** settings, the resources used by each partition are displayed in the Chip Planner with the same colors used for these partitions in the Design Partition Planner. You can access the Design Partition Planner on the Tools menu. For example, **Routing Utilization** indicates the relative routing utilization, and **Physical Timing Estimate** indicates the relative physical timing.

Each predefined task in the Chip Planner has a **Background Color Map**, a set of displayed layers, and an editing mode associated with it. Click the Layers icon (shown in Figure 12–1) to display the Layers Settings window (Figure 12–2). In this window you can select the layers and background color map for each task.

Figure 12–2. Layers in the Chip Planner



The Chip Planner operates in either **Assignment** or **ECO** mode. You can use either of these modes to perform design analyses. Use the **Floorplan Editor (Assignment)** task in the **Assignment** mode to manipulate LogicLock regions and location assignments in your design. The **Post Compilation Changes (ECO)** task in **ECO** mode allows you to implement ECO changes in your design. The **Partition Display (Assignment)** task allows you to view the placement of nodes and color-codes the nodes based on their partition. When you select the **Clock Regions (Assignment)** task, you can see the regions in your device that are driven by global clock networks. The **Power Analysis (Assignment)** task allows you to view high and low power resources in Stratix IV and Stratix III devices.

For more information about the **ECO** mode of operation, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

You can also create and save your own custom tasks. When you create a custom task, you can turn on or off any layer in your task. Layers can be turned on or off by checking the appropriate box located next to each layer. You can also select different **Background Color Maps** to be used for your custom task. After selecting the required settings, click **Save Task As** to save your custom task.

LogicLock Regions

LogicLock regions are user-defined regions within the device. Normally, LogicLock region are rectangular in shape. However, you can also create regions that are effectively non-rectangular in shape.

You can use LogicLock regions to create a floorplan for your design. Your floorplan can contain several LogicLock regions. A LogicLock region is defined by its size (height and width) and location (where the region is located on the device). You can specify the size or location of a region, or both, or the Quartus II software can generate these properties automatically. The Quartus II software bases the size and location of a region on the region's contents and the module's timing requirements. Table 12–2 describes the options for creating LogicLock regions.

Table 12–2. Types of LogicLock Regions

Properties	Values	Behavior
State	Floating (default), Locked	Floating regions allow the Quartus II software to determine the region's location on the device. Locked regions represent user-defined locations for a region and are shown with a solid boundary in the floorplan. A locked region must have a fixed size.
Size	Auto (default), Fixed	Auto-sized regions allow the Quartus II software to determine the appropriate size of a region given its contents. Fixed regions have a user-defined shape and size.
Reserved	Off (default), On, Limited	The reserved property allows you to define whether the Fitter can use the resources within a region for entities that are not assigned to the region. If the reserved property is turned on, only items assigned to the region can be placed within its boundaries. When you set it to limited, the Fitter does not place any logic from the parent region.
Origin	Any Floorplan Location	The origin is the origin of the LogicLock region's placement on the floorplan. For Arria GX, Stratix, and Cyclone series devices, and MAX II devices, the origin is located in the lower left corner. For other Altera® device families, the origin is located in the upper left corner.

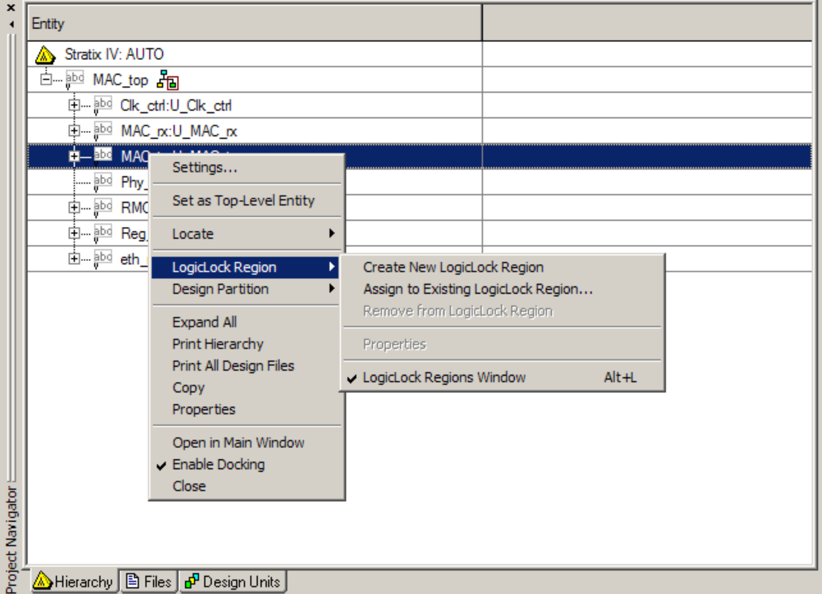
The Quartus II software cannot automatically define a region's size if the location is locked. Therefore, if you want to specify the exact location of the region, you must also specify the size.

You can use the Design Partition Planner in conjunction with LogicLock regions to create a floorplan for your design. For more information about using the Design Partition Planner, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Designs* and the *Best Practices for Incremental Compilation Partition and Floorplan Assignments* chapters in volume 1 of the *Quartus II Handbook*.

Creating LogicLock Regions

After you perform either a full compilation or analysis and elaboration on the design, the Quartus II software displays the hierarchy of the design. On the View menu, click **Project Navigator.** With the hierarchy of the design fully expanded, as shown in Figure 12–3, right-click on any design entity in the design and click **Create New LogicLock Region** to create a LogicLock region.

Figure 12–3. Using the Project Navigator to Create LogicLock Regions



Placing LogicLock Regions

A fixed region must contain all resources required for the module. Although the Quartus II software can automatically place and size LogicLock regions to meet resource and timing requirements, you can manually place and size regions to meet your design requirements. To do so, follow these guidelines:

- Place LogicLock regions with pin assignments on the periphery of the device, adjacent to the pins. For the Arria GX, Stratix, and Cyclone series of devices and MAX II devices, you must also include the I/O block within the LogicLock Region.
- Floating LogicLock regions cannot overlap.

- Avoid creating fixed and locked regions that overlap.

If you want to import multiple instances of a module into a top-level design, you must ensure that the device has two or more locations with exactly the same device resources. If the device does not have another area with exactly the same resources, the Quartus II software generates a fitting error during compilation of the top-level design.

When you import a LogicLock region, the Quartus II software changes the property to "floating" and assigns a new unique name. You can change the property to "fixed" to guarantee the same placement achieved previously. You can import or export LogicLock regions across devices within a family but not between families.

Placing Device Features into LogicLock Regions

A LogicLock region includes all device resources within its boundaries, including memory and pins. You can assign pins to LogicLock regions; however, this placement puts location constraints on the region. When the Quartus II software places a floating auto-sized region, it places the region in an area that meets the requirements of the LogicLock region's contents.

Pin assignments to LogicLock regions are effective only in fixed and locked regions. Pins assigned to floating regions do not influence the region's placement.

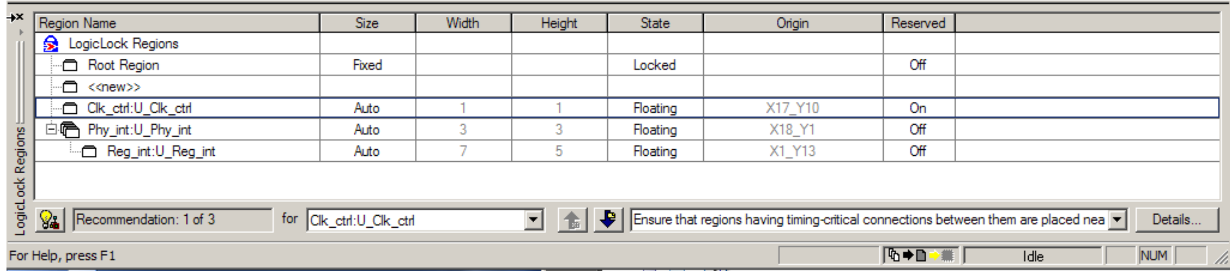
Only one LogicLock region can claim a device resource. If the boundary includes part of a device resource, the Quartus II software allocates the entire resource to the LogicLock region.

LogicLock Regions Window

The LogicLock window consists of the LogicLock Regions window (Figure 12–4) and the **LogicLock Region Properties** dialog box. Use the LogicLock Regions window to create LogicLock regions and assign nodes and entities to them. The dialog box provides a summary of all LogicLock regions in your design. In the LogicLock Regions window, you can modify a LogicLock region's properties size, state, width, height, origin, and whether the region is a reserved region. The LogicLock Regions window also has a recommendations toolbar at the bottom. Select a LogicLock region from the drop-down list in the recommendations toolbar to display the relevant suggestions to optimize that LogicLock region. When the region is back-annotated, the placement of each node within the region is relative to the region's origin, and the region's node placements are maintained during subsequent compilations.

The origin location varies, depending on the device family. For Arria GX, Stratix, and Cyclone series devices, and MAX II devices, the LogicLock region's origin is located at the lower-left corner of the region. For all other supported devices, the origin is located at the upper-left corner of the region.

Figure 12–4. LogicLock Regions Window



You can customize the LogicLock Regions window by dragging and dropping the various columns. Columns can also be hidden.

For designs that target Arria GX, Stratix, and Cyclone series and MAX II devices, the Quartus II software automatically creates a LogicLock region that encompasses the entire device. This default region is labelled `Root_region`, and it is effectively locked and fixed.

Use the **LogicLock Region Properties** dialog box to obtain detailed information about your LogicLock region, such as which entities and nodes are assigned to your region and what resources are required. The **LogicLock Region Properties** dialog box shows the properties of the current selected regions. You can also modify the settings for the regions you have created in this dialog box.

To open the **LogicLock Region Properties** dialog box, double-click any region in the LogicLock Regions window, or right-click the region and click **Properties**.

Hierarchical (Parent and Child) LogicLock Regions

You can define a hierarchy for a group of regions by declaring parent and child regions. The Quartus II software places a child region completely within the boundaries of its parent region, allowing you to further constrain module locations. Additionally, parent and child regions allow you to further improve a module's performance by constraining the nodes in the module's critical path.

To make one LogicLock region a child of another LogicLock region, in the LogicLock Regions window, select the new child region and drag and drop it in its new parent region.

The LogicLock region hierarchy does not have to be the same as the design hierarchy.

You can create both fixed and floating LogicLock regions within a fixed parent LogicLock region. A floating child region's location can float within its parent. If a child region is type fixed, its location remains locked relative to its parent's origin. A locked parent region's location is locked relative to the device. If the child's location is locked and the parent's location is changed, the child's origin changes but maintains the same placement relative to the origin of its parent. Either you or the Quartus II

software can determine a child region's size; however, the child region must fit entirely within the parent region. Although there is no limitation to the levels of hierarchy in LogicLock regions, remember that very complicated hierarchical regions might result in some LABs not being utilized; thus, effectively increasing the resource utilization in the device.

Reserved LogicLock Region

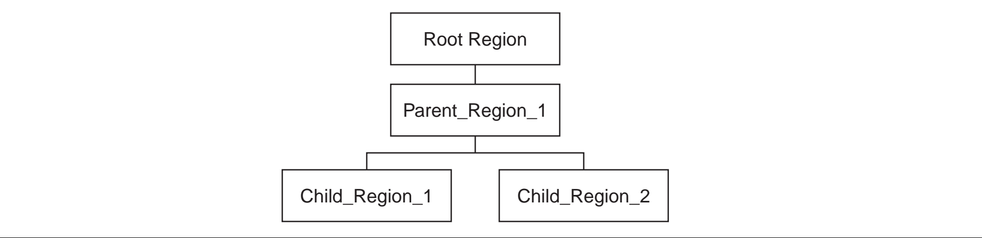
The Quartus II software honors all entity and node assignments to LogicLock regions. Occasionally, entities and nodes do not occupy an entire region, which leaves some of the region's resources unoccupied. To increase the region's resource utilization and performance, the Quartus II software's default behavior fills the unoccupied resources with other nodes and entities that have not been assigned to another region. You can prevent this behavior by turning on the **Reserved** option on the **General** tab of the **LogicLock Region Properties** dialog box. When this option is turned on, your LogicLock region only contains the entities and nodes that you specifically assigned to your LogicLock region. When you set the reserved property for a LogicLock region to **Limited**, the Fitter prevents logic from the immediate parent LogicLock region to be placed within the assigned area, but it might place other logic in the associated region.

In a team-based design environment, the **Limited** option is helpful in creating a device floorplan. When this option is turned on, each team can be assigned a portion of the device floorplan where placement and optimization of each submodule occurs. Device resources can be distributed to every module without affecting the performance of other modules.

Creating Non-Rectangular LogicLock Regions

You can use the reserved property of LogicLock regions to create regions that are effectively non-rectangular in shape. For example, consider a case in which there is one LogicLock region under the Root region and two child regions under this region (Figure 12–5).

Figure 12–5. Example 1

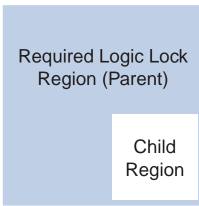


You can set the **Reserved** property of a LogicLock region to **On**, **Off**, or **Limited**. If you create a LogicLock region for Child_Region_1 with its **Reserved** property set to **Limited**, the Fitter does not place nodes that are members of Parent_Region_1 or Child_Region_2 into the boundary of Child_Region_1. However, the Fitter can place nodes that are not members of Parent_Region_1 or Child_Region_1 (such as members of the Root_Region) into Child_Region_1. On the other hand, if Child_Region_1 is set to exclude all non-members, the Fitter can only place nodes that are members of Child_Region_1 into the region.

If the Parent Region's reserved property is turned off, then the Fitter might place other logic in the allocated region.

If you want to create a non-rectangular region as shown in Figure 12–6, you can create two rectangular hierarchical LogicLock regions. Turn off the reserved property on the parent LogicLock and set the reserved property on the child LogicLock region to **Limited** to prevent the Fitter from placing any logic of the module assigned to the parent LogicLock region. Because of this, logic that is external to the parent LogicLock region might be placed in the area allocated to the child region. This gives a non-rectangular LogicLock region.

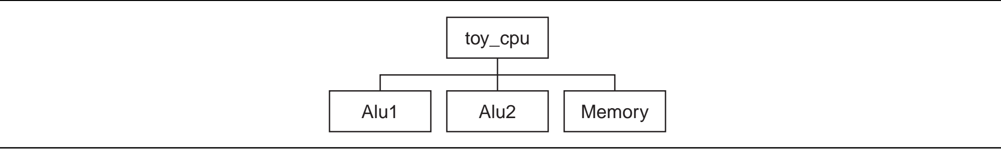
Figure 12–6. Non-Rectangular Region



Examples of Non-Rectangular LogicLock Regions Using Reserved Property

The following examples use the design hierarchy shown in Figure 12–7.

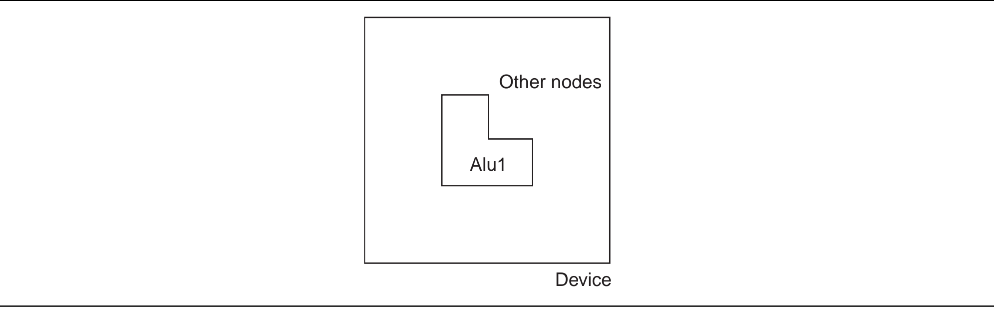
Figure 12–7. An Example Design Hierarchy



Example 1: Creating an L-Shaped Region

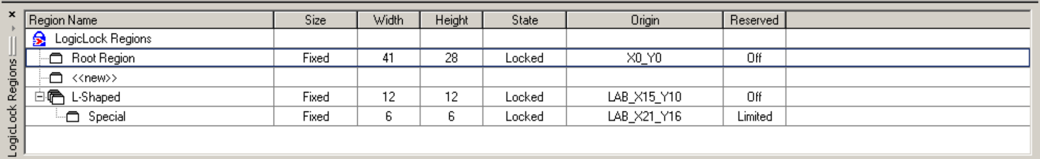
In the design hierarchy example in Figure 12–7, suppose you want to create an L-shaped region, such that the Alu1 module is placed completely inside the region, and the non-Alu1 nodes can be placed anywhere on the chip (as shown in Figure 12–8).

Figure 12–8. Creating an L-Shaped Region



The L-shaped region defines a rectangular region that is carved out by a child LogicLock region (**Special**) to achieve the L-shape effect. The **Reserved** property of this child LogicLock region is set to **Limited**, such that the Fitter does not require logic from members of Alu1 (which is the parent region of the region named **Special**) inside it while letting other nodes in. Not displayed in Figure 12–8, the Alu1 entity instance is assigned as a member to the L_Shaped region. This can be achieved by creating a hierarchical LogicLock region as shown in Figure 12–9.

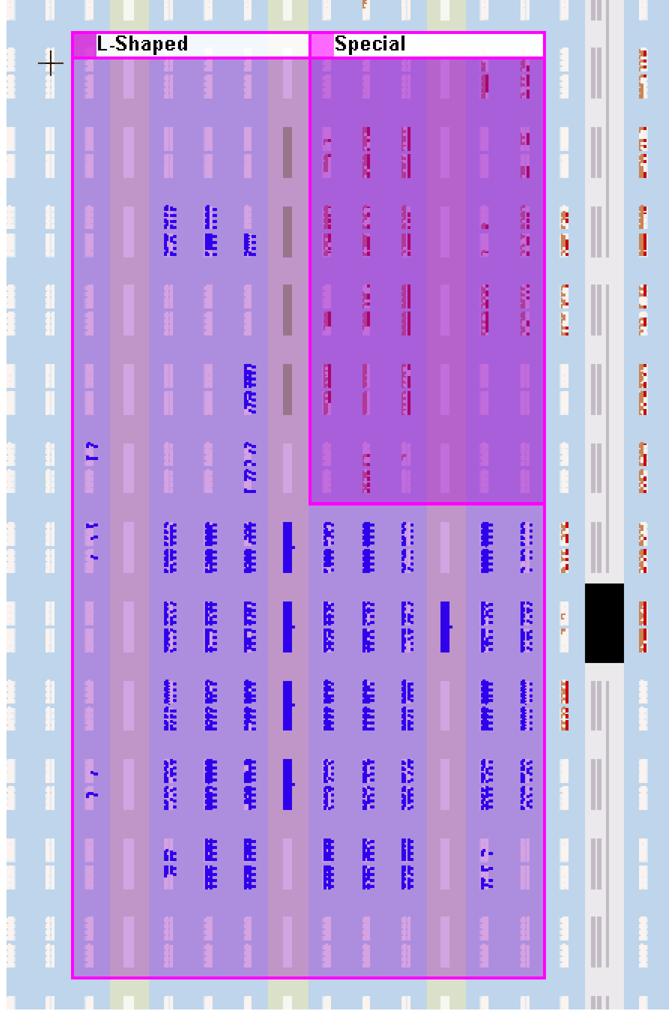
Figure 12–9. Hierarchical LogicLock Region



Region Name	Size	Width	Height	State	Origin	Reserved
LogicLock Regions						
Root Region	Fixed	41	28	Locked	X0_Y0	Off
<<new>>						
L-Shaped	Fixed	12	12	Locked	LAB_X15_Y10	Off
Special	Fixed	6	6	Locked	LAB_X21_Y16	Limited

Figure 12–10 illustrates the expected fitting results with these LogicLock regions. Nodes from the Alu1 entity instance are colored blue, while nodes from the rest of the design are colored red.

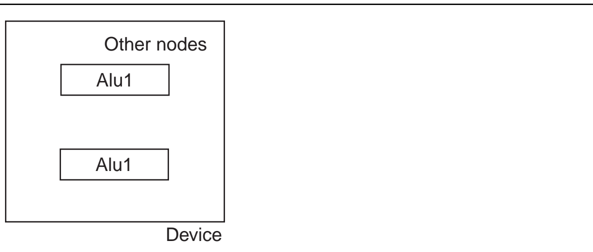
Figure 12–10. Expected Fitting Results with LogicLock Regions



Example 2: Region with Disjoint Areas

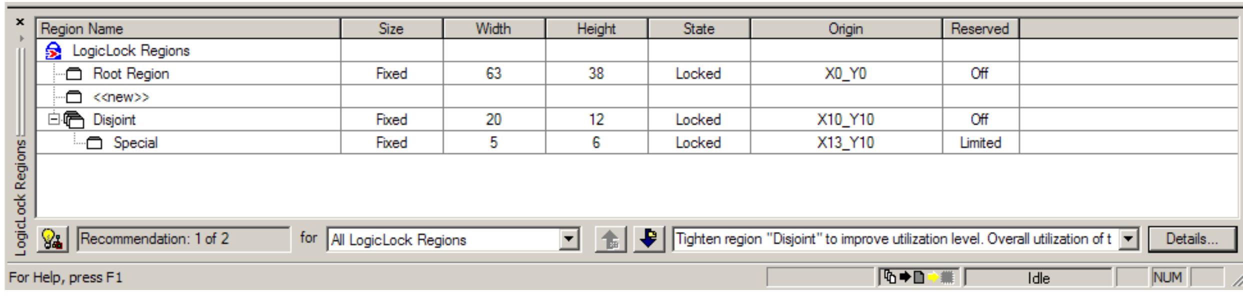
Suppose you want to create a region consisting of two disjoint rectangles (or any number of disjoint areas), such that the Alu1 module is placed completely inside the region, and the non-Alu1 nodes can be placed anywhere on the chip as shown in Figure 12–11.

Figure 12–11. Region Consisting of Two Disjointed Rectangles



You can achieve a region with disjoint areas using the following region hierarchy example in Figure 12–12.

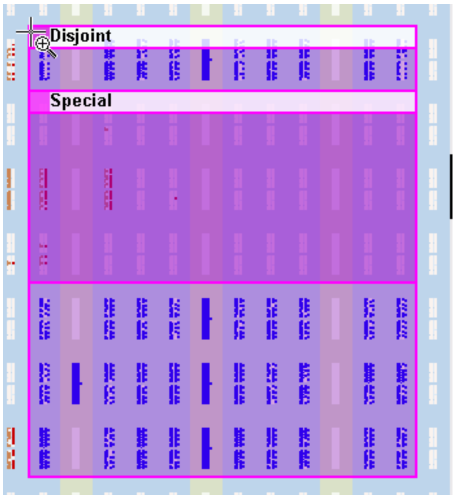
Figure 12–12. Region with Disjoint Areas



The disjoint region defines a rectangular region that is carved out by the Special child region to achieve the disjoint effect. Notice that the Special region is set to reserved "from members of parent region hierarchy" to prevent the Alu1 nodes from being placed inside it, while letting other nodes in. The Alu1 entity instance should be assigned to the Disjoint LogicLock region.

Figure 12–13 shows the expected fitting results with the LogicLock regions. Nodes from the Alu1 entity instance are colored blue, while nodes from the rest of the design are colored red and brown.

Figure 12–13. Expected Fitting Results with the LogicLock Regions



Excluded Resources

The Excluded Resources feature allows you to easily exclude specific device resources such as DSP blocks or M4K memory blocks from a LogicLock region. For example, you can specify resources that belong to a specific entity that are assigned to a LogicLock region, and specify that these resources be included with the exception of the DSP blocks. Use the Excluded Resources feature on a per-LogicLock region member basis.

To exclude certain device resources from an entity, in the **LogicLock Region Properties** dialog box, highlight the entity in the **Design Element** column, and click **Edit**. In the **Edit Node** dialog box, under **Excluded Element Types**, click the Browse button. In the **Excluded Resources Element Types** dialog box, you can select the device resources you want to exclude from the entity. When you have selected the resources to exclude, the **Excluded Resources** column is updated in the **LogicLock Region Properties** dialog box to reflect the excluded resources.

The Excluded Resources feature prevents certain resource types from being included in a region, but it does not prevent the resources from being placed inside the region unless the region's **Reserved** property is set to **On**. To inform the Fitter that certain resources are not required inside a LogicLock region, define a resource filter.

Additional Quartus II LogicLock Design Features

To complement the **LogicLock Regions** dialog box and **Device Floorplan** view, the Quartus II software has additional features to help you design with the LogicLock regions.

Tooltips

When you move the mouse pointer over a LogicLock region name on the **LogicLock Regions** dialog box, or over the top bar of the LogicLock region in the Chip Planner or Timing Closure Floorplan, the Quartus II software displays a tooltip with information about the properties of the LogicLock region.

Placing the mouse pointer over **Fitter-placed LogicLock regions** displays the maximum routing delay within the LogicLock region. To turn this feature on, on the View menu, point to **Routing** and click **Show Intra-region Delay**.

Show Critical Paths

You can display the critical paths in the design by turning on the **Show Critical Paths** option. Use this option with the **Critical Paths Settings** option to display paths based on the Timing Analysis report.

Analysis and Synthesis Resource Utilization by Entity

The Compilation Report contains an **Analysis and Synthesis Resource Utilization by Entity** section, which reports accurate resource usage statistics, including entity-level information. This feature is useful when manually creating LogicLock regions.

Path-Based Assignments

You can assign paths to LogicLock regions based on source and destination nodes, allowing you to easily group critical design nodes into a LogicLock region. Any of the following types of nodes can be the source and destination nodes:

- Valid register-to-register path, meaning that the source and destination nodes must be registers
- Valid pin-to-register path, meaning the source node is a pin and the destination node is a register
- Valid register-to-pin path, meaning that the source node is a register and the destination node is a pin

- Valid pin-to-pin path, meaning that both the source and destination nodes are pins

To open the **Paths** dialog box, on the **General** tab of the **Logic Lock Regions** dialog box, click **Add Path**.

Both "*" and "?" wildcard characters are allowed for the source and destination nodes. When creating path-based assignments, you can exclude specific nodes using the **Name exclude** field in the **Paths** dialog box. The Quartus II software ignores all paths passing through the nodes that match the setting in the **Name exclude** field. For example, consider a case with two paths between the source and destination—one passing through node A and the other passing through node B. If you specify node B in the **Name exclude** field, only the path assignment through node A is valid.

You can also use the Quartus II Timing Analysis Report to create path-based assignments by following these steps:

1. Expand the **Timing Analyzer** section in the Compilation Report.
2. Select any of the clocks in the section labeled "Clock Setup:<*clock name*>."
3. Locate a path that you want to assign to a LogicLock region. Drag this path from the Report window and drop it in the appropriate row in the LogicLock Region pane in the Quartus II GUI.

This operation creates a path-based assignment from the source register to the destination register as shown in the Timing Analysis Report.

Quartus II Revisions Feature

When you evaluate different LogicLock regions in your design, you might require experiments with different configurations to achieve your desired results. The Quartus II software Revisions feature provides a convenient way to organize the same project with different settings until an optimum configuration is found.

On the Project menu, click **Revisions**. In the **Revisions** dialog box, you can create and specify revisions. Revision can be based on the current design or any previously created revisions. Each revision can have an associated description. Revisions are a convenient way to organize the placement constraints created for your LogicLock regions.

LogicLock Assignment Precedence

Conflicts can arise during the assignment of entities and nodes to LogicLock regions. For example, an entire top-level entity might be assigned to one region and a node within this top-level entity assigned to another region. To resolve conflicting assignments, the Quartus II software maintains an order of precedence for LogicLock assignments. The following order of precedence, from highest to lowest, applies:

1. Exact node-level assignments
2. Path-based and wildcard assignments
3. Hierarchical assignments

However, conflicts can also occur within path-based and wildcard assignments. Path-based and wildcard assignment conflicts arise when one path-based or wildcard assignment contradicts another path-based or wildcard assignment. For example, a path-based assignment is made containing a node labeled `X` and assigned to LogicLock region `PATH_REGION`. A second assignment is made using wildcard assignment `X*` with node `X` being placed into region `WILDCARD_REGION`. As a result of these two assignments, node `X` is assigned to two regions: `PATH_REGION` and `WILDCARD_REGION`.

To resolve this type of conflict, the Quartus II software maintains the order in which the assignments were made and treats the most recent assignment created with the highest priority.

Open the **Priority** dialog box by selecting **Priority** on the **General** tab of the **LogicLock properties** dialog box. You can change the priority of path-based and wildcard assignments by using the **Up** and **Down** buttons in the **Priority** dialog box. To prioritize assignments between regions, you must select multiple LogicLock regions. Once the regions have been selected, you can open the **Priority** dialog box from the LogicLock Properties window.

Normally all nodes assigned to a particular LogicLock region reside within the boundaries of that region.

Virtual Pins

When you compile a design in the Quartus II software, all I/O ports are directly mapped to pins on the targeted device. The I/O port mapping can create problems for a modular and hierarchical design as lower-level modules can have I/O ports that exceed device pins available on the targeted device. Also, the I/O ports might not directly feed a device pin, but instead drive other internal nodes. The Quartus II software accommodates this situation by supporting virtual pins.

The Virtual Pin assignment communicates to the Quartus II software which I/O ports of the design module are internal nodes in the top-level design. These assignments prevent the number of I/O ports in the lower-level modules from exceeding the total number of available device pins. Every I/O port that is designated a virtual pin is mapped to either an LCELL or an adaptive logic module (ALM) depending on the target device.

Bidirectional, registered I/O pins, and I/O pins with output enable signals cannot be virtual pins.

In the top-level design, these virtual pins are connected to an internal node of another module. Making assignments to virtual pins allows you to place them in the same location or region on the device as that of the corresponding internal nodes in the top-level module. This feature has the added benefit of providing accurate timing information during lower-level module optimization.

Use the following guidelines for creating virtual pins in the Quartus II software:

- Do not declare clock pins
- Nodes or signals that drive physical device pins in the top-level design should not be declared as virtual pins

In the Node Finder, setting **Filter Type** to **Pins: Virtual** allows you to display all assigned virtual pins in the design. From the Assignment Editor, to access the Node Finder, double-click the **To** field; when the arrow appears on the right side of the field, click the arrow and select **Node Finder**.

Using LogicLock Regions in the Chip Planner

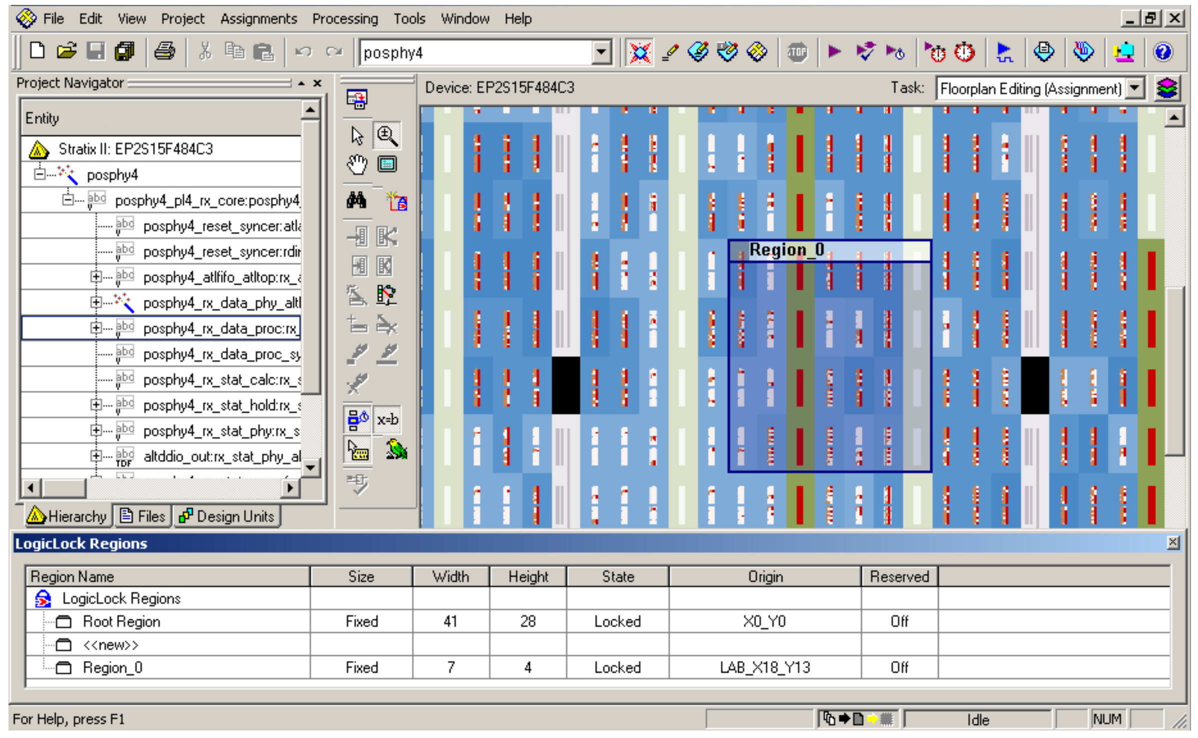
You can easily edit properties of existing LogicLock regions or assign resources to them in the Chip Planner. You can also create new LogicLock regions using the Chip Planner.

Assigning LogicLock Region Content

When you have defined a LogicLock region, you must assign resources to it using the Chip Planner, the **LogicLock Regions** dialog box, or a Tcl script.

You can drag selected logic displayed in the **Hierarchy** tab of the Project Navigator, in the Node Finder, or in a schematic design file, and drop it into the Chip Planner or the **LogicLock Regions** dialog box. Figure 12–14 shows logic that has been dragged from the **Hierarchy** tab of the Project Navigator and dropped into a LogicLock region in the Chip Planner.

Figure 12–14. Drag and Drop Logic in the Chip Planner



You can also drag logic from the **Hierarchy** tab of the Project Navigator and drop it in the LogicLock Regions **Properties** dialog box. Logic can also be dropped into the **Design Element Assigned** column of the **Contents** tab of the **LogicLock Region Properties** box.

You must assign pins to a LogicLock region manually. The Quartus II software does not include pins automatically when you assign an entity to a region. The software only obeys pin assignments to locked regions that border the periphery of the device. For the Stratix and Cyclone series of devices, and MAX II devices, the locked regions must include the I/O pins as resources.

Creating LogicLock Regions with the Chip Planner

In the View menu of the Chip Planner, click **Create LogicLock Region**. In the Chip Planner, click and drag to create a region of your preferred location and size.

Viewing Connections Between LogicLock Regions in the Chip Planner

You can view and edit LogicLock regions using the Chip Planner. Select the **Floorplan Editing (Assignment)** task or select any task with **User-assigned LogicLock regions** setting enabled to manipulate LogicLock regions.

The Chip Planner shows the connections between LogicLock regions. Rather than showing multiple connection lines from one LogicLock region to another, you can select the option of viewing connections between LogicLock regions as a single bundled connection. To use this option, open the Chip Planner floorplan and on the View menu, click **Generate Inter-region Bundles**.

In the **Generate Inter-region Bundles** dialog box, specify the **Source node to region fanout less than** and the **Bundle width greater than** values.

For more information about the parameters in the **Generate Inter-region Bundles** dialog box, refer to the Quartus II Help.

Design Floorplan Analysis Using the Chip Planner

The Chip Planner assists you in visually analyzing the floorplan of your design at any stage of your design cycle. With the Chip Planner, you can view post-compilation placement, connections, and routing paths. You can also create LogicLock regions and location assignments. The Chip Planner allows you to create new logic cells and I/O atoms and to move existing logic cells and I/O atoms using the architectural floorplan of your design. You can also see global and regional clock regions within the device, and the connections between both I/O atoms and PLLs and the different clock regions.

From the Chip Planner, you can launch the Resource Property Editor. The Resource Property Editor lets you make changes to the properties and parameters of device resources, and modify connectivity between certain types of device resources. Changes that you perform are logged within the Change Manager. The Change Manager helps you track the various changes you make on your design floorplan, so that you can selectively undo the changes if necessary.

For more information about the Resource Property Editor and the Change Manager, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

The following sections present design analysis procedures and views of the Chip Planner, which you can use with any predefined task of the Chip Planner (unless explicitly stated that a certain procedure requires a particular task or editing mode).

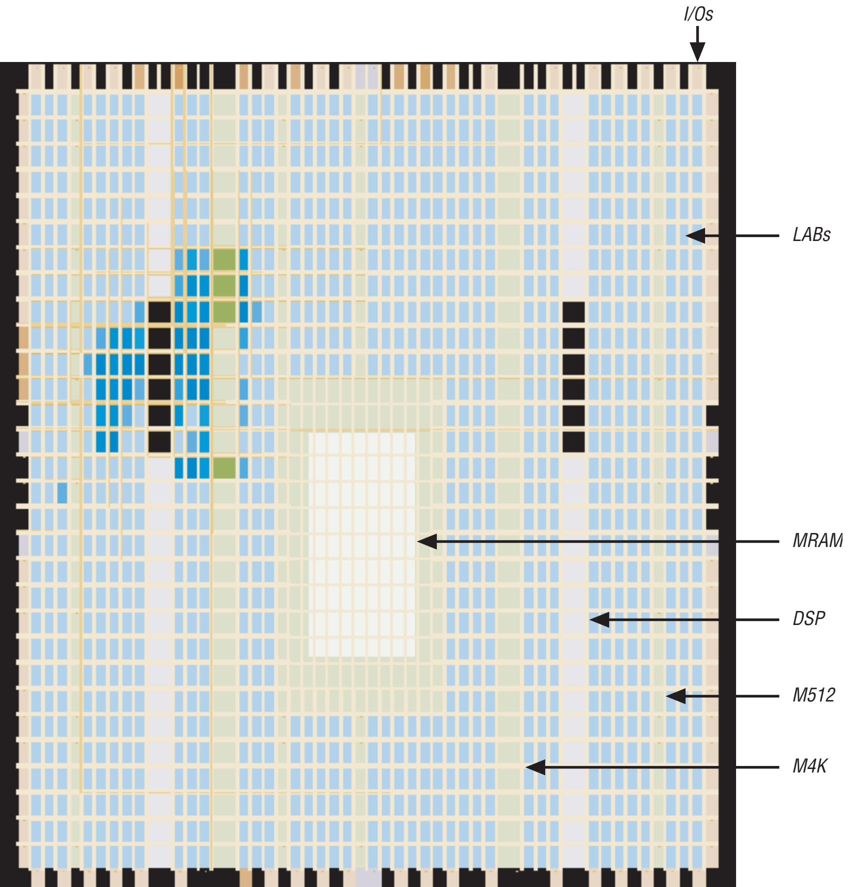
Chip Planner Floorplan Views

The Chip Planner uses a hierarchical zoom viewer that shows various abstraction levels of the targeted Altera device. As you increase the zoom level, the level of abstraction decreases, thus revealing more detail about your design.

First-Level View

The first level provides a high-level view (LAB level view) of the entire device floorplan. You can locate a node and view the placement of that node in your design. Figure 12–15 shows the Chip Planner's Floorplan first-level view of a Stratix device.

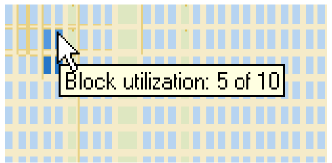
Figure 12–15. Chip Planner's First-Level Floorplan View



Each resource is shown in a different color. The Chip Planner floorplan uses a gradient color scheme in which the color becomes darker as the utilization of a resource increases. For example, as more LEs are used in the logic array block (LAB), the color of the LAB becomes darker.

When you place the mouse pointer over a resource at this level, a tooltip appears that describes, at a high level, the utilization of the resource (Figure 12–16).

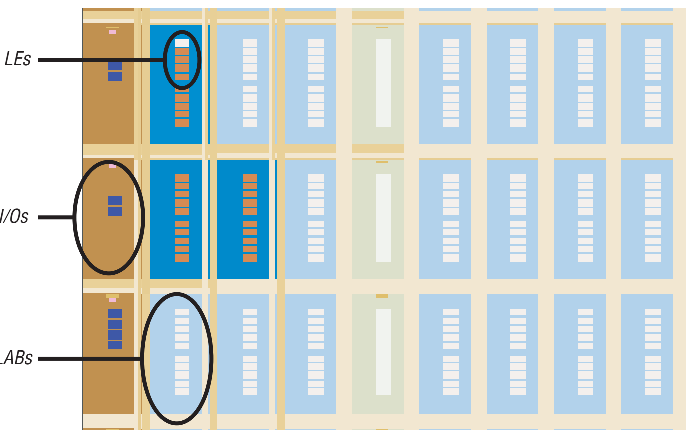
Figure 12–16. Tooltip Message: First-Level View



Second-Level View

As you zoom in, the level of detail increases. Figure 12–17 shows the second-level view of the Chip Planner Floorplan for a Stratix device.

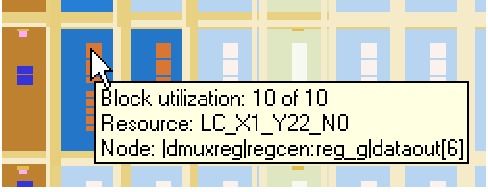
Figure 12–17. Chip Planner's Second-Level Floorplan View



At this level, the contents of LABs and I/O banks and the routing channels that are used to connect resources are all visible.

When you place the mouse pointer over an LE or ALM at this level, a tooltip is displayed (Figure 12–18) that shows the name of the LE/ALM, the location of the LE/ALM, and the number of resources that are used with that LAB. When you place the mouse pointer over an interconnect, the tooltip shows the routing channels that are used by that interconnect. At this level, you can move LEs, ALMs, and I/Os from one physical location to another.

Figure 12–18. Tooltip Message: Second-Level View



Third-Level View

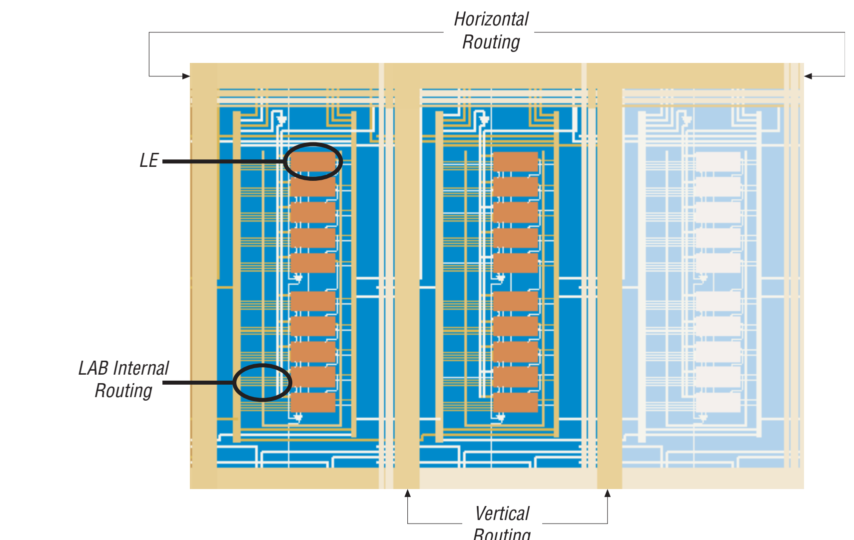
At the third level, which provides a more detailed view, you can see each routing resource that is used within a LAB in the FPGA. Figure 12–19 shows the level of detail at the third-level view for a Stratix device.

From the third level, you can move LEs, ALMs, and I/Os from one physical location to another. You can move a resource by selecting, dragging, and dropping it into the desired location. At this level, you can also create new LEs and I/Os when you are in the post-compilation (ECO) mode.

You can delete a resource only after all of its fan-out connections are removed. Moving nodes in the **Floorplan Editing (Assignment)** task creates an assignment. However, if you move logic nodes in the **Post-Compilation Editing (ECO)** task, that change is considered an ECO change. For more information about Floorplan Assignments, refer to "Viewing Assignments in the Chip Planner" on page 12–37.

For more information about performing ECOs, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook.*

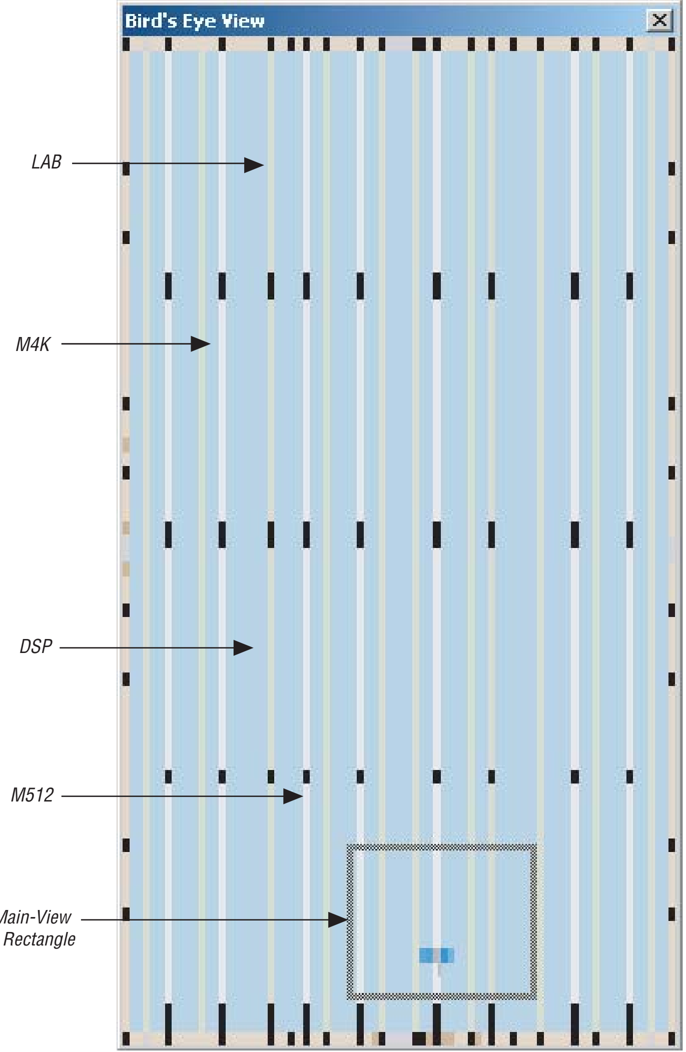
Figure 12–19. Chip Planner's Third-Level Floorplan View



Bird's Eye View

The Bird's Eye View (Figure 12–20) displays a high-level picture of resource usage for the entire chip and provides a fast and efficient way to navigate between areas of interest in the Chip Planner.

Figure 12–20. Bird's Eye View



The Bird's Eye View is displayed as a separate window that is linked to the Chip Planner floorplan. When you select an area of interest in the Bird's Eye View, the Chip Planner floorplan automatically refreshes to show that region of the device. As you change the size of the main-view rectangle in the Bird's Eye View window, the main Chip Planner floorplan window also zooms in (or zooms out). You can make the main-view rectangle smaller in the Bird's Eye View to see more detail on the Chip Planner floorplan window by right-clicking and dragging inside the Bird's Eye View.

The Bird's Eye View is particularly useful when parts of your design that you are interested in are at opposite ends of the chip, and you want to quickly navigate between resource elements without losing your frame of reference.

Viewing Architecture-Specific Design Information

With the Chip Planner, you can view the following architecture-specific information related to your design:

- **Device routing resources used by your design**—View how blocks are connected, as well as the signal routing that connects the blocks.
- **LE configuration**—View how a logic element (LE) is configured within your design. For example, you can view which LE inputs are used; if the LE utilizes the register, the look-up table (LUT), or both; as well as the signal flow through the LE.
- **ALM configuration**—View how an ALM is configured within your design. For example, you can view which ALM inputs are used, if the ALM utilizes the registers, the upper LUT, the lower LUT, or all of them. You can also view the signal flow through the ALM.
- **I/O configuration**—View how the device I/O resources are used. For example, you can view which components of the I/O resources are used, if the delay chain settings are enabled, which I/O standards are set, and the signal flow through the I/O.
- **PLL configuration**—View how a phase-locked loop (PLL) is configured within your design. For example, you can view which control signals of the PLL are used with the settings for your PLL.
- **Timing**—View the delay between the inputs and outputs of FPGA elements. For example, you can analyze the timing of the `DATAB` input to the `COMBOUT` output.

In addition, you can modify the following properties of an Altera device with the Chip Planner:

- LEs and ALMs
- I/O cells
- PLLs
- Registers in RAM and DSP blocks
- Connections between elements
- Placement of elements

For more information about LEs, ALMs, and other resources of an FPGA device, refer to the relevant device handbook.

Viewing Available Clock Networks in the Device

When you select the **Clock Regions (Assignment)** from the **Task** list, you can view the areas of the chip that are driven by the global and regional clock networks available in the device. This global clock display feature is available only for Stratix IV, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone III, and HardCopy II device families.

When you select the **Clock Regions** task, the Chip Planner displays various types of regional and global clocks and the regions they cover in the device. The connectivity between clock regions, pins, and PLLs is also shown. Clock regions are shown with rectangular overlay boxes with name labels of clock type and index.You can select each clock network region by clicking on it. The clock-shaped icon at the top-left corner indicates that the region represents a clock network region.

Clock types are listed in the Layer Settings window. You can change the color of the clock network in the Chip Planner on the **Options** page of the Tools menu.

You can customize your view of the global clock networks by using the layers setting in the Chip Planner GUI. You can turn on or off the display of all clock regions with the **All types** option. When the selected device does not contain a specific clock region, the option for that category is turned off in the dialog box. Figure 12–21 shows the potential fan-in in the Chip Planner.

Figure 12–21. Potential Fan-In

To trace the possible connectivity to each clock network region, select the clock network region and use the **Generate Potential Fan-In** and **Generate Potential Fan-Out** commands.

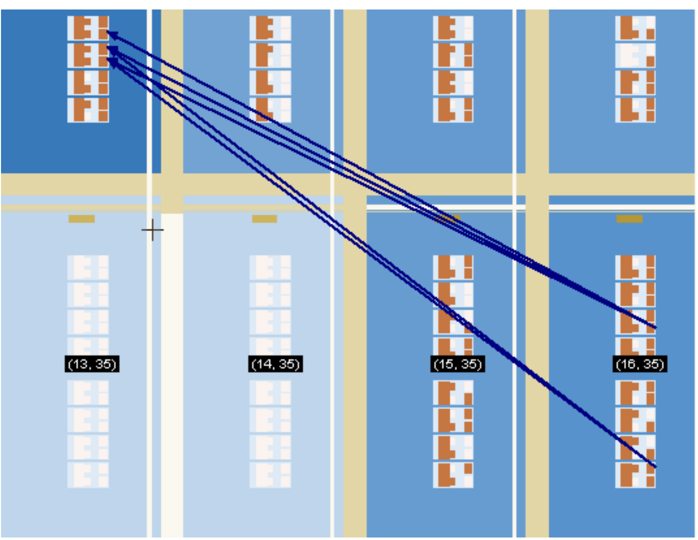
If you are interested in locating the clock regions that a pin or PLL can feed, select the pin or the PLL, then use the **Generate Fan-Out Connections** command. Connection arrows are drawn from the selected pins or PLLs to their clock regions.

When you use the **Generate Fan-In Connections** and **Generate Fan-Out Connections** commands, the Chip Planner shows connections that are actually used in the netlist for the selected clock region.

Viewing Critical Paths

Critical paths are timing paths in your design that have a negative slack. These timing paths can span from device I/Os to internal registers, registers-to-registers, or registers-to-devices I/Os. The View Critical Paths feature displays routing paths in the Chip Planner, as shown in Figure 12–22. The criticality of a path is determined by its slack and is shown in the timing analysis report. Design analysis for timing closure is a fundamental requirement for optimal performance in highly complex designs. The Quartus II Chip Planner helps you close timing on complex designs with its analytical capability.

Figure 12–22. Chip Planner Showing Critical Path

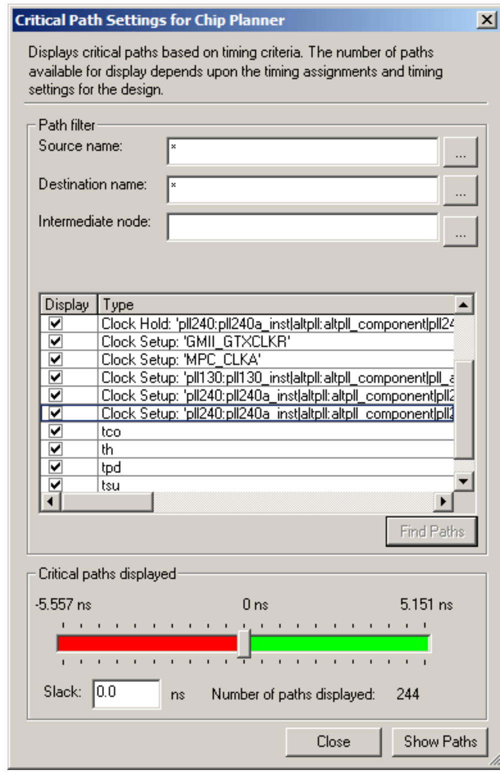


Viewing critical paths in the Chip Planner helps you analyze why a specific path is failing. You can see if any modification in the placement can potentially reduce the negative slack. You can display details of a path (to expand/collapse the path to/from the connections in the path) by clicking on Expand Connections/Paths button in the toolbar, or by clicking on the "+/-" on the label.

To view critical paths in the Chip Planner, on the View menu, click **Critical Path Settings**. In the **Critical Path Settings** dialog box, click **Show Path** (refer to Figure 12–23 on page 12–27).

If you are using the TimeQuest Timing Analyzer, you can locate the failing paths starting from the timing report. To locate the critical paths, run the Report Timing task from the Custom Reports group in the Tasks pane of the TimeQuest GUI. From the View pane, which lists the failing paths, you can right-click on any failing path or node, and select **Locate Path**. From the pop-up dialog box, select **Chip Planner** to see the failing path in the Chip Planner.

Figure 12–23. Critical Path Settings for the Chip Planner



When viewing critical paths, you can specify the clock in the design you want to view. You determine the paths to be displayed by specifying the slack threshold in the slack field of the **Critical Path Settings** dialog box. This dialog box also helps you to filter specific paths based on the source and destination registers.

Timing settings must be made and a timing analysis performed for paths to be displayed in the floorplan.

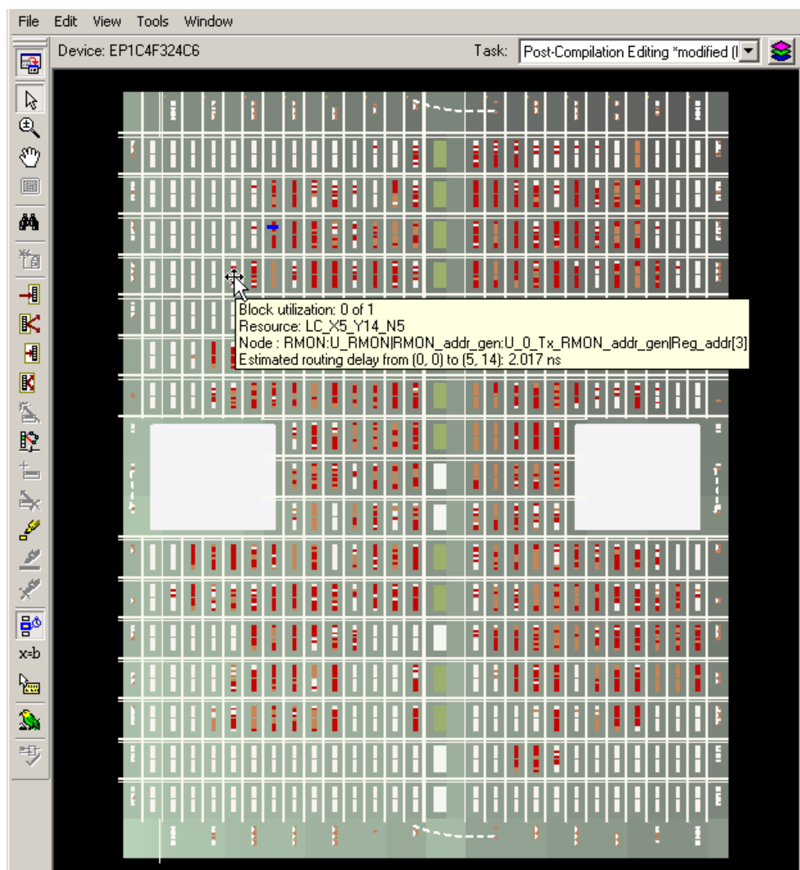
For more information about performing static timing analysis with the Quartus II Classic Timing Analyzer, refer to the *Quartus II Classic Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*. For more information about performing static timing analysis with the Quartus II TimeQuest Timing Analyzer, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Viewing Physical Timing Estimates

In the Chip Planner, you can select a resource and see the approximate delay to any other resource on the device. After you select a resource, the delay is represented by the color of potential destination resources. The lighter the color of the resource, the longer the delay.

To see the physical timing map of the device, in the Chip Planner, click the **Layers** icon located next to the Task menu. **Under Background Color Map**, select **Physical Timing Estimate**. Select a source and move your cursor to a destination resource. The Chip Planner displays the approximate routing delay between your selected source and destination register (Figure 12–24).

Figure 12–24. Chip Planner Displaying Routing Delay



You can use the physical timing estimate information when attempting to improve the Fitter results by manually moving logic in a device or when creating LogicLock regions to group logic together. This feature allows you to estimate the physical routing delay between different nodes so that you can place critical nodes and modules closer together, and move non-critical or unrelated nodes and modules further apart.

In addition to reducing delay between critical nodes, you can make placement assignments to reduce the routing congestion between critical and noncritical entities and modules. This allows the Quartus II Fitter to meet the design timing requirements.

Moving logic and creating manual placements is an advanced technique to meet timing requirements and must be done after careful analysis of the design. Moving nodes in the **Floorplan Editing (Assignment)** task creates an assignment. However, if you move logic nodes in the **Post-Compilation Editing (ECO)** task, that change is considered an ECO change.

For more information about Floorplan Assignments, refer to "Viewing Assignments in the Chip Planner" on page 12–37.

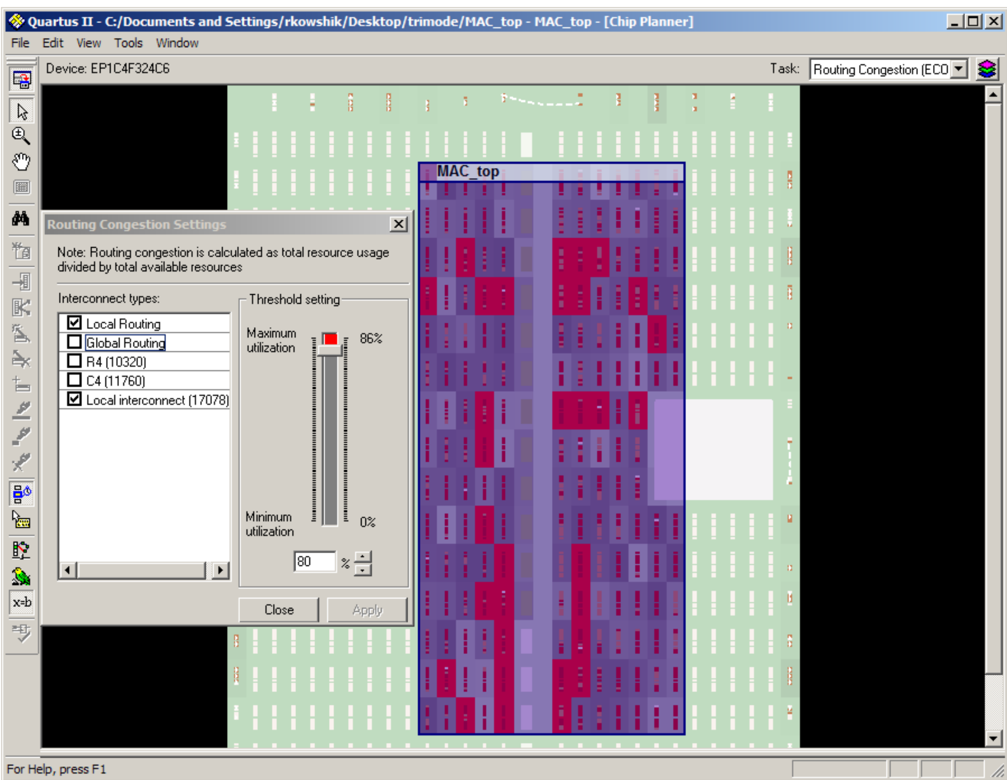
For more information about performing ECOs, refer to the *Engineering Change Management* with the Chip Planner chapter in volume 2 of the *Quartus II Handbook*.

Viewing Routing Congestion

The Routing Congestion view allows you to determine the percentage of routing resources used after a compilation. This feature identifies where there is a lack of routing resources. This information helps you make decisions about design changes that might be necessary to ease the routing congestion and thus meet design requirements. The congestion is visually represented by the color and shading of logic resources. The darker shading represents a greater routing resource utilization.

You can set a routing congestion threshold to identify areas of high routing congestion with the **Routing Congestion Settings** dialog box by selecting the **Routing Congestion (ECO)** task from the drop-down task list or when you select **Routing Utilization** from the layers setting. In the **Routing Congestion Settings** dialog box, set the threshold level for congestion indication and click **Apply**. You can also select the interconnect type you are interested in. All areas that exceed the threshold you have set appear in red (Figure 12–25).

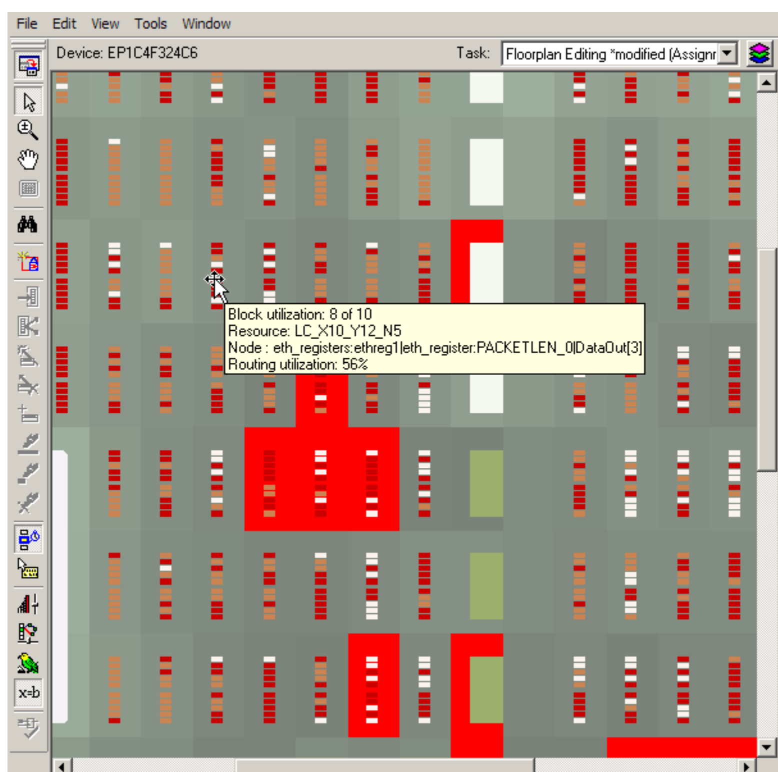
Figure 12–25. Areas Exceeding Threshold



If you are using a HardCopy II device, turn on **Routing Congestion** to see the routing congestion in the device by selecting **Routing Utilization** from the Layers Settings window.

To view the routing congestion in the Chip Planner, click the Layers icon located next to the Task menu. Under **Background Color Map**, select the **Routing Utilization** map (Figure 12–26). Any areas that exceed the threshold appear red. Use this congestion information to evaluate if you could modify the floorplan, or make changes to the RTL to reduce routing congestion.

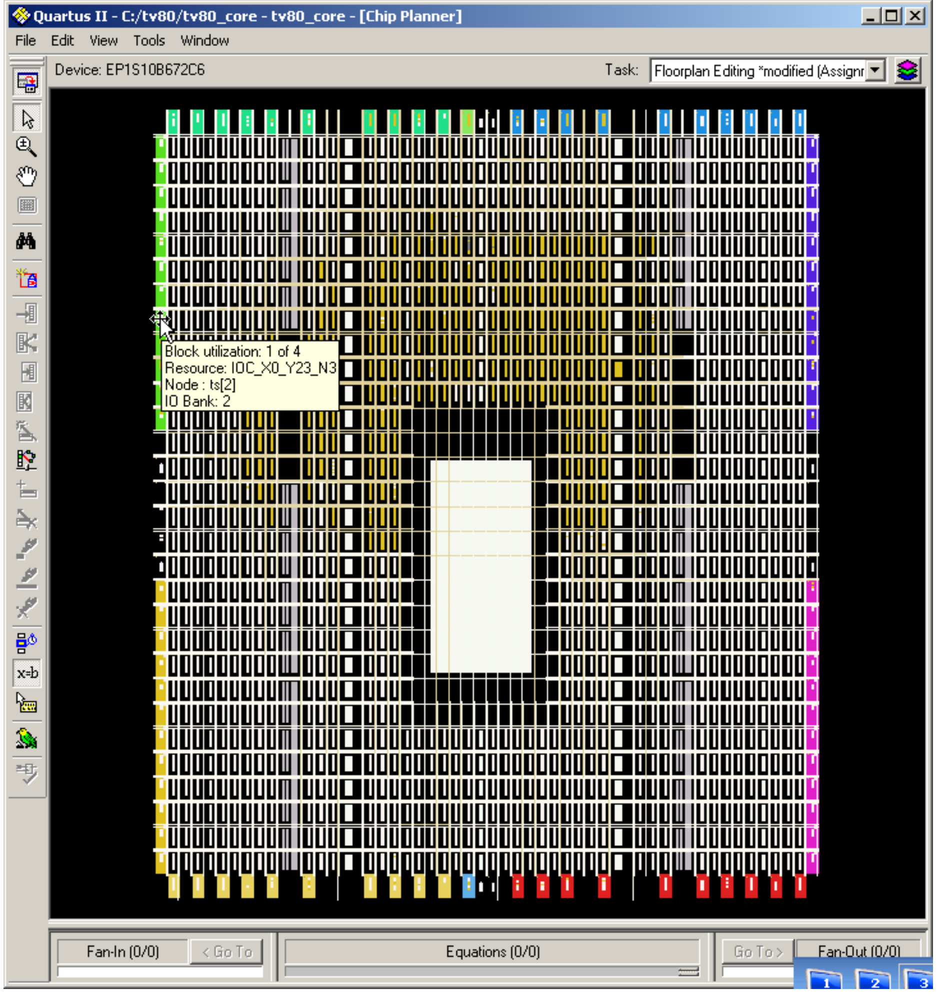
Figure 12–26. Viewing Routing Congestion Map in the Chip Planner



Viewing I/O Banks

The Chip Planner can show all of the I/O banks of the device. To see the I/O bank map of the device, click the Layers icon located next to the Task menu. Under **Background Color Map**, select **I/O Banks**. Refer to Figure 12–27.

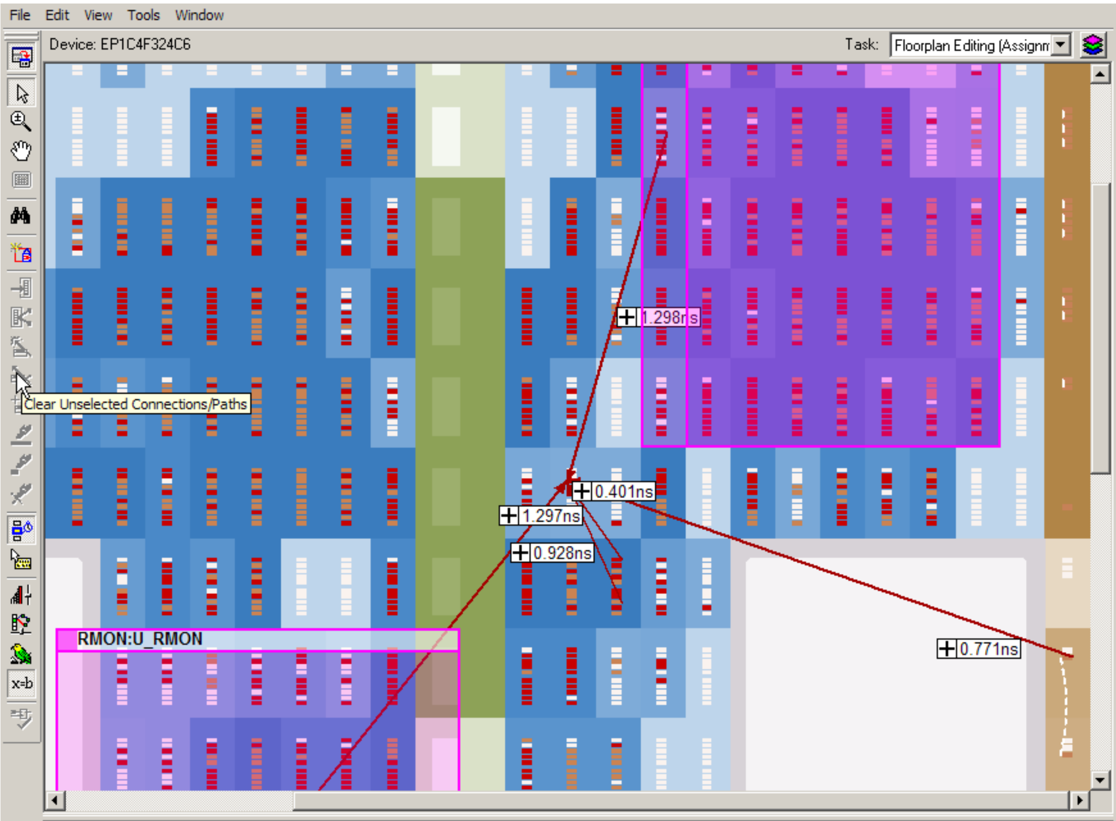
Figure 12–27. Viewing I/O Banks in the Chip Planner



Generating Fan-In and Fan-Out Connections

This feature enables you to view the atoms that fan-in to or fan-out from the selected atom. To remove the connections displayed, use the Clear Unselected Connections/Paths icon in the Chip Planner toolbar. Figure 12–28 shows the fan-in connections for the selected resource.

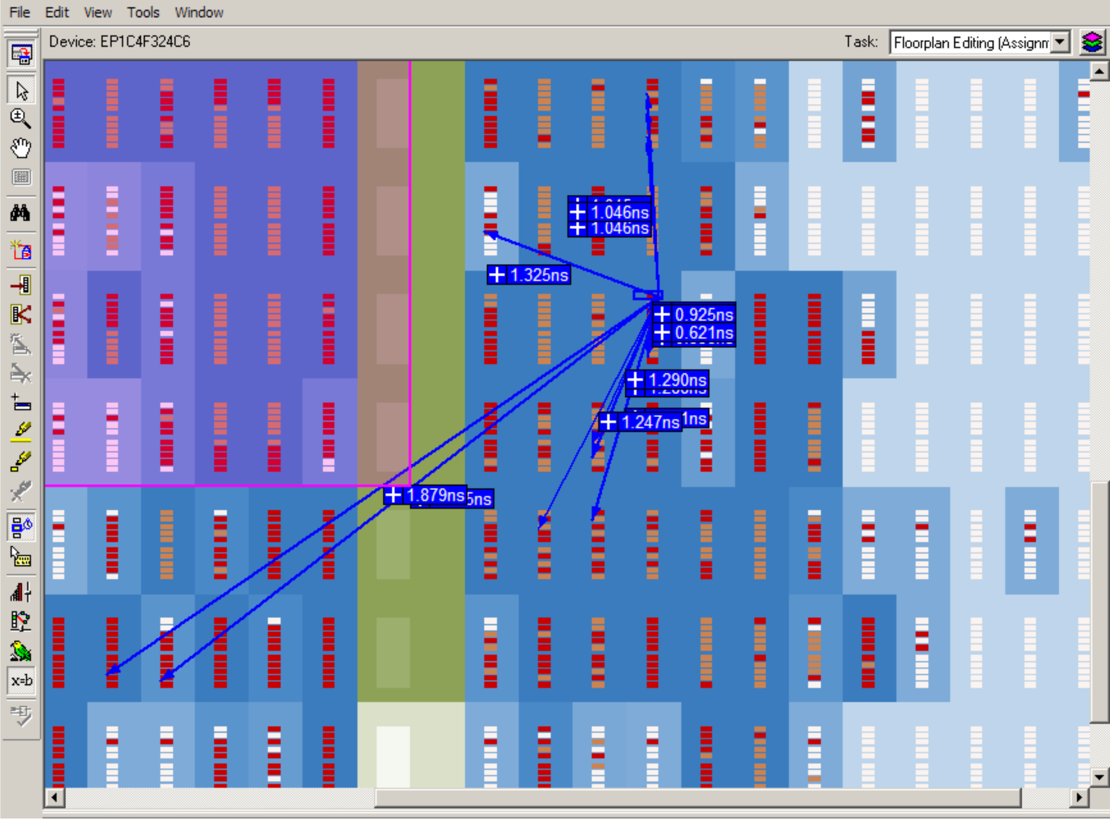
Figure 12–28. Generated Fan-In



Generating Immediate Fan-In and Fan-Out Connections

This feature enables you to view the immediate resource that is the fan-in or fan-out connection for the selected atom. For example, selecting a logic resource and choosing to view the immediate fan-in enables you to see the routing resource that drives the logic resource. You can generate immediate fan-in and fan-outs for all logic resources and routing resources. To remove the connections that are displayed, click the Clear Connections icon in the toolbar. Figure 12–29 shows the immediate fan-out connections for the selected resource.

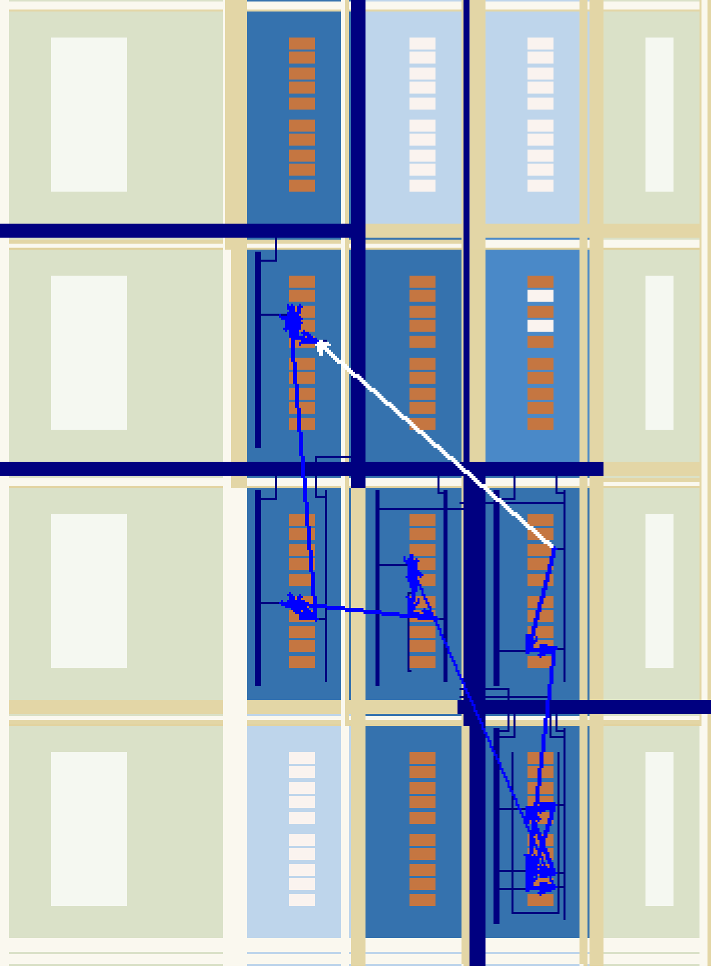
Figure 12–29. Immediate Fan-Out Connection



Highlight Routing

This feature enables you to highlight the routing resources used for a selected path or connection. Figure 12–30 shows the routing resources used between two logic elements.

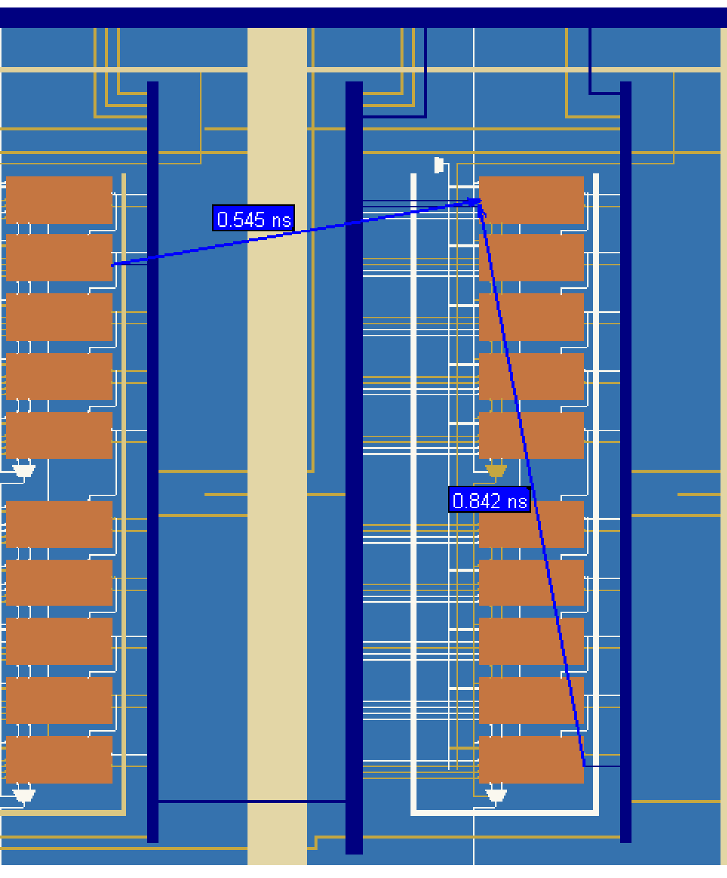
Figure 12–30. Highlight Routing



Show Delays

You can view the timing delays for the highlighted connections when generating connections between elements. For example, you can view the delay between two logic resources or between a logic resource and a routing resource. Figure 12–31 shows the delays between several logic elements.

Figure 12–31. Show Delays



Exploring Paths in the Chip Planner

You can use the Chip Planner to explore paths between logic elements. The following example uses the Chip Planner to traverse paths from the Timing Analysis report.

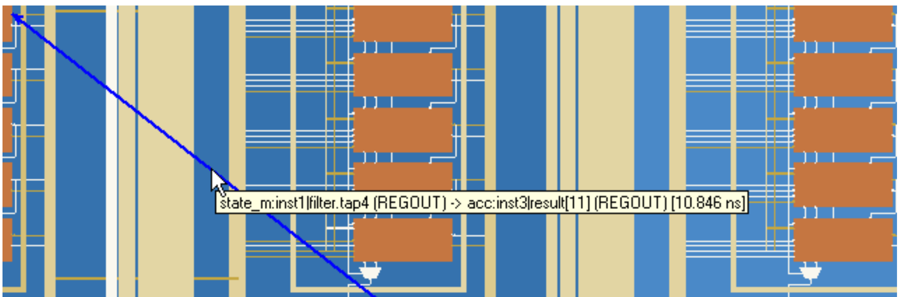
Locate Path from the Timing Analysis Report to the Chip Planner

To locate a path from the Timing Analysis Report to the Chip Planner, perform the following steps:

1. Select the path you want to locate.
2. Right-click the path in the Timing Analysis Report, point to **Locate**, and click **Locate in Chip Planner (Floorplan & Chip Editor)**.

Figure 12–32 shows the path that is displayed in the Chip Planner.

Figure 12–32. Resulting Path

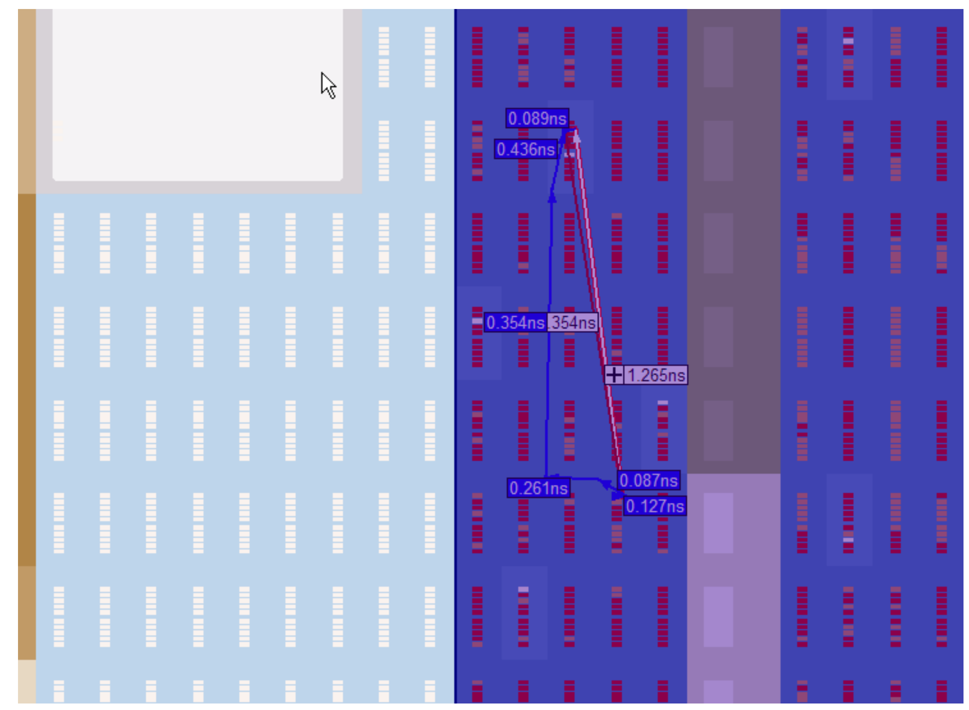


To view the routing resources taken for a path you have located in the Chip Planner, click the Highlight Routing icon in the Chip Planner toolbar, or from the View menu, click **Highlight Routing**.

Analyzing Connections for a Path

To determine the connections between items in the Chip Planner, click the Expand Connections/Paths icon on the toolbar. To add the timing delays between each connection, click the Show Delays icon on the toolbar. Figure 12–33 shows the connections for the selected path that are displayed in the Chip Planner. To see the constituent delays on the selected path, click on the "+" sign next to the path delay displayed in the Chip Planner.

Figure 12–33. Path Analysis

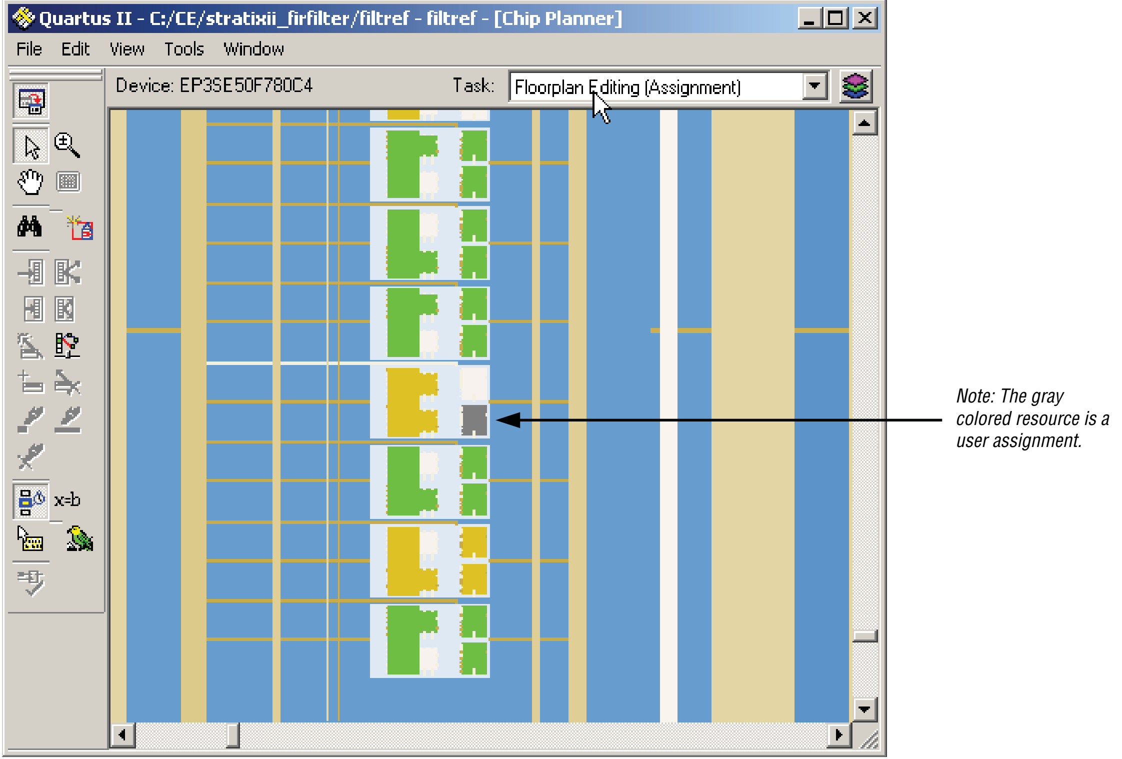


Viewing Assignments in the Chip Planner

Location assignments can be viewed by selecting the appropriate layer set from the tool. To view location assignments in the Chip Planner, select the **Floorplan Editing (Assignment)** task or any custom task with Assignment editing mode. See Figure 12–34.

The Chip Planner shows location assignments graphically, by displaying assigned resources in a particular color (gray, by default). You can create or move an assignment by dragging the selected resource to a new location.

Figure 12–34. Viewing Assignments in the Chip Planner



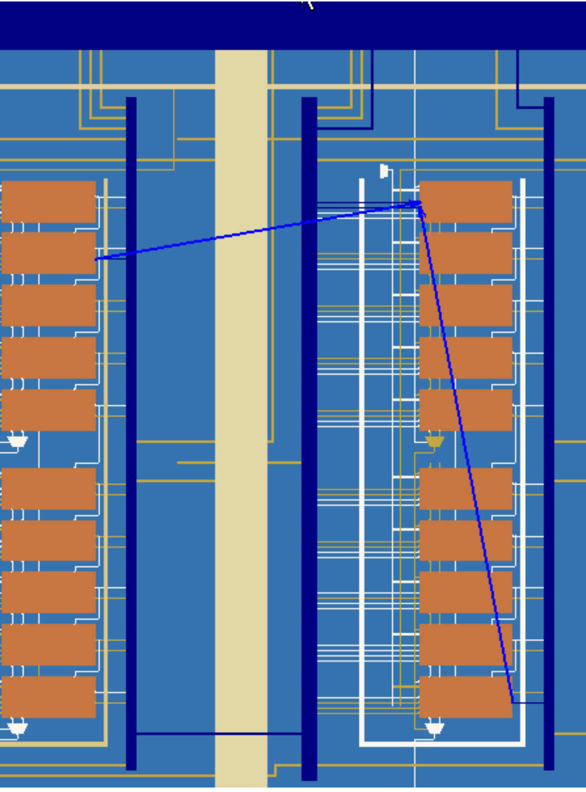
You can make node and pin location assignments and assignments to LogicLock regions and custom regions using the drag-and-drop method in the Chip Planner. The assignments that you create are applied by the Fitter during the next place-and-route operation.

To learn more about working with location assignments, refer to the Quartus II Help.

Viewing Routing Channels for a Path in the Chip Planner

To determine the routing channels between connections, click the Highlight Routing icon on the toolbar. Figure 12–35 shows the routing channels used for the selected path in the Chip Planner.

Figure 12–35. Highlight Routing

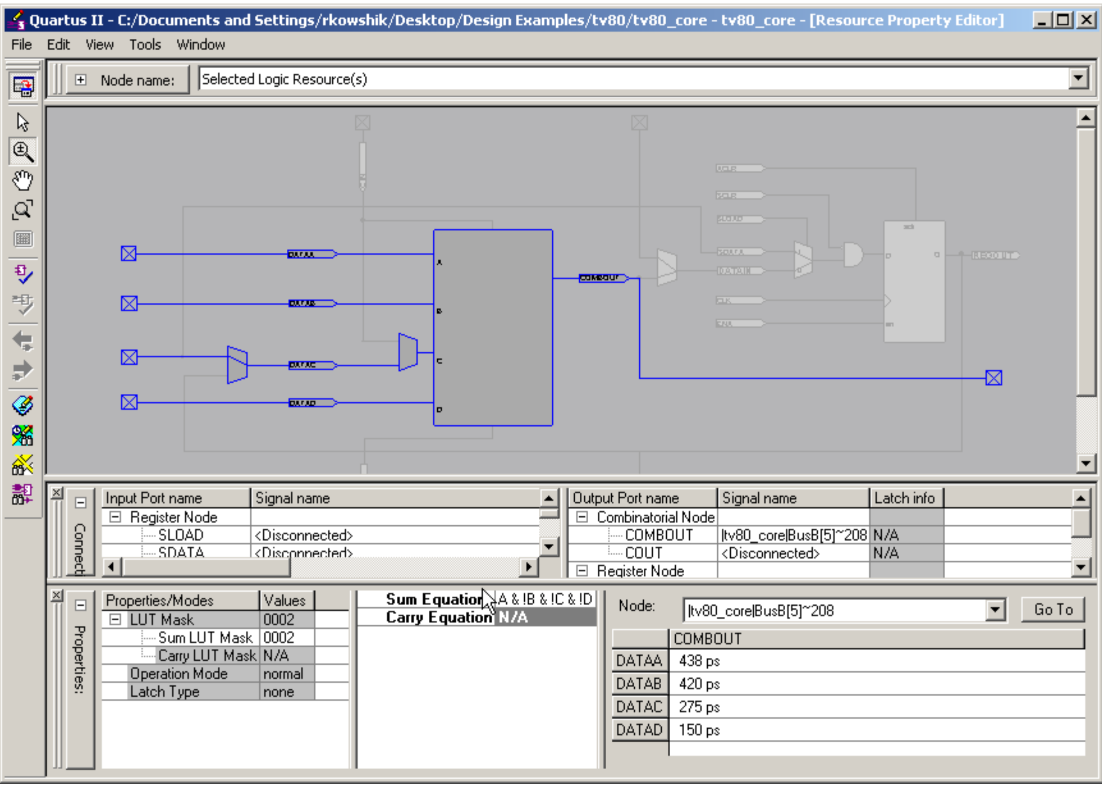


You can view and edit resources in the FPGA using the Resource Property Editor mode of the Chip Planner tool. For more information, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

Cell Delay Table

You can view the propagation delay from all inputs to all outputs for any LE in your design. To see the Cell Delay Table for an atom, select the atom in the Chip Planner and right-click. From the pop-up menu, click **Locate** and then click **Locate in Resource Property Editor**. The Resource Property window shows you the atom properties along with the Cell Delay Table, indicating the propagation delay from all inputs to all outputs. Figure 12–36 shows the Cell Delay Table.

Figure 12–36. Cell Delay Table



Timing numbers are displayed only when there is a direct path between the source input port and the destination output port. In cases where there is no path, or the path requires an intermediate buried timing node, the displayed cell delay is given as "N/A."

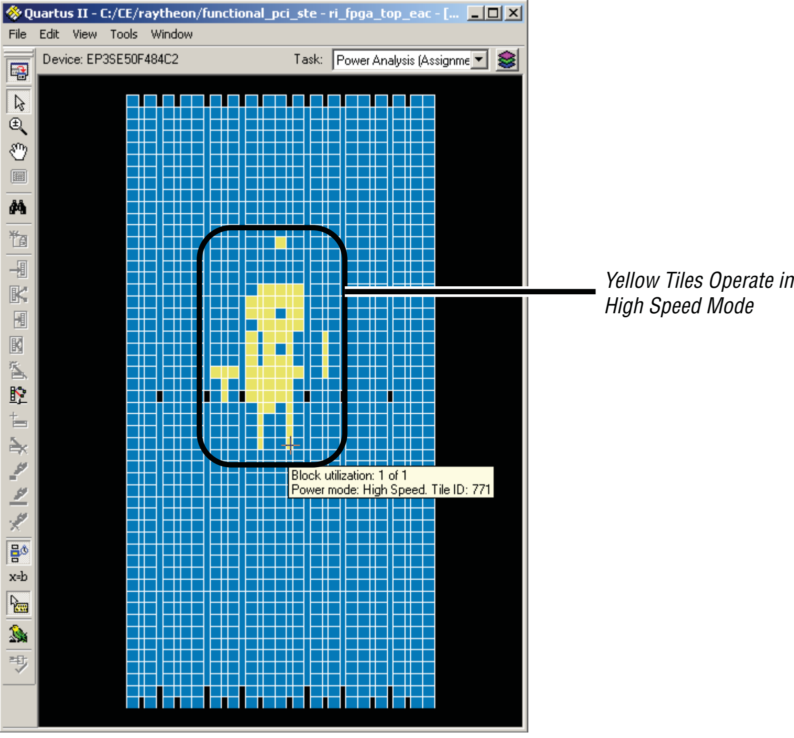
Viewing High-Speed and Low Power Tiles in Stratix III Devices in the Chip Planner

The Chip Planner has a predefined task, **Power Analysis (Assignment)**, which shows the power map of a Stratix III device. Stratix III devices have ALMs that can operate in either high-speed mode or low-power mode. The power mode is set during the fitting process in the Quartus II software. These ALMs are grouped together to form larger blocks, called "tiles."

To learn more about power analyses and optimizations in Stratix III devices, refer to *AN 437: Power Optimization in Stratix III FPGAs*.

When the **Power Analysis (Assignment)** task is selected in the Chip Planner for Stratix III devices, low-power and high-speed tiles are displayed in different colors; yellow tiles operate in a high-speed mode, while blue tiles operate in a low-power mode (see Figure 12–37). In this mode, you can perform all floorplan-related functions for this task; however, you cannot edit any tiles to change the power mode.

Figure 12–37. Viewing High-Speed and Low Power Tiles in a Stratix III Device



Design Analysis Using the Timing Closure Floorplan

For older device families not supported by the Chip Planner, you can perform floorplan analysis using the Timing Closure Floorplan. The APEX, ACEX, FLEX 10K, and MAX 7000 device families are supported only by the Timing Closure Floorplan. This section explains how to use the Timing Closure Floorplan to enhance your FPGA design analysis.

Table 12–1 on page 12–1 lists the device families supported by the Timing Closure Floorplan Editor and the Chip Planner.

The Timing Closure Floorplan Editor allows you to analyze your design visually before and after performing a full design compilation in the Quartus II software. This floorplan editor, used in conjunction with the Quartus II Timing Analyzer, provides a method for performing design analysis.

To start the Timing Closure Floorplan Editor, on the Assignments menu, click **Timing Closure Floorplan**.

If the device in your project is not supported by the Timing Closure Floorplan, the following message appears: `Can't display a floorplan: the current device family is only supported by Chip Planner`.

If your target device is supported by the Timing Closure Floorplan, you can also start the Timing Closure Floorplan tool by right-clicking any of the following sources, pointing to **Locate**, and clicking **Locate in Timing Closure Floorplan**:

- Compilation Report
- Node Finder
- Project Navigator
- RTL source code
- RTL Viewer
- Simulation Report
- Timing Report

Figure 12–38 shows the icons in the Timing Closure Floorplan toolbar.

Figure 12–38. Timing Closure Floorplan Icons

Timing Closure Floorplan Views

The Timing Closure Floorplan Editor provides the following views of your design:

- Field view
- Interior Cells view
- Interior LAB view
- Interior MegaLABs view

Additionally, the following two views are available, which open up the Pin Planner:

- Package Top view
- Package Bottom view

Field View

The Field view provides a color-coded, high-level view of the resources used in the device floorplan. All device resources, such as embedded system blocks (ESBs) and MegaLAB blocks, are outlined.

To view the details of a resource in the Field view, select the resource, right-click, and click **Show Details**. To hide the details, select all the resources, right-click, and click **Hide Details** (Figure 12–39).

Figure 12–39. Show and Hide Details of a Logic Array Block in Field View

Other Views

You can also view your design in the Timing Closure Floorplan Editor with the Interior Cells, Interior LABs, Package Top, and Package Bottom views. Use the View menu to display the various floorplan views. The Interior Cells view provides a detailed view of device resources, including device pins and individual logic elements within a MegaLAB.

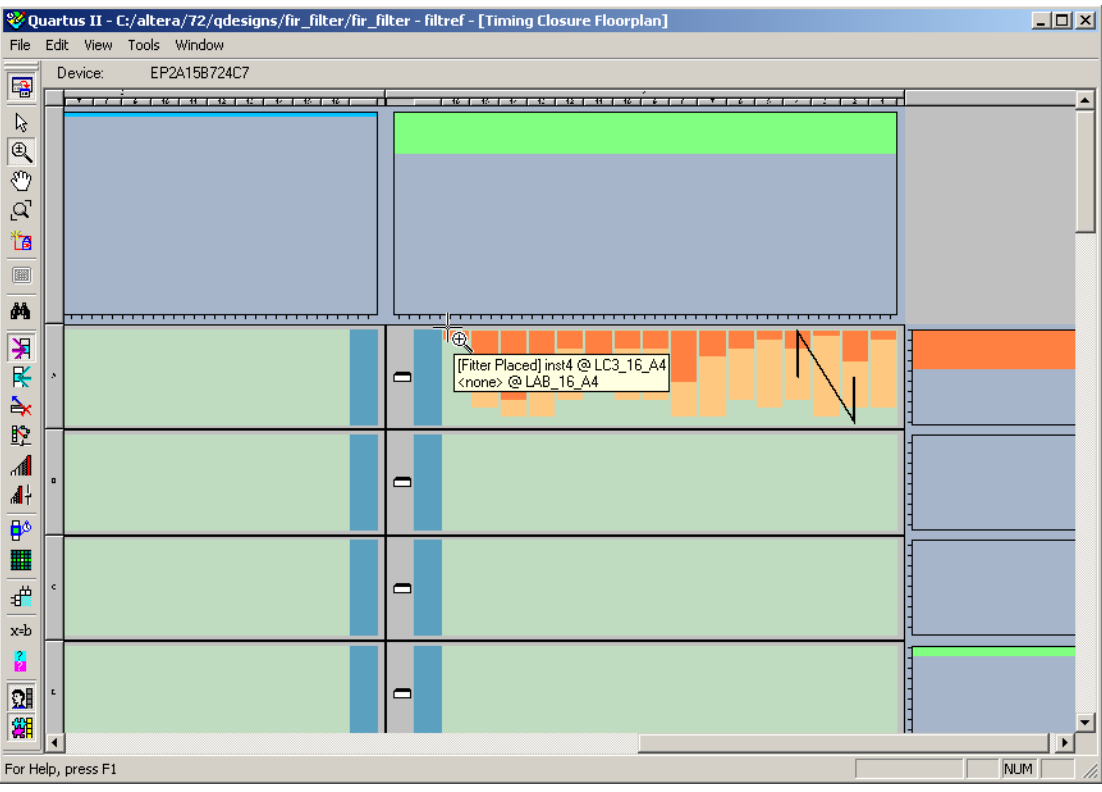
Viewing Assignments

The Timing Closure Floorplan Editor differentiates between user assignments and Fitter placements. User assignments include LogicLock regions and are made by a user.

If the device is changed after a compilation, the user assignment and Fitter placement options cannot be used together. When this situation occurs, the Fitter placement displays the last compilation result and the user assignment displays the floorplan of the newly selected device.

To see the user assignments, click the Show User Assignments icon in the Floorplan Editor toolbar, or, on the View menu, point to **Assignments** and click **Show User Assignments**. To see the Fitter placements, click the Show Fitter Placements icon in the Floorplan Editor toolbar, or, on the View menu, point to **Assignments** and click **Show Fitter Placements**. Figure 12–40 shows the Fitter placements.

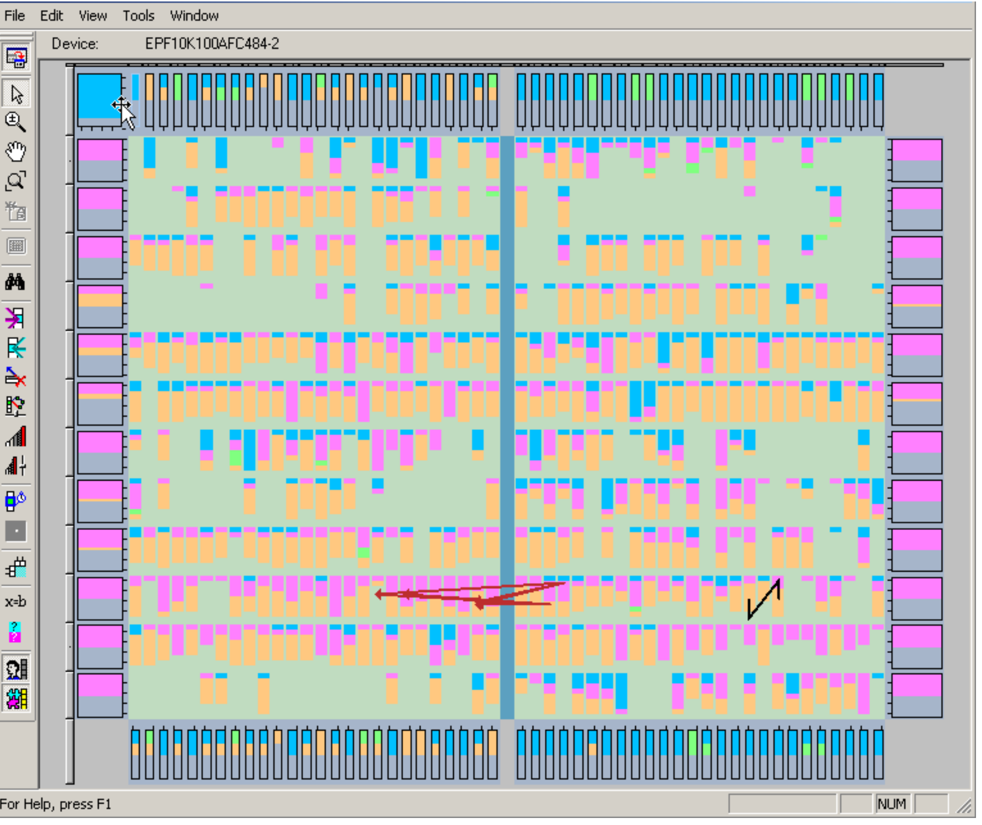
Figure 12–40. Fitter Placements



Viewing Critical Paths

The View Critical Paths feature displays routing paths in the floorplan, as shown in Figure 12–41. The criticality of a path is determined by its slack and is also shown in the timing analysis report.

Figure 12–41. Critical Paths



To view critical paths in the Timing Closure Floorplan, click the Critical Path Settings icon on the toolbar, or, on the View menu, point to **Routing** and click **Critical Path Settings**.

When viewing critical paths, you can specify the clock in the design to be viewed. You can determine which paths to display by specifying the slack threshold in the slack field.

Timing settings must be made and timing analysis performed for paths to be displayed in the floorplan.

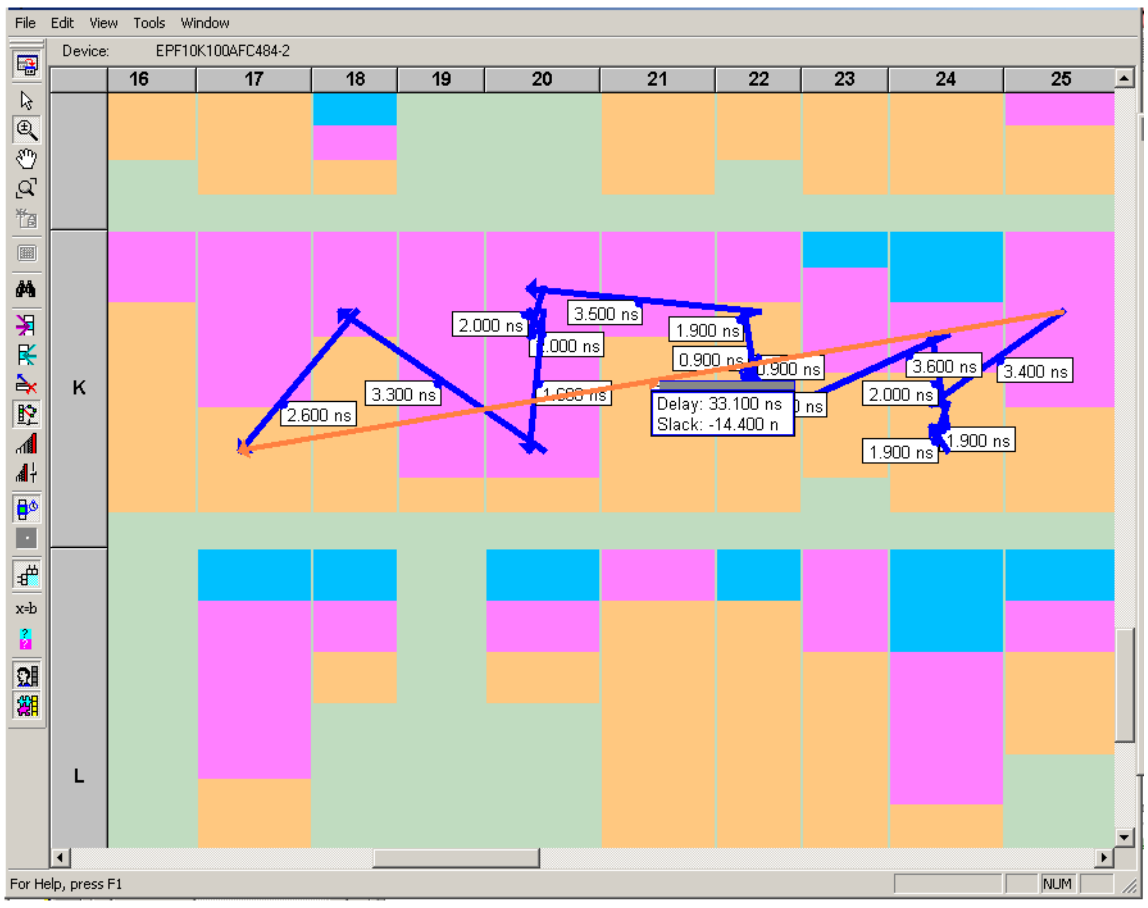
For more information about performing static timing analyses of your design with a timing analyzer, refer to the *Quartus II Classic Timing Analyzer* and the *Quartus II TimeQuest Timing Analyzer* chapters in volume 3 of the *Quartus II Handbook*.

Viewing the critical paths is useful for determining the criticality of nodes based on placement. There are a number of ways to view the details of the critical path.

The default view in the Timing Closure Floorplan shows the path with the source and destination registers displayed. You can also view all the combinational nodes along the worst-case path between the source and destination nodes. To view the full path, click on the delay label to select the path, right-click, and select **Show Path Edges**. Figure 12–42 shows the critical path through combinational nodes. To hide the combinational nodes, select the path, right-click, and select **Hide Path Edges**.

You must view the routing delays to select a path.

Figure 12–42. Worst-Case Combinational Path Showing Path Edges



To assign the path to a LogicLock region using the **Paths** dialog box, select the path, right-click, and select **Properties**.

You can determine the maximum routing delay between two nodes within a LogicLock region. To use this feature, on the View menu, point to **Routing** and click **Show Intra-region Delay**. Place your cursor over a Fitter-placed LogicLock region to see the maximum delay.

For more information about making path assignments with the **Paths** dialog box, refer to "Timing Closure Floorplan View" on page 12–48.

After running timing analysis, you can locate timing paths from the timing reports file produced. Right-click on any row in the report file, point to **Locate**, and click **Locate in Timing Closure Floorplan**. The Timing Closure Floorplan window opens with the timing path highlighted.

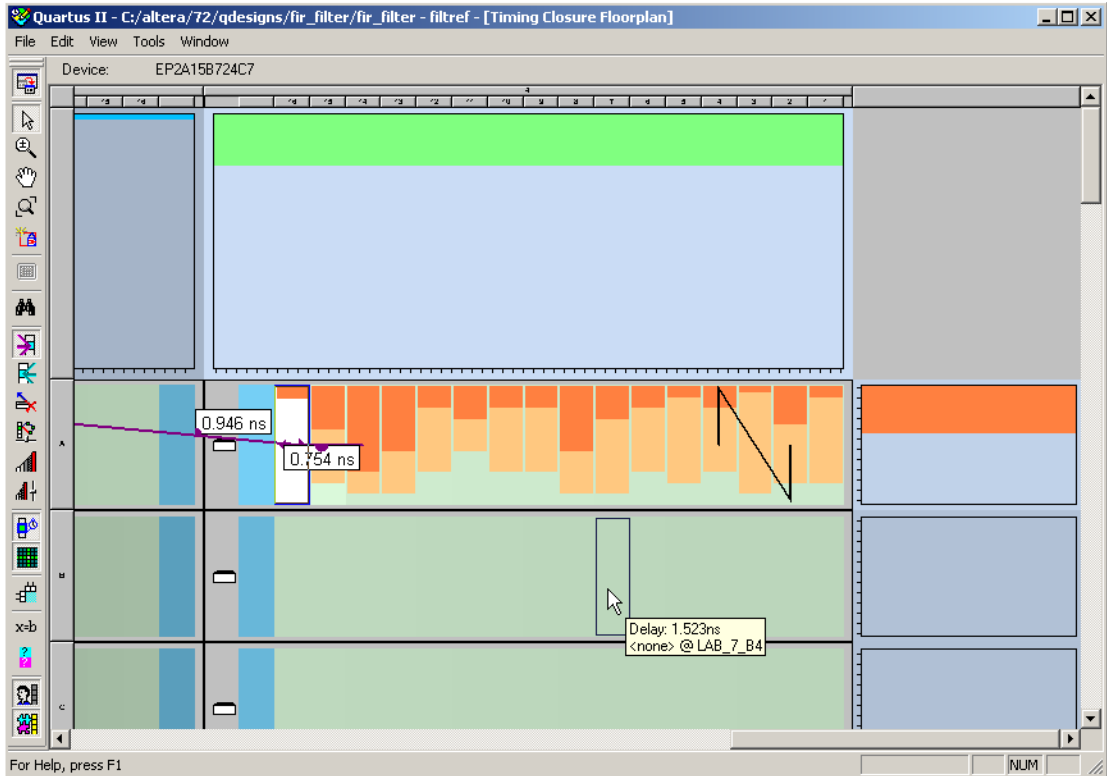
For more information about optimizing your design in the Quartus II software, refer to the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*. With the options and tools available in the Timing Closure Floorplan and the techniques described in that chapter, the Quartus II software can help you achieve timing closure in a more time-efficient manner.

Physical Timing Estimates

In the Timing Closure Floorplan Editor, you can select a resource and see the approximate delay to any other resource on the device. After you select a resource, the delay is represented by the color of potential destination resources. The darker the color of the resource, the longer the delay.

You can also obtain an approximation of the delay between two points by selecting a source and holding your cursor over a potential destination resource (Figure 12–43).

Figure 12–43. Delay for Physical Timing Estimate in the Timing Closure Floorplan



The delays represent an estimate based on probable best-case routing. The delay can be greater than what is shown, depending on the availability of routing resources. In general, there is a strong correlation between the probable and actual delay.

To view the physical timing estimates, click the Show Physical Timing Estimate icon, or, on the View menu, point to **Routing** and click **Show Physical Timing Estimates**.

You can use the physical timing estimate information when manually placing logic in a device. This information allows you to place critical nodes and modules closer together, and non-critical or unrelated nodes and modules further apart, reducing the routing congestion between critical and non-critical entities and modules. This placement enables the Quartus II Fitter to meet the timing requirements.

Viewing Routing Congestion

The View Routing Congestion feature allows you to determine the percentage of routing resources used after a compilation. This feature identifies where there is a lack of routing resources.

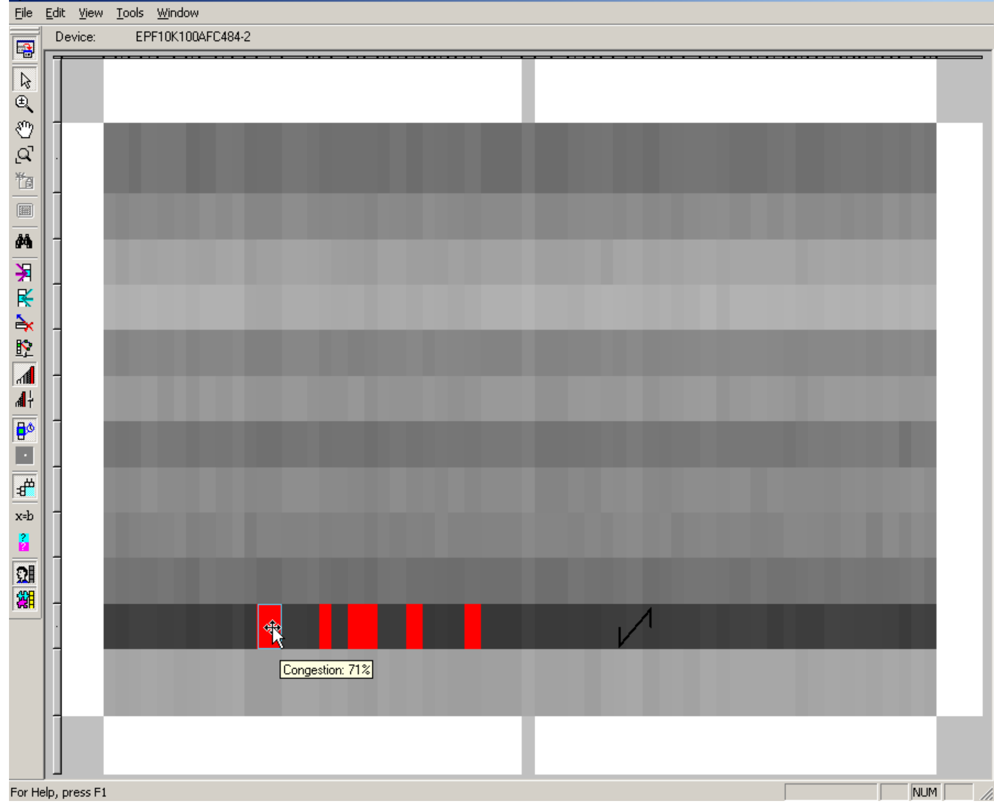
The congestion is shown by the color and shading of logic resources. The darker shading represents a greater routing resource utilization. Logic resources that are red have routing resource utilization greater than the specified threshold.

The routing congestion view is only available from the View menu when you enable the Field view. To view routing congestion in the floorplan, click the Show Routing Congestion icon, or on the View menu, point to **Routing** and click **Show Routing Congestion**. To set the criteria for the critical path you want to view, click the Routing Congestion Settings icon, or on the View menu, point to **Routing** and click **Routing Congestion Settings**.

In the **Routing Congestion Settings** dialog box, you can choose the routing resource (interconnect type) you want to examine and set the congestion threshold. Routing congestion is calculated based on the total resource usage divided by the total available resources.

If you use the routing congestion viewer to determine where there is a lack of routing resources, examine each routing resource individually to determine which ones use close to 100% of the available resources (Figure 12–44). Use this congestion information to evaluate whether you should modify the floorplan, or make changes to the RTL to reduce routing congestion.

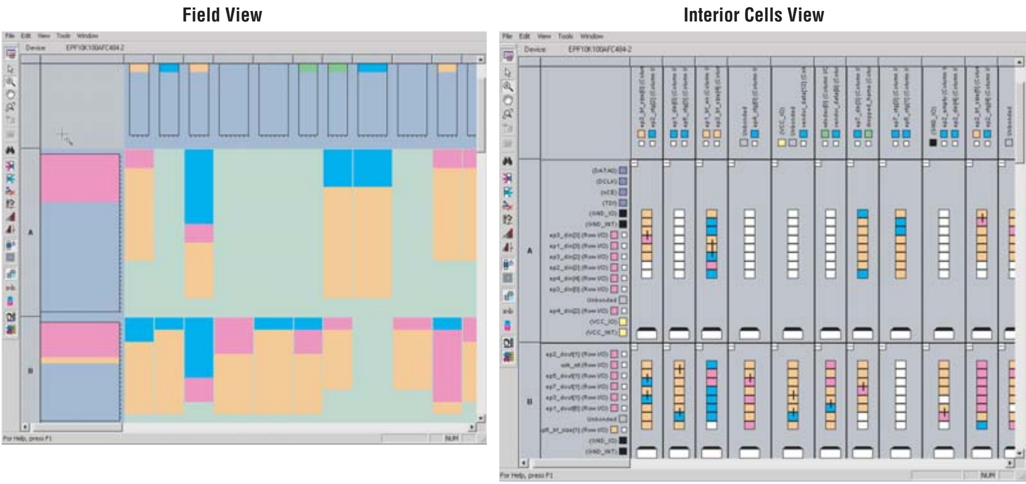
Figure 12–44. Routing Congestion of a Sample Design in a Cyclone Device



Timing Closure Floorplan View

The Timing Closure Floorplan view provides you with current and previous compilation assignments on one screen. You can display device resources in either of two views: the Field view or the Interior Cells view, as shown in Figure 12–45. The Field view provides an uncluttered view of the device floorplan in which all device resources, such as embedded system blocks (ESBs) and MegaLAB blocks, are outlined. The Interior Cells view provides a detailed view of device resources, including individual logic elements within a MegaLAB and device pins.

Figure 12–45. Timing Closure Floorplan Editor



LogicLock Regions in the Timing Closure Floorplan

If you have defined a LogicLock region in a device supported by the Timing Closure Floorplan, then you must assign resources to it using the Timing Closure Floorplan, the LogicLock Regions dialog box, or a Tcl script.

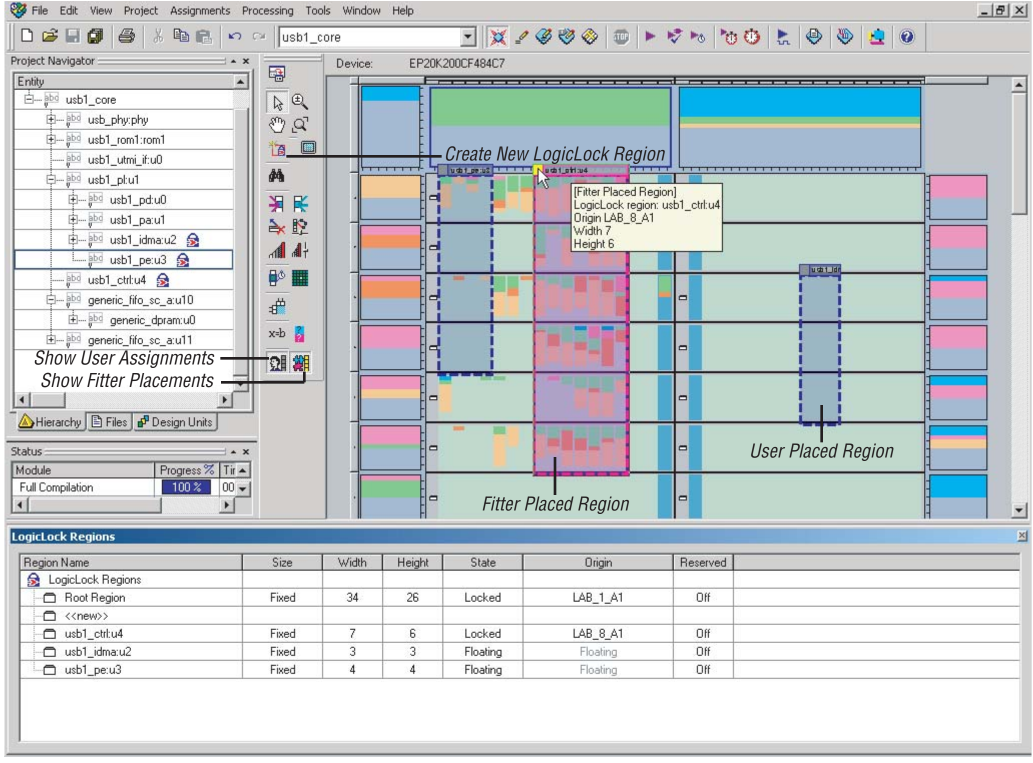
Creating LogicLock Regions in the Timing Closure Floorplan Editor

The Timing Closure Floorplan Editor has toolbar buttons that are used to manipulate LogicLock regions as shown in Figure 12–46. You can use the Create New LogicLock Region icon to draw LogicLock regions in the device floorplan.

The Timing Closure Floorplan Editor displays LogicLock regions when you click the Show User Assignments or Show Fitter Placements icons. The type of region determines its appearance in the floorplan.

The Timing Closure Floorplan Editor differentiates between user assignments and Fitter placements. When the **Show User Assignments** option is turned on in the Timing Closure Floorplan, you can see current assignments made to a LogicLock region. When the **Fitter Placement** option is turned on, you can see the properties of the LogicLock region after the most recent compilation. User-assigned LogicLock regions appear in the Timing Closure Floorplan Editor with a dark blue border. Fitter-placed regions appear in the Timing Closure Floorplan Editor with a magenta border (Figure 12–46).

Figure 12–46. Timing Closure Floorplan Editor Toolbar Buttons



Using Drag and Drop to Place Logic

You can drag selected logic displayed in the **Hierarchy** tab of the Project Navigator, in the Node Finder, or in a schematic design file, and drop it into the Timing Closure Floorplan or the **LogicLock Regions** dialog box. Figure 12–14 on page 12–18 shows logic that has been dragged from the **Hierarchy** tab of the Project Navigator and dropped into a LogicLock region in the Timing Closure Floorplan.

Rubber Banding

On the View menu, click **Routing**, and select **Rubber Banding** to show existing connections between LogicLock regions and nodes during movement of LogicLock regions within the Timing Closure Floorplan Editor.

Show Connection Count

You can determine the number of connections between LogicLock regions by turning on the **Show Connection Count** option.

Analyzing LogicLock Region Connectivity Using the Timing Closure Floorplan

To see how logic in LogicLock regions is connected, view the connectivity between LogicLock regions. This capability is extremely useful when entities are assigned to LogicLock regions. You can also see the fan-in and fan-out of selected LogicLock regions.

To view the connections in the Timing Closure Floorplan, on the View menu, point to **Routing** and click **Show LogicLock Regions Connectivity**. Figure 12–47 shows standard LogicLock region connections.

Figure 12–47. LogicLock Region Connections with Connection Count

File Edit View Tools Window
Device: EP2A15B724C7
usb_tx
19
generic_dpram
usb_rx_r

54
usb1_ctrl:u4
For Help, press F1
NUM

As shown in Figure 12–47, the thickness of the connection line indicates how many connections exist between regions. To see the number of connections between regions, on the View menu, point to **Routing** and click **Show Connection Count**.

LogicLock region connectivity is applicable only when the user assignments are enabled in the Timing Closure Floorplan. When you use floating LogicLock regions, the origin of the user-assigned region is not necessarily the same as that of the Fitter-placed region. You can change the origin of your floating LogicLock regions to that of the most recent compilation either in the LogicLock Regions window or by selecting **Back-Annotate Origin and Lock** under **Location** in the **LogicLock Regions Properties** dialog box.

To view the fan-in or fan-out of a LogicLock region in the Timing Closure Floorplan, select the user-assigned LogicLock region while the fan-in or the fan-out option is turned on.

To turn on the **fan-in** option, click the Show Node Fan-In icon, or, on the View menu, point to **Routing** and click **Show Node Fan-In**. To turn on the fan-out option, click the Show Node Fan-Out icon, or on the View menu, point to **Routing** and click **Show Node Fan-Out**. Only the nodes that have user assignments are visible when viewing fan-in or fan-out of LogicLock regions.

Using LogicLock Methodology for Older Device Families

The LogicLock methodology is recommended as an optimization method only for older device families, such as the MAX II and APEX II device families, which do not support incremental compilation. In this methodology, you optimize your design and lock it down one module at a time. With the LogicLock feature, you can create and implement each logic module independently in a hierarchical or team-based design. You can use this LogicLock methodology to optimize and preserve timing, placement, or both for devices that do not support incremental compilation.

Using the LogicLock methodology as an optimization strategy is less effective on newer device families such as those device families in the Cyclone and Stratix series of devices. Altera does not recommend using the LogicLock methodology for designs in such devices, although the feature can be supported on some devices in these series. However, you can use LogicLock regions in conjunction with incremental compilation to create a floorplan and preserve timing results for these devices in the Stratix and Cyclone series of devices.

For more information about hierarchical and team-based design, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

The Quartus II LogicLock Methodology

When you use the LogicLock methodology for older devices, you can place the logic in each netlist file in a fixed or floating region in an Altera device. You can then maintain the placement and, if necessary, the routing of your blocks in the Altera device, thus retaining performance.

If you want to follow this methodology, create a LogicLock region in a supported device and then assign logic to the region. After you optimize the logic placed within the boundaries of a region to achieve the required performance, you must back-annotate the region's contents to lock the logic placement and routing. Locking the placement and routing preserves the performance when you integrate the region with the rest of the design.

Figure 12–48 compares the traditional design flow with the LogicLock design flow.

Figure 12–48. Traditional Design Flow Compared with Quartus II LogicLock Design Flow

Traditional Design Flow

Design → Integrate → Optimize → Verify

LogicLock Design Flow

Design, Optimize & Verify → Integrate → Verify

For more information about block-based design with the LogicLock feature, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Improving Design Performance

LogicLock methodology helps you optimize and preserve performance. You can use the LogicLock regions to place modules, entities, or any group of logic into regions in a device's floorplan. LogicLock assignments can be hierarchical, which allows you to have more control over the placement and performance of each module and group of modules.

In addition to hierarchical blocks, you can apply LogicLock constraints to individual nodes; for example, you can make a wildcard path-based LogicLock assignment on a critical path. This technique is useful if the critical path spans multiple design blocks.

Although LogicLock constraints can improve performance, they can also degrade performance if they are not applied correctly. They can also result in increased resource usage.

LogicLock Restrictions

During the design process, placing restrictions on nodes or entities in the design is often necessary. These restrictions can conflict with the node or entity assignments for a LogicLock region. To avoid conflicts, consider the order of precedence given to constraints by the Quartus II software during fitting. The following assignments have priority over LogicLock region assignments:

- Assignments to device resources and location assignments
- Fast input-register and fast output-register assignments
- Local clock assignments for Stratix devices
- Custom region assignments
- I/O standard assignments

The Quartus II software removes nodes and entities from LogicLock regions if any of these constraints are applied to them.

After a LogicLock region is back-annotated, the Quartus II software can place the region only in areas of the device with exactly the same resources.

You can compare the performance with and without some of the LogicLock back-annotated node assignments without deleting the LogicLock regions when you optimize your design with the LogicLock flow. Select the specific LogicLock region from the LogicLock regions window, right-click and select **Properties**. Go to the **Content Back-annotation** tab and turn on **Disable back-annotated node locations**.

Preserving Timing Results Using the LogicLock Flow

To preserve the timing results for a design module in the Quartus II software, you must preserve the placement and routing information for all the logic in the design module. For older device families, you can use the LogicLock design methodology to back-annotate logic locations within a LogicLock region, which makes assignments to each node in the design.

When preserving logic placement in an Altera device using LogicLock back-annotation, an atom netlist preserves the node names in subblocks of your design. An atom netlist contains design information that fully describes the submodule logic in terms of the device architecture. In the atom netlist, the nodes are fixed as Altera primitives and the node names do not change if the atom netlist does not change. If a node name changes, any placement information associated with that node, such as LogicLock assignments made when back-annotating a region, is invalid and ignored by the compiler.

If all the netlists are contained in one Quartus II project, use the LogicLock flow to back-annotate the logic in each region. If a design region changes, only the netlist associated with the changed region is affected. When you place and route the design using the Quartus II software, the software has to re-fit only the LogicLock region associated with the changed netlist file.

Turn on the **Prevent further netlist optimization** option when back-annotating a region with the **Synthesis Netlist Optimizations** option, the **Physical Synthesis Optimization** option, or both, turned on. This sets the **Netlist Optimizations** option to **Never Allow** for all nodes in the region, preventing node name changes in the top-level design when the region is recompiled.

You must remove previously back-annotated assignments for a modified block if the node names are different in the newly synthesized version. When you recompile with one new netlist file, the placement and assignments for the unchanged netlist files assigned to other LogicLock regions are not affected. Therefore, you can make changes to code in an independent block and not interfere with another designer's changes, even when all the blocks are integrated into the same top-level design.

With the LogicLock design methodology, you can develop and test submodules without affecting other areas of a design.

For the Quartus II software to achieve optimal placement, you must specify timing assignments, including t_{SU}, t_{CO}, and t_{PD}, for all clock signals in the design.

To facilitate the LogicLock design flow, the Timing Closure Floorplan highlights resources that have back-annotated LogicLock regions.

Atom Netlist Design Information

The atom netlist contains design information that fully describes the module's logic in terms of an Altera device architecture. If the design was synthesized using a third-party tool and then brought into the Quartus II software, an atom netlist already exists and all the nodes have assigned names. You do not have to generate another atom netlist. However, if you use any synthesis netlist optimizations or physical synthesis optimizations, you must generate a Verilog Quartus Mapping Netlist File (**.vqm**) using the Quartus II software, because the original atom netlist might have changed as a result of these optimizations.

Turn on the **Prevent further netlist optimization** option when back-annotating a region with the **Synthesis Netlist Optimizations** option, the **Physical Synthesis Optimization** option, or both, turned on. This sets the **Netlist Optimizations** to **Never Allow** for all nodes in the region, avoiding the possibility of a node name change when the region is imported into the top-level design.

If you synthesized the design from a VHDL Design File (**.vhd**), Verilog Design File (**.v**), Text Design File (**.tdf**), or Block Design File (**.bdf**) in the Quartus II software, you must also create an atom netlist to fix the node names. During compilation, the Quartus II software creates a **.vqm** file in the **atom_netlists** subdirectory in the project directory.

If the atom netlist is generated by a third-party synthesis tool and the design has a black box library of parameterized modules (LPM) functions or Altera megafunctions, you must generate a Quartus II **.vqm** file for the black box modules.

For instructions about creating an atom netlist in the Quartus II software, refer to *Saving Synthesis Results in a Verilog Quartus Mapping File* in the Quartus II Help.

Placement Information

The **.qsf** file contains the module's LogicLock constraint information, including clock settings, pin assignments, and relative placement information for back-annotated regions. To maintain performance, you must back-annotate the module.

Routing Information

The **.rcf** file located in your project directory contains the module's LogicLock routing information. To maintain performance, you must back-annotate the module. When you export LogicLock regions with the **Export back-annotated routing** option, the Quartus II software automatically places the **.rcf** file in the **atom_netlists** directory.

Back-Annotating Routing Information

LogicLock regions not only allow you to preserve the placement of logic from one compilation to the next, they also allow you to retain the routing inside the LogicLock regions. With both placement and routing locked, you have an extremely portable design module that can be used many times in a top-level design without requiring further optimization.

If you back-annotate the routing in a LogicLock region with auto size and floating properties, the Quartus II software automatically changes the region properties to **Fixed** and **Locked**. The reason for this property change is that routing resources are generally different in different locations of the Altera device.

Back-annotate routing only when necessary, because doing so can prevent the Quartus II Fitter from finding an optimal fit for your design.

Back-annotate the routing from the Assignments menu, by choosing **Routing** from the **Back-Annotate Assignments** dialog box.

If you are not using an atom netlist, you must turn on the **Save a node-level netlist of the entire design into a persistent source file** option (on the Assignments menu, click **Back-Annotate Assignments**) if back-annotation of routing is selected. Writing out a **.vqm** file causes the Quartus II software to enforce persistent naming of nodes when saving the routing information. The **.vqm** file is then used as the design's source.

Back-annotated routing information is valid only for regions with fixed sizes and locked locations. The Quartus II software ignores the routing information for LogicLock regions you specify as floating and automatically sized.

The **Disable Back-Annotated Node locations** option in the **LogicLock Region Properties** dialog box is not available if the region contains both back-annotated routing and back-annotated nodes.

Back-Annotating LogicLock Regions

To back-annotate the contents of your LogicLock regions, perform the following steps:

1. In the **LogicLock Region Properties** dialog box, click **Back-Annotate Contents**. The **Back-Annotate Assignments** dialog box appears.
2. In the **Back annotation type** list, select **Advanced** and click **OK**.
3. Click **OK**.

If you are using the incremental compilation flow, logic back-annotation is not required. Preserve placement results using the Post-Fit Netlist Type instead of making placement assignments with back-annotation as described in this section.

You can also back-annotate routing within LogicLock regions to preserve performance of the regions. For more information about back-annotating routing, refer to "Back-Annotating Routing Information" on page 12–55.

Back-annotation is not supported for newer device families, such as the Stratix IV GX, Stratix III, and Cyclone III devices.

When you back-annotate a region's contents, all of the design element nodes appear under **Back-annotated nodes** with an assignment to a device resource under **Node Location**; for example, LAB, memory block, or DSP block. Each node's location is the placement of the node after the most recent compilation. If the origin of the region changes, the node's location changes to maintain the same relative placement. This relative placement preserves the performance of the module. If cell assignments are demoted, the nodes are assigned to LABs rather than directly to logic cells. This provides more flexibility to the Fitter, and improves the chances of a fit.

Scripting Support

You can run procedures and create the settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II command-line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ↵
```

The same information is available in the Quartus II Help, and in PDF format in the *Quartus II Scripting Reference Manual*.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

For information about all settings and constraints in the Quartus II software, refer to the *Quartus II Settings File Reference Manual*.

Initializing and Uninitializing a LogicLock Region

You must initialize the LogicLock data structures before creating or modifying any LogicLock regions and before executing any of the Tcl commands listed below.

Use the following Tcl command to initialize the LogicLock data structures:

```
initialize_logiclock
```

Use the following Tcl command to uninitialize the LogicLock data structures before closing your project:

```
uninitialize_logiclock
```

Creating or Modifying LogicLock Regions

Use the following Tcl command to create or modify a LogicLock region:

```
set_logiclock -auto_size true -floating true -region \ <my_region-name>
```

In the above example, the region's size is set to auto and the state is set to floating.

If you specify a region name that does not exist in the design, the command creates the region with the specified properties. If you specify the name of an existing region, the command changes all properties you specify and leaves unspecified properties unchanged.

For more information about creating LogicLock regions, refer to the sections "Creating LogicLock Regions" on page 12–7 and "Creating LogicLock Regions with the Chip Planner" on page 12–19.

Obtaining LogicLock Region Properties

Use the following Tcl command to obtain LogicLock region properties. This example returns the height of the region named `my_region`:

```
get_logiclock -region my_region -height
```

Assigning LogicLock Region Content

Use the following Tcl commands to assign or change nodes and entities in a LogicLock region. This example assigns all nodes with names matching `fifo*` to the region named `my_region`.

```
set_logiclock_contents -region my_region -to fifo*
```

You can also make path-based assignments with the following Tcl command:

```
set_logiclock_contents -region my_region -from fifo -to ram*
```

For more information about assigning LogicLock Region Content, refer to "Assigning LogicLock Region Content" on page 12–18.

Prevent Further Netlist Optimization

Use this Tcl code to prevent further netlist optimization for nodes in a back-annotated LogicLock region. In your code, specify the name of your LogicLock region.

```
foreach node [get_logiclock_contents -region \
<region name> -node_locations] {
    set node_name [lindex $node 0]
    set_instance_assignment -name ADV_NETLIST_OPT_ALLOWED \
"NEVER ALLOW" -to $node_name}
```

The `get_logiclock_contents` command is in the `logiclock` package.

Save a Node-Level Netlist for the Entire Design into a Persistent Source File

Make the following assignments to cause the Quartus II Fitter to save a node-level netlist for the entire design into a **.vqm** file:

```
set_global_assignment-name LOGICLOCK_INCREMENTAL_COMPILE_ASSIGNMENT ON
set_global_assignment-name LOGICLOCK_INCREMENTAL_COMPILE_FILE <file
name>
```

Any path specified in the file name is relative to the project directory. For example, specifying **atom_netlists/top.vqm** places **top.vqm** in the **atom_netlists** subdirectory of your project directory.

A **.vqm** file is saved in the directory specified at the completion of a full compilation.

For more information about saving a node-level netlist, refer to "Atom Netlist Design Information" on page 12–55.

This is not supported for designs targeting newer devices such as the Stratix IV, Stratix III, Cyclone III, Arria II GX, or Arria GX.

 © March 2009 Altera Corporation

Setting LogicLock Assignment Priority

Use the following Tcl code to set the priority for a LogicLock region's members. This example reverses the priorities of the LogicLock region in your design.

```
set reverse [list]
for each member [get_logiclock_member_priority] {
    set reverse [insert $reverse 0 $member]
{
set_logiclock_member_priority $reverse
```

For more information about setting the LogicLock assignment priority, refer to "LogicLock Restrictions" on page 12–53.

Assigning Virtual Pins

Use the following Tcl command to turn on the virtual pin setting for a pin called `my_pin`:

```
set_instance_assignment -name VIRTUAL_PIN ON -to my_pin
```

For more information about assigning virtual pins, refer to "Virtual Pins" on page 12–17.

Back-Annotating LogicLock Regions

The Quartus II software provides the back-annotate Tcl package that allows you to back-annotate the contents of a LogicLock region.

```
logiclock_back_annotate [-h | -help] [-long_help]
[-region <region name>] [-from <source name>]
[-to <destination name>] [-exclude_from] [-exclude_to] [-path_exclude
<path_exclude name>]
[-no_delay_chain] [-no_contents] [-lock] [-routing]
[-resource_filter <resource_filter value>] [-no_dont_touch]
[-remove_assignments] [-no_demote_lab] [-no_demote_mac]
[-no_demote_pin] [-no_demote_ram]
```

For example, the following command back-annotates all nodes and routing in the region `one_region`.

```
package require ::quartus::backannotate
logiclock_back_annotate -routing -lock -no_demote_lab -region \
one_region
```

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Conclusion

Design floorplan analysis is a valuable method for achieving timing closure and timing closure optimal performance in highly complex designs. With their analysis capability, the Quartus II Chip Planner and the Timing Closure Floorplan tools help you close timing quickly on your designs. Using these tools together with LogicLock and Incremental Compilation enables you to compile your designs hierarchically, preserving the timing results from individual compilation runs. You can use

LogicLock regions as part of an incremental compilation methodology to improve your productivity. You can also include a module in one or more projects while maintaining performance and reducing development costs and time-to-market. LogicLock region assignments give you complete control over logic and memory placement to improve the performance of non-hierarchical designs as well.

13. Netlist Optimizations and Physical Synthesis

QII52007-9.0.0

Introduction

The Quartus® II software offers physical synthesis optimizations to optimize your design beyond the optimization performed in the normal course of the Quartus II compilation flow. The effect of these options depends on the structure of your design. Physical synthesis optimizations can help improve the performance of your design, regardless of the synthesis tool used.

Netlist optimization options work with your design's atom netlist, which describes a design in terms of Altera®-specific primitives. An atom netlist file can take the form of an Electronic Design Interchange Format (**.edf**) file or a Verilog Quartus Mapping (**.vqm**) file generated by a third-party synthesis tool, or a netlist used internally by the Quartus II software. Physical synthesis optimizations are applied at different stages of the Quartus II compilation flow, either during synthesis, fitting, or both.

This chapter explains how the physical synthesis optimizations in the Quartus II software can modify your design's netlist and help improve your quality of results. This chapter also provides information about preserving your compilation results through back-annotation and writing out a new netlist, and provides guidelines for applying the various options.

Because the node names for primitives in the design can change when you use the physical synthesis option, evaluate whether your design flow requires fixed node names. If you use a verification flow that might require fixed node names, such as the SignalTap® II Embedded Logic Analyzer, formal verification, or the LogicLock based optimization flow (for legacy devices), you must turn off the synthesis netlist optimization and physical synthesis options.

WYSIWYG Primitive Resynthesis

If you use a third-party tool to synthesize your design, use the **Perform WYSIWYG primitive resynthesis** option to apply optimizations to the synthesized netlist.

The **Perform WYSIWYG primitive resynthesis** option directs the Quartus II software to un-map the logic elements (LEs) in an atom netlist to logic gates, and then re-map the gates back to Altera-specific primitives. Third-party synthesis tools generate an atom netlist file that specifies Altera-specific primitives. Atom netlist files can take the form of either an **.edf** or **.vqm** file generated by the third-party synthesis tool. When you turn on this option, the Quartus II software can work on different techniques specific to the device architecture during the re-mapping process. This feature re-maps the design using the **Optimization Technique** specified for your project (**Speed**, **Area**, or **Balanced**).

This option has no effect if you are using Quartus II integrated synthesis to synthesize your design.

To turn on this option, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.

2. In the **Category** list, select **Analysis and Synthesis Settings**. The **Analysis & Synthesis Settings** page appears.
3. Select **Perform WYSIWYG Primitive Resynthesis**. Turn on the setting and click **OK**.

If you want to perform WYSIWYG resynthesis on only a portion of your design, you can use the Assignment Editor to assign the **Perform WYSIWYG primitive resynthesis** logic option to a lower-level entity in your design. This option can be used with Arria® II GX, Arria GX, HardCopy® series, Stratix® series, Cyclone® series, MAX® II, or APEX™ series device families.

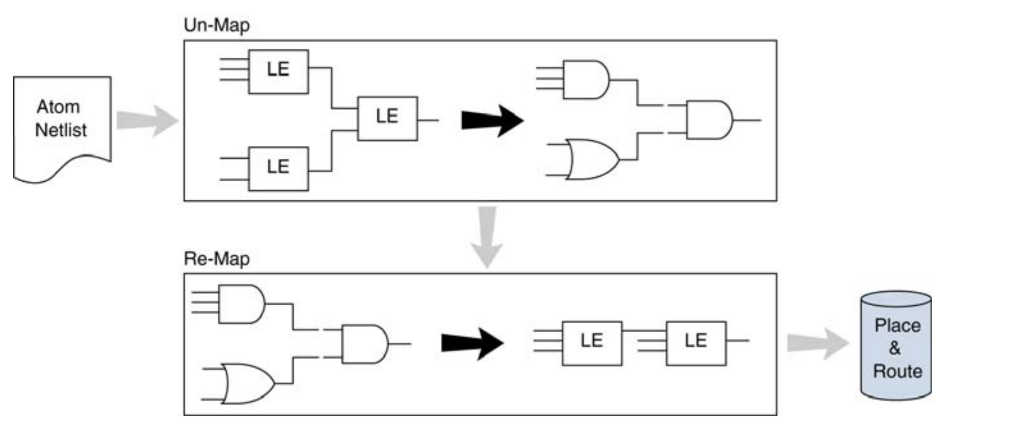
The results of the remapping are dependent on the **Optimization Technique** chosen for your project. To select the **Optimization Technique**, perform the following steps:

1. In the **Category** list, select **Analysis & Synthesis Settings**. The **Analysis & Synthesis Settings** page appears.
2. Under **Optimization Technique**, select from **Speed**, **Area**, or **Balanced** to specify how the Quartus II technology mapper optimizes the design. The **Balanced** setting is the default for many Altera device families; this setting optimizes the timing critical parts of the design for speed and the rest for area.
3. Click **OK**.

Refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook* for details on the Optimization Technique option.

Figure 13–1 shows the Quartus II software flow for this feature.

Figure 13–1. WYSIWYG Primitive Resynthesis



The **Perform WYSIWYG primitive resynthesis** option is not applicable if you are using Quartus II integrated synthesis to synthesize your design because the design does not contain Altera primitives.

The **Perform WYSIWYG primitive resynthesis** option unmaps and remaps only logic cells, also referred to as LCELL or LE primitives, and regular I/O primitives (which may contain registers). Double data rate (DDR) I/O primitives, memory primitives, digital signal processing (DSP) primitives, and logic cells in carry/cascade chains are not touched. Logic specified in an encrypted **.vqm** file or an **.edf** file, such as third-party intellectual property (IP), is not touched.

Turning on this option can cause drastic changes to the node names in the **.vqm** file or **.edf** file from your third-party synthesis tool, because the primitives in the atom netlist are broken apart and then remapped within the Quartus II software. Registers can be minimized away and duplicates removed, but registers that are not removed have the same name after remapping.

Any nodes or entities that have the **Netlist Optimizations** logic option set to **Never Allow** are not affected during WYSIWYG primitive resynthesis. To apply this logic option, on the Assignments menu, click **Assignment Editor**. This option disables WYSIWYG resynthesis for parts of your design.

Primitive node names are specified during synthesis. When netlist optimizations are applied, node names might change because primitives are created and removed. HDL attributes applied to preserve logic in third-party synthesis tools cannot be maintained because those attributes are not written into the atom netlist read by the Quartus II software.

If you use the Quartus II software to synthesize, you can use the **Preserve Register (preserve)** and **Keep Combinational Logic (keep)** attributes to maintain certain nodes in the design.

For more information about using these attributes during synthesis in the Quartus II software, refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook.*

Performing Physical Synthesis Optimizations

Traditionally, the Quartus II design flow has involved separate steps of synthesis and fitting. The synthesis step optimizes the logical structure of a circuit for area, speed, or both. The Fitter then places and routes the logic cells to ensure critical portions of logic are close together and use the fastest possible routing resources. While you are using this push-button flow, the synthesis stage is unable to anticipate the routing delays seen in the Fitter. Because routing delays are a significant part of the typical critical path delay, performing synthesis operations with physical delay knowledge allows the tool to target its timing-driven optimizations at these parts of the design. This tight integration of the fitting and synthesis processes is known as physical synthesis.

The following sections describe the physical synthesis optimizations available in the Quartus II software, and how they can help improve your performance results. Physical synthesis optimization options can be used with Arria II GX, Arria GX, the Stratix and Cyclone series device families, and HardCopy ASIC series.

If you are migrating your design to a HardCopy II device, you can target physical synthesis optimizations to the FPGA architecture in the FPGA-first flow or to the HardCopy II architecture in the HardCopy-first flow. The optimizations are mapped to the other device architecture during the migration process.

You cannot target optimizations to optimize for both device architectures individually because doing so would result in a different post-fitting netlist for each device.

For more information about using physical synthesis with HardCopy devices, refer to the *Quartus II Support of HardCopy Series Devices* chapter in volume 1 of the *Quartus II Handbook*.

You can choose the physical synthesis optimization options you want for your design during synthesis and fitting in the **Physical Synthesis Optimizations** page. The settings include optimizations for improving performance and fitting in the selected device.

You can also set the effort level for physical synthesis optimizations. Normally, physical synthesis optimizations increase the compilation time. Choose the **Fast** option if you want to reduce the impact on compilation time. When you choose this effort level, the Quartus II software performs limited register retiming operations during fitting. The **Extra** option runs additional algorithms to get the best possible results, with maximum impact on the compilation time.

To optimize the performance, the following options are available:

- **Perform physical synthesis for combinational logic**
- **Perform register retiming**
- **Perform automatic asynchronous signal pipelining**
- **Perform register duplication**

To optimize for better fitting, you can choose from the following options:

- **Perform physical synthesis for combinational logic**
- **Perform logic to memory mapping**

To view and modify the physical synthesis optimization options, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, click the "+" icon to expand **Compilation Process Settings** and select **Physical Synthesis Optimizations**. The **Physical Synthesis Optimizations** page appears.
3. Specify the options for performing physical synthesis optimizations.

Some physical synthesis options affect only registered logic and some options affect only combinational logic. Select options based on whether you want to keep the registers intact or not. For example, if your verification flow involves formal verification, you might have to keep the registers intact.

You can control the effect of physical synthesis with the **Effort Level** option. The default selection is **Normal**. The **Extra** effort setting uses extra compilation time to try to achieve extra circuit performance, while the **Fast** effort setting uses less compilation time than **Normal** but might not achieve the same gains.

All Physical Synthesis optimizations write results to the **Netlist Optimizations** report. To access this report, on the Processing menu, click **Compilation Report**. In the **Compilation Report** list, click the "+" icon to expand **Fitter** and select **Netlist Optimizations**. This report provides a list of atom netlist files that were modified, created, and deleted during physical synthesis. Similarly, physical synthesis optimizations performed during synthesis write results to the synthesis report. To access this report, on the Processing menu, click **Compilation Report**. In the **Compilation Report** list, select **Analysis & Synthesis**.

Nodes or entities that have the **Netlist Optimizations** logic option set to **Never Allow** are not affected by the physical synthesis algorithms. To access this logic option, on the Assignments menu, click **Assignment Editor**. Use this option to disable physical synthesis optimizations for parts of your design.

Automatic Asynchronous Signal Pipelining

The **Perform automatic asynchronous signal pipelining** option on the **Physical Synthesis Optimizations** page in the **Compilation Process Settings** section of the **Settings** dialog box allows the Quartus II Fitter to perform automatic insertion of pipeline stages for asynchronous clear and asynchronous load signals during fitting when these signals negatively affect performance. You can use this option if asynchronous control signal recovery and removal times are not achieving their requirements.

This option improves performance for designs in which asynchronous signals in very fast clock domains cannot be distributed across the chip fast enough due to long global network delays. This optimization performs automatic pipelining of these signals, while attempting to minimize the total number of registers inserted.

The **Perform automatic asynchronous signal pipelining** option adds registers to nets driving the asynchronous clear or asynchronous load ports of registers. This adds register delays (adds latency) to the reset, adding the same number of register delays for each destination using the reset. Thus, changing the behavior of the signal in the design. Use this only if adding latency to reset signals does not violate any design requirements. This option also prevents the promotion of signals to global routing resources.

The Quartus II software performs automatic asynchronous signal pipelining only if **Enable Recovery/Removal analysis** is enabled. If you use the TimeQuest Timing Analyzer, **Enable Recovery/Removal analysis** is turned on by default. Pipelining is allowed only on asynchronous signals that have the following properties:

- The asynchronous signal is synchronized to a clock (a synchronization register drives the signal)
- The asynchronous signal fans-out only to asynchronous control ports of registers

To use **Enable Recovery/Removal analysis** with the Classic Timing Analyzer, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, click the “+” icon to expand **Timing Analysis Setting** and select **Classic Timing Analyzer Settings**. The **Classic Timing Analyzer Settings** page appears.
3. Click **More Settings**. The **More Timing Settings** dialog box appears.
4. In the **Name** list, select **Enable Recovery/Removal analysis**. In the **Setting** list, select **On**.
5. Click **OK**.
6. Click **OK**.

The Quartus II software does not perform automatic asynchronous signal pipelining on asynchronous signals that have the **Netlist Optimization** logic option set to **Never Allow**.

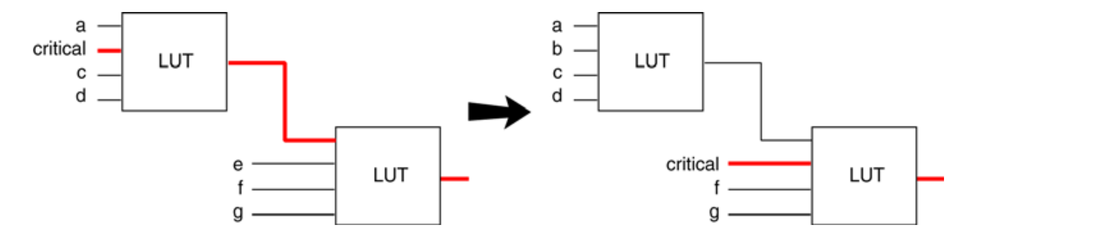
Physical Synthesis for Combinational Logic

To optimize the design and reduce delay along the critical paths, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, click the "+" icon to expand **Compilation Process Settings** and select **Physical Synthesis Optimizations**. The **Physical Synthesis Optimizations** page appears.
3. Turn on **Perform physical synthesis for combinational logic** by checking the appropriate box.

The software can accomplish this type of optimization by swapping the look-up table (LUT) ports within LEs so that the critical path has fewer layers through which to travel. See Figure 13–2 for an example. This option also allows the duplication of LUTs to enable further optimizations on the critical path.

Figure 13–2. Physical Synthesis for Combinational Logic



In the first case, the critical input feeds through the first LUT to the second LUT. The Quartus II software swaps the critical input to the first LUT with an input feeding the second LUT. This reduces the number of LUTs contained in the critical path. The synthesis information for each LUT is altered to maintain design functionality.

The **Physical synthesis for combinational logic** option affects only combinational logic in the form of LUTs. These transformations might occur during the synthesis stage or the Fitter stage during compilation. The registers contained in the affected logic cells are not modified. Inputs into memory blocks, DSP blocks, and I/O elements (IOEs) are not swapped.

The Quartus II software does not perform combinational optimization on logic cells that have the following properties:

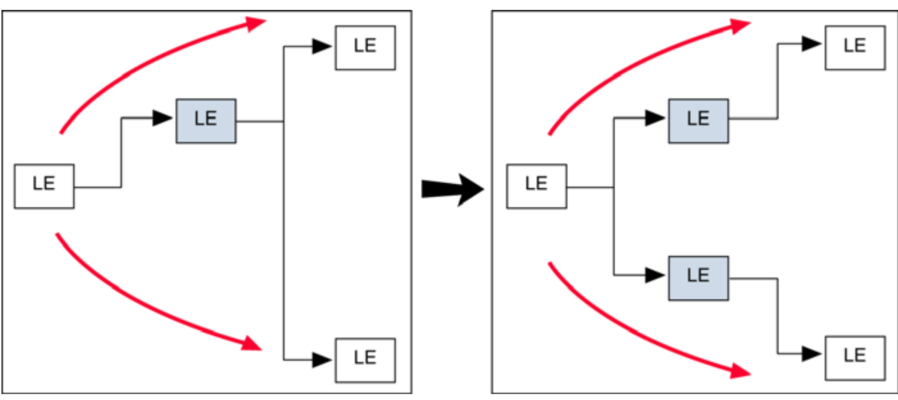
- Are part of a chain
- Drive global signals
- Are constrained to a single logic array block (LAB) location
- Have the **Netlist Optimizations** option set to **Never Allow**

If you consider logic cells with any of these conditions for physical synthesis, you can override these rules by setting the **Netlist Optimizations** logic option to **Always Allow** on a given set of nodes.

Physical Synthesis for Registers—Register Duplication

The **Perform register duplication** option on the **Physical Synthesis Optimizations** page in the **Compilation Process Settings** section of the **Settings** dialog box allows the Quartus II Fitter to duplicate registers based on Fitter placement information. You can also duplicate combinational logic when this option is enabled. A logic cell that fans out to multiple locations can be duplicated to reduce the delay of one path without degrading the delay of another. The new logic cell can be placed closer to critical logic without affecting the other fan-out paths of the original logic cell. Figure 13–3 shows an example of register duplication.

Figure 13–3. Register Duplication



The Quartus II software does not perform register duplication on logic cells that have the following properties:

- Are part of a chain
- Contain registers that drive asynchronous control signals on another register
- Contain registers that drive the clock of another register
- Contain registers that drive global signals
- Contain registers that are constrained to a single LAB location
- Contain registers that are driven by input pins without a t_{SU} constraint
- Contain registers that are driven by a register in another clock domain
- Are considered virtual I/O pins
- Have the **Netlist Optimizations** option set to **Never Allow**

For more information about virtual I/O pins, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook.*

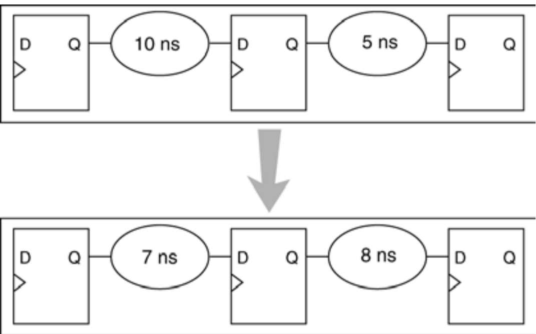
If you want to consider logic cells that meet any of these conditions for physical synthesis, you can override these rules by setting the **Netlist Optimizations** logic option to **Always Allow** on a given set of nodes.

Physical Synthesis for Registers—Register Retiming

The Register Retiming option enables the movement of registers across combinational logic, allowing the Quartus II software to trade off the delay between timing critical paths and non-critical paths. Register Retiming can be done during Quartus II integrated synthesis or during the Fitter stages of design compilation.

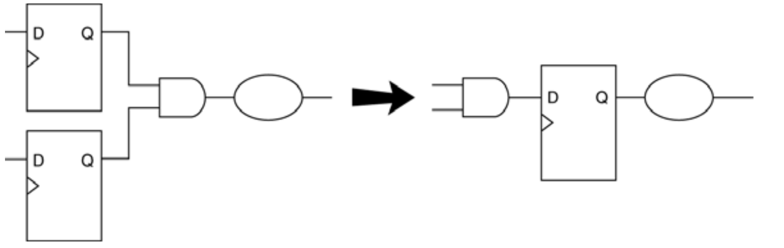
Figure 13–4 shows an example of register retiming in which the 10-ns critical delay is reduced by moving the register relative to the combinational logic.

Figure 13–4. Register Retiming Diagram



Retiming can create multiple registers at the input of a combinational block from a register at the output of a combinational block. In this case, the new registers have the same clock and clock enable. The asynchronous control signals and power-up level are derived from previous registers to provide equivalent functionality. Retiming can also combine multiple registers at the input of a combinational block to a single register (Figure 13–5).

Figure 13–5. Combining Registers with Register Retiming



To move registers across combinational logic to balance timing, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, click the “+” icon to expand **Compilation Process Settings** and select **Physical Synthesis Optimizations**. The **Physical Synthesis Optimizations** page appears.
3. Specify your preferred option under **Physical synthesis for performance** and **Effort level**.
4. Click **OK**.

If you want to prevent register movement during register retiming, you can set the **Netlist Optimizations** logic option to **Never Allow**. This option can be applied either to individual registers or entities in the design using the Assignment Editor.

In digital circuits, synchronization registers are instantiated on cross clock domain paths to reduce the possibility of metastability. The Quartus II software detects such synchronization registers and they are not moved, even if register retiming is turned on.

The following sets of registers are not moved during register retiming:

- Both registers in a direct connection from input pin-to-register-to-register if both registers have the same clock and the first register does not fan-out to anywhere else. These registers are considered synchronization registers.
- Both registers in a direct connection from register-to-register if both registers have the same clock, the first register does not fan-out to anywhere else, and the first register is fed by another register in a different clock domain (directly or through combinational logic). These registers are considered synchronization registers.

By default, the Quartus II software assumes that a synchronization register chain consists of a set of two registers. If your design has synchronization register chains that are longer than two, you must indicate the number of registers in your synchronization chains, so that those are not affected by when register retiming is enabled. To do this, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Analysis & Synthesis Settings**. The **Analysis & Synthesis Setting** page appears.
3. Click **More Settings**. The **More Analysis & Synthesis Settings** dialog box appears.
4. In the **Name** list, select **Synchronization Register Chain Length** and modify the setting to match the synchronization register length used in your design. If you set a value of 1 for the **Synchronization Register Chain Length**, it means that any registers connected to the first register in a register-to-register connection can be moved during retiming. A value of $n > 1$ means that any registers in a sequence of length 1, 2,… *n* are not moved during register retiming.

In general, the Quartus II software does not perform register retiming on logic cells that have the following properties:

- Are part of a cascade chain
- Contain registers that drive asynchronous control signals on another register
- Contain registers that drive the clock of another register
- Contain registers that drive a register in another clock domain
- Contain registers that are driven by a register in another clock domain
- Contain registers that are constrained to a single LAB location
- Contain registers that are connected to SERDES
- Are considered virtual I/O pins
- Registers that have the **Netlist Optimizations** logic option set to **Never Allow**

For more information about virtual I/O pins, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

If you want to consider logic cells that meet any of these conditions for physical synthesis, you can override these rules by setting the **Netlist Optimizations** logic option to **Always Allow** on a given set of registers.

Preserving Your Physical Synthesis Results

The Quartus II software generates the same results on every compilation for the same source code and settings on a given system. Therefore, it is typically not necessary to take steps to preserve your results from compilation to compilation. When changes are made to the source code or to the settings, you usually get the best results by allowing the software to compile without using previous compilation results or location assignments. In some cases, if you avoid performing analysis and synthesis or `quartus_map`, and run the Fitter or another desired Quartus II executable instead, you can skip the synthesis stage of the compilation.

When you use the Quartus II incremental compilation flow, you can preserve synthesis results for a particular partition of your design by choosing a netlist type of post-synthesis. If you want to preserve fitting results between compilation runs, choose a netlist type of post-fit during incremental compilation. The rest of this section is relevant only for those designs using older devices that do not support incremental compilation.

For information about the incremental compilation design methodology, refer to the *Quartus II Incremental Compilation for Hierarchical and Team Based Design* chapter in volume 1 of the *Quartus II Handbook*.

You can preserve the resulting nodes from physical synthesis in older devices that do not support incremental compilation. Preserving the nodes might be required if you use the LogicLock flow to back-annotate placement and/or import one design into another. Use this only for older devices such as the APEX or ACEX family. If you use older devices (such as the APEX or ACEX series) with LogicLock as an optimization strategy, you might have to use this option to preserve the nodes resulting from netlist optimizations. For newer devices, use incremental compilation to preserve results. When using the incremental compilation flow, you do not have to use this option even if you have LogicLock regions in the design.

To preserve the nodes from Quartus II physical synthesis optimization options for older devices that do not support incremental compilation, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Compilation Process Settings**. The **Compilation Process Settings** page appears.
3. Turn on **Save a node-level netlist of the entire design into a persistent source file**. This setting is not available for Cyclone III, Stratix III, and newer devices.
4. Click **OK**.

The **Save a node-level netlist of the entire design into a persistent source file** option saves your final results as an atom-based netlist in **.vqm** file format. By default, the Quartus II software places the **.vqm** file in the **atom_netlists** directory under the current project directory. To create a different **.vqm** file using different Quartus II settings, in the **Compilation Process Settings** page, change the **File name** setting.

If you use synthesis netlist optimizations (and not physical synthesis optimizations), generating a **.vqm** file is optional. To lock down the location of all logic and device resources in the design with or without a Quartus II-generated **.vqm** file, on the Assignments menu, click **Back-Annotate Assignments** and specify the desired options. You should use back-annotated location assignments unless the design has been finalized. Making any changes to the design invalidates your back-annotated location assignments. If you require changes later, use the new source HDL code as your input files, and remove the back-annotated assignments corresponding to the old code or netlist.

If you create a **.vqm** file to recompile the design, use the new **.vqm** file as the input source file and turn off the synthesis netlist optimizations for the new compilation.

If you use the physical synthesis optimizations and want to lock down the location of all LEs and other device resources in the design with the **Back-Annotate Assignments** command, a **.vqm** file netlist is required. The **.vqm** file preserves the changes that were made to your original netlist. Because the physical synthesis optimizations depend on the placement of the nodes in the design, back-annotating the placement changes the results from physical synthesis. Changing the results means that node names are different, and your back-annotated locations are no longer valid.

You should not use a Quartus II-generated **.vqm** file or back-annotated location assignments with physical synthesis optimizations unless the design has been finalized. Making any changes to the design invalidates your physical synthesis results and back-annotated location assignments. If you require changes later, use the new source HDL code as your input files, and remove the back-annotated assignments corresponding to the Quartus II-generated **.vqm** file.

To back-annotate logic locations for a design that was compiled with physical synthesis optimizations, first create a **.vqm** file. When recompiling the design with the hard logic location assignments, use the new **.vqm** file as the input source file and turn off the physical synthesis optimizations for the new compilation.

If you are importing a **.vqm** file and back-annotated locations into another project that has any **Netlist Optimizations** turned on, it is important to apply the **Never Allow** constraint to make sure node names don’t change; otherwise, the back-annotated location or LogicLock assignments are invalid.

For newer devices, such as the Stratix, Cyclone, or Arria GX series, use incremental compilation to preserve compilation results instead of using logic back-annotation.

Physical Synthesis Options for Fitting

The Quartus II software enables you to use the physical synthesis option to improve the fitting results. To access these settings, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.

2. In the **Category** list, click the "+" icon to expand **Compilation Process Settings** and select **Physical Synthesis Optimizations**. The **Physical Synthesis Optimizations** page appears.
3. Under **Optimize for fitting** (physical synthesis for density), there are two physical synthesis options available to improve fitting your design in the target device: **Physical synthesis for combinational logic** and **Perform logic to memory mapping** (Table 13–1).

Table 13–1. Physical Synthesis Optimizations Options

Option	Function
Physical Synthesis for Combinational Logic	When you select this option, the Fitter detects duplicate combinational logic and optimizes combinational logic to improve the fit.
Perform Logic to Memory Mapping	When you select this option, the Fitter can remap registers and combinational logic in your design into unused memory blocks and achieves a fit.

Applying Netlist Optimization Options

Netlist optimizations options can have various effects on different designs. Designs that are well coded or have already been restructured to balance critical path delays might not see a noticeable difference in performance.

To obtain optimal results when using netlist optimization options, you might have to vary the options applied to find the best results. By default, all options are off. Turning on additional options leads to the largest effect on the node names in the design. Take this into consideration if you are using a LogicLock-based optimization strategy (for older devices such as APEX and ACEX), or verification flow, such as the SignalTap II Embedded Logic Analyzer or formal verification that requires fixed or known node names. Applying all of the physical synthesis options at the **Extra** effort level generally produces the best results for those options, but adds significantly to the compilation time. You can also use the **Physical synthesis effort level** options to decrease the compilation time.

Typically, the WYSIWYG primitive resynthesis does not add much compilation time relative to the overall design compilation time.

To find the best results, you can use the Quartus II Design Space Explorer (DSE) to apply various sets of netlist optimization options.

For more information about using DSE, refer to the *Design Space Explorer* chapter in volume 2 of the *Quartus II Handbook*.

Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ↵
```

The *Scripting Reference Manual* includes the same information in PDF form. For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. Refer to the *Quartus II Settings File Reference Manual* for information about all settings and constraints in the Quartus II software. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

You can specify many of the options described in this section either on an instance, or at a global level, or both.

Use the following Tcl command to make a global assignment:

```
set_global_assignment -name <QSF variable name> <value> ↵
```

Use the following Tcl command to make an instance assignment:

```
set_instance_assignment -name <QSF variable name> <value> \
-to <instance name> ↵
```

Synthesis Netlist Optimizations

Table 13–2 lists the Quartus II Settings File (**.qsf**) variable names and applicable values for the settings discussed in "WYSIWYG Primitive Resynthesis" on page 13–1. The **.qsf** file variable name is used in the Tcl assignment to make the setting along with the appropriate value. The **Type** column indicates whether the setting is supported as a global setting, an instance setting, or both.

Table 13–2. Synthesis Netlist Optimizations and Associated Settings

Setting Name	Quartus II Settings File Variable Name	Values	Type
Perform WYSIWYG Primitive Resynthesis	ADV_NETLIST_OPT_SYNTH_WYSIWYG_REMAP	ON, OFF	Global, Instance
Optimization Technique	*<Device Family Name>*_OPTIMIZATION_TECHNIQUE	AREA, SPEED, BALANCED	Global, Instance
Power-Up Don't Care	ALLOW_POWER_UP_DONT_CARE	ON, OFF	Global
Save a node-level netlist into a persistent source file	LOGICLOCK_INCREMENTAL_COMPILE_ASSIGNMENT	ON, OFF	Global
	LOGICLOCK_INCREMENTAL_COMPILE_FILE	*<filename>*	
Allow Netlist Optimizations	ADV_NETLIST_OPT_ALLOWED	"ALWAYS ALLOW", DEFAULT, "NEVER ALLOW"	Instance

Physical Synthesis Optimizations

Table 13–3 lists the **.qsf** file variable name and applicable values for the settings discussed in "Performing Physical Synthesis Optimizations" on page 13–3. The **.qsf** file variable name is used in the Tcl assignment to make the setting, along with the appropriate value. The **Type** column indicates whether the setting is supported as a global setting, an instance setting, or both.

Table 13–3. Physical Synthesis Optimizations and Associated Settings

Setting Name	Quartus II Settings File Variable Name	Values	Type
Physical Synthesis for Combinational Logic	PHYSICAL_SYNTHESIS_COMBO_LOGIC	ON, OFF	Global
Automatic Asynchronous Signal Pipelining	PHYSICAL_SYNTHESIS_ASYNCHRONOUS_SIGNAL_PIPELINING	ON, OFF	Global
Perform Register Duplication	PHYSICAL_SYNTHESIS_REGISTER_DUPLICATION	ON, OFF	Global
Perform Register Retiming	PHYSICAL_SYNTHESIS_REGISTER_RETIMING	ON, OFF	Global
Power-Up Don't Care	ALLOW_POWER_UP_DONT_CARE	ON, OFF	Global, Instance
Power-Up Level	POWER_UP_LEVEL	HIGH,LOW	Instance
Allow Netlist Optimizations	ADV_NETLIST_OPT_ALLOWED	"ALWAYS ALLOW", DEFAULT, "NEVER ALLOW"	Instance
Save a node-level netlist into a persistent source file	LOGICLOCK_INCREMENTAL_COMPILE_ASSIGNMENT	ON, OFF	Global
	LOGICLOCK_INCREMENTAL_COMPILE_FILE	*<filename>*	

Incremental Compilation

For information about scripting and command line usage for incremental compilation as mentioned in "Preserving Your Physical Synthesis Results" on page 13–10, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Back-Annotating Assignments

You can use the `logiclock_back_annotate` Tcl command to back-annotate resources in your design. This command can back-annotate resources in LogicLock regions, and resources in designs without LogicLock regions.

For more information about back-annotating assignments, refer to "Preserving Your Physical Synthesis Results" on page 13–10.

The following Tcl command back-annotates all registers in your design:

```
logiclock_back_annotate -resource_filter "REGISTER"
```

The `logiclock_back_annotate` command is in the `backannotate` package.

Conclusion

Physical synthesis optimizations restructure and optimize your design netlist. Taking advantage of these Quartus II netlist optimizations can help improve your quality of results.

Document Revision History

Table 13–4 shows the revision history for this chapter.

Table 13–4. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Was chapter 11 in the 8.1.0 release. ■ Updated the “Physical Synthesis for Registers—Register Retiming” and“Physical Synthesis Options for Fitting” ■ Updated “Performing Physical Synthesis Optimizations” ■ Deleted Gate-Level Register Retiming section. ■ Updated the referenced documents	Updated GUI references and procedure steps, and document structure for the Quartus II software 9.0 release.
November 2008 v8.1.0	Changed to 8½” × 11” page size. No change to content.	Updated for the Quartus II 8.1 software release.
May 2008 v8.0.0	Updated “Physical Synthesis Optimizations for Performance on page 11-9 Added Physical Synthesis Options for Fitting on page 11-16	Updated for Quartus II 8.0 version.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

14. Design Space Explorer

QII52008-9.0.0

Introduction

The Quartus® II software includes many advanced optimization algorithms to help you achieve timing closure, optimize area, and reduce dynamic power. The various settings and parameters control the behavior of the algorithms. These options provide complete control over the Quartus II software optimization and power techniques.

Each FPGA design is unique. There is no standard set of options that always results in the best performance or power utilization. Each design requires a unique set of options to achieve optimal performance. This chapter describes Design Space Explorer (DSE), a utility written in Tcl/Tk that automates finding the best set of options for your design. DSE explores the design space of your design by applying various optimization techniques and analyzing the results.

DSE is a valuable tool to use in the late phases of your design cycle. You can take advantage of DSE's capability to automatically sweep multiple options to close timing, minimize area, or reduce power consumption on a design that is nearing completion.

DSE Concepts

This section explains the concepts and terminology used by DSE.

Exploration Space and Exploration Point

Before DSE explores a design, DSE creates an exploration space, which consists of Synthesis and Fitter settings available in the Quartus II software. Each group of settings in an exploration space is referred to as a point. An exploration space contains one or more points. DSE traverses the points in the exploration space to determine optimal settings for your design.

Seed and Seed Sweeping

The Quartus II Fitter uses a seed to specify the starting value that randomly determines the initial placement for the current design. The seed value can be any non-negative integer value. Changing the starting value may or may not produce better fitting. However, varying the value of the seed or seed sweeping allows the Quartus II software to determine an optimal value for the current design.

DSE extends Fitter seed sweeping in exploration spaces by providing a method for sweeping through general compilation and Fitter parameters to find the best options for your design. You can run DSE in various exploration space modes, ranging from an exhaustive try-all-options-and-values mode to a mode that focuses on one parameter.

DSE Exploration

DSE compares all exploration point results with the results of a base compilation, generated from the initial settings that you specify in the original Quartus II project files. As DSE traverses all points in the exploration space, all settings not explicitly modified by DSE default to the base compilation setting. For example, if an exploration point turns on register retiming but does not modify the register packing setting, the register packing setting defaults to the value you specified in the base compilation.

DSE performs the base compilation with the settings you specified in the original Quartus II project. These settings are restored after DSE traverses all points in the exploration space. DSE makes a copy of your base revision and uses this copy for changing the settings required to traverse through all other points in the chosen exploration space. Your base revision is not affected by DSE exploration.

General Description

You can use DSE in either the graphical user interface (GUI) or from a command line. To run DSE with the GUI, either click **Launch Design Space Explorer** on the Tools menu in the Quartus II software, or type the following at the command prompt:

```
quartus_sh --dse ↵
```

To run DSE from a command line, type the following command at the command prompt:

```
quartus_sh --dse -nogui [<options>] ↵
```

You can run DSE with the following options:

```
-archive
-concurrent-compiles [0..6]
-custom-file <filename>
-decision-column <"column name">
-exploration-space <"space">
-ignore-failed-base
-llr-restructuring
-lower-priority
-lsf-queue <queue name>
-nogui
-optimization-goal <"goal"
-report-all-resource-usage
-project <project name>
-revision <revision name>
-run-power
-search-method <"method">
-seeds <seed list>
-skip-base
-slaves <"slave1, slave2, slave3......">
-stop-after-time <dd:hh:mm>
-stop-after-zero-failing-paths
-use-lsf
```

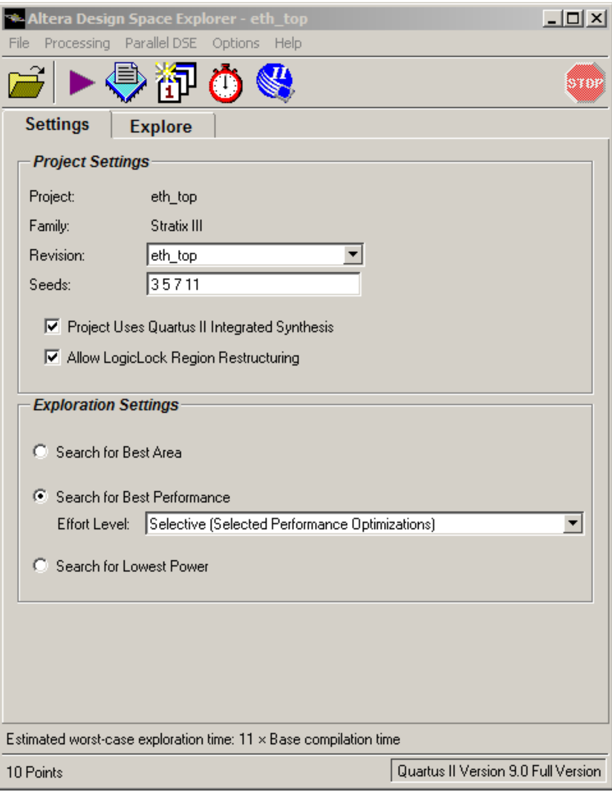
DSE script **dse.tcl** is located in <*Quartus II installation directory*>**/common/tcl/apps/dse** on Windows and Linux operating systems.

To launch DSE from the Quartus II software user interface, on the Tools menu, click **Launch Design Space Explorer**.

For more information about DSE, launch the DSE GUI. On the **Help menu**, click **Contents** or press the F1 key.

Figure 14–1 shows DSE user interface. The **Settings** tab is divided into two sections: **Project Settings** and **Exploration Settings**.

Figure 14–1. DSE User Interface



Timing Analyzer Support

DSE supports both the Quartus II Classic Timing Analyzer and the Quartus II TimeQuest Timing Analyzer. You must set the timing analyzer prior to opening the project in DSE. After the timing analyzer is set, DSE performs the design exploration with the selected timing analyzer.

You can directly launch the TimeQuest Timing Analyzer from DSE if you have set the default timing analyzer to TimeQuest and have specified the timing constraints in an **.sdc** file.

DSE Flow

You can run DSE at any point in the design process. However, Altera recommends that you run DSE late in your design cycle when your focus is on optimizing performance and power. The results gained from different combinations of optimization options early in the design cycle may not persist over large changes in a design.

DSE runs the Quartus II software for every point in the exploration space. The Quartus II software always attempts to achieve all your timing requirements regardless of whether or not you are running DSE. The **Exploration Settings** you choose in DSE will determine the settings to be used for compilation. DSE does not change the behavior of the Quartus II software.

DSE provides a summary of results for all the compilations and flags the best compilation run based on exploration setting you have chosen. Specifying all timing requirements before you use DSE to explore your design is very important to ensure that DSE finds the optimal set of parameters for your design based on design criteria you set in your initial design.

You can change the initial placement configuration used by the Quartus II Fitter by varying the **Fitter See**d value. You can enter seed values in the **Seeds** field of DSE user interface.

To set the seed value in the Quartus II software, on the Assignments menu, click **Settings** and select **Fitter Settings**.

Compilation time increases as DSE exploration spaces become more comprehensive. Increased compilation time results from running several compilations and comparing the generated results with the original base compilation results.

For a typical design, varying only the seed value varies the f_{MAX} within a range of +/-5%. For example, when compiling with three different seeds, one-third of the time f_{MAX} does not improve over the initial compilation, one-third of the time f_{MAX} improves by 5%, and one-third of the time f_{MAX} improves by 5%.

DSE Support for Altera Device Families

DSE support varies across Altera device families. The Stratix® series of devices, the Cyclone® series of devices, and the Arria® GX series of devices can take advantage of all the available DSE optimization methods. The MAX® II series of devices and older families, such as the APEX™ series of devices and the FLEX® series of devices, support a subset of DSE options.

DSE Project Settings

This section provides the following information about DSE project settings:

- Setting up DSE work environment
- Specifying the revision
- Setting the initial seed
- Quartus II integrated synthesis
- Restructuring LogicLock regions

Setting Up the DSE Work Environment

From the DSE GUI, you can open a Quartus II project for a design exploration by clicking **Open Project** on the File menu and then browsing to your project. Clicking on the Quartus II icon in the DSE GUI closes the DSE GUI and opens the project.

Specifying the Revision

You can specify the revision to be explored with the **Revision** field in the DSE GUI. The **Revision** field is populated after the Quartus II project has been opened.

If no revisions were created in the Quartus II project, the default revision, which is the top-level entity, is used. For more information, refer to the *Managing Quartus II Projects* chapter in volume 2 of the *Quartus II Handbook*.

Setting the Initial Seed

To specify the seed that DSE uses for an exploration, specify a non-negative integer value in the **Seeds** box under **Project Settings** on the **Settings** tab. The seed value determines your design's initial placement in a Quartus II compilation.

To specify a range of seeds, type the low end of the range followed by a hyphen, followed by the high end of the range. For example, 2-5 specifies that DSE uses the values 2, 3, 4, and 5 as seeds.

Project Uses Quartus II Integrated Synthesis

Make sure to check the **Project Uses Quartus II Integrated Synthesis** option if you use Quartus II integrated synthesis to synthesize your design. The DSE explores several options that affect, and can help, the synthesis stage of compilation when this option is enabled.

For more information about integrated synthesis options, refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*.

Restructuring LogicLock Regions

The **Allow LogicLock Region Restructuring** option allows DSE to modify LogicLock region properties in your design, if any exist. DSE applies the Soft property to LogicLock regions to improve timing. In addition, DSE can remove LogicLock regions that negatively affect the performance of the design.

DSE makes a copy of your base revision and modifies the LogicLock region settings on the new copy to see if the timing improves with the **Allow Logiclock Region Restructuring** option. Your original revision remains intact.

Exploration Settings

Use the **Exploration Settings** list to select the type of exploration to perform: **Search for Best Area**, **Search for Best Performance**, or **Search for Lowest Power**.

The **Search for Best Area** option uses a predefined exploration space that targets device utilization improvements for your design.

The **Search for Best Performance** option uses a predefined exploration space that targets performance improvements for your design. Depending on the device that your design targets, you can select up to five predefined exploration spaces: **Low** (**Seed Sweep**), **Medium** (**Extra Effort Space**), **High (Physical Synthesis Space)**, **Highest** (**Physical Synthesis with Retiming Space**), and **Selective** (**Selected Performance Optimizations**). As you move from **Low** to **Highest**, the number of options explored by DSE increases, which causes compilation time to increase.

The **Search for Lowest Power** option uses a predefined exploration space that targets overall power improvements for your design. When **Search for Lowest Power** is selected, DSE automatically runs the PowerPlay Power Analyzer for each point in the space. You must ensure that the PowerPlay Power Analyzer is configured correctly to ensure accurate results. DSE issues a warning if the confidence level for any power estimate is low.

The **Search for Best Area** option uses a predefined exploration space that targets device utilization improvements for your design.

Using DSE to Search for the Best Performance

This section describes using DSE to search for the best performance in your design.

Effort Level

When you select **Search for Best Performance** under the **Exploration Settings** in the DSE GUI, you can select the effort level you wish to use to compile your design in DSE. The effort levels are **Low** (**Seed Sweep**), **Medium** (**Extra Effort Space**), **High** (**Physical Synthesis Space**), **Highest** (**Physical Synthesis with Retiming Space**) and **Selective** (**Selected Performance Optimizations**). DSE traverses the points in the exploration space, applies the settings to the design, and compares compilation results to determine the best settings for your design based on your chosen effort level. Search time increases proportionally with the breadth of the options being explored. The exploration space search time increases with the number, type, and combination of options DSE explores.

DSE offers the following exploration space types:

- “Seed Sweep”
- “Extra Effort Space”
- “Physical Synthesis Space”
- “Physical Synthesis with Retiming Space”
- “Selective Performance Optimization”

Seed Sweep

Enter the seed values in the **Seeds** field in the DSE user interface. There are no “magic” seeds. The variation between seeds is truly random, any non-negative integer value is as likely to produce good results. DSE defaults to seeds 3, 5, 7, and 11. The **Low (Seed Sweep)** option exploration space does not change your netlist.

The **Seeds** field accepts individual seed values, for example, 2, 3, 4, and 5, or seed ranges, for example, 2-5.

Each seed value you specify requires an additional compilation. For example, if you enter five seeds, the compilation time increases to 5 times the initial (or base) compilation time.

Extra Effort Space

The **Extra Effort Space** effort level adds the **Register Packing** option to the exploration space done by the **Seed Sweep**. The **Extra Effort Space** effort level also increases the Quartus II Fitter effort during placement and routing. However, the **Extra Effort Space** effort level does not change your netlist.

Physical Synthesis Space

The **Physical Synthesis Space** effort level adds physical synthesis options such as register retiming and physical synthesis for combinational logic to the options included in the **Extra Effort Space** effort level. These netlist optimizations move registers in your design. Look-up tables (LUTs) are modified by these options. However, the design behavior is not affected by these options.

For more information about physical synthesis, refer to the *Netlist Optimizations and Physical Synthesis* chapter in volume 2 of the *Quartus II Handbook*.

Physical Synthesis with Retiming Space

The **Physical Synthesis with Retiming Space** effort level includes all the options in the **Physical Synthesis Space** effort level, and it explores various Quartus II Integrated Synthesis optimization options and register retiming. Register retiming can move registers in your design.

The **Physical Synthesis with Retiming Space** effort level works only for designs that have been synthesized using Quartus II Integrated Synthesis.

Selective Performance Optimization

The **Selective Performance Optimization** effort level combines a seed sweep with various performance Fitter settings to improve the timing of your design. The seed sweep is performed over a limited number of points in such a way that the base settings are not replicated. This is the recommended option for large designs where other spaces may be too large. Use this exploration space for first-time DSE searches on your designs to evaluate the range of results.

Table 14–1 shows the settings adjusted by each effort level.

Table 14–1. Summaries of Effort Levels (Part 1 of 2) *(Note 1)*

Optimization Options	Effort Levels			
	Seed Sweep	Extra Effort	Physical Synthesis	Retiming
Analysis and Synthesis Settings				
Optimization technique	—	—	✓	✓
Perform WYSIWYG resynthesis	—	—	✓	✓
Fitter Settings				
Fitter seed	✓	✓	✓	✓

Table 14–1. Summaries of Effort Levels (Part 2 of 2) *(Note 1)*

Optimization Options	Effort Levels			
	Seed Sweep	Extra Effort	Physical Synthesis	Retiming
Register packing	—	✓	✓	✓

(1) For effort levels that include Quartus II Integrated Synthesis Projects, DSE increases the synthesis effort.

DSE Flow Options

You can control the configuration of DSE with the following options:

- Create a Revision from the DSE Point
- Stop Flow When Zero Failing Paths are Achieved
- Continue Exploration Even If Base Compilation Fails
- Run Quartus II PowerPlay Power Analyzer During Exploration
- Archive All Compilations
- Stop Flow After Time
- Skip Base Analysis and Compilation If Possible

Create a Revision from the DSE Point

After you have performed a design exploration with DSE, a Quartus II revision can be made from any exploration point. This option facilitates the creation of multiple revisions based on the same space point for further optimization within the Quartus II software.

Stop Flow When Zero Failing Paths are Achieved

Instructs DSE to stop exploring the space after it encounters any point, including the base point, that has zero failing paths. DSE uses the failing path count reported in the **All Failing Paths report** column to make this decision.

Continue Exploration Even If Base Compilation Fails

With the **Continue Exploration Even If Base Compilation Fails** option turned on, DSE continues the exploration even when a design compilation error occurs. For example, if timing settings are not applied to your design, a DSE error occurs. To cause DSE to continue with the exploration instead of halting when an error occurs, turn on this option.

Run Quartus II PowerPlay Power Analyzer During Exploration

Turn on **Run Quartus II PowerPlay Power Analyzer During Exploration** to run the Quartus II PowerPlay Analyzer for every exploration performed by DSE. Using this option can help you debug your design and determine trade-offs between power requirements and performance optimization.

Archive All Compilations

Turn on **Archive all Compilations** to create a Quartus II Archive File (**.qar**) for each compilation. These archive files are saved to the **dse** directory in the design's working directory.

The result of each DSE run is saved as a **.qar** file in the **dse** subdirectory under your project directory. Each run is identified by a number. The best result of DSE run is saved with the name **best.qar**.

The **dse** directory also contains a spreadsheet (**results.csv**) that compares the results of all the individual runs in your DSE compilation.

Stop Flow After Time

Turn on Stop Flow After Time to stop further exploration after a specified number of days, hours, and/or minutes.

Exploration time might exceed the specified value because DSE does not stop in the middle of a compilation.

Skip Base Analysis and Compilation If Possible

The **Skip Base Analysis & Compilation if Possible** option allows DSE to skip the Analysis and Elaboration stage or the compilation of the base point if base point compilation results are available from a previous Quartus II compilation.

DSE Configuration File

Many options exist that allow you to customize the behavior of each DSE exploration. For example, you can specify seed values or a list of slave computers to be used for a Parallel DSE run. Each time you close the DSE GUI, it saves these values in a configuration file, **dse.conf**. The next time you launch the DSE GUI, it reads the values from **dse.conf** and restores the previous exploration settings.

Where the **dse.conf** file is stored varies depending on the operating system that launches DSE. Table 14–2 specifies the locations where **dse.conf** files are stored.

Table 14–2. DSE Configuration File Location

OS	File Location (default)	Comment
Windows	**%APPDATA%/Altera/dse.conf**	If the variable %APPDATA% is not defined, the configuration file is saved to **%HOME%\.altera.quartus\dse.conf**
Linux	**~/.altera.quartus/dse.conf**	

Settings specified in the DSE command-line mode are not saved to a **dse.conf** configuration file.

Parallel DSE Information

This section covers the **Parallel DSE** option, which enables you to run an exploration on multiple computers concurrently. This feature increases the processing efficiency of design space exploration. You can access the settings for **Parallel DSE** from the Parallel DSE menu in the DSE GUI.

Computer Load Sharing Using Parallel DSE

DSE uses cluster computing technology to decrease exploration time when you click **Distribute Compilations to Other Machines** (on the Parallel DSE menu). DSE uses multiple client computers to compile points in the specified exploration space.

Parallel DSE functions in one of the following modes:

- **Use LSF Resources—**DSE uses the Platform LSF grid computing technology to distribute exploration space points to a computing network.
- **Use QSlave—**This function uses a Quartus II master process. DSE acts as a master and distributes exploration space points to client computers.

When you use the **Distribute Compilations to Other Machines** option, different exploration points in the exploration space are compiled on different slave client computers at the same time. Concurrent compilations requires a separate license for each instance of the Quartus II software being used to compile the design. Each compilation also might require licenses for any IP cores in the design. Therefore, the number of parallel distributed compilations can be limited to the number of licenses available for the Quartus II software or the IP core used in your design.

Parallel DSE Using LSF Resources

The easiest way to use distributed DSE technology is to submit the compilations to a preconfigured LSF cluster at your local site. For more information about LSF software, refer to www.platform.com, or contact your system administrator. To run Parallel DSE using LSF resources, on the Parallel DSE menu, click **Configure Resources**.

Parallel DSE Using a Quartus II Master Process

Before DSE can use computers in the local area network to compile points in the exploration space, you must create Quartus II software slave instances on the computers that will be used as clients. Type the following command at a command prompt on a client computer:

```
quartus_sh --qslave ↵
```

Repeating this command on several computers creates a cluster of Quartus II software slaves for DSE to use. After you have created a set of Quartus II software slaves on the network, add the names of each slave computer in the **QSlave** tab of the **Configure Resources** dialog box.

To access the **Configure Resources** dialog box, on the Parallel DSE menu, click **Configure Resources**. To add resources, click the **QSlave** tab and click **Add** and type the client name. Click **OK**.

At the start of an exploration, DSE assumes the role of a Quartus II software master process and submits points to the slaves on the list to compile. If the list is empty, DSE issues an error and the search stops.

For more information about running and configuring Quartus II slaves, type the following command at the command prompt:

```
quartus_sh --help=qslave ↵
```

Parallel DSE uses a protocol based on FTP to move files between the master and the slaves. By default, the qslave client listens to port number 1977 for communication with the master. If you are running a firewall on a computer that is running the qslave client, make sure you configure the firewall software such that it allows incoming and outgoing transmission control protocol (TCP) and user datagram protocol (UDP) packets on the port used by qslave.

You must set this configuration in every computer that is used as a slave in a distributed DSE environment.

You can change the default port number used by qslave by typing the following command at a command prompt:

```
quartus_sh --qslave port=<new_port_number> ↵
```

You must use the same version of the Quartus II software to run the slave processes as you use to run DSE. To determine which Quartus II software version you are using to run DSE, select Help and click **About DSE.** Unexpected results can occur if you mix different Quartus II software versions when using the Parallel DSE feature.

When you are using ClearCase revision control software, Parallel DSE compilations launched within a ClearCase view might fail. ClearCase catches system I/O calls that can prevent communication between the DSE master and its slave computers. To avoid this problem, run Parallel DSE outside of the ClearCase environment.

Concurrent Local Compilations

To reduce compilation time, DSE can compile exploration points concurrently. The **Concurrent Local Compilations** option allows you to specify up to six concurrent compilations by choosing an integer value ranging from 0 through 6. You can use this option in conjunction with Parallel DSE. However, your system must have the appropriate resources and licenses to perform concurrent compilations, and distributed processing. Multiprocessor or multicore systems are recommended for concurrent local compilations.

Concurrent Local Compilations require a separate Quartus II software license for each concurrent compilation. For example, if you compile four concurrent compilations, you must have four licenses. Ensure that sufficient licenses are available before you choose a **Concurrent Local Compilations** value and start compilation.

You can use Concurrent compilations and the distributed compiles with other computer options at the same time if you use the QSlave approach for distributing compiles to other computers.

If you use LSF, all the jobs are submitted to the LSF system.

Section IV. Engineering Change Management

Programmable logic can accommodate changes to a system specification late in the design cycle. Last-minute design changes, commonly referred to as engineering change orders (ECOs), are small changes to the functionality of a design after the design has been fully compiled. This section describes how the Chip Planner feature in the Quartus® II software supports ECOs by allowing quick and efficient changes to your logic late in the design cycle.

This section includes the following chapter:

- Chapter 15, Engineering Change Management with the Chip Planner

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

15. Engineering Change Management with the Chip Planner

QII52017-9.0.0

Introduction

Programmable logic can accommodate changes to a system specification late in the design cycle. In a typical engineering project development cycle, the specification for the programmable logic portion is likely to change after engineering development begins or while integrating all system elements.

Last-minute design changes, commonly referred to as engineering change orders (ECOs), are small changes to the functionality of a design after the design has been fully compiled. A design is fully compiled when synthesis and place-and-route are completed.

The Chip Planner supports ECOs by allowing quick and efficient changes to your logic late in the design cycle. It provides a visual display of your post place-and-route design mapped to the device architecture of your chosen FPGA, from LAB placement in the device to each mapped Logic Element (LE) or Adaptive Logic Module (ALM). You can analyze your design with the visual display to alter how device resources are mapped to support ECOs.

This chapter addresses the impact that ECOs have on the design cycle, discusses the design flow for performing ECOs, and describes how you can use the Chip Planner to perform ECOs.

In addition to performing ECOs, the Chip Planner allows you to perform detailed analysis on routing congestion, relative resource usage, logic placement, LogicLock™ and customized regions, fan-ins and fan-outs, paths between registers, and delay estimates for paths.

For detailed information about using the Chip Planner for design analysis, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

The Chip Planner does not support the following device families:

- MAX® 7000
- ACEX®
- APEX™ series
- FLEX® series

For floorplan analysis using these devices, use the Timing Closure Floorplan. ECOs are not supported for these device families.

Engineering Change Orders

ECOs are typically performed during the verification stage of a design cycle. When a small change is required on a design, such as modifying a PLL for a different clock frequency or routing a signal out to a pin for analysis, recompilation of the entire design can be time consuming, especially for larger designs. Because several iterations of small design changes can occur during the verification cycle, recompilation times can quickly add up. Furthermore, a full recompilation due to a small design change can result in the loss of previous design optimizations. Performing ECOs, instead of performing a full recompilation on your design, limits the change only to the affected portions of logic.

This section discusses the areas in which ECOs have an impact on a system design and how the Quartus® II software can help you optimize the design in these areas. The following topics are discussed in this section:

- "Performance"
- "Compilation Time" on page 15–3
- "Verification" on page 15–3
- "Documentation" on page 15–3

Performance

Making a small change to the design functionality can result in a loss of previous design optimizations. Typical examples of design optimizations are floorplan optimizations and physical synthesis. Ideally, you should preserve previous design optimizations.

The Chip Planner allows you to perform ECOs directly on the post place-and-route database of your design. Any changes you make are restricted to the affected device resources, so the timing performance of the remaining portions of your design are not affected. The Chip Planner performs design rule checks on all changes to prevent illegal modifications to your design.

Additionally, the Quartus II software offers an incremental compilation feature that preserves the optimizations and placement of your design during recompilation. This feature allows you to create partitions of your design, so that if a change is required after the design is fully placed and optimized, only the affected partition is recompiled to implement the change.

The incremental compilation flow fully supports performing ECOs with the Chip Planner.

When recompiling a project with the Quartus II incremental compilation enabled, the compiler preserves all ECOs performed with the Chip Planner in partitions that have not been modified.

For more information about how to use the incremental compilation feature in the Quartus II software, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

For more information about using the ECO flow in conjunction with incremental compilation, refer to "Using Incremental Compilation in the ECO Flow" on page 15–32.

Compilation Time

In the traditional programmable logic design flow, a small change in the design requires a complete recompilation of the design. A complete recompilation of the design consists of synthesis and place-and-route. Making small changes to the design to reach the final implementation on a board can be a long process. Since the Chip Planner works only on the post place-and-route database, you can implement your design changes in minutes without performing a full compilation.

Verification

After you make a design change, you can verify the impact to your design. To verify that you have not violated timing, you can perform a static timing analysis using the Quartus II Classic Timing Analyzer or the Quartus II TimeQuest Timing Analyzer after you check and save your netlist changes within the Chip Planner.

For more information about the Quartus II TimeQuest Timing Analyzer, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*. For more information about the Quartus II Classic Timing Analyzer, refer to the *Quartus II Classic Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Additionally, you can perform a gate-level or timing simulation of the ECO-modified design by using the post place-and-route netlist generated by the Quartus II software.

Documentation

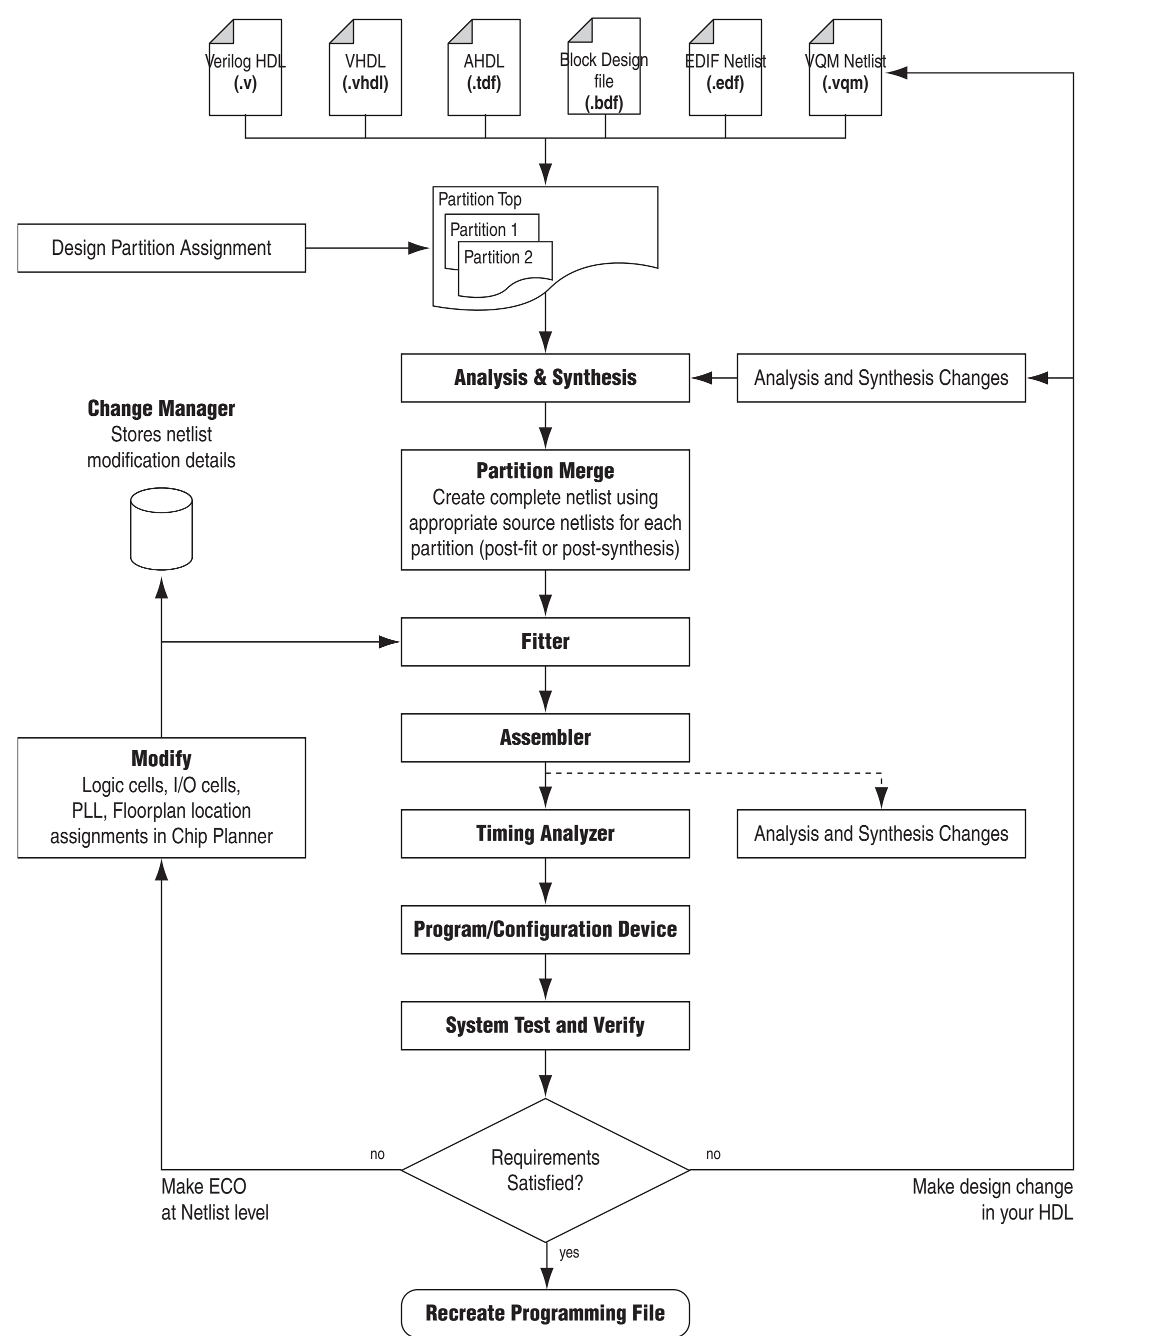
All ECOs made with the Chip Planner are logged in the Change Manager to provide a track record of all changes. By using the Change Manager, you can easily revert back to the original post-fit netlist or you can pick and choose which ECOs you want to have applied.

Additionally, the Quartus II software provides support for multiple compilation revisions of the same project. You can use ECOs made with the Chip Planner in conjunction with revision support to compare several different ECO changes and to provide the ability to revert back to previous project revisions.

ECO Design Flow

Figure 15–1 shows the design flow for performing ECOs.

Figure 15–1. Design Flow to Support ECO Changes



For iterative verification cycles, implementing small design changes at the netlist level can be faster than making an RTL code change. As such, making ECO changes are especially helpful when you debug the design on silicon and require a fast turnaround to generate a programming file for debugging the system.

A typical ECO application occurs when you uncover a problem on the board and isolate the problem to the appropriate nodes or I/O cells on the device. You must be able to correct the functionality quickly and generate a new programming file. Performing small changes using the Chip Planner allows you to modify the post place-and-route netlist directly. This bypasses having to perform synthesis and logic mapping, thus decreasing the turnaround time for programming file generation during the verification cycle. If the change corrects the problem, no modification of the HDL source code is necessary. You can use the Chip Planner to perform the following ECO-related changes to your design:

- Document the changes made with the Change Manager
- Easily recreate the steps taken to produce design changes
- Generate EDA simulation netlists for design verification
- Perform static timing analysis on the design

The Quartus II software can help reduce recompilation time with incremental recompilation for more complex changes that require HDL source code modifications.

The Chip Planner Overview

The Chip Planner provides a visual display of device resources. It shows the arrangement and usage of the resource atoms in the device architecture that you are targeting. Resource atoms are the building blocks for your device, such as ALMs, LEs, PLLs, DSP blocks, memory block, or I/O elements (IOEs).

The Chip Planner also provides an integrated platform for design analysis and for making ECOs to your design after place-and-route. The toolset consists of the Chip Planner (providing a device floorplan view of your mapped design) and two integrated subtools—the Resource Property Editor and the Change Manager.

For analysis, the Chip Planner can show logic placement, LogicLock and custom regions, relative resource usage, detailed routing information, routing congestion, fan-ins and fan-outs, paths between registers, and delay estimates for paths. Additionally, the Chip Planner allows you to create location constraints or resource assignment changes, such as moving or deleting logic cells or I/O atoms using the device floorplan. For ECO changes, the Chip Planner enables you to create, move, or delete logic cells in the post place-and-route netlist for fast programming file generation. Additionally, you can open the Resource Property Editor from the Chip Planner to edit the properties of resource atoms or to edit the connections between them. All changes to resource atoms and connections are logged automatically with the Change Manager.

Opening the Chip Planner

To open the Chip Planner, on the Tools menu, click **Chip Planner**. Alternatively, click the **Chip Planner** icon on the Quartus II software toolbar.

Optionally, the Quartus II software supports cross-probing to open the Chip Planner. To open the Chip Planner by cross-probing, use the shortcut menu in the following tools:

- Compilation Report

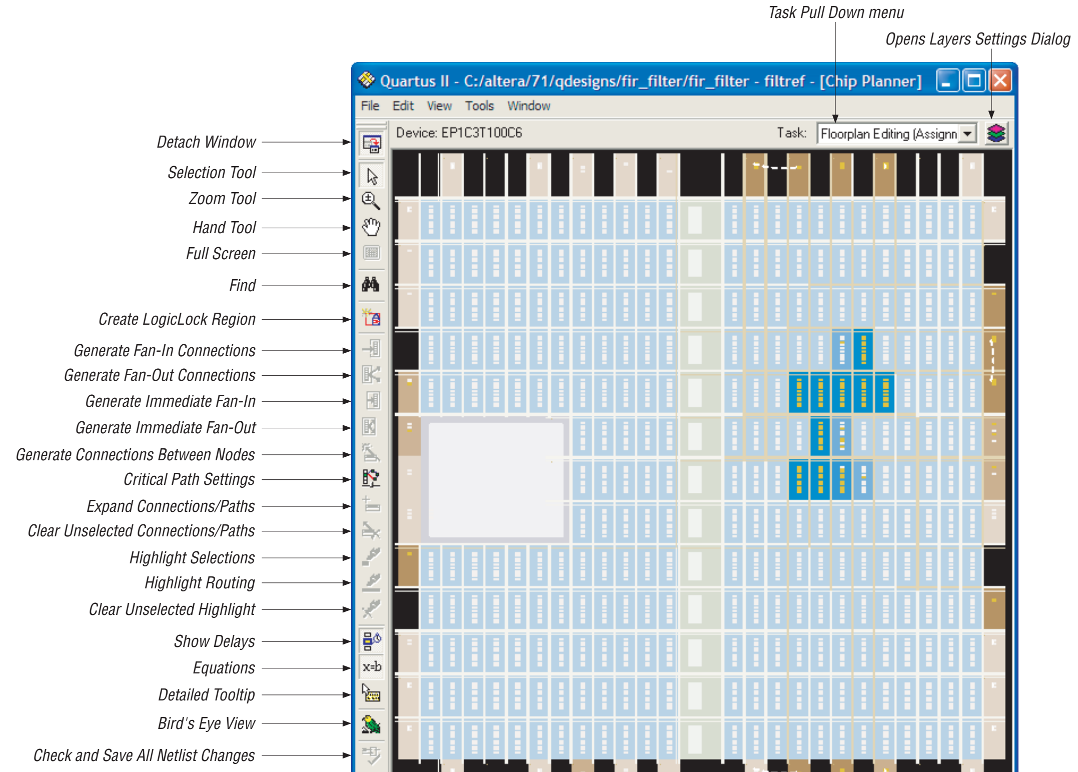
- Project Navigator window
- RTL source code
- Timing Closure Floorplan
- Node Finder
- Simulation Report
- RTL Viewer

For more information about the Timing Closure Floorplan, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

The Chip Planner Toolbar

The Chip Planner gives you design analysis capabilities with a user-friendly GUI. You can perform many functions within the Chip Planner from the menu items or by clicking the icons on the toolbar. Figure 15–2 shows an example of the Chip Planner toolbar and describes the commonly used icons.

Figure 15–2. Chip Planner Toolbar



You can also customize the icons on the Chip Planner toolbar. To customize the icons on the toolbar if the Chip Planner window is attached, on the Tools menu, click **Customize Chip Planner**. If the Chip Planner window is detached, on the Tools menu, click **Customize**.

For more information about using the Chip Planner for analyzing your design, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

The Chip Planner Tasks and Layers

The Chip Planner enables you to set up tasks to quickly implement ECO changes or manipulate assignments for the floorplan of the device. Each task consists of an editing mode and a set of customized layer settings.

The editing modes available in the Chip Planner are the Assignment mode and the ECO mode. Assignment mode enables you to create or manipulate LogicLock regions and make location constraints on the resource atoms used in your design. Assignments made are reflected in the Quartus II Settings File (**.qsf)** and the Assignment Editor. With ECO mode, you can create atoms, delete atoms, and move existing atoms to different locations. The changes made with ECO mode are made in the post place-and-route database. You can analyze your design with both modes.

The layers settings enable you to specify the displayed graphic elements for a given task. You can turn off the display of specific graphic elements to increase the window refresh speed and reduce visual clutter when viewing complex designs. The Background Color Map indicates the relative level of resource usage for different areas of the device. For example, **Routing Utilization** indicates the relative routing utilization and **Physical Timing Estimate** indicates the relative physical timing.

The Chip Planner has predefined tasks that enable you to quickly implement ECO changes or manipulate assignments for the floorplan of the device. The Chip Planner provides the following predefined tasks:

- Post-Compilation Editing (ECO)
- Floorplan Editing (Assignment)
- Partition Display (Assignment)
- Global Clock Network (Assignment)
- Power Analysis (Assignment)—available for Stratix® III, Stratix II, Stratix II GX, Cyclone® III, Cyclone II, and HardCopy® II devices only

You can choose the predefined task by selecting it in the **Task** list located in the upper right corner of the Chip Planner floorplan view.

To customize your own task, click on the Layers icon that is next to the **Task** list to open the **Layers Settings** dialog box.

For more information about assignments and analysis with the Chip Planner, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

For more information about performing ECOs using the ECO mode, refer to "Performing ECOs with the Chip Planner (Floorplan View)" on page 15–12.

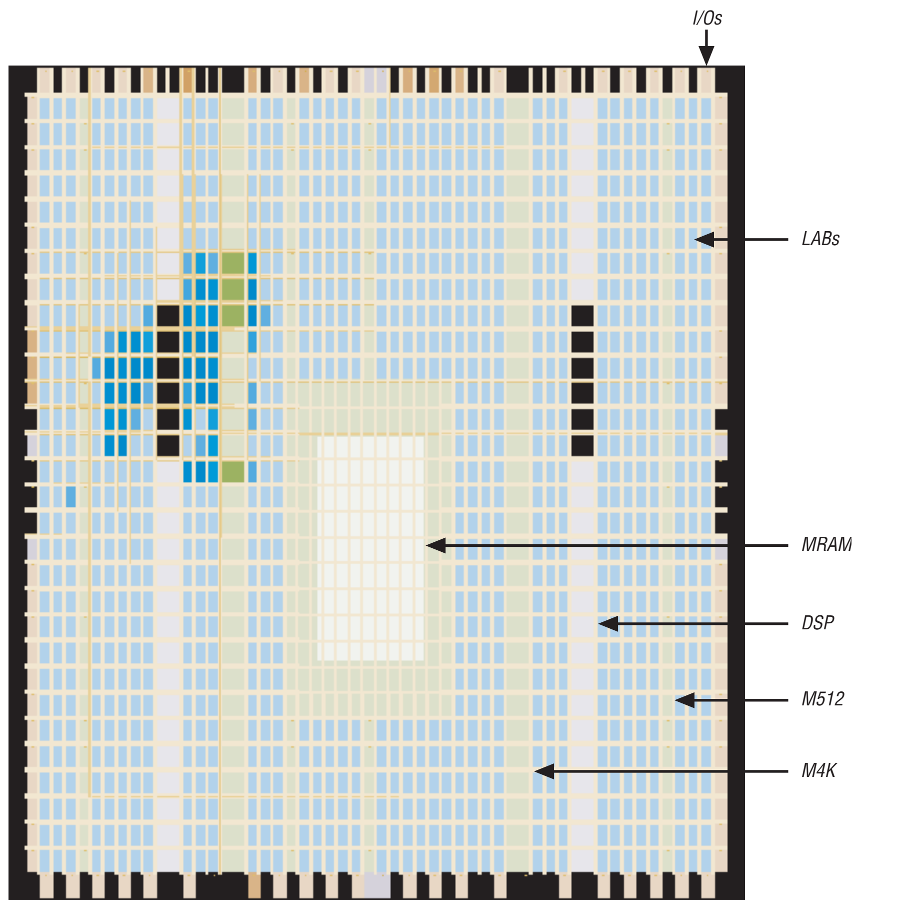
The Chip Planner Floorplan Views

The Chip Planner uses a hierarchical zoom viewer that shows various abstraction levels of the targeted Altera device. As you increase the zoom level, the level of abstraction decreases, thus revealing more detail about your design.

First-Level View

The first zoom level provides a high-level view of the entire device floorplan. This view provides a level of detail similar to the Field View in the Quartus II Timing Closure Floorplan. You can locate and view the placement of any node in your design. Figure 15–3 shows the Chip Planner Floorplan first-level view of a Stratix device.

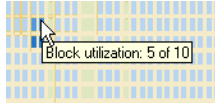
Figure 15–3. The Chip Planner First-Level (Highest) Floorplan View (Stratix Family Device)



Each resource is shown in a different color to help you distinguish between resources. The Chip Planner Floorplan uses a gradient color scheme in which the color becomes darker as the utilization of a resource increases. For example, as more LEs are used in the LAB, the color of the LAB becomes darker.

When you place the mouse pointer over a resource at this level, a tooltip appears that describes, at a high level, the utilization of the resource (Figure 15–4).

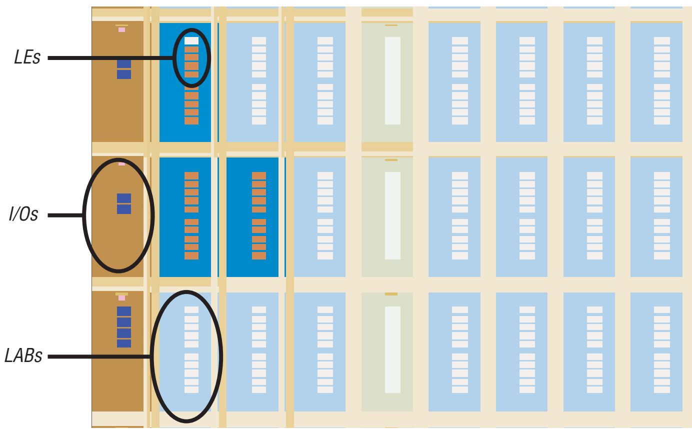
Figure 15–4. Tooltip Message: First-Level View



Second-Level View

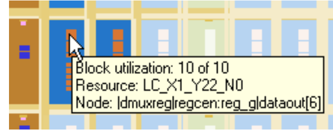
As you zoom in, you see an increase in the level of detail. Figure 15–5 shows the second-level view of the Chip Planner Floorplan for a Stratix device.

Figure 15–5. The Chip Planner Second-Level Floorplan View (Stratix Family Device)



At this level you can see the contents of LABs and I/O banks. You also see the routing channels that are used to connect resources. When you place the mouse pointer over an LE or ALM at this level, a tooltip is displayed (Figure 15–6) that shows the name of the LE/ALM, the location of the LE/ALM, and the number of resources that are used with that LAB. When you place the mouse pointer over an interconnect, the tooltip shows the routing channels that are used by that interconnect.

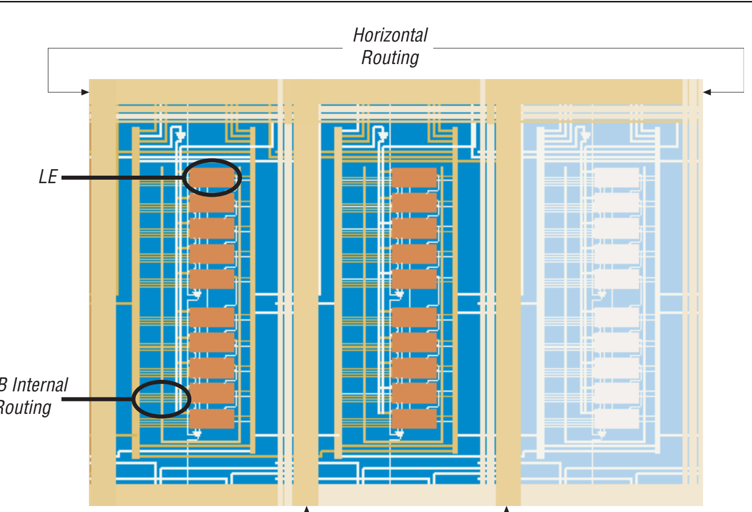
Figure 15–6. Tooltip Message: Second-Level View



Third-Level View

At the third level, which provides the greatest level of detail, you can see each routing resource that is used within a LAB in the FPGA. Figure 15–7 shows the level of detail at the third-level view for a Stratix device.

Figure 15–7. The Chip Planner Third-Level View



The second and third levels of zoom allow you to move LEs, ALMs, and I/Os from one physical location to another. You can move a resource by selecting, dragging, and dropping it into the desired location. At these levels, you can also create new LEs and I/Os.

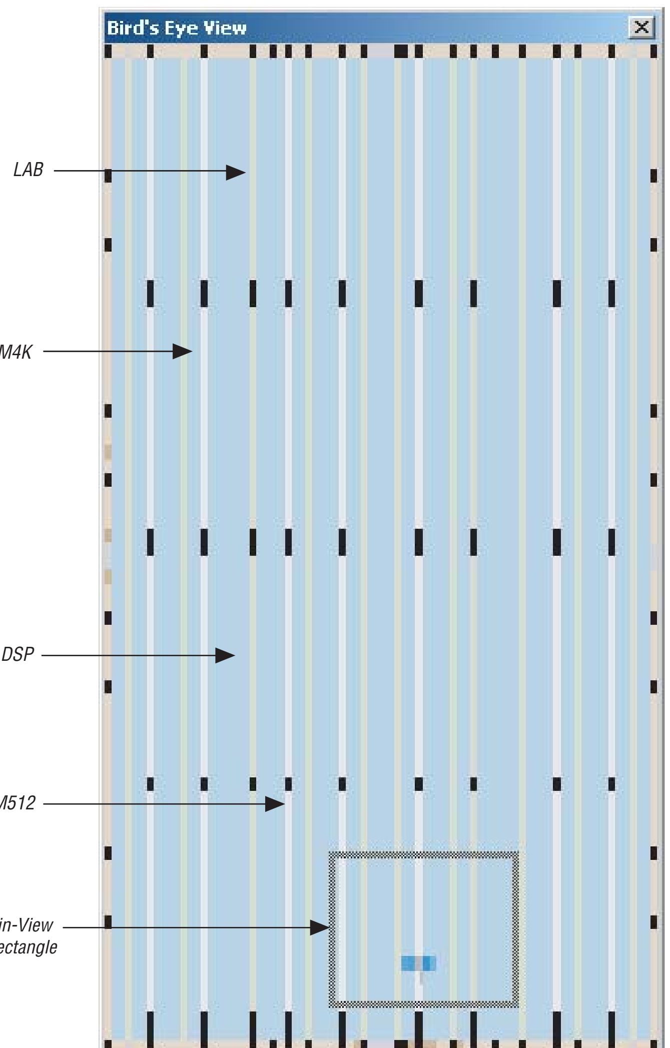
For more information about creating atoms, deleting atoms, or reallocating device atoms, refer to "Performing ECOs with the Chip Planner (Floorplan View)" on page 15–12.

For more information about creating Floorplan Assignments, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

Bird's Eye View

The Bird's Eye View (Figure 15–8) displays a high-level picture of resource usage for the entire chip and provides a fast and efficient way to navigate between areas of interest in the Chip Planner.

Figure 15–8. Bird's Eye View



The Bird's Eye View is displayed as a separate window that is linked to the Chip Planner Floorplan. When you select an area of interest in the Bird's Eye View, the Chip Planner Floorplan automatically refreshes to show that region of the device. As you change the size of the main-view rectangle in the Bird's Eye View window, the main Chip Planner Floorplan window also zooms in (or zooms out). You can make the main-view rectangle smaller in the Bird's Eye View to see more detail on the Chip Planner Floorplan window.

The Bird's Eye View is particularly useful when the parts of your design that you are interested in are at opposite ends of the chip and you want to quickly navigate between resource elements without losing your frame of reference.

Performing ECOs with the Chip Planner (Floorplan View)

You can manipulate resource atoms in the Chip Planner when you select the **ECO** editing mode. The following ECO changes can be performed with the Chip Planner Floorplan view:

- "Creating Atoms"
- "Deleting Atoms" on page 15–16
- "Moving Atoms" on page 15–16

To configure the properties of atoms, such as managing the connections between different LEs/ALMs, use the Resource Property Editor.

Refer to "Resource Property Editor" on page 15–16 for details about editing atom resource properties.

To select the **ECO** editing mode in the Chip Planner, perform the following steps with the Chip Planner open:

1. On the View menu, click **Layers Settings**, or click on the Layers icon next to the **Task** list. The **Layers Settings** dialog box appears.
2. Under **Editing Mode**, select **ECO**.

Creating Atoms

While in the **ECO** editing mode, the Chip Planner enables you to easily create atoms by moving the mouse pointer over the desired resource atom, right-clicking, and clicking **Create Atom**. After the atoms are created, the properties can be edited by double-clicking the resource atom, which opens the Resource Property Editor.

The type of atoms that you can create are:

- ALMs (for the appropriate device families)
- LEs (for the appropriate device families)
- IOEs

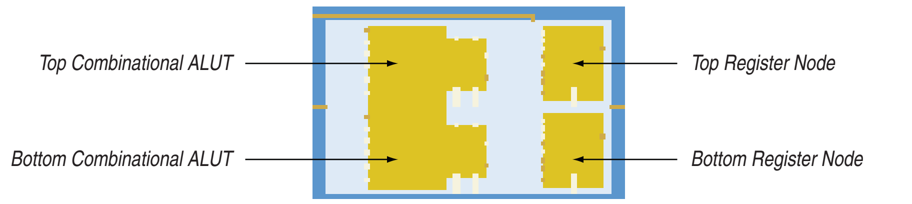
Creating resource atoms is not supported in the **Assignment** editing mode.

For the architectural details and resource atoms supported by your device, refer to the device data sheet.

Creating ALM Atoms

Each ALM has two combinational LUT outputs and two registered outputs. In the Chip Planner, you can divide each ALM into four resource atoms according to the type of output path. Figure 15–9 shows an ALM as shown in the Chip Planner.

Figure 15–9. ALM in the Chip Planner



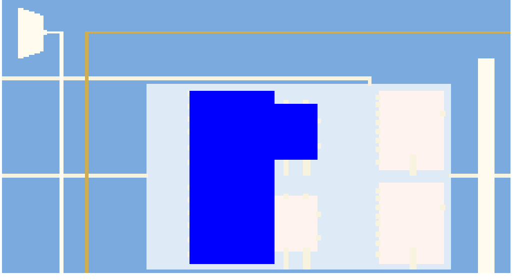
To create a combinational ALM LUT atom, perform the following steps:

1. Right click on the left side of any unused (not shaded) ALM and click **Create Atom**. The **Resource Selection** dialog box appears.
2. In the **Resource Selection** dialog box, select the atom that you wish to create. The lower index number refers to the top combinational node and the higher index refers to the bottom combinational node.
3. Click **OK**. The **Create** <*Altera device*> **LUT Atom** dialog box appears.
4. In the **Atom Name** box, type the name of the resource atom.
5. Under **LUT Mode**, select **Normal**, **Extended**, or **Arithmetic**.
6. If applicable, in the **Partition** list, select the partition that the newly created atom should reside in. The default partition for newly created atoms is the top-level partition.
7. Click **OK**.

For more information about the LUT mode, refer to the data sheet of the appropriate device.

When you have successfully created a combinational output, the combinational element is colored in the Chip Planner. Figure 15–10 shows a combinational ALUT atom.

Figure 15–10. Combinational ALUT Atom



To create a registered ALM atom, perform the following steps:

1. Right click on any ALM register resource and click **Create Atom**. The **Create Register Atom** dialog box appears.
2. In the **Atom Name** box, type the atom name.
3. Click **OK**.

Creating Logic Element Atoms

The Chip Planner shows resource atoms for Stratix, Cyclone, and MAX device families as logic elements. For all other LE-based device families, the Chip Planner shows resource atoms as the combinational output of the logic element LUT and the registered output of the logic element. Figure 15–11 shows an example of an atom resource in the Chip Planner for the Stratix, Cyclone, and MAX devices. Figure 15–12 shows a Cyclone II resource atom in the Chip Planner.

Figure 15–11. Logic Element for Stratix, Cyclone, and MAX Devices in the Chip Planner

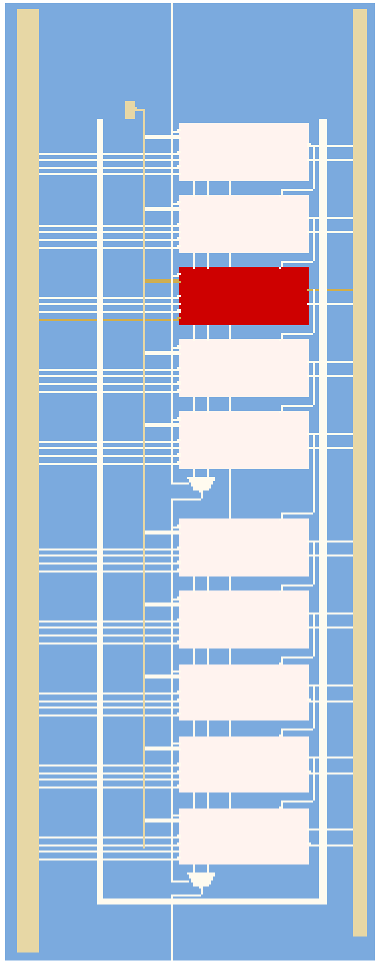


Figure 15–12. Logic Element for a Cyclone II Device in the Chip Planner

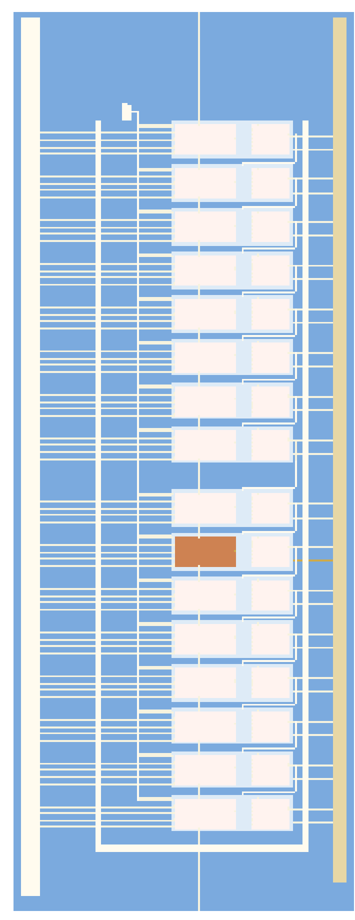


To create a logic element resource for Stratix, Cyclone, and MAX device families, perform the following steps:

1. Right-click on any available (unshaded) LE resource and click **Create Atom**. The **Create Logic Cell Atom** dialog box appears.
2. If applicable, in the **Partition** list, select the partition in which the newly created atom should reside. The default partition for newly created atoms is the top-level partition.
3. In the **Atom Name** box, type the atom name.
4. Click **OK**.

To create a combinational resource atom for all other LE-based device families, perform the following steps:

1. Right-click on the left side of an available (unshaded) LE resource and click **Create Atom**. The **Create** <*device family*> **LUT Atom** dialog box appears.
2. If applicable, in the **Partition** list, select the partition in which the newly created atom should reside. The default partition for newly created atoms is the top-level partition.
3. In the **Atom Name** box, type the atom name.

4. Click **OK**.

To create a register resource atom for Cyclone II devices, perform the following steps:

1. Right-click on right side of an available (unshaded) LE resource and click **Create Atom**. The **Create** <*device family*> **Register Atom** dialog box appears.
2. If applicable, in the **Partition** list, select the partition in which the newly created atom should reside. The default partition for newly created atoms is the top-level partition.
3. In the **Atom Name** box, type the atom name.
4. Click **OK**.

Deleting Atoms

To delete a resource atoms, right-click on the desired resource atom in the Chip Planner and click **Delete Atom**.

You can delete a resource only after all of its fan-out connections are removed. Protected resources, such as resources in megafunctions or IP cores, cannot be deleted.

Refer to "Resource Property Editor" on page 15–16 for more details about removing fan-out connections.

Moving Atoms

You can move resource ALMs, LEs, and FPGA I/O atoms by clicking on the desired resource and dragging the selected atom to a free resource atom. Moving nodes as an ECO can only be done in the ECO editing mode. Changes made while in Assignment mode create location constraints on the design and require a recompilation to incorporate the change.

Resource atoms from protected resources, such as resources of megafunction IP cores, cannot be moved.

Check and Save Netlist Changes

After making all ECOs, you can run the Fitter to incorporate the changes by clicking on the Check and Save Netlist Changes icon in the Chip Planner toolbar. The Fitter compiles the ECO changes, performs design rule checks on the design, and generates a programming file.

Resource Property Editor

You can view and edit the following resources with the Resource Property Editor:

- "Logic Element" on page 15–17
- "Adaptive Logic Module" on page 15–19
- "FPGA IOEs" on page 15–21
- "PLL Properties" on page 15–35
- "FPGA RAM Blocks" on page 15–27
- "FPGA DSP Blocks" on page 15–28

Logic Element

An Altera LE contains a four-input LUT, which is a function generator that can implement any function of four variables. In addition, each LE contains a register that is fed by the output of the LUT or by an independent function generated in another LE.

You can use the Resource Property Editor to view and edit any LE in the FPGA. Open the Resource Property Editor for an LE by pointing to **Locate** on the Project menu and clicking **Locate in Resource Property Editor** in one of the following views:

- RTL Viewer
- Technology Map Viewer
- Node Finder
- Chip Planner

For more information about LE architecture for a particular device family, refer to the device family handbook or data sheet.

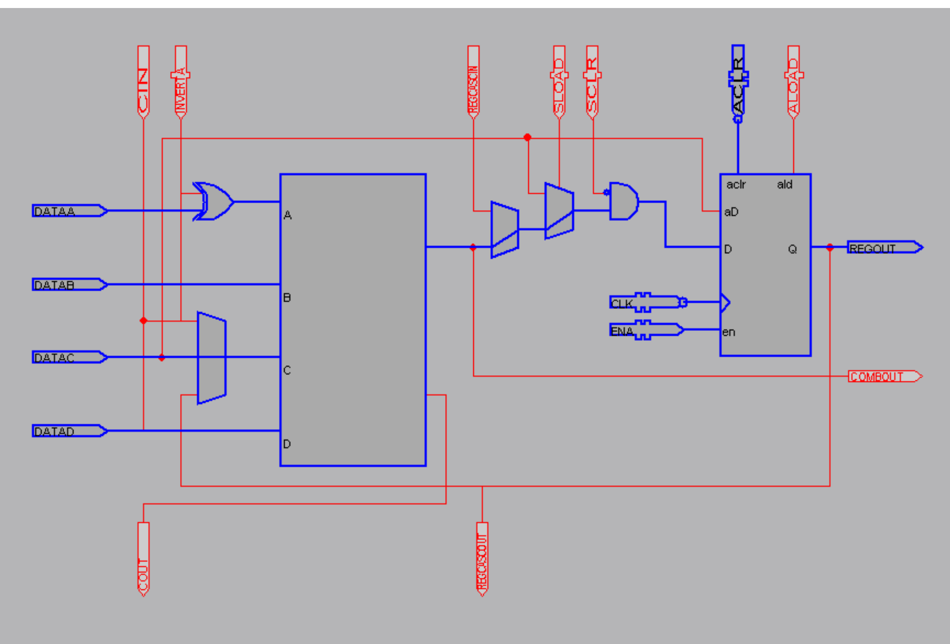
You can use the Resource Property Editor to change the following LE properties:

- Data input to the LUT
- LUT mask or LUT equation

Logic Element Schematic View

Figure 15–13 shows how the LE appears in the Resource Property Editor.

Figure 15–13. Stratix LE Architecture *(Note 1)*, *(2)*



Notes to Figure 15–13:

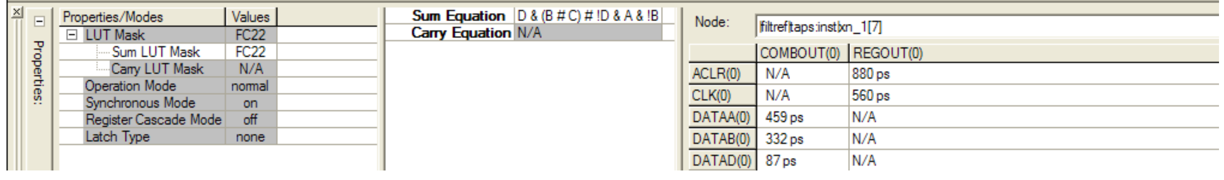
(1) By default, the Quartus II software displays the used resources in blue and the unused in gray. For Figure 15–13, the used resources are in blue and the unused resources are in red.

(2) For more information about the Stratix device's LE Architecture, refer to the *Stratix Device Handbook.*

LE Properties

Figure 15–14 shows an example of the properties that can be viewed for a selected LE in the Resource Property Editor. To view LE properties, on the View menu, click **View Properties** to view these properties.

Figure 15–14. LE Properties



Modes of Operation

LUTs in an LE can operate in either normal or arithmetic mode.

For more information about LE modes of operation, refer to volume 1 of the appropriate device handbook.

When an LE is configured in normal mode, the LUT in the LE can implement a function of four inputs.

When the LE is configured in arithmetic mode, the LUT in the LE is divided into two 3-input LUTs. The first LUT generates the signal that drives the output of the LUT, while the second LUT generates the carry-out signal. The carry-out signal can only drive a carry-in signal of another LE.

Sum and Carry Equations

You can change the logic function implemented by the LUT by changing the sum and carry equations. When the LE is configured in normal mode, you can only change the SUM equation. When the LE is configured in arithmetic mode, you can change both the SUM and the CARRY equations.

The LUT mask is the hexadecimal representation of the LUT equation output. When you change the LUT equation, the Quartus II software automatically changes the LUT mask. Conversely, when you change the LUT mask, the Quartus II software automatically computes the LUT equation.

sload and sclear Signals

Each LE register contains a synchronous load (`sload`) signal and a synchronous clear (`sclr`) signal. You can invert either the `sload` or `sclr` signal feeding into the LE. If the design uses the `sload` signal in an LE, the signal and its inversion state must be the same for all other LEs in the same LAB. For example, if two LEs in a LAB have the `sload` signal connected, both LEs must have the `sload` signal set to the same value. This is also true for the `sclr` signal.

Register Cascade Mode

When register cascade mode is enabled, the cascade-in port feeds the input to the register. The register cascade mode is used most often when the design implements shift registers. You can change the register cascade mode by connecting (or disconnecting) the cascade in the port. However, if you create this port, you must ensure that the source port LE is directly above the destination LE.

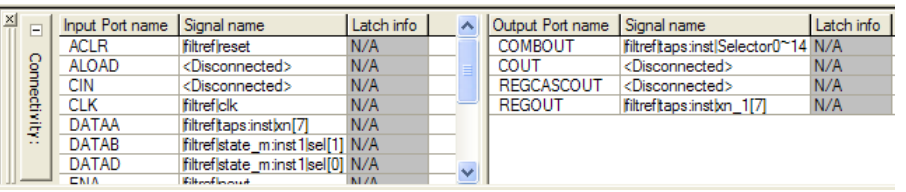
Cell Delay Table

The cell delay table describes the propagation delay from all inputs to all outputs for the selected LE.

LE Connections

On the View menu, click **View Port Connections** to view the connections that feed in and out of an LE. Figure 15–15 shows the LE connections in the Connectivity window.

Figure 15–15. View Connections



Delete an LE

To delete an LE, perform the following steps:

1. Right click the desired LE in the Chip Planner, point to **Locate** and click **Locate in Resource Property Editor**.
2. You must remove all fan-out connections from an LE prior to deletion. To delete fan-out connections, right-click each connected output signal, point to remove, and click **Fanouts**. Select all of the fan-out signals in the dialog box that appear and click **OK**.
3. To delete an atom after all fan-out connections are removed, right-click the atom in the Chip Planner and click **Delete Atom**.

Adaptive Logic Module

Each ALM contains LUT-based resources that can be divided between two adaptive LUTs (ALUTs). With up to eight inputs to the two ALUTs, each ALM can implement various combinations of two functions. This adaptability allows the ALM to be completely backward-compatible with four-input LUT architectures. One ALM can implement any function with up to six inputs and certain seven-input functions. In addition to the adaptive LUT-based resources, each ALM contains two programmable registers, two dedicated full adders, a carry chain, a shared arithmetic chain, and a register chain. The ALM can efficiently implement various arithmetic functions and shift registers using these dedicated resources.

You can implement the following types of functions in a single ALM:

- Two independent 4-input functions
- An independent 5-input function and an independent 3-input function
- A 5-input function and a 4-input function, if they share one input
- Two 5-input functions, if they share two inputs
- An independent 6-input function
- Two 6-input functions, if they share four inputs and share function
- Certain 7-input functions

You can use the Resource Property Editor to change the following ALM properties:

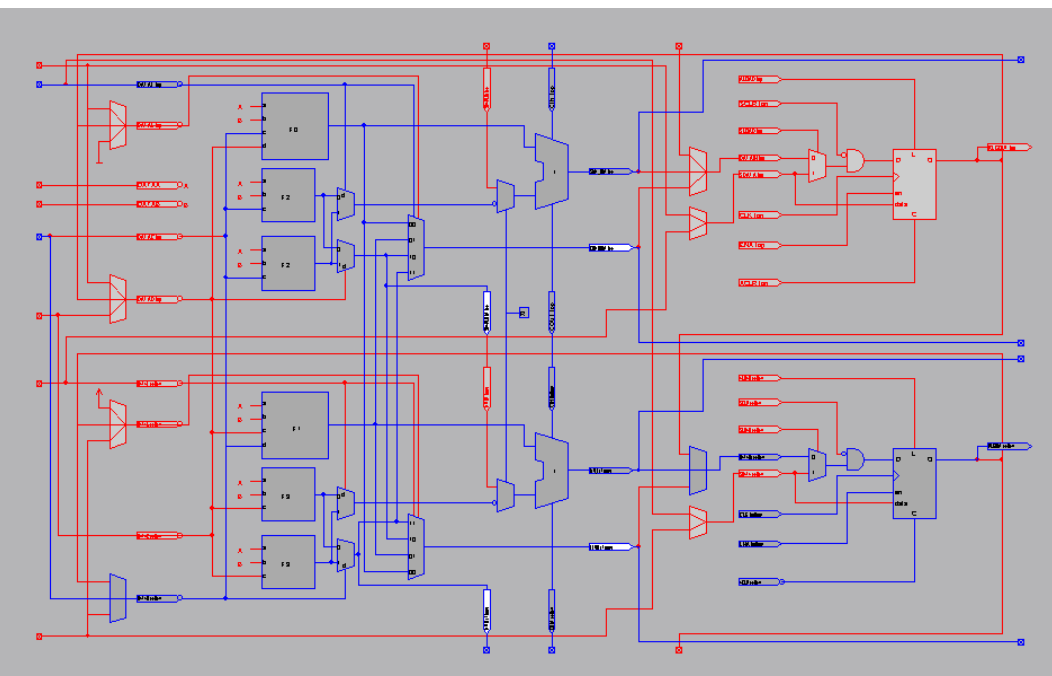
- Data input to the LUT
- LUT mask or LUT equation

ALM Schematic

You can view and edit any ALM atom with the Resource Property Editor by right-clicking the ALM in the RTL Viewer, the Node Finder, or the Chip Planner, and clicking **Locate in Resource Property Editor** (Figure 15–16).

For a detailed description of the ALM, refer to the device handbooks of devices based on an ALM architecture.

Figure 15–16. ALM Schematic *(Note 1)*



Note to Figure 15–16:

(1) By default, the Quartus II software displays the used resources in blue and the unused in gray. For Figure 15–16, the used resources are in blue and the unused resources are in red.

ALM Properties

The properties that you can display for the ALM include an equations table that shows the name and location of each of the two combinational nodes and two register nodes in the ALM, the individual LUT equations for each of the combinational nodes, and the `combout`, `sumout`, `carryout`, and `shareout` equations for each combinational node.

ALM Connections

On the View menu, click **View Port Connections** to view the connections that feed in and out of an ALM.

FPGA IOEs

Altera FPGAs that have high-performance IOEs, including up to six registers, are equipped with support for a number of I/O standards that allow you to run your design at peak speeds. Use the Resource Property Editor to view, change connectivity, and edit the properties of the IOEs. Use the Chip Planner (Floorplan view) to change placement, delete, and create new IOEs.

For a detailed description of the device IOEs, refer to the applicable device handbook.

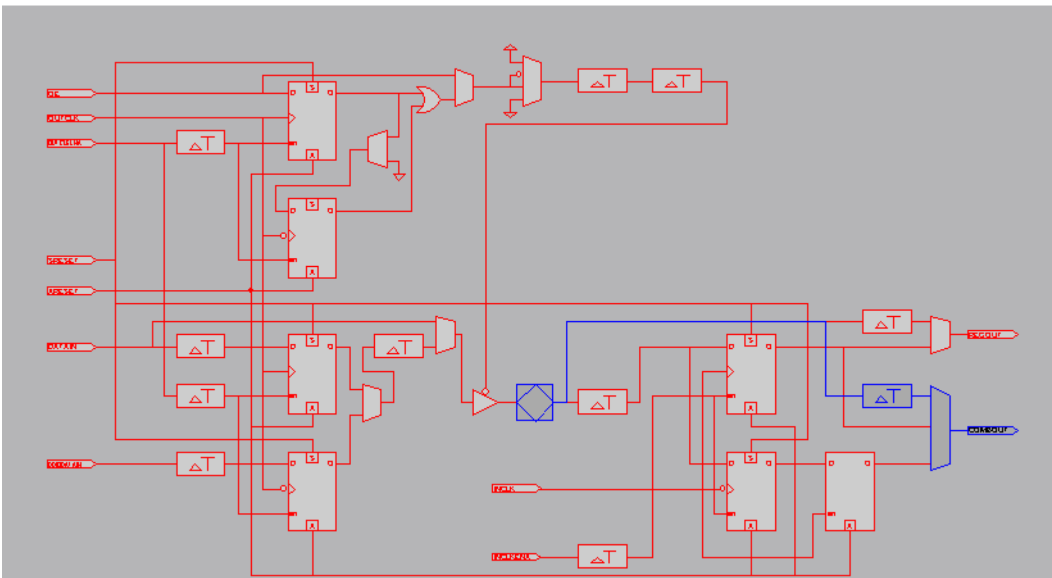
You can change the following I/O properties:

- Delay chain
- Bus hold
- Weak pull up
- Slow slew rate
- I/O standard
- Current strength
- Extend OE disable
- PCI I/O
- Register reset mode
- Register synchronous reset mode
- Register power up
- Register mode

Arria GX, Stratix II, Stratix, and Stratix GX IOEs

The IOEs in Stratix series device families and Arria GX devices contain a bidirectional I/O buffer, six registers, and a latch for a complete bidirectional single data rate or DDR transfer. Figure 15–17 shows the Stratix and Stratix GX IOE structure. The IOE structure contains two input registers (plus a latch), two output registers, and two output enable registers.

Figure 15–17. Stratix and Stratix GX Device IOE and Structure *(Note 1)*, *(2)*



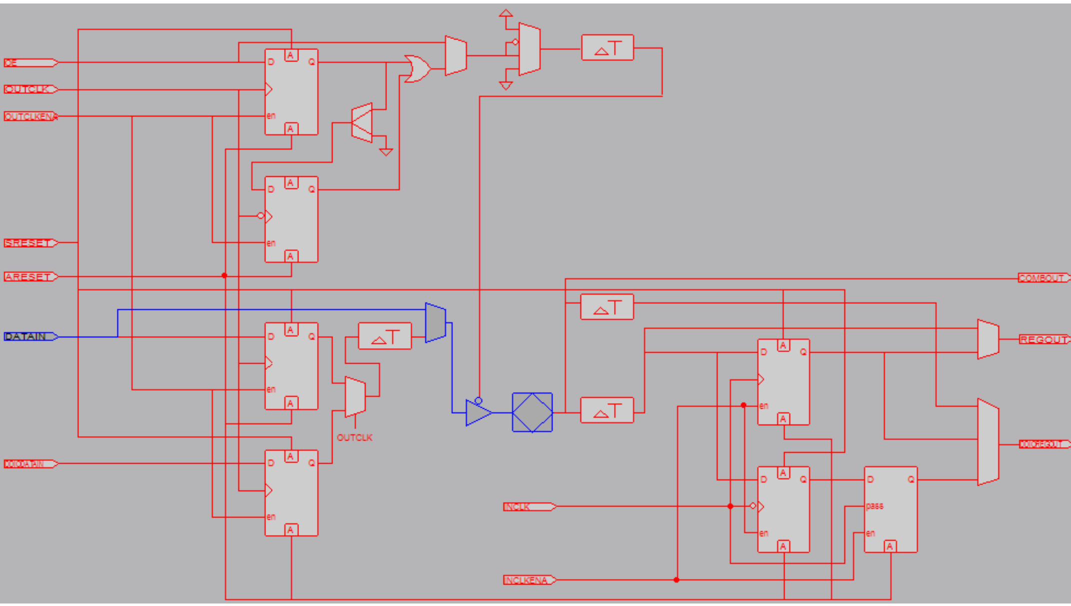
Notes to Figure 15–17:

(1) By default, the Quartus II software displays the used resources in blue and the unused resources in gray. In Figure 15–17, the used resources are in blue and the unused resources are in red.

(2) For more information about IOEs in Stratix and Stratix GX devices, refer to the *Stratix Device Handbook* and the *Stratix GX Device Handbook*.

Figure 15–18 shows the Arria GX and Stratix II IOE structures.

Figure 15–18. Arria GX Device and Stratix II IOE and Structure *(Note 1)*, *(2)*, *(3)*



Notes to Figure 15–18:

(1) By default, the Quartus II software displays the used resources in blue and the unused resources in gray. In Figure 15–18, the used resources are in blue and the unused resources are in red.

(2) For more information about IOEs in Arria GX and Stratix II devices, refer to the appropriate device handbook.

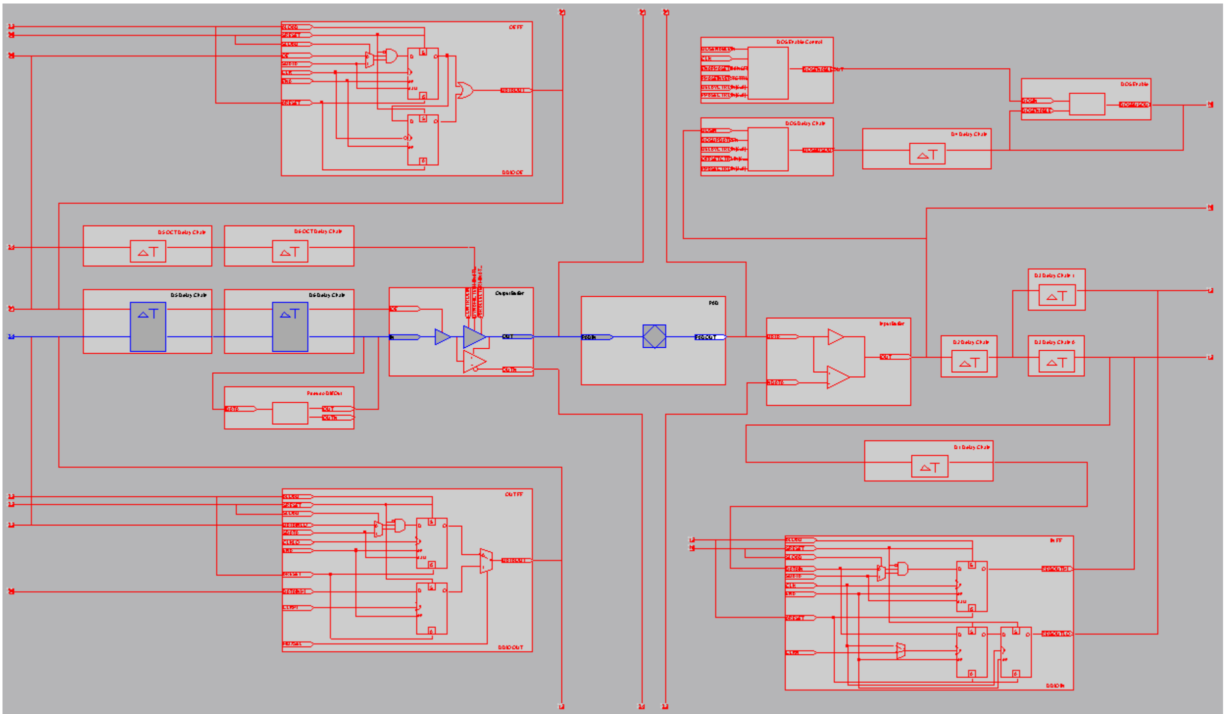
(3) Current IOE shown in a DQS pin. Non-DQS pins do not contain DQS delay circuitry.

Stratix III IOE

The IOE in Stratix III devices contain a bi-directional I/O buffer and I/O registers to support a complete embedded bi-directional single data rate or DDR transfer (shown in Figure 15–19). The I/O registers are composed of the input path for handling data from the pin to the core, the output path for handling data from the core to the pin, and the output enable (OE) path for handling the OE signal for the output buffer. Each path consists of a set of delay elements that allow you to fine-tune the timing characteristics of each path for skew management.

For more information about programmable IOEs in Stratix III devices, refer to *AN 474: Implementing Stratix III Programmable I/O Delay Settings in the Quartus II Software*.

Figure 15–19. Stratix III Device IOE and Structure *(Note 1)*, *(2)*



Notes to Figure 15–19:

(1) By default, the Quartus II software displays the used resources in blue and the unused resources in gray. In Figure 15–19, the used resources are in blue and the unused resources are in red.

(2) For more information about IOEs in Stratix III devices, refer to the *Stratix III Device Handbook*. For Stratix IV devices, refer to the *Stratix IV Device Handbook*.

Cyclone II and Cyclone IOEs

The IOEs in Cyclone II and Cyclone devices contain a bidirectional I/O buffer and three registers for complete bidirectional single data-rate transfer. Figure 15–20 shows the Cyclone II and Cyclone IOE structure. The IOE contains one input register, one output register, and one output enable register.

Figure 15–20. Cyclone II and Cyclone Device IOEs and Structure *(Note 1)*, *(2)*

Notes to Figure 15–20:

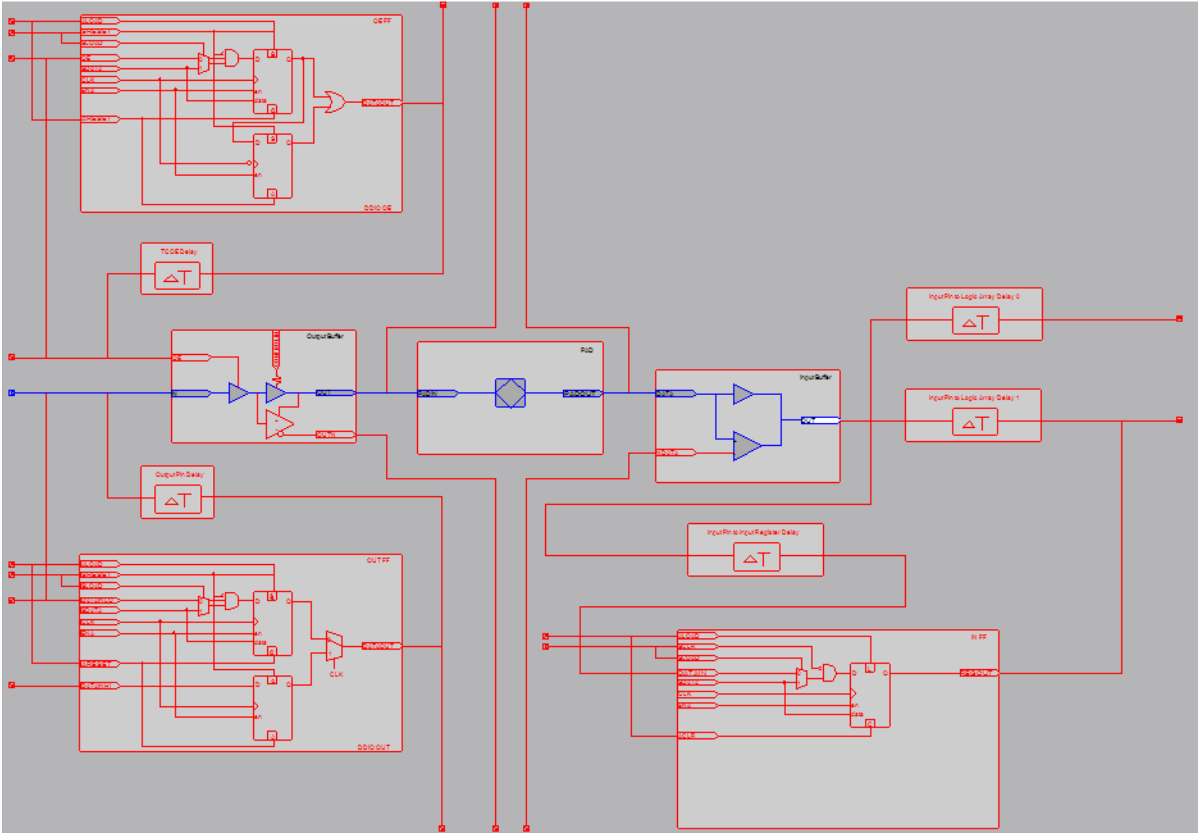
(1) By default, the Quartus II software displays the used resources in blue and the unused resources in gray. In Figure 15–20, the used resources are in blue and the unused resources are in red.

(2) For more information about IOEs in Cyclone II and Cyclone devices, refer to the *Cyclone II Device Handbook* and *Cyclone Device Handbook*, respectively.

Cyclone III IOEs

Cyclone III device IOEs contain a bidirectional I/O buffer and five registers for complete embedded bidirectional single-data rate transfer. Figure 15–21 shows the Cyclone III IOE structure. The IOE contains one input register, two output registers, and two output-enable registers. The two output registers and two output-enable registers are utilized for double-data rate (DDR) applications. You can use the input registers for fast setup times and the output registers for fast clock-to-output times. Additionally, you can use the output-enable (OE) registers for fast clock-to-output enable timing. You can use IOEs for input, output, or bidirectional data paths.

Figure 15–21. Cyclone III Device IOEs and Structure *(Note 1)*, *(2)*



Notes to Figure 15–21:

(1) By default, the Quartus II software displays the used resources in blue and the unused resources in gray. In Figure 15–21, the used resources are in blue and the unused resources are in red.

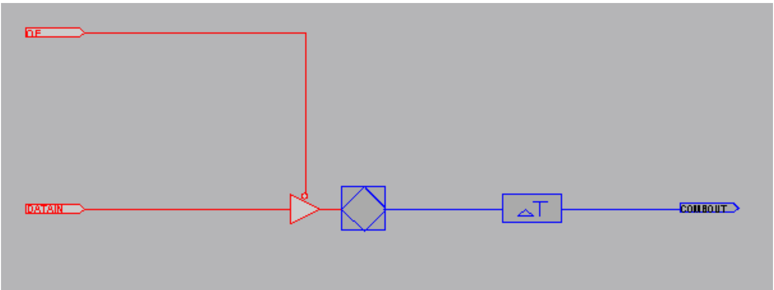
(2) For more information about IOEs in Cyclone III devices, refer to the *Cyclone III Device Handbook*.

© March 2009 Altera Corporation

MAX II IOEs

MAX II device IOEs contain a bidirectional I/O buffer. Figure 15–22 shows the MAX II IOE structure. Registers from adjacent LABs can drive to or be driven from the IOE's bidirectional I/O buffers.

Figure 15–22. MAX II Device IOEs and Structure *(Note 1)*, *(2)*



Notes to Figure 15–22:

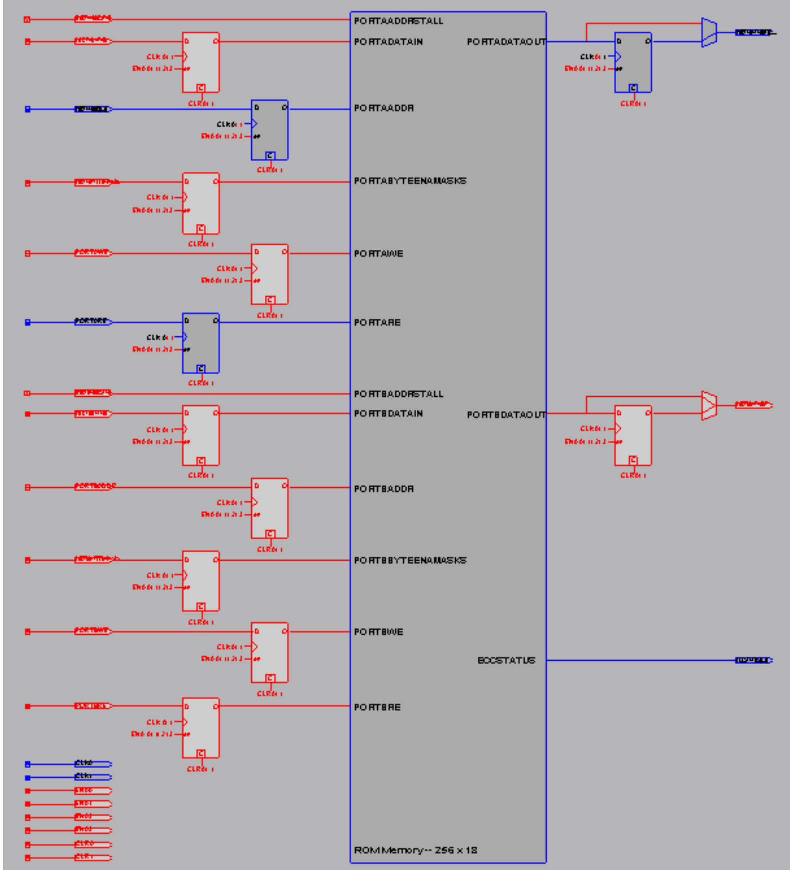
(1) By default, the Quartus II software displays the used resources in blue and the unused resources in gray. In Figure 15–22, the used resources are in blue and the unused resources are in red.

(2) For more information about IOEs in MAX II devices, refer to the *MAX II Device Handbook*.

FPGA RAM Blocks

With the Resource Property Editor, you can view the architecture of different RAM blocks in the device, modify the input and output registers from the RAM blocks, and modify the connectivity of the input and output ports. Figure 15–23 shows a M9K RAM view in a Stratix III device.

Figure 15–23. M9k RAM View in a Stratix III Device *(Note 1)*



Note to Figure 15–23:

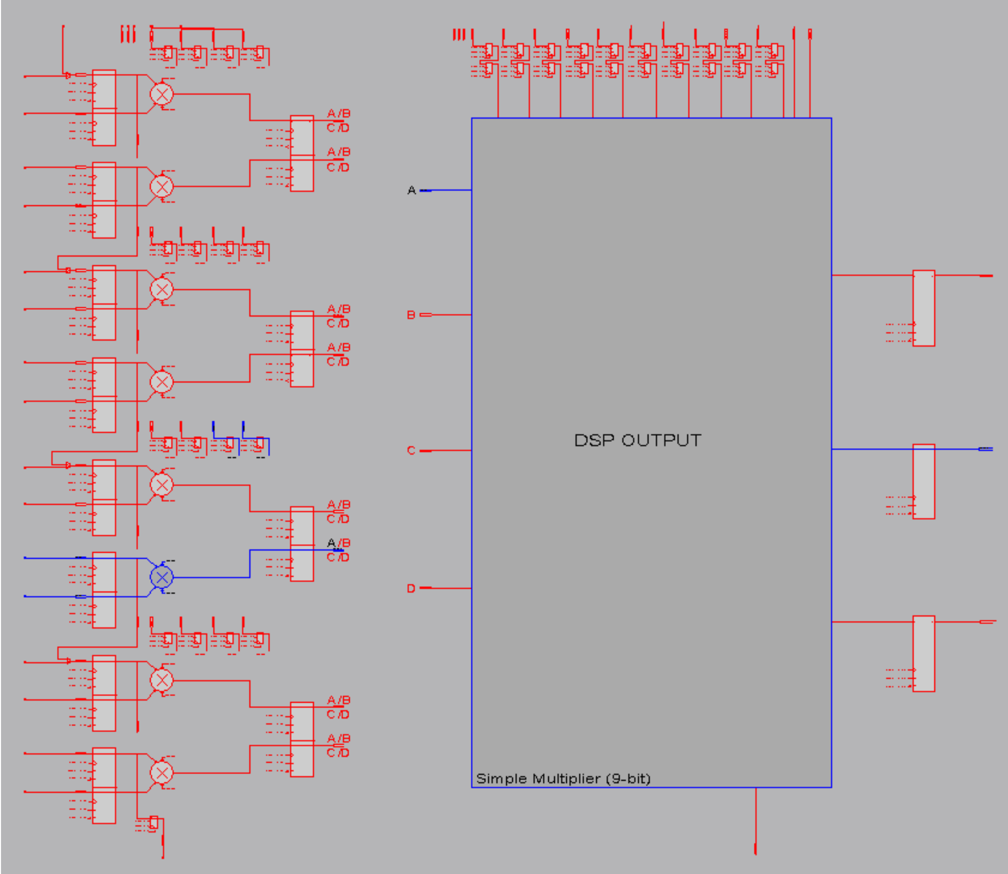
(1) By default, the Quartus II software displays the used resources in blue and the unused resources in gray. In Figure 15–23, the used resources are in blue and the unused resources are in red.

FPGA DSP Blocks

Dedicated hardware DSP circuit blocks in Altera devices provide performance benefits for the critical DSP functions in your design. The Resource Property Editor allows you to view the architecture of DSP blocks in the Resource Property Editor for the Stratix and Cyclone series of devices. The Resource Property Editor also allows you to modify the signal connections to and from the DSP blocks and modify the input and output registers from the DSP blocks.

Figure 15–24 shows a view of a DSP architecture in a Stratix III device.

Figure 15–24. DSP Block View in a Stratix III Device *(Note 1)*



Note to Figure 15–24:

(1) By default, the Quartus II software displays the used resources in blue and the unused resources in gray. In Figure 15–24, the used resources are in blue and the unused resources are in red.

Change Manager

The Change Manager maintains a record of every change that you perform with the Resource Property Editor. Each row in the Change Manager represents one ECO performed. The changes are numbered sequentially, such that the larger the number, the more recent the change.

More complex changes are marked in the Change Manager with a plus icon. You can expand a complex entry in the Change Manager by clicking the plus icon to reveal all the changes that occurred. An example of a complex change is the creation or deletion of an atom.

Table 15–1 summarizes the information shown by the Change Manager.

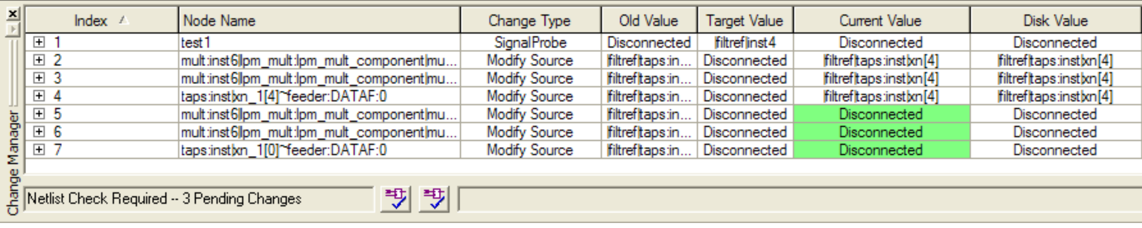
Table 15–1. Change Manager Information

Column Name	Description
Index	Identifies, by a sequential number, change records corresponding to changes made in the Chip Planner or Resource Property Editor. In the case of complex change records, the index column identifies not only the main change, but also any component changes.
Node Name	Uniquely identifies the resource to which a change has been made.
Change Type	Identifies the type of change that has been made to the resource.
Old Value	Lists the value of the resource immediately prior to the change being made.
Target Value	Lists the desired target value (new value) that you have established using the Resource Property Editor, Chip Planner, or SignalProbe.
Current Value	Lists the value of the resource in the netlist that is currently active in memory (as opposed to the value in the netlist saved on disk, which may be different if you have made changes and not yet used the **Check & Save All Netlist Changes** command).
Disk Value	Lists the current value of the resource on disk.
Comment	Lets you add a comment to a change record in the Change Manager. To add a comment to a change record, double-click in the **Comment** field of the record you want to annotate, and type the desired comment.

After you complete all of your design modifications, check the integrity of the netlist by right-clicking in the Change Manager and clicking **Check & Save All Netlist Changes**. If the applied changes successfully pass the netlist check, they are written to disk. If the changes do not pass the netlist check, all changes made since the previous successful netlist check are reversed. Figure 15–25 shows the Change Manager.

Colored indicators in the **Current Value** and **Disk Value** columns indicate the present status of the data in those columns. Green in the **Current Value** column indicates that the change has been recorded. Blue in the **Disk Value** column indicates that the change has successfully passed a **Check & Save Netlist Changes** operation. Choose **Check & Save All Netlist Changes**.

Figure 15–25. Change Manager Results



For more information about SignalProbe pins, refer to the *Quick Design Debugging Using SignalProbe* chapter in volume 3 of the *Quartus II Handbook*.

Each line in the Change Manager represents a change record. Simple changes appear as a single line. More complex changes, which require that several actions be performed to achieve the change, appear as a single line marked by a plus icon. Click the plus icon to show all the component actions performed as part of the change.

Complex Changes in the Change Manager

Certain types of changes that you make in the Resource Property Editor or the Chip Planner (including creating or deleting atoms and changing connectivity) can appear to be self-contained, but these changes are actually composed of multiple actions. Complex changes are indicated with a plus icon in the **Index** column.

The change record in the Change Manager is a single-line representation of the actual change actions that occurred. You expand the change record to show the component actions that make up the change by clicking the plus icon.

After expanding a change entry in the Change Manager, you can see that creation of an atom consists of three actions:

- The creation of a new logic cell
- The creation of an output port on the newly created logic cell
- The assignment of a location index to the newly created logic cell

You cannot select individual components of a complex change record; if you select any part of a complex change record, the entire complex change record is selected.

For examples of managing changes with the Change Manager, refer to "Example of Managing Changes With the Change Manager" in the Quartus II Help.

Managing SignalProbe Signals

The SignalProbe pins that you create from the **SignalProbe Pins** dialog box are recorded in the Change Manager. After you have created a SignalProbe assignment, you can use the Change Manager to quickly disable SignalProbe assignments by selecting **Revert to Last Saved Netlist** from the right-click menu in the Change Manager.

For more information about SignalProbe pins, refer to the *Quick Design Debugging Using SignalProbe* chapter in volume 3 of the *Quartus II Handbook*.

Exporting Changes

You can export all your changes to a tool command language (Tcl) script, a Comma Separated Value (**.csv)** file, or a Text **(.txt)** file. The Tcl file enables you to write a script that reapplies changes that were deleted by compilation. You can also write a script that applies to other Quartus II software projects that you create. The **.csv** or **.txt** files provide a list of changes in a tabular format. To export changes, perform the following steps:

1. On the right-click menu, click **Export Changes.**
2. Specify the Tcl file name.
3. Click **OK**.

The resulting Tcl script can also implement similar changes to another Quartus II design.

Using Incremental Compilation in the ECO Flow

Beginning with the Quartus II software version 6.1, the incremental compilation feature is turned on by default. The top-level design is automatically set to a design partition when the incremental compilation feature is on. A design partition during incremental compilation can have different netlist types (netlist types can be set to source HDL, post synthesis, or post-fit). The netlist type indicates whether that partition should be resynthesized or refit during the recompilation. Incremental compilation saves you time and preserves the placement of unchanged partitions in your design if small changes must be made to some partitions late in the design cycle.

For more information about partitions, their netlist types, and Quartus II incremental compilation, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

The behavior of ECOs during an incremental compilation depends on the netlist type of your design partitions. The Quartus II software preserves ECOs if the partition containing the ECO satisfies the following two conditions:

- The netlist type of the affected partition is set to post-fit.
- There are no source code changes in the affected partition that would cause the partition to be resynthesized during recompilation.

If you have ECOs that affect multiple partitions in your design, the Quartus II software preserves your ECOs during recompilation if any of the affected partitions are set to post-fit.

Whenever an ECO affects multiple partitions, all of the affected partitions become linked. All of the higher-level "parent" partitions up to their nearest common parent are also linked. In such cases, the connection between the partitions is actually defined outside of the two partitions immediately affected, so all the partitions must be compiled together. The linked partition inherits the netlist type of the partition with the highest level of preservation. For example, if an ECO is performed on a lower-level partition of a post-fit type and a top-level partition of a post-synthesis type, the two partitions will be linked and will have a post-fit netlist type.

If the partitions are set to use the source code or a post-synthesis netlist, the software issues a warning and the post-fit ECO changes are not included in the new compilation.

For example, if your top-level partition netlist type is set to post-synthesis, and either you have no other lower-level partitions or the lower-level partitions netlist type is also set to post-synthesis, during recompilation, your ECOs are not preserved and a warning message appears in the messages window, indicating that ECO modifications are discarded; however, all of the ECO information is retained in the Change Manager. In this case, you can apply ECOs from the Change Manager and perform the **Check & Save All Netlist Changes** step as described in "ECO Flow without Quartus II Incremental Compilation" on page 15–33.

ECO Flow without Quartus II Incremental Compilation

If you do not use the Quartus II incremental compilation feature and have implemented ECOs, those ECOs are not preserved during recompilation of your design; however, all of the ECOs remain in the Change Manager. To apply an ECO, right click the Change Manager and click **Apply Selected Change**. (If the Change Manager window is not visible at the bottom of your screen, from the View menu, point to **Utility Windows** and click **Change Manager**.)

After applying the selected ECO, perform one of the following steps:

- From the menu within the Change Manager, click **Check & Save All Netlist Changes**.

  or

- From the Processing menu, point to **Start** and click **Start Check & Save All Netlist Changes**.

Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. The Tcl commands for controlling the Chip Planner are located in the `chip_planner` package of the `quartus_cdb` executable. A comprehensive list of Tcl commands for the Chip Planner can be found in the *Quartus Scripting Reference Manual*.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. For more information about all settings and constraints in the Quartus II software, refer to the *Quartus II Settings File Reference Manual*. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Common ECO Applications

This section provides examples of the situations in which you might use an ECO to make a post-compilation change to your design. To help build your system quickly, you can use Chip Planner functions to perform the following activities:

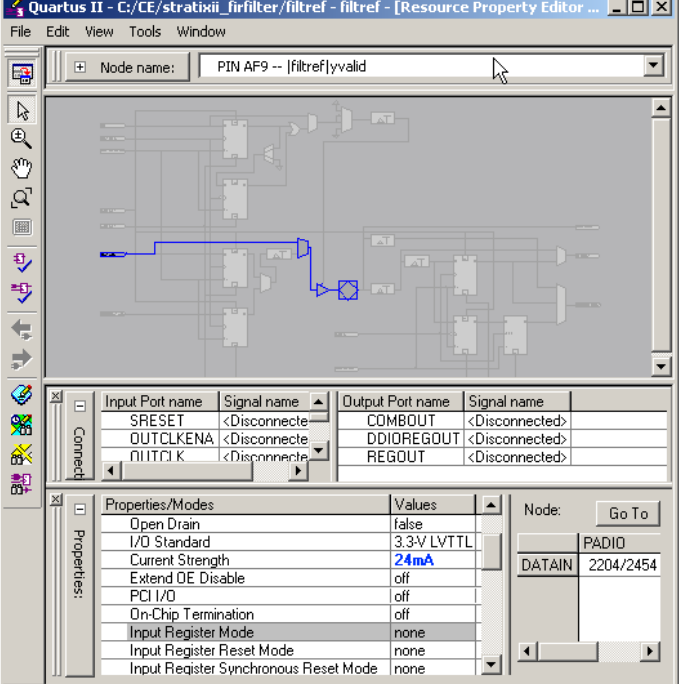
- Adjust the drive strength of an I/O using the Chip Planner
- Modify the PLL properties using the Resource Property Editor (see “Modify the PLL Properties Using the Chip Planner” on page 15–34)
- Modify the connectivity between new resource atoms

Adjust the Drive Strength of an I/O Using the Chip Planner

To adjust the drive strength of an I/O, follow the steps in this section to run the Fitter and assembler to incorporate the ECO changes into the netlist of the design.

1. In the Chip Planner, select the **Post Compilation Editing (ECO)** task.
2. Locate the I/O in the **Resource Property Editor**, as shown in Figure 15–26.

Figure 15–26. I/O in the Resource Property Editor



3. Click the **Current Strength** box for the selected I/O, then click **Edit**.
4. Change the value for the desired current strength.
5. Right-click the ECO change in the Change Manager tool and click **Check & Save All Netlist Changes** to apply the ECO change.

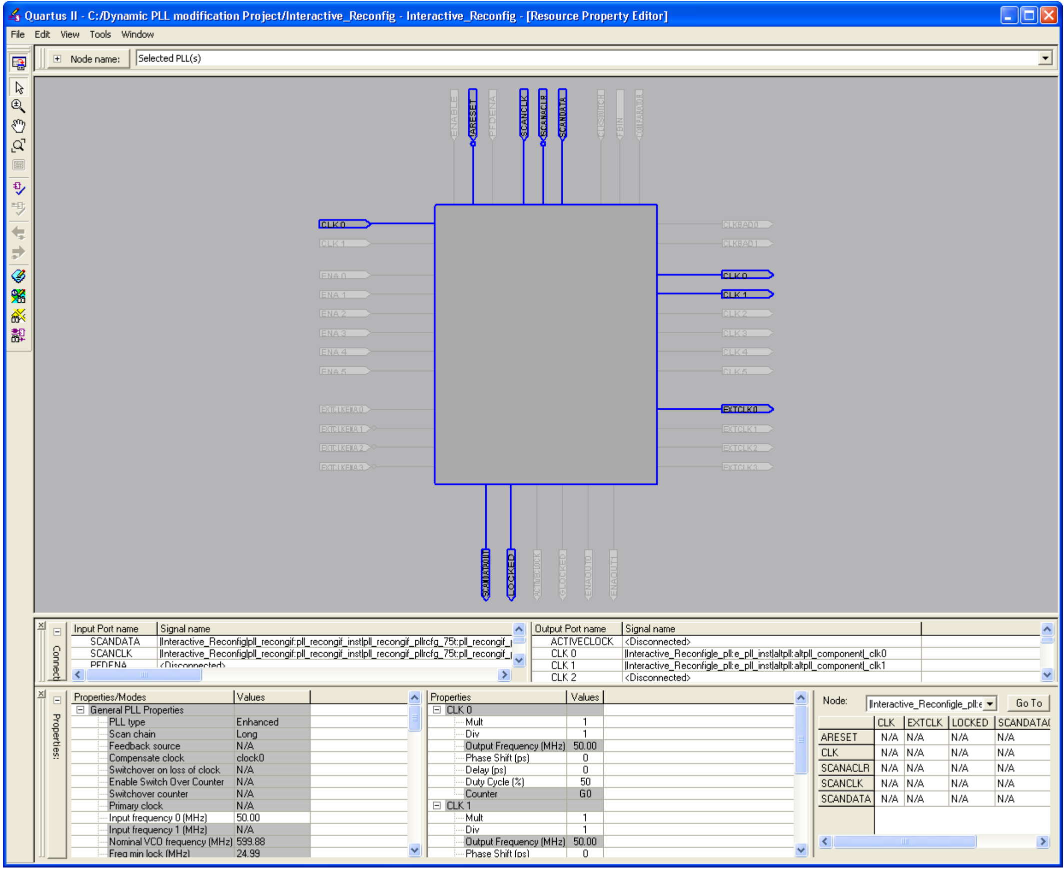
Changing the pin locations of input/output ports can be done using the ECOs flow as well. You can drag and move the signal from an existing pin location to a new location while in the Post Compilation Editing (ECO) task in the Chip Planner. Afterward, you can set **Check & Save All Netlist Changes** to compile the ECO.

Modify the PLL Properties Using the Chip Planner

PLLs are used to modify and generate clock signals to meet design requirements. Additionally, PLLs are used for distributing clock signals to different devices in a design, reducing clock skew between devices, improving I/O timing, and generating internal clock signals.

The Resource Property Editor enables you to view and modify PLL properties to meet your design requirements. Using the Stratix PLL as an example, the rest of this section describes the adjustable PLL properties and the equations as a function of the adjustable PLL properties that govern the PLL output parameters. Figure 15–27 shows a Stratix PLL as shown in the Resource Property Editor.

Figure 15–27. PLL View in a Stratix Device



PLL Properties

The Resource Property Editor enables you to modify PLL options, such as phase shift, output clock frequency, and duty cycle. You can also change the following PLL properties with the Resource Property Editor:

- Input frequency
- M V_{CO} tap
- M initial
- M value
- N value
- M counter delay
- N counter delay
- M2 value
- N2 value
- SS counter
- Charge pump current
- Loop filter resistance

- Loop filter capacitance
- Counter delay
- Counter high
- Counter low
- Counter mode
- Counter initial
- V_{CO} tap

Post-compilation PLL properties can also be viewed in the Compilation Report. To do so, in the Compilation Report, select **Fitter** and then select **Resource Section**.

Adjusting the Duty Cycle

Use Equation 15–1 to adjust the duty cycle of individual output clocks.

Equation 15–1.

$$\text{High \%} = \frac{\text{Counter High}}{(\text{Counter High} + \text{Counter Low})}$$

Adjusting the Phase Shift

Use Equation 15–2 to adjust the phase shift of an output clock of a PLL.

Equation 15–2.

$$\text{Phase Shift} = (\text{Period } V_{CO} \times 0.125 \times \text{Tap } V_{CO}) + (\text{Initial } V_{CO} \times \text{Period } V_{CO})$$

For normal mode Period V_{CO}, Tap V_{CO}, and Initial V_{CO} are governed by the following settings:

$$\text{Tap } V_{CO} = \text{Counter Delay} - \text{M Tap } V_{CO}$$

$$\text{Initial } V_{CO} = \text{Counter Initial} - \text{M Initial}$$

$$\text{Period } V_{CO} = \text{In Clock Period} \times N \div M$$

For external feedback mode, Tap V_{CO}, Initial V_{CO}, and Period V_{CO} are governed by the following settings:

$$\text{Tap } V_{CO} = \text{Counter Delay} - \text{M Tap } V_{CO}$$

$$\text{Initial } V_{CO} = \text{Counter Initial} - \text{M Initial}$$

$$\text{Period } V_{CO} = \frac{\text{In Clock Period} \times N}{(M + \text{Counter High} + \text{Counter Low})}$$

For a detailed description of the settings, refer to the Quartus II Help. For more information about Stratix device PLLs, refer to the *Stratix Architecture* chapter in volume 1 of the *Stratix Device Handbook*. For more information about PLLs in Arria GX, Stratix II, Cyclone II, and Cyclone devices, refer to the appropriate device handbook.

Adjusting the Output Clock Frequency

Use Equation 15–3 to adjust the PLL output clock in normal mode.

Equation 15–3.

$$\text{Output Clock Frequency} = \text{Input Frequency} \bullet \frac{M \text{ value}}{N \text{ Value} + \text{Counter High} + \text{Counter Low}}$$

Use Equation 15–4 to adjust the PLL output clock in external feedback mode.

Equation 15–4.

$$\text{OUTCLK} = \frac{M \text{ value} + \text{External Feedback Counter High} + \text{External Feedback Counter Low}}{N \text{ value} + \text{Counter High} + \text{Counter Low}}$$

Adjusting the Spread Spectrum

Use Equation 15–5 to adjust the spread spectrum for your PLL.

Equation 15–5.

$$\% \text{ spread} = \frac{M_2 N_1}{M_1 N_2}$$

Modify the Connectivity between Resource Atoms

The Chip Planner and Resource Property Editor allow you to create new resource atoms and manipulate the existing connection between resource atoms in the post-fit netlist. This feature is useful for small changes during the debugging stage, such as manually inserting pipeline registers into a combinational path that fails timing, or to route a signal to a spare I/O pin for analysis. Use the following procedure to create a new register in a Cyclone III device and route register output to a spare I/O pin. This example illustrates the mechanics of creating a new resource atom and modifying the connections between resource atoms.

To create new resource atoms and manipulate the existing connection between resource atoms in the post-fit netlist, perform the following steps:

1. Create a new register in the Chip Planner Floorplan.
2. Locate the atom in the Resource Property Editor.
3. Assign a clock signal to the register: Right-click the clock input port for the register, point to **Edit connection,** and click **Other**. Use the Node Finder to assign a clock signal from your design.
4. Tie the SLOAD input port to V_{CC}: Right-click the clock input port for the register, point to **Edit connection**, and click **VCC**.
5. Assign a data signal from your design to the SDATA port.
6. In the connectivity window, under the output port names, copy the port name of the register.
7. In the Chip Planner Floorplan, locate a free I/O resource and create an output buffer.

8. Locate the new I/O atom in the Resource Property Editor.
9. On the input port to the output buffer, right-click, point to **Edit connection**, and click **Other**.
10. In the dialog box that appears, type the output port name of the register you have created.
11. Run the ECO Fitter to apply the changes by clicking the **Check and Save Netlist Changes** button.

A successful ECO connection is subject to the available routing resources. You can view the relative routing utilization by selecting Routing Utilization as the Background Color Map in the **Layers Settings** dialog box. Also, you can view individual routing channel utilization from local, row, and column interconnects using the tooltips created from positioning your mouse pointer over the appropriate resource. Refer to the device data sheet for more information about the architecture of the routing interconnects of your device.

Post ECO Steps

This section describes the operations you can perform after making an ECO change with the Chip Planner.

Performing Static Timing Analysis

After you make an ECO change with the Chip Planner, you must perform static timing analysis of your design with either the Quartus II Classic Timing Analyzer or the Quartus II TimeQuest Timing Analyzer to ensure that your changes have not adversely affected your design's timing performance.

For example, when you turn on one of the delay chain settings for a specific pin, you change the I/O timing. Therefore, to ensure that all timing requirements are still met, you should perform static timing analysis.

Whenever you change your design using the Chip Planner, Altera also recommends that you perform a gate-level timing simulation on your design with either the Quartus II Simulator or a third-party EDA simulation tool.

For more information about performing a static timing analysis of your design, refer to the *Quartus II Classic Timing Analyzer* or *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the Quartus II *Handbook*.

Conclusion

As the time-to-market pressure mounts, it is more and more important to produce a fully functional design in the shortest amount of time. To address this challenge, Altera developed the Chip Planner in the Quartus II software suite. The Chip Planner enables you to analyze and modify your design floorplan. Also, ECO changes made with the Chip Planner do not require a full recompilation, eliminating the lengthy process of RTL modification, resynthesis, and another place-and-route cycle. In summary, the Chip Planner shortens the verification cycle and brings timing closure to your design in a shorter period of time.

Document Revision History

Table 15–2 shows the revision history for this chapter.

Table 15–2. Document Revision History

Date and Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Updated Figure 15–19 ■ Made minor editorial updates ■ Chapter 15 was previously Chapter 13 in the 8.1.0 release.	Updated for the Quartus II software release 9.0.
November 2008 v8.1.0	Corrected preservation attributes for ECOs in the section “Using Incremental Compilation in the ECO Flow” on page 15–32. Minor editorial updates. Changed to 8½” x 11” page size.	Updated for the Quartus II software release 8.1.
May 2008 v8.0.0	■ Updated device support list ■ Modified description for ECO support for block RAMs and DSP blocks ■ Corrected Stratix PLL ECO example ■ Added an application example to show modifying the connectivity between resource atoms	Updated for the Quartus II software release 8.0.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

About this Handbook

This handbook provides comprehensive information about the Altera® Quartus® II design software, version 9.0.

How to Contact Altera

For the most up-to-date information about Altera products, see the following table.

Contact *(Note 1)*	Contact Method	Address
Technical support	Website	www.altera.com/support
Technical training	Website	www.altera.com/training
	Email	custrain@altera.com
Altera literature services	Email	literature@altera.com
Non-technical support (General)	Email	nacomp@altera.com
(Software Licensing)	Email	authorization@altera.com

Note:

(1) You can also contact your local Altera sales office or sales representative.

Third-Party Software Product Information

Third-party software products described in this handbook are not Altera products, are licensed by Altera from third parties, and are subject to change without notice. Updates to these third-party software products may not be concurrent with Quartus II software releases. Altera has assumed responsibility for the selection of such third-party software products and its use in the Quartus II 9.0 software release. To the extent that the software products described in this handbook are derived from third-party software, no third party warrants the software, assumes any liability regarding use of the software, or undertakes to furnish you any support or information relating to the software. EXCEPT AS EXPRESSLY SET FORTH IN THE APPLICABLE ALTERA PROGRAM LICENSE SUBSCRIPTION AGREEMENT UNDER WHICH THIS SOFTWARE WAS PROVDED TO YOU, ALTERA AND THIRD-PARTY LICENSORS DISCLAIM ALL WARRANTIES WITH RESPECT TO THE USE OF SUCH THIRD-PARTY SOFTWARE CODE OR DOCUMENTATION IN THE SOFTWARE, INCLUDING, WITHOUT LIMITATION, ANY WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, TITLE, AND NONINFRINGEMENT. For more information, including the latest available version of specific third-party software products, refer to the documentation for the software in question.

Typographic Conventions

The following table shows the typographic conventions that this document uses.

Visual Cue	Meaning
Bold Type with Initial Capital Letters	Command names, dialog box titles, checkbox options, and dialog box options are shown in bold, initial capital letters. Example: **Save As** dialog box.
bold type	External timing parameters, directory names, project names, disk drive names, file names, file name extensions, and software utility names are shown in bold type. Examples: $\mathbf{f_{MAX}}$, **\qdesigns** directory, **d:** drive, **chiptrip.gdf** file.
Italic Type with Initial Capital Letters	Document titles are shown in italic type with initial capital letters. Example: *AN 75: High-Speed Board Design.*
Italic type	Internal timing parameters and variables are shown in italic type. Examples: t_{PIA}, $n + 1$. Variable names are enclosed in angle brackets (< >) and shown in italic type. Example: <*file name*>, <*project name*>**.pof** file.
Initial Capital Letters	Keyboard keys and menu names are shown with initial capital letters. Examples: Delete key, the Options menu.
"Subheading Title"	References to sections within a document and titles of on-line help topics are shown in quotation marks. Example: "Typographic Conventions."
`Courier type`	Signal and port names are shown in lowercase Courier type. Examples: `data1`, `tdi`, `input`. Active-low signals are denoted by suffix `n`, e.g., `resetn`. Anything that must be typed exactly as it appears is shown in Courier type. For example: `c:\qdesigns\tutorial\chiptrip.gdf`. Also, sections of an actual file, such as a Report File, references to parts of files (e.g., the AHDL keyword `SUBDESIGN`), as well as logic function names (e.g., `TRI`) are shown in Courier.
1., 2., 3., and a., b., c., etc.	Numbered steps are used in a list of items when the sequence of the items is important, such as the steps listed in a procedure.
■ ■	Bullets are used in a list of items when the sequence of the items is not important.
✓	The checkmark indicates a procedure that consists of one step only.
☞	The hand points to information that requires special attention.
CAUTION	A caution calls attention to a condition or possible situation that can damage or destroy the product or the user's work.
WARNING	A warning calls attention to a condition or possible situation that can cause injury to the user.
↵	The angled arrow indicates you should press the Enter key.
(feet)	The feet direct you to more information on a particular topic.

Chapter 11. Synopsys PrimeTime Support

Introduction 11-1
Quartus II Settings for Generating the PrimeTime Software Files 11-1
Files Generated for the PrimeTime Software Environment 11-2
The Netlist 11-3
The SDO File 11-3
Generating Multiple Operating Conditions with TimeQuest 11-3
The Tcl Script 11-5
Generated File Summary 11-6

Running the PrimeTime Software 11-7
Analyzing Quartus II Projects 11-8
Other pt_shell Commands 11-8
PrimeTime Timing Reports 11-8
Sample of the PrimeTime Software Timing Report 11-8
Comparing Timing Reports from the Quartus II Classic Timing Analyzer and the PrimeTime Software 11-9
Clock Setup Relationship and Slack 11-10
Clock Hold Relationship and Slack 11-13
Input Delay and Output Delay Relationships and Slack 11-16
Static Timing Analyzer Differences 11-18
The Quartus II Classic Timing Analyzer and the PrimeTime Software 11-18
Rise/Fall Support 11-18
Minimum and Maximum Delays 11-18
Recovery/Removal Analysis 11-18
Encrypted Intellectual Property Blocks 11-19
Registered Clock Signals 11-19
Multiple Source and Destination Register Pairs 11-19
Latches 11-20
LVDS I/O 11-20
Clock Latency 11-20
Input and Output Delay Assignments 11-20
Generated Clocks Derived from Generated Clocks 11-20
The Quartus II TimeQuest Timing Analyzer and the PrimeTime Software 11-21
Encrypted Intellectual Property Blocks 11-21
Latches 11-21
LVDS I/O 11-21
The Quartus II TimeQuest Timing Analyzer SDC File and PrimeTime Compatibility 11-21
Clock and Data Paths 11-22
Inverting and Non-Inverting Propagation 11-22
Multiple Rise/Fall Numbers For a Timing Arc 11-22
Virtual Generated Clocks 11-22
Generated Clocks Derived from Generated Clocks 11-22
Conclusion 11-22

Document Revision History 11-23

Section III. Power Estimation and Analysis

Chapter 12. PowerPlay Power Analysis

Introduction 12-1
Quartus II Early Power Estimator File 12-2
PowerPlay Early Power Estimator File Generator Compilation Report 12-3
Types of Power Analyses 12-5
Factors Affecting Power Consumption 12-5
Device Selection 12-5
Environmental Conditions 12-6
Air Flow 12-6
Heat Sink and Thermal Compound 12-6
Ambient Temperature 12-6
Board Thermal Model 12-6
Design Resources 12-6
Number, Type, and Loading of I/O Pins 12-7

Number and Type of Logic Elements, Multiplier Elements, and RAM Blocks 12-7
Number and Type of Global Signals 12-7
Signal Activities 12-7
PowerPlay Power Analyzer Flow 12-8
Operating Conditions 12-8
Signal Activities Data Sources 12-9
Simulation Results 12-10
Using Simulation Files in Modular Design Flows 12-11
Complete Design Simulation 12-12
Modular Design Simulation 12-12
Multiple Simulations on the Same Entity 12-13
Overlapping Simulations 12-13
Partial Simulations 12-14
Node Name Matching Considerations 12-14
Glitch Filtering 12-14
Node and Entity Assignments 12-16
Timing Assignments to Clock Nodes 12-16
Default Toggle Rate Assignment 12-17
Vectorless Estimation 12-17
Using the PowerPlay Power Analyzer 12-17
Common Analysis Flows 12-17
Signal Activities from Full Post-Fit Netlist (Timing) Simulation 12-18
Signal Activities from RTL (Functional) Simulation, Supplemented by Vectorless Estimation . . . .
. . . . 12-18
Signal Activities from Vectorless Estimation, User-Supplied Input Pin Activities 12-18
Signal Activities from User Defaults Only 12-18
Generating a .saf or .vcd File Using the Quartus II Simulator 12-18
Generating a VCD File Using a Third-Party Simulator 12-21
Generating a VCD File from ModelSim Software 12-22
Running the PowerPlay Power Analyzer Using the Quartus II GUI 12-23
PowerPlay Power Analyzer Compilation Report 12-27
Summary 12-27
Settings 12-27
Simulation Files Read 12-27
Operating Conditions Used 12-28
Thermal Power Dissipated by Block 12-28
Thermal Power Dissipation by Block Type (Device Resource Type) 12-28
Thermal Power Dissipation by Hierarchy 12-28
Core Dynamic Thermal Power Dissipation by Clock Domain 12-28
Current Drawn from Voltage Supplies 12-28
Confidence Metric Details 12-29
Signal Activities 12-29
Messages 12-29
Specific Rules for Reporting 12-29
Scripting Support 12-29
Running the PowerPlay Power Analyzer from the Command Line 12-30
Conclusion 12-31
Referenced Documents 12-31
Document Revision History 12-31

Section IV. In-System Design Debugging

Introduction IV-1
On-Chip Debugging Ecosystem IV-1

Analysis Tools for RTL Nodes IV-3
Resource Usage IV-4
Pin Usage IV-5
Usability Enhancements IV-6
Stimulus-Capable Tools IV-8
In-System Sources and Probes IV-8
In-System Memory Content Editor IV-8
Virtual JTAG Interface Megafunction IV-9
Conclusion IV-9

Chapter 13. Quick Design Debugging Using SignalProbe

Introduction 13-1
Debugging Using the SignalProbe Feature 13-1
Reserve the SignalProbe Pins 13-2
Perform a Full Compilation 13-3
Assign a SignalProbe Source 13-3
Add Registers to the Pipeline Path to SignalProbe Pin 13-4
Perform a SignalProbe Compilation 13-5
Analyze the Results of the SignalProbe Compilation 13-5
SignalProbe ECO Flows 13-6
SignalProbe ECO Flow with Quartus II Incremental Compilation 13-6
SignalProbe ECO Flow without Quartus Incremental Compilation 13-7
Common Questions About the SignalProbe Feature 13-8
Why Did I Get the Following Error Message, “Error: There are No Enabled SignalProbes to Process”? 13-8
How Can I Retain My SignalProbe ECOs during Re-Compilation of My Design? 13-8
Why Did My SignalProbe Source Disappear in the Change Manager? 13-8
What is an ECO and Where Can I Find More Information about ECOs? 13-9
How Do I Migrate My Previous SignalProbe Assignments in the Quartus II Software Version 5.1 and Earlier to Version 6.0 and Later? 13-9
What are all the Changes for the SignalProbe Feature between the Quartus II Software Version 5.1 and Earlier, and Version 6.0 and Later? 13-9
Why Can't I Reserve a SignalProbe Pin? 13-10
Scripting Support 13-11
Make a SignalProbe Pin 13-11
Delete a SignalProbe Pin 13-11
Enable a SignalProbe Pin 13-11
Disable a SignalProbe Pin 13-11
Perform a SignalProbe Compilation 13-11
Migrate Previous SignalProbe Pins to the Quartus II Software Versions 6.0 and Later 13-12
Script Example 13-12
Using SignalProbe with the APEX Device Family 13-12
Adding SignalProbe Sources 13-12
Performing a SignalProbe Compilation 13-13
Running SignalProbe with Smart Compilation 13-13
Understanding the Results of a SignalProbe Compilation 13-14
Analyzing SignalProbe Routing Failures 13-15
SignalProbe Scripting Support for APEX Devices 13-15
Reserving SignalProbe Pins 13-16
Adding SignalProbe Sources 13-16
Assigning I/O Standards 13-16
Adding Registers for Pipelining 13-16
Run SignalProbe Automatically 13-17
Run SignalProbe Manually 13-17

Enable or Disable All SignalProbe Routing 13-17
Running SignalProbe with Smart Compilation 13-17
Allow SignalProbe to Modify Fitting Results 13-17
Conclusion 13-18
Referenced Documents 13-18
Document Revision History 13-18

Chapter 14. Design Debugging Using the SignalTap II Embedded Logic Analyzer
Introduction 14-1
Hardware and Software Requirements 14-2
Design Flow Using the SignalTap II Embedded Logic Analyzer 14-4
SignalTap II Embedded Logic Analyzer Task Flow 14-4
Add the SignalTap II Embedded Logic Analyzer to Your Design 14-5
Configure the SignalTap II Embedded Logic Analyzer 14-5
Define Trigger Conditions 14-6
Compile the Design 14-6
Program the Target Device or Devices 14-6
Run the SignalTap II Embedded Logic Analyzer 14-6
View, Analyze, and Use Captured Data 14-6
Add the SignalTap II Embedded Logic Analyzer to Your Design 14-6
Creating and Enabling a SignalTap II File 14-7
Creating a SignalTap II File 14-7
Enabling and Disabling a SignalTap II File for the Current Project 14-8
Embedding Multiple Analyzers in One FPGA 14-9
Monitoring FPGA Resources Used by the SignalTap II Embedded Logic Analyzer 14-9
Using the MegaWizard Plug-In Manager to Create Your Embedded Logic Analyzer 14-10
Creating an HDL Representation Using the MegaWizard Plug-In Manager 14-10
SignalTap II Megafunction Ports 14-13
Instantiating the SignalTap II Embedded Logic Analyzer in Your HDL 14-14
Configure the SignalTap II Embedded Logic Analyzer 14-14
Assigning an Acquisition Clock 14-14
Adding Signals to the SignalTap II File 14-15
Signal Preservation 14-17
Assigning Data Signals Using the Node Finder 14-17
Assigning Data Signals Using the Technology Map Viewer 14-18
Node List Signal Use Options 14-19
Untappable Signals 14-19
Adding Signals with a Plug-In 14-19
Adding Finite State Machine State Encoding Registers 14-20
Modifying and Restoring Mnemonic Tables for State Machines 14-22
Additional Considerations 14-22
Specifying the Sample Depth 14-23
Capturing Data to a Specific RAM Type 14-23
Choosing the Buffer Acquisition Mode 14-23
Non-Segmented Buffer 14-24
Segmented Buffer 14-24
Using the Storage Qualifier Feature 14-25
Input Port Mode 14-27
Transitional Mode 14-28
Conditional Mode 14-29
Start/Stop Mode 14-30
State-Based 14-31
Showing Data Discontinuities 14-31
Disable Storage Qualifier 14-31

Managing Multiple SignalTap II Files and Configurations 14-32
Define Triggers 14-33
Creating Basic Trigger Conditions 14-33
Creating Advanced Trigger Conditions 14-34
Examples of Advanced Triggering Expressions 14-35
Trigger Condition Flow Control 14-36
Sequential Triggering 14-36
Custom State-Based Triggering 14-38
SignalTap II Trigger Flow Description Language 14-42
State Labels 14-42
Boolean_expression 14-43
Action_list 14-43
Resource Manipulation Action 14-43
Buffer Control Action 14-44
State Transition Action 14-44
Using the State-Based Storage Qualifier Feature 14-45
Specifying the Trigger Position 14-48
Creating a Power-Up Trigger 14-49
Enabling a Power-Up Trigger 14-49
Managing and Configuring Power-Up and Runtime Trigger Conditions 14-50
Using External Triggers 14-51
Trigger In 14-51
Trigger Out 14-51
Using the Trigger Out of One Analyzer as the Trigger In of Another Analyzer 14-52
Compile the Design 14-53
Faster Compilations with Quartus II Incremental Compilation 14-53
Enabling Incremental Compilation for Your Design 14-54
Using Incremental Compilation with the SignalTap II Embedded Logic Analyzer 14-55
Preventing Changes Requiring Recompilation 14-57
Timing Preservation with the SignalTap II Embedded Logic Analyzer 14-57
Performance and Resource Considerations 14-57
Program the Target Device or Devices 14-59
Programming a Single Device 14-59
Programming Multiple Devices to Debug Multiple Designs 14-60
Run the SignalTap II Embedded Logic Analyzer 14-60
Running with a Power-Up Trigger 14-62
Running with Runtime Triggers 14-62
Performing a Force Trigger 14-62
Runtime Reconfigurable Options 14-63
SignalTap II Status Messages 14-65
View, Analyze, and Use Captured Data 14-66
Viewing Captured Data 14-66
Capturing Data Using Segmented Buffers 14-67
Creating Mnemonics for Bit Patterns 14-69
Automatic Mnemonics with a Plug-In 14-69
Locating a Node in the Design 14-69
Saving Captured Data 14-70
Converting Captured Data to Other File Formats 14-70
Creating a SignalTap II List File 14-71
Other Features 14-71
Using the SignalTap II MATLAB MEX Function to Capture Data 14-71
Using SignalTap II in a Lab Environment 14-73
Remote Debugging Using the SignalTap II Embedded Logic Analyzer 14-73
Equipment Setup 14-73

Software Setup on the Remote PC 14-73
Software Setup on the Local PC 14-74
SignalTap II Setup on the Local PC 14-75
Using the SignalTap II Embedded Logic Analyzer in Devices with Configuration Bitstream Security 14-75
Backward Compatibility with Previous Versions of Quartus II Software 14-76
SignalTap II Scripting Support 14-76
SignalTap II Command-Line Options 14-76
SignalTap II Tcl Commands 14-78
Design Example: Using SignalTap II Embedded Logic Analyzers in SOPC Builder Systems 14-79
Custom Triggering Flow Application Examples 14-79
Design Example 1: Specifying a Custom Trigger Position 14-80
Design Example 2: Trigger When triggercond1 Occurs Ten Times between triggercond2 and triggercond3 14-80
Conclusion 14-81
Referenced Documents 14-81
Document Revision History 14-82

Chapter 15. In-System Debugging Using External Logic Analyzers

Introduction 15-1
Choosing a Logic Analyzer 15-1
Required Components 15-2
FPGA Device Support 15-3
Debugging Your Design Using the Logic Analyzer Interface 15-3
Creating an LAI File 15-4
Creating a New Logic Analyzer Interface File 15-5
Opening an Existing External Analyzer Interface File 15-5
Saving the External Analyzer Interface File 15-5
Configuring the Logic Analyzer Interface File Core Parameters 15-5
Mapping the Logic Analyzer Interface File Pins to Available I/O Pins 15-6
Mapping Internal Signals to the Logic Analyzer Interface Banks 15-7
Using the Node Finder 15-7
Enabling the Logic Analyzer Interface Before Compiling Your Quartus II Project 15-8
Compiling Your Quartus II Project 15-8
Programming Your FPGA Using the Logic Analyzer Interface 15-9
Using the Logic Analyzer Interface with Multiple Devices 15-10
Configuring Banks in the Logic Analyzer Interface File 15-10
Acquiring Data on Your Logic Analyzer 15-10
Advanced Features 15-11
Using the Logic Analyzer Interface with Incremental Compilation 15-11
Creating Multiple Logic Analyzer Interface Instances in One FPGA 15-11
Conclusion 15-12
Referenced Documents 15-12
Document Revision History 15-12

Chapter 16. In-System Updating of Memory and Constants

Introduction 16-1
Overview 16-1
Device Megafunction Support 16-2
Using In-System Updating of Memory and Constants with Your Design 16-2
Creating In-System Modifiable Memories and Constants 16-3
Running the In-System Memory Content Editor 16-3
Instance Manager 16-4

Editing Data Displayed in the Hex Editor . . . 16-6
Importing and Exporting Memory Files . . . 16-6
Viewing Memories and Constants in the Hex Editor . . . 16-6
Scripting Support . . . 16-8
Programming the Device Using the In-System Memory Content Editor . . . 16-8
Example: Using the In-System Memory Content Editor with the SignalTap II Embedded Logic Analyzer . . . 16-9
Conclusion . . . 16-9
Referenced Documents . . . 16-9
Document Revision History . . . 16-10

Chapter 17. Design Debugging Using In-System Sources and Probes

Introduction . . . 17-1
Overview . . . 17-1
Hardware and Software Requirements . . . 17-3
Design Flow Using In-System Sources and Probes . . . 17-3
Configuring the altsource_probe Megafunction . . . 17-4
Instantiating the altsource_probe Megafunction . . . 17-6
Compiling the Design . . . 17-6
Running the In-System Sources and Probes Editor . . . 17-7
Programming Your Device Using the JTAG Chain Configuration Window . . . 17-8
Instance Manager . . . 17-8
Sources and Probes Editor Window . . . 17-10
Reading Probe Data . . . 17-10
Writing Data . . . 17-10
Data Organization . . . 17-10
Tcl Support . . . 17-11
Design Example: Dynamic PLL Reconfiguration . . . 17-14
Conclusion . . . 17-17
Referenced Documents . . . 17-17
Document Revision History . . . 17-17

Section V. Formal Verification

Chapter 18. Cadence Encounter Conformal Support

Introduction . . . 18-1

Chapter Revision Dates

The chapters in this book, *Quartus II Handbook Version 9.0 Volume 3: Verification*, were revised on the following dates. Where chapters or groups of chapters are available separately, part numbers are listed.

Chapter 1 Quartus II Simulator
Revised: *March 2009*
Part Number: *QII53017-9.0.0*

Chapter 2 Mentor Graphics ModelSim Support
Revised: *March 2009*
Part Number: *QII53001-9.0.0*

Chapter 3 Synopsys VCS and VCS-MX Support
Revised: *March 2009*
Part Number: *QII53002-9.0.0*

Chapter 4 Cadence NC-Sim Support
Revised: *March 2009*
Part Number: *QII53003-9.0.0*

Chapter 5 Aldec Active-HDL Support
Revised: *March 2009*
Part Number: *QII53023-9.0.0*

Chapter 6 Simulating Altera IP in Third-Party Simulation Tools
Revised: *March 2009*
Part Number: *QII53014-9.0.0*

Chapter 7 The Quartus II TimeQuest Timing Analyzer
Revised: *March 2009*
Part Number: *QII53018-9.0.0*

Chapter 8 Best Practices for the Quartus II TimeQuest Timing Analyzer
Revised: *March 2009*
Part Number: *QII53024-9.0.0*

Chapter 9 Switching to the Quartus II TimeQuest Timing Analyzer
Revised: *March 2009*
Part Number: *QII53019-9.0.0*

Chapter 10 Quartus II Classic Timing Analyzer
Revised: *March 2009*
Part Number: *QII53004-9.0.0*

Chapter 11 Synopsys PrimeTime Support
Revised: *March 2009*
Part Number: *QII53005-9.0.0*

Chapter 12 PowerPlay Power Analysis
Revised: *March 2009*
Part Number: *QII53013-9.0.0*

Chapter 13 Quick Design Debugging Using SignalProbe
Revised: *March 2009*
Part Number: *QII53008-9.0.0*

Chapter 14 Design Debugging Using the SignalTap II Embedded Logic Analyzer
Revised: *March 2009*
Part Number: *QII53009-9.0.0*

Chapter 15 In-System Debugging Using External Logic Analyzers
Revised: *March 2009*
Part Number: *QII53016-9.0.0*

Chapter 16 In-System Updating of Memory and Constants
Revised: *March 2009*
Part Number: *QII53012-9.0.0*

Chapter 17 Design Debugging Using In-System Sources and Probes
Revised: *March 2009*
Part Number: *QII53021-9.0.0*

Chapter 18 Cadence Encounter Conformal Support
Revised: *March 2009*
Part Number: *QII53011-9.0.0*

Chapter 19 Quartus II Programmer
Revised: *March 2009*
Part Number: *QII53022-9.0.0*

Section I. Simulation

As the design complexity of FPGAs continues to rise, verification engineers are finding it increasingly difficult to simulate their system-on-a-programmable-chip (SOPC) designs in a timely manner. The verification process is now the bottleneck in the FPGA design flow. You can perform functional and timing simulation of your design by using the Quartus® II Simulator. The Quartus II software also provides a wide range of features for performing simulation of designs in EDA simulation tools.

This section includes the following chapters:

- Chapter 1, Quartus II Simulator
- Chapter 2, Mentor Graphics ModelSim Support
- Chapter 3, Synopsys VCS and VCS-MX Support
- Chapter 4, Cadence NC-Sim Support
- Chapter 5, Aldec Active-HDL Support
- Chapter 6, Simulating Altera IP in Third-Party Simulation Tools

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

1. Quartus II Simulator

QII53017-9.0.0

Introduction

With today's FPGAs becoming faster and more complex, designers face challenges in validating their designs. Simulation verifies the correctness of the design, reducing board testing and debugging time.

The Altera® Quartus® II Simulator is included in the Quartus® II software to assist designers with design verification. The Quartus II Simulator has a comprehensive set of features that are covered in the following sections:

- "Simulation Flow"
- "Waveform Editor" on page 1–4
- "Simulator Settings" on page 1–12
- "Simulation Report" on page 1–15
- "Debugging with the Quartus II Simulator" on page 1–18
- "Scripting Support" on page 1–20

This chapter describes how to perform different types of simulations with the Quartus II Simulator.

The Quartus II Simulator supports the following device families:

- Arria® GX
- Stratix® III, Stratix II, Stratix, Stratix GX, Stratix II GX
- Cyclone® III, Cyclone II, Cyclone
- HardCopy® II, HardCopy
- MAX® II, MAX 3000A, MAX 7000AE, MAX 7000B, MAX 7000S
- ACEX® 1K
- APEX™ 20KC, APEX 20KE, APEX II
- FLEX® 10K, FLEX 10KA, FLEX 10KE, FLEX 6000

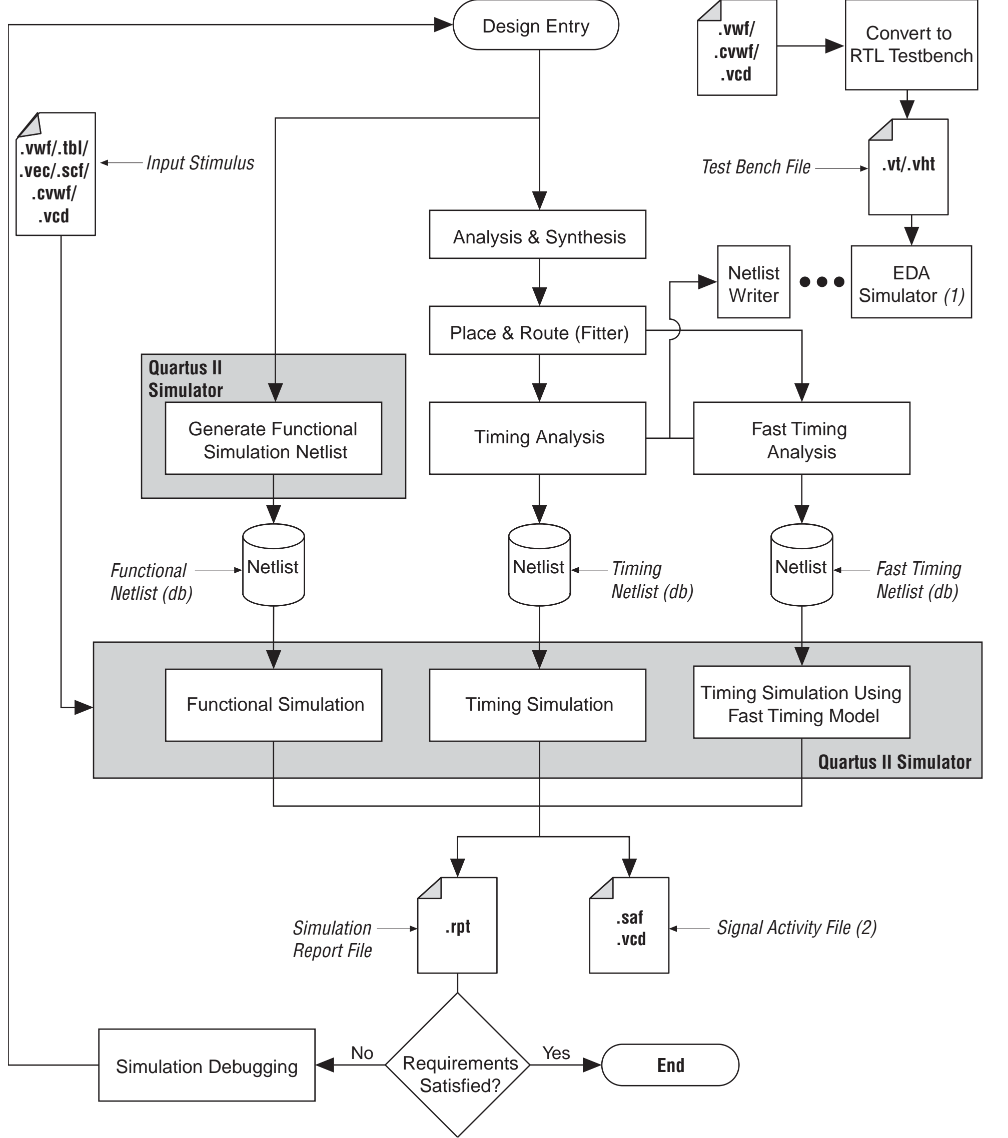
The Quartus II Simulator does not support newer devices introduced after Stratix III and Quartus II software version 8.1 and later. Use the ModelSim-Altera Edition to run simulations on designs targeting device introductions after Stratix III. For more information about the ModelSim-Altera Edition simulator, refer to the *Mentor Graphics ModelSim Support* chapter in volume 3 of the *Quartus II Handbook*.

Simulation Flow

You can perform functional and timing simulations with the Quartus II Simulator. Both types of simulation verify the correctness and behavior of your design. Functional simulations are run at the beginning of the Quartus II design flow and timing simulations are run at the end.

Figure 1–1 shows the Quartus II Simulator flow.

Figure 1–1. Simulation Flow



Notes to Figure 1–1:

(1) For more information about EDA Simulators, refer to the *Simulation* section in volume 3 of the *Quartus II Handbook*.

(2) You can use Signal Activity Files (**.saf**) or Value Change Dump Files (**.vcd**) in the PowerPlay Power Analyzer to check power resources.

As shown in Figure 1–1, your design simulation can happen at the functional level, where your design's logical behavior is verified and no timing information is used in simulation. Timing simulation can happen after your design has been compiled (synthesized and placed and routed) and after you use the timing data of your design's resources. In Timing simulation, your design's logical behavior is verified with the device's worst-case timing models. Timing simulation using the Fast Timing Model is also a type of timing simulation where best-case timing data is used.

To perform functional simulations with the Quartus II Simulator, you must first generate a functional simulation netlist. A functional netlist file is a flattened netlist extracted from the design files that does not contain timing information.

For timing simulations, you must first perform place-and-route and static timing analysis to generate a timing simulation netlist. A timing simulation netlist includes timing delays of each device atom block and the routing delays.

If you want to use third-party EDA simulation tools, you can generate a netlist using EDA Netlist Writer. You can use this netlist with your testbench files in third-party simulation tools.

For more information about third-party simulators, refer to the respective EDA Simulation chapter in the *Simulation* section in volume 3 of the *Quartus II Handbook*.

The Quartus II Simulator supports Functional, Timing, and Timing using Fast Timing Model simulations. The following sections describe how to perform these simulations.

Functional Simulation

To run a functional simulation, perform the following steps:

1. On the Processing menu, click **Generate Functional Simulation Netlist**. This flattens the functional simulation netlist extracted from the design files. The netlist does not contain timing information.
2. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
3. In the **Category** list, select **Simulator Settings**. The **Simulator Settings** page appears.
4. In the **Simulation mode** list, select **Functional**.
5. In the **Simulation input** box, specify the vector source. You must specify the vector file to run the simulation.
6. Click **OK**.
7. On the Processing menu, click **Start Simulation**.

Timing Simulation

To run a timing simulation, perform the following steps:

1. On the Processing menu, click **Start Compilation** or click the **Compilation** button on the toolbar. This flattens the design and generates an internal netlist with timing delay information annotated.
2. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
3. In the **Category** list, select **Simulator Settings**. The **Simulator Settings** page appears.
4. In the **Simulation mode** list, select **Timing**.
5. In the **Simulation input** list, specify the vector source. You must specify the vector file to run the simulation.
6. Click **OK**.

7. On the Processing menu, click **Start Simulation**.

Timing Simulation Using Fast Timing Model Simulation

To run a timing simulation using a fast timing model, perform the following steps:

1. On the Processing menu, point to **Start** and click **Start Analysis and Synthesis**.
2. On the Processing menu, point to **Start** and click **Start Fitter**.

You must perform fast timing analysis before you can perform a timing simulation using the fast timing models.

1. On the Processing menu, point to **Start** and click **Start Classic Timing Analyzer (Fast Timing Model)**.
2. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
3. In the **Category** list, select **Simulator Settings**. The **Simulator Settings** page appears.
4. In the **Simulation mode** list, select **Timing using Fast Timing Model**.
5. In the **Simulation input** box, specify the vector source. You must specify the vector file to run the simulation.
6. Click **OK**.
7. On the Processing menu, click **Start Simulation**.

Waveform Editor

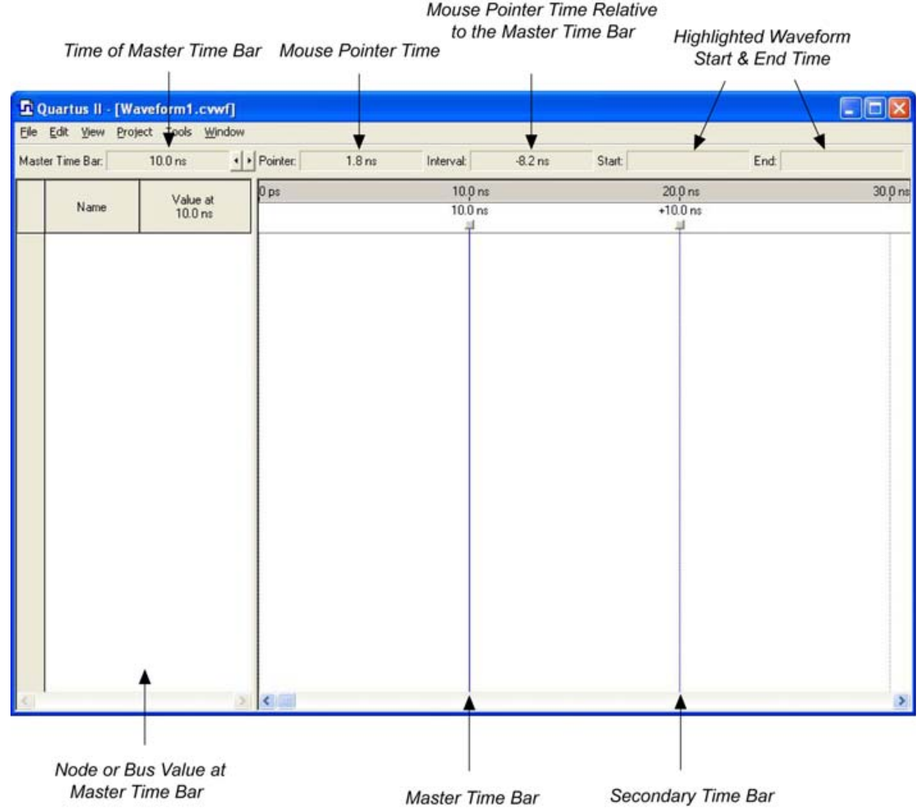
The most common input stimulus for the Quartus II Simulator are Vector Waveform Files (**.vwf** files). You can use the Quartus II Waveform Editor to generate a **.vwf** file.

Creating .vwf Files

To create a **.vwf** file, perform the following steps:

1. On the File menu, click **New**. The **New** dialog box appears.
2. Select **Vector Waveform File**.
3. Click **OK**. A blank Waveform Editor window appears (Figure 1–2).

Figure 1–2. Waveform Editor Window

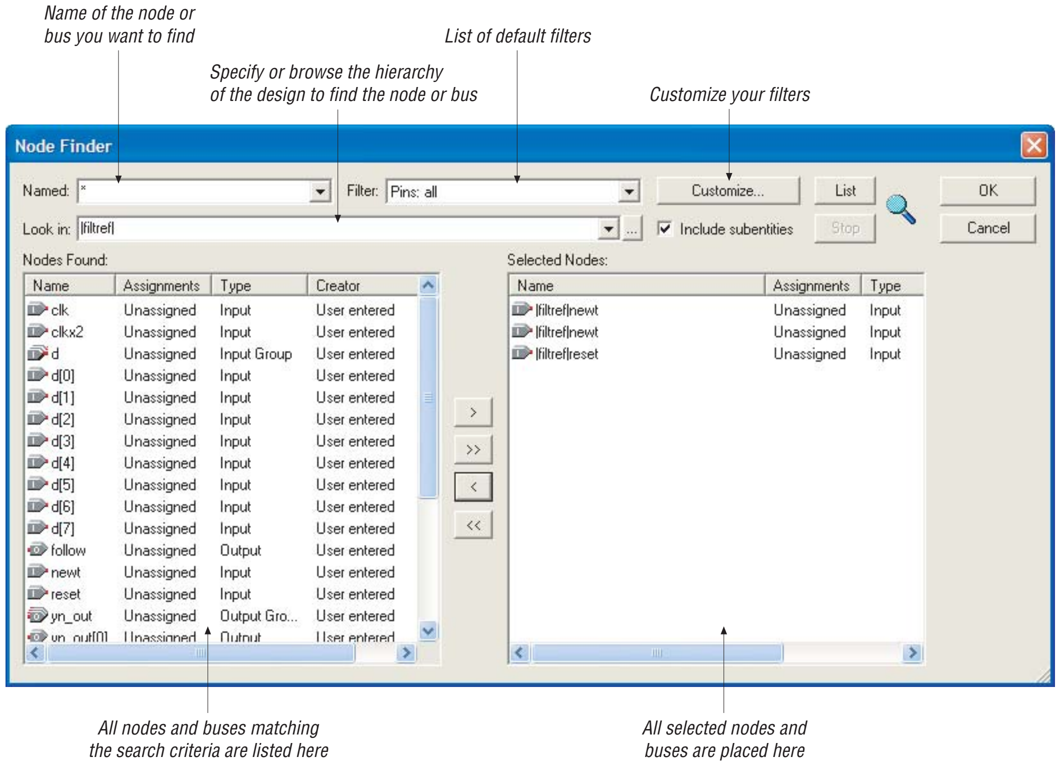


4. Add nodes and buses. To add a node or bus, on the Edit menu, click **Insert** and click **Insert Node or Bus**. The **Insert Node or Bus** dialog box appears. All nodes and buses, as well as the internal signals, are listed under **Name** in the Waveform Editor window.

You can also open the **Insert Node or Bus** dialog box by double-clicking under **Name** in the Waveform Editor.

5. You can customize the type of node or bus you want to add. If you have a large design with many nodes or buses, you may want to use the Node Finder for node or bus selection. To use the Node Finder, click **Node Finder**. The **Node Finder** dialog box appears (Figure 1–3).

Figure 1–3. Node Finder Dialog Box



You can use the Node Finder to find your nodes for simulation among all the nodes and buses in your design. Use the Node Finder to filter and add nodes to your waveform. The Node Finder is equipped with multiple default filter options. By using the correct filter in the Node Finder, you can find the internal node's name and add it to your Vector Waveform File for simulation.

Your node might not appear in the simulation waveform and might be ignored during simulation. This happens because the node has been renamed or synthesized away by the Quartus II software. To prevent this from happening, Altera recommends using the register and pin nodes to simulate your design.

Table 1–1 describes twelve of the Node Finder default filters.

Table 1–1. Filter Options (Part 1 of 2)

Filter	Description
Pins: input	Finds all input pin names in your design file(s).
Pins: output	Finds all output pin names in your design file(s).
Pins: bidirectional	Finds all bidirectional pin names in your design file(s).
Pins: virtual	Finds all virtual pin names.
Pins: all	Finds all pin names in your design file(s).
Registers: pre-synthesis	Finds all user-entered register names contained in the design after design elaboration, but before physical synthesis does any synthesis optimizations.

 © March 2009 Altera Corporation

Table 1–1. Filter Options (Part 2 of 2)

Filter	Description
Registers: post-fitting	Finds all user-entered register names in your design file(s) that survived physical synthesis and fitting.
Design Entry (all names)	Finds all user-entered names in your design file(s).
Post-Compilation	Finds all user-entered and compiler-generated names that do not have location assignments and survived fitting.
SignalTap II: pre-synthesis	Finds all internal device nodes in the pre-synthesis netlist that can be analyzed by the SignalTap® II Logic Analyzer.
SignalTap II: post-fitting	Finds all internal device nodes in the post-fitting netlist that can be analyzed by the SignalTap II Logic Analyzer.
SignalProbe	Finds all SignalProbe device nodes in the post-fitting netlist.

To customize your own filters in the Node Finder, perform the following steps:

a. Click **Customize**. The **Customize Filter** dialog box appears.

b. To configure settings, click **New**. The **New Custom Filter** dialog box appears.

c. In the **Filter name** box, type the name of the custom filter.

d. In the **Copy settings from filter** list, select the filter setting.

e. Click **OK**.

f. You can now customize your filters in the **Customize Filter** dialog box.

6. In the **Look in** box, you can view and edit the current search hierarchy path. You can type the search hierarchy path or you can browse for the hierarchy path by clicking the browse button.

   You can move up the search hierarchy by selecting hierarchical names in the **Select Hierarchy Level** dialog box. This ensures that in a large design with many signals, you can specify which hierarchy you would like to get the node from to reduce the amount of signals displayed.

7. After you have configured the filter and specified the correct hierarchy in the **Node Finder** dialog box, click **List** to display all relevant nodes or buses.

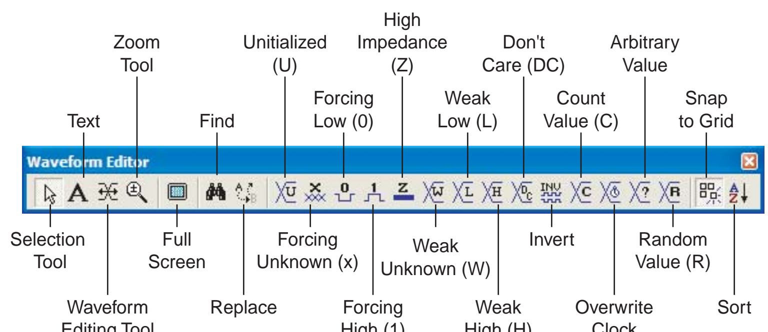
   Select any node(s) or bus(es) from the **Nodes Found** list and click **>** to include it in the waveform, or you can click **>>** to include all nodes and buses displayed in the **Nodes Found** list.

8. Click **OK**.

You can also add nodes to the Waveform Editor by dragging nodes from the Project Navigator, Netlist Viewers, or Block Diagram, and dropping them into the Waveform Editor.

9. Create a waveform for a signal. The Quartus II Waveform Editor toolbar includes some of the most common waveform settings, making waveform vector drawings easier and user friendly. Figure 1–4 shows the options available on the Waveform Editor toolbar.

Figure 1–4. Waveform Editor Toolbar



10. After you edit your waveform, save the waveform. On the File menu, click **Save As**. The **Save As** dialog box appears. Type your file name, specify the file type, and click **Save**.

Instead of using the Node Finder to insert your nodes for your **.vwf** file, you can also drag-and-drop any nodes from the Netlist Viewer to your Simulation Vector Waveform File. For more information about Netlist Viewers, refer to the *Analyzing Designs with the Quartus II Netlist Viewers* chapter in volume 1 of the *Quartus II Handbook*.

Count Value

Count Value applies a count value to a bus to increment the value of the bus by a specified time interval. Instead of manually editing the values for each node, the Count Value feature on the Waveform Editor toolbar automatically creates the counting values for buses. This feature enables you to specify a starting value for a bus, what time interval to increment, and when to stop counting. You can also configure transition occurrences while setting the count type and increment number. When you click on the **Count Value** button in the Waveform Editor toolbar, the **Count Value** dialog box appears. You can also open the **Count Value** dialog box by right-clicking the selected node, pointing to **Value**, and clicking **Count Value**.

Clock

You can use the Clock feature in the Waveform Editor toolbar to automatically generate the clock wave, rather than drawing each clock triggering pulse. To generate a clock signal with the **Clock** dialog box, click the **Overwrite Clock** button on the Waveform Editor toolbar. You can also determine the start and end time of a clock signal, whether to manually configure the period (the offset and the duty cycle), or whether to generate the clock based on a specified clock.

Arbitrary Value

Arbitrary Value allows you to overwrite a node value over the selected waveform, waveform interval, or across one or more nodes or groups. To overwrite a node value, perform the following steps:

1. Select a node or a bus and click the **Arbitrary Value** button on the Waveform Editor toolbar (Figure 1–4). The **Arbitrary Value** dialog box appears.

2. Under **Time range**, specify the start and end time you want to overwrite for the node value.
3. In the **Radix** list, select the radix type.
4. Specify the new value you want overwritten in the **Numeric or named value** box.
5. Click **OK**.

Random Value

Random Value allows you to generate random node values over the selected waveform, waveform interval, or across one or more nodes or groups.

You can generate random node values by every grid interval, every half grid interval, at random intervals, or at fixed intervals.

Generating a Testbench

You can export your **.vwf** file as a VHDL Test Bench File (**.vht**) or Verilog Test Bench File (**.vt**). This is useful when you want to use a vector waveform in different EDA tools. You must run an analysis and elaboration before you can export a waveform vector. To export a waveform vector, have your vector waveform open and perform the following steps:

1. On the File menu, click **Export**. The **Export** dialog box appears.
2. In the **Save as type** list, select **VHDL Test Bench File (*.vht)** or **Verilog Test Bench File (*.vt)**.
3. You can optionally turn on **Add self-checking code to file**. This option adds additional logic to check the results of the output and compares it to the original **.vwf** file.

You must open your project in the Quartus II software before you can export a **.vwf** file.

For more information about using the generated testbench in other EDA tools, refer to the respective EDA simulator chapter in the *Simulation* section in volume 3 of the *Quartus II Handbook*.

Grid Size

When you select portions of your waveform, the selection area snaps to time intervals specified in the **Grid Size** dialog box. You can customize the grid size in the Waveform Editor. You can change the grid size based on the clock settings or by setting the time period. To customize the grid size, on the Edit menu, click **Grid Size**.

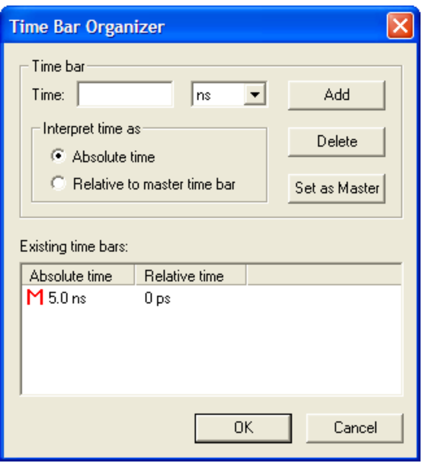
Time Bars

Add time bars in the Waveform Editor to compare edges between different signals. You can also use time bars to jump forward and backward to the next edge transition in the selected signal, and read the logic level of signals by sliding the Time Bar in your waveform. The logic level is displayed in the **Value at** column of the Waveform Editor.

The **Time Bar Organizer** dialog box enables you to create, delete, and edit a time bar, and to create a master time bar. Only one master time bar is allowed per waveform file. To use the Time Bar Organizer, on the Edit menu, point to **Time Bar** and click **Time Bar Organizer**.

Under **Existing time bars**, in the **Absolute time** column, the red **M** indicates the master time bar (Figure 1–5).

Figure 1–5. Time Bar Organizer Dialog Box



Stretch or Compress a Waveform Interval

You can stretch or compress a waveform interval in the Waveform Editor, which enables you to analyze the effects on a waveform. For example, you can check the behavior of your design at high speeds for a short interval by using the compress option to compress the waveform. You can also use this feature to delay the transition of a signal by stretching the waveform.

You have to specify the original start and end time, and the new time for the waveform you want to stretch or compress. If you want to stretch or compress all the nodes or buses, deselect all nodes and buses and set the stretch or compress feature.

To stretch or compress a waveform interval, on the Edit menu, point to **Value** and click **Stretch or Compress Waveform Interval**. The **Stretch or Compress Waveform Interval** dialog box appears.

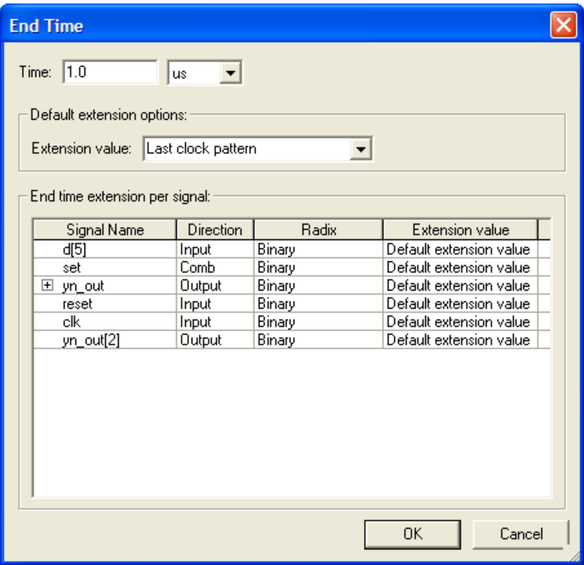
The "To time value" end time specified in the **Stretch or Compress Waveform Interval** dialog box cannot be larger than the "End Time" specified in the **Simulator Settings** page of the **Settings** dialog box. Otherwise, the Quartus II software displays a message indicating the invalid time value.

End Time

The End Time setting enables you to change the end time of the **.vwf** file. The end time represents the maximum length of time in the **.vwf** file. You can specify the end time and your preferred time unit, and have different extension values for different nodes or buses. With the waveform open, specify the end time by performing the following steps:

1. On the Edit menu, click **End Time**. The **End Time** dialog box appears (Figure 1–6).

Figure 1–6. End Time Dialog Box



2. In the **Time** box, specify the end time and select the time unit in the **Time** list.
3. Under **Default extension options**, in the **Extension value** list, select the value.
4. Under **End time extension per signal**, you can select specific extension values for each signal by clicking in the **Extension value** column.

The options in the **End time** dialog box are different settings than those under **Simulation period** in the **Settings** dialog box. Simulation period is the period that the Quartus II software simulates the stimuli. End time is the maximum length of time in the **.vwf** file. For information on the simulation period, refer to Table 1–2 on page 1–12.

Arrange Group or Bus in LSB or MSB Order

You can arrange a group or bus in LSB or MSB order. If you arrange in LSB order, the LSB is on top and the MSB is at the bottom. If you arrange in MSB order, the MSB is on top and the LSB is at bottom.

To arrange a group or bus in LSB or MSB order, perform the following steps:

1. Select the bus that you want to change the LSB or MSB order. You can also select multiple buses in the waveform editor.
2. On the Edit menu, point to **Group and Bus Bit Order** and click either **MSB on top, LSB on Bottom** to change the bus or group in MSB order, or click **LSB on top, MSB on Bottom** to change the bus or group in LSB order.

Simulator Settings

You can enhance your output, reduce debugging time, and provide better coverage before running a simulation. This section covers the different simulation modes supported by the Quartus II Simulator. Additionally, the Quartus II Simulator offers common setup features like glitch filtering, setup and hold violation detection, and simulation coverage.

To set up simulation settings, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulator Settings**. The **Simulator Settings** page appears.

Table 1–2 shows the options in the **Simulator Settings** page.

Table 1–2. Quartus II Simulator Settings (Part 1 of 2)

Settings and Options	Description
Simulation mode *(1)*	**Functional** This simulation mode uses a pre-synthesis compiler database to simulate the logical performance of a project without the timing information. This mode enables you to check the functionality of the design. All nodes and buses are preserved in this simulation because functional simulation is performed before synthesis, partitioning, or fitting. A **.vwf** file is required to perform this simulation mode. **Timing** This simulation mode uses the compiled netlist that includes timing information. With this simulation mode, you can check setup, hold violation, glitches, and simulation coverage. You can remove nodes or buses using the Quartus II Compiler when logic is optimized. This simulation mode uses the worst case timing model. **Timing using Fast Timing Model** This simulation mode is similar to timing simulation but this mode uses the best-case timing model.
Simulation input	You must include the vector file in the **Simulation input** box. You can type the name of the file or use the browse button to open the **Select File** dialog box. In the **Files of type** list, you can select Vector Waveform File (***.vwf**), Compressed Vector Waveform File (***.cvwf**), Value Change Dump File (***.vcd**), Vector Table Output File (***.tbl**), Vector Text File (***.vec**), Simulation Channel File (**.scf**), or **All Files (*.*)**. TBL files contain input vectors and output logic levels in a tabular-format list. You can generate this file using a **.vwf** file. However, if you would like to maintain, view, or update the vectors, **.vwf** files offer better visibility. **.vwf** or TBL file formats are interchangeable. You can generate TBL files from **.vwf** files and vice versa. You can create a **.vwf** with the Waveform Editor. For more information about the Waveform Editor, refer to "Waveform Editor" on page 1–4. The Quartus II software also supports MAX+PLUS® II simulation vector files, such as **.vec** and **.scf** files. A **.cvwf** file is the simplified version, non-readable format of the **.vwf** file format. This file type is in binary format and is generally smaller in file size. You can use **.cvwf** files in the Waveform Editor and simulation. A **.vcd** file is an ASCII file that contains header information, variable definitions, and the value changes for specified variables, or all variables, in a given design. The value changes for a variable are given in scalar or vector format based on the nature of the variable.

Table 1–2. Quartus II Simulator Settings (Part 2 of 2)

Settings and Options	Description
Simulation period	The simulation period determines the length of time that the simulator runs the stimuli with the maximum period being equal to the end time of a **.vwf** file. If the simulation period is configured shorter than the end time, all signals beyond the simulation period are displayed as Unknown (X). Therefore, you can also shorten the simulation period or end the simulation earlier by selecting **End Simulation at** and specifying the time and selecting the time unit. If the simulation period is configured longer than the end time, the simulation will stop at the end time. For information on the end time, refer to "End Time" on page 1–10.
Glitch filtering options	Specifies whether to enable glitch filtering for simulations. You can select one of the following options: **Auto**—The Simulator performs glitch filtering when **.saf** file generation is enabled in the **Simulation Output Files** page of the **Settings** dialog box. **Always**—The Simulator always performs glitch filtering, even if **.saf** file generation is not enabled. **Never**—The Simulator never performs glitch filtering, even if **.saf** file generation is enabled.
More Settings	If you click **More Settings**, the **More Simulator Settings** dialog box appears. The following options are available under **Existing option settings**. **Cell Delay Model Type** Specifies the type of delay model to be used for cell delays: transport or inertial. The default is transport. **Interconnect Delay Model Type** Specifies the type of delay model to be used for interconnect delays: transport or inertial. The default is transport. **Preserve fewer signal transition to reduce memory requirements** This option is effective on lower performance workstations because turning on this option flushes signal transitions from memory to disk for memory optimization.

Note to Table 1–2:

(1) The Quartus II Simulator may flag an error message if zero-time oscillation occurs in your design. Zero-time oscillation occurs when a particular output signal does not achieve a stable output value at a particular fixed time, which may be due to your design containing combinational logic path loops.

Simulation Verification Options

Table 1–3 shows the options in the **Simulation Verification** page.

Table 1–3. Quartus II Simulation Verification

Settings and Options	Description
Check outputs	**Check outputs** checks expected outputs against actual outputs in the simulation report. After turning on **Check outputs**, click the **Waveform Comparison Settings** button. The **Waveform Comparison Settings** dialog box appears. In the **Waveform Comparison Settings** dialog box, you can specify the waveform comparison time frame and the comparison options. You can also set the tolerance level for all the signals by specifying the tolerance limit in the **Default comparison timing tolerance** box. The **Maximum comparison mismatches** box is the amount of mismatches the Quartus II Simulator is allowed to accept before it stops comparing. You can also set the type of transition the comparison should trigger in the **Waveform Comparison Settings** dialog box. You can assign trigger comparisons based on **Input signal transition edges**, **All signal transition edges**, or **Selected Signal transition edges**. To customize the waveform comparison matching rules, you can also click the **Comparison Rules** button. The **Comparison Rules** dialog box appears, allowing you to customize the comparison matching rules.
Setup and hold time violation detection	This option detects setup and hold time violation. Setup time is the period required by a synchronous signal to stabilize before the arrival of a clock edge. Hold time is the time required by a synchronous signal to maintain after the same clock edge. If the **Setup and hold time violation detection** option is turned on, a warning in the Messages window appears if any setup or hold time violation is detected during the simulation. This option is only for Timing and Timing using Fast Timing Model simulation modes.
Glitch detection	Conditions occur when two or more signals toggle simultaneously and can cause glitches or unwanted short pulses. The **Glitch detection** option enables you to detect glitches and specify the time interval that defines a glitch. If two logic level transitions occur in a period shorter than the specified time period, the resulting glitch is detected and reported in the **Processing** tab of the Messages window. If you turn on the **Glitch detection** option, you can specify the acceptable glitch width. A Messages window appears when a pulse is smaller than the specified glitch width that is detected. The **Glitch detection** option is only available for Timing and Timing using Fast Timing Model simulation modes.
Simulation coverage reporting	This option reports the ratio of outputs (coverage) actually simulated to the number of outputs in the netlist and is expressed as a percentage. When you turn on the **Simulation coverage reporting** option, the **Report Settings** button is available. If you click **Report Settings**, the **Report Settings** dialog box appears. The three types of coverage reports you can select from are **Display complete 1/0 value coverage report**, **Display missing 1-value coverage report**, and **Display missing 0-value coverage report**.
Disable setup and hold time violation detection for input registers of bi-directional pins	This option enables you to disable setup and hold time violation detection in input registers of all bidirectional pins in the simulated design during Timing or Timing using Fast Timing Model simulation.

Simulation Output Files Options

Table 1–4 shows the options in the **Simulation Output Files** page.

Table 1–4. Quartus II Simulation Output Files

Setting and Options	Description
Simulation output waveform	Specify the simulation output waveform options. **Automatically add pins to simulation output waveforms** This option automatically adds all outputs that are available in the design to the waveform reports. If your design has large amounts of outputs, turning on this option ensures all outputs are monitored during simulation. **Overwrite simulation input file with simulation results** This option overwrites the vector source file with simulation results. This option is ignored when the **Check outputs** setting is turned on. This option adds the result to the vector file and generally, it can give you more visibility during the debugging process. *(1)* **Group bus channel in simulation results** This option automatically groups bus channels in the output waveform that are shown in the simulation reports. By turning off this option, all output waveforms have a node to represent each bus signal.
Signal activity output for power analysis	When you perform your simulation with the Quartus II Simulator, you can generate a **.saf** file, which is used by the PowerPlay Power Analyzer to assist you with power analysis. *(2)*, *(3)*
VCD output for power analysis	When you perform simulation with the Quartus II Simulator, you can generate a **.vcd** file, which is used by the PowerPlay Power Analyzer to assist you with power analysis. *(2)*, *(3)*

Notes to Table 1–4:

(1) A backup copy of the source vector file is saved under the **db** folder with the name <*project*>**.sim_ori.** <*vector file format type*>.

(2) Instead of using the **.saf** file or Generate **.vcd** file (***.vcd**), you can also save your output waveform as a **.vcd** file to perform power analysis.

(3) For more information about the PowerPlay Power Analyzer, refer to the *PowerPlay Power Analysis* chapter in volume 3 of the *Quartus II Handbook*.

Simulation Report

Comprehensive reports are shown after the completion of each simulation. These reports are important to ensure designs meet timing and logical correctness. These simulation reports also play an important role in debugging.

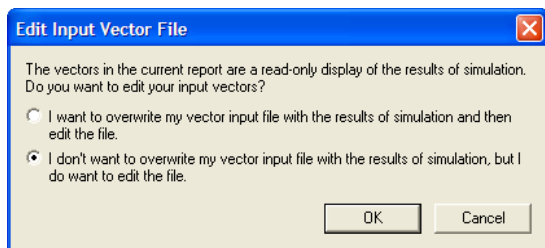
Simulation Waveform

Simulation Waveforms are part of the Simulation report. In this report, the stimuli and the results of the simulation are displayed.

You can export the simulation waveform as a VHDL Test Bench File or a Verilog Test Bench File for use in other EDA tools. You can also save a simulation as a **.vwf** file or Vector Table Output File for use with the Quartus II software.

When you try to edit the Simulation Waveform, the **Edit Input Vector File** dialog box appears, asking whether you would like to edit the vector input file with the results of the simulation or if you would like to overwrite the vector input file with other vector inputs (Figure 1–7).

Figure 1–7. Edit Input Vector File



You can overwrite your simulation input file with the simulation results so that your input vector file is updated with the resulting waveform after a simulation. For more information, refer to the **Overwrite simulation input file with simulation results** option in Table 1–2.

If you do not want to overwrite the simulation input file in every simulation run, perform the following to overwrite simulation input files with simulation results after a simulation:

On the Processing Menu, point to **Simulation Debug** and click **Overwrite Vector Inputs with Simulation Outputs**.

Simulating Bidirectional Pin

A bidirectional pin is represented in the waveform by two channels. One channel represents the input to the bidirectional pin, and the other channel represents the output from the bidirectional pin. You can enter the input channel into the waveform by using the **Node Finder** dialog box. The output channel is automatically created by the Quartus II Simulator and named <*bidir pin name*> `~result`.

Logical Memories Report

The Quartus II software writes out the contents of each memory module after simulation. Therefore, if you use memory cells in your design, you can analyze the contents of the logic memory structures in the device in the Logical Memories Report. The Logical Memories Report displays individual reports for each memory block and contains the data stored in the memory cell used at the end of simulation.

After being simulated, a memory module's contents are stored in the Logical Memories section of the simulation report file.

To view this section, perform the following steps:

1. On the Processing menu, click **Simulation Report**. The Simulation Report window appears.
2. In the report window, click the "+" next to **Logical Memories**.

Simulation Coverage Reports

The **Coverage Summary** report contains the following summary information for the simulation:

- Total toggling coverage as a percentage
- Total nodes checked in the design
- Total output ports checked
- Total output ports with complete 1/0-value coverage
- Total output ports with no 1/0-value coverage
- Total output ports with no 1-value coverage
- Total output ports with no 0-value coverage

The **Complete 1/0-Value Coverage** report lists the following information:

- Node name
- Output port name
- Output port type for output ports that toggle between 1 and 0 during the simulation

The **Missing 0-Value Coverage** report and **Missing 1-Value Coverage** report list the following information:

- Node name
- Output port name
- Output port type for output ports that do not toggle to the designated value

For more information about Simulation Coverage reports, refer to the **Simulation coverage reporting** option in Table 1–2 on page 1–12.

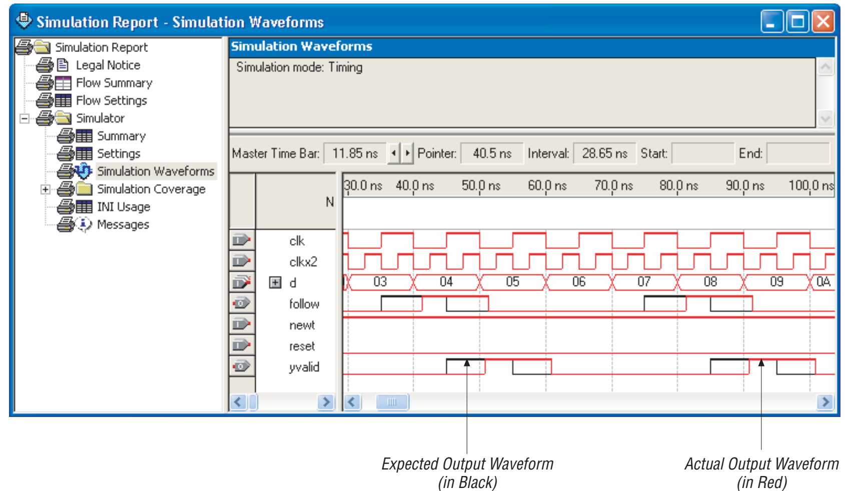
The following are individual reports and their definitions:

- **Complete 1/0 value coverage report**—Displays all the nodes or buses that toggle between 1 and 0 during simulation.
- **Missing 1-value coverage** and **Missing 0-value coverage reports**—Displays all the nodes that do not toggle to the designated value.

Comparing Two Waveforms

You can compare your simulation results against previous simulations using the compare option. To compare two waveforms in the Simulation Report, turn on the **Check outputs** option. For more information about the **Check outputs** option, refer to Table 1–2 on page 1–12. With the **Check outputs** option turned on, the two comparable waveforms are visible in black and red. The black waveforms represent the original output or the expected output, and the red waveforms represent the compared output or the actual output. Figure 1–8 shows an example of expected output waveform versus actual output waveform.

Figure 1–8. Example of Simulation Waveform from the Simulation Report When Check Output is Turned On



Debugging with the Quartus II Simulator

The Quartus II software includes tools to help with simulation debugging. This section covers some debugging tools and their use.

Breakpoints

Inserting breakpoints into the simulation process enables the simulator to break at the desired time or on the desired node or bus condition. You can monitor the activity of nodes or buses during specified times and pinpoint the cause of mismatched signal levels between expected and actual. To use breakpoints, perform the following steps:

1. On the Processing menu, point to **Simulation Debug** and click **Breakpoints**. The **Breakpoints** dialog box appears.
2. In the Equation text box, click **condition**. You can configure the logical conditions of individual nodes or buses, or you can set the time.
3. After you configure the equation conditions, select the action for the Quartus II Simulator. In the **Action** pull-down list, select **Stop**, **Warning Message**, **Error Message**, or **Information Message**. This selection defines the action when the condition is met.
4. You can also enter the text that appears when the Simulator encounters the breakpoint. If you do not make an entry in this box, the Quartus II software displays a default message.

Updating Memory Content

If your design includes memories, when the simulator stops at a breakpoint, you can view and edit the contents of the memories. To view your memories during a breakpoint in the simulation, on the Processing menu, point to **Simulation Debug** and click **Embedded Memory**.

Last Simulation Vector Outputs

The **Last Simulation Vector Outputs** command opens the Output Simulation Waveforms report generated by the last simulation. To use this command, on the Processing menu, point to **Simulation Debug** and click **Last Simulation Vector Outputs**.

You can open the current input vectors that you defined in the **Simulator Settings** dialog box with the **Current Vector Inputs** command. To use this command, on the Processing menu, point to **Simulation Debug** and click **Current Vector Inputs**. Lastly, you can overwrite the vector source file with the simulation outputs that open the resulting file.

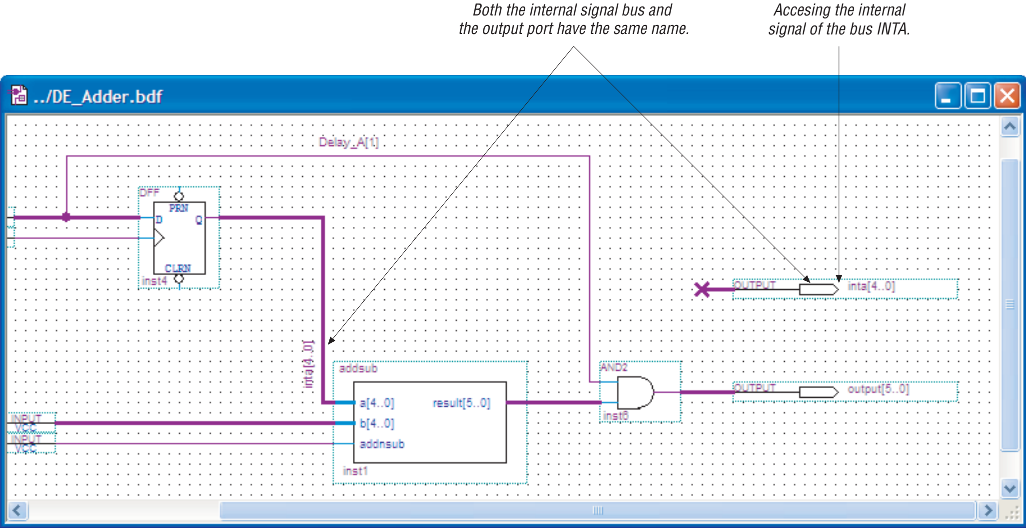
Conventional Debugging Process

During the design phase, tapping out internal signals is a common practice to debug simulation errors. Therefore, the Quartus II software enables you to tap out the signal for simulation debug and also enables you to pull out the internal signal to the physical I/O. The Quartus II software also offers SignalTap II and SignalProbe to further assist you with debugging.

Accessing Internal Signals for Simulation

You can conventionally debug by probing out the internal signals, which enables you to preserve the internal signals during synthesis. You can probe the internal signal by selecting the node or bus and specifying a name, and then adding an output port to the schematic with a similar name. Figure 1–9 shows an example of accessing internal signals for simulation from a schematic diagram.

Figure 1–9. Example of Tapping Out Internal Signal



For timing simulations, the simulation netlist is based on the Compilation post-Synthesis and post-Fitting netlist. Therefore, some of the internal nodes or buses are optimized away during compilation of the netlist. If an internal node is optimized away, the Quartus II software displays a warning message similar to the following in the **Warning** tab of the Messages window:

```
Warning: Compiler packed, optimized or synthesized away node "DataU".
Ignored vector source file node.
```

This internal node is ignored by the Quartus II Simulator.

If you would like to tap out the D and Q ports of registers, turn on **Add D and Q ports of register node to Simulation Output Waveform** from the Assignment Editor. This feature is only available for functional simulations.

Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following at the command prompt:

```
quartus_sh --qhelp ↵
```

The *Quartus II Scripting Reference Manual* includes the same information in PDF form.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. Refer to the *Quartus II Settings File Manual* for information about all settings and constraints in the Quartus II software. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

You can change the Functional, Timing, or Timing using Fast Timing Model simulation modes by typing the following at the command prompt:

```
simulation_mode <mode> ↵
```

To initialize the simulation for the current design, use the following command. During initialization, the Simulator builds the simulation netlist and sets the simulation time to zero.

The option `-ignore_vector_file` is set to **Off** by default when the source vector file exists for simulation. The Quartus II software ignores the source vector file during simulation if the option `-ignore_vector_file` is set to **On**. The `-end_time` option is used only when the `-ignore_vector_file` option is set to **On**.

```
initialize_simulation [-h | -help] [-long_help] [-check_outputs <On | Off>] \
[-end_time <end_time>] [-glitch_filtering <On | Off>] [-ignore_vector_file <On | Off>] \
[-memory_limiter <On | Off>] [-power_vcd_output <target_file>] \
[-read_settings_files <On | Off>] [-saf_output <target_file>] \
[-sim_mode <functional | timing | timing_using_fast_timing_model >] \
[-vector_source <vector_source_file>] [-write_settings_files <On | Off>] \
-simulation_results_format <.vwf | .cvwf | .vcd> -vector_source <vector source file>
```

To force the specified signal or group of signals to the specified value, type the following at the command prompt:

```
force_simulation_value [-h | -help] [-long_help] -node <hpath> <value> ↵
```

To turn on the simulator to simulate the design for a specified time, type the following at a command prompt:

```
run_simulation [-h | -help] [-long_help] [-time <time>] ↵
```

If you do not set a specific length of time for the simulation run, it runs a complete simulation.

To create a breakpoint with a specified equation and action, type the following at the command prompt:

```
create_simulation_breakpoint [-h | -help] [-long_help] \
-action [Give Warning | Give Info | Give Error] \
-breakpoint <breakpoint_name> -equation <equation> [-user_message <message_text>]↵
```

To delete a breakpoint with a specified name, type the following at the command prompt:

```
delete_simulation_breakpoint [-h | -help] [-long_help] -breakpoint <breakpoint_name> ↵
```

Conclusion

Simulation plays an important role in ensuring the quality of a product. The Quartus II software offers various tools to assist you with simulation and helps reduce debugging time with the introduction of features like Glitch Filtering and Breakpoints.

2. Mentor Graphics ModelSim Support

QII53001-9.0.0

Introduction

An Altera® Quartus® II software subscription includes a no-cost entry-level software version of the ModelSim®-Altera software on a PC or UNIX platform. Altera also offers the ModelSim-Altera Subscription Edition software that has full support for Altera devices. You can use the ModelSim-Altera Starter Edition software to perform register transfer level (RTL) functional, post-synthesis, and gate-level timing simulations for either Verilog HDL or VHDL designs that target an Altera FPGA. This chapter provides detailed instructions about how to simulate your design in the ModelSim-Altera version or the Mentor Graphics® ModelSim software version. This chapter provides details about the specific libraries that are needed for an RTL functional, post-synthesis, and gate-level timing simulation.

The following topics are discussed in this chapter:

- "Background"
- "Software Compatibility" on page 2–3
- "Altera Design Flow with ModelSim-Altera or ModelSim Software" on page 2–3
- "Simulation Libraries" on page 2–4
- "Simulation Netlist Files" on page 2–12
- "Perform Simulation Using the ModelSim-Altera Software" on page 2–18
- "Perform Simulation Using the ModelSim Software" on page 2–38
- "Simulating Designs that Include Transceivers" on page 2–64
- "Using the NativeLink Feature with ModelSim-Altera or ModelSim Software" on page 2–70
- "Generating a Timing VCD File for PowerPlay" on page 2–78
- "Viewing a Waveform from a .wlf File" on page 2–78
- "Scripting Support" on page 2–79
- "Software Licensing and Licensing Setup in ModelSim-Altera Subscription Edition" on page 2–80

For more information about the current Quartus II software version, refer to the Altera website at www.altera.com.

Background

ModelSim-Altera software is included with your Altera software subscription and can be licensed for PC, Solaris, or Linux platforms to support either Verilog HDL or VHDL simulation. ModelSim-Altera software supports RTL functional, post-synthesis, and gate-level timing simulations for all Altera devices.

Table 2–1 describes the differences between the Mentor Graphics ModelSim SE/PE and ModelSim-Altera software versions.

Table 2–1. Comparison of ModelSim Software Versions

Product Feature	ModelSim SE	ModelSim PE	ModelSim-Altera	ModelSim-Altera Starter Edition
100% VHDL, Verilog HDL, mixed-HDL support	Optional	Optional	Supports only single-HDL simulation	Supports only single-HDL simulation
Complete HDL debugging environment	✓	✓	✓	✓
Optimized direct compile architecture	✓	✓	✓	✓
Industry-standard scripting	✓	✓	✓	✓
Flexible licensing	✓	Optional	✓	—
Verilog PLI support. Interfaces Verilog HDL designs to customer C code and third-party software	✓	✓	✓	✓
VHDL FLI support. Interfaces VHDL designs to customer C code and third-party software	✓	—	—	—
Standard Delay Format File annotation	✓	✓	✓ (1)	✓ (1)
Advanced debugging features and language-neutral licensing	✓	—	—	—
Customizable, user-expandable GUI and integrated simulation performance analyzer	✓	—	—	—
Integrated code coverage analysis and SWIFT support	✓	—	—	—
Accelerated VITAL and Verilog HDL primitives (3 times faster), and register transfer level (RTL) acceleration (5 times faster)	✓	—	—	—
Platform support	PC, UNIX, Linux	PC only	PC, UNIX, Linux	PC, UNIX, Linux
Precompiled libraries	No	No	Yes	Yes

Note to Table 2–1:

(1) ModelSim-Altera software only allows SDF annotation to modules in the Altera library.

Software Compatibility

Table 2–2 shows which ModelSim-Altera and ModelSim software version is compatible with the Quartus II software versions. ModelSim versions provided directly from Mentor Graphics do not correspond to specific Quartus II software versions.

For help with the ModelSim-Altera licensing setup, refer to "Software Licensing and Licensing Setup in ModelSim-Altera Subscription Edition" on page 2–80.

Table 2–2. Compatibility Between Software Versions

ModelSim-Altera Software	Quartus II Software *(1)*
ModelSim-Altera and ModelSim software version 6.4a	Quartus II software version 9.0
ModelSim-Altera and ModelSim software version 6.3g_p1	Quartus II software version 8.1
ModelSim-Altera and ModelSim software version 6.1g	Quartus II software version 6.1, 7.0, 7.1, 7.2, and 8.0
ModelSim-Altera and ModelSim software version 6.1d	Quartus II software version 6.0
ModelSim-Altera and ModelSim software version 6.0e	Quartus II software version 5.1
ModelSim-Altera and ModelSim software version 6.0c	Quartus II software version 5.0
ModelSim-Altera and ModelSim software version 5.8.e ModelSim-Altera and ModelSim software version 5.8	Quartus II software version 4.2

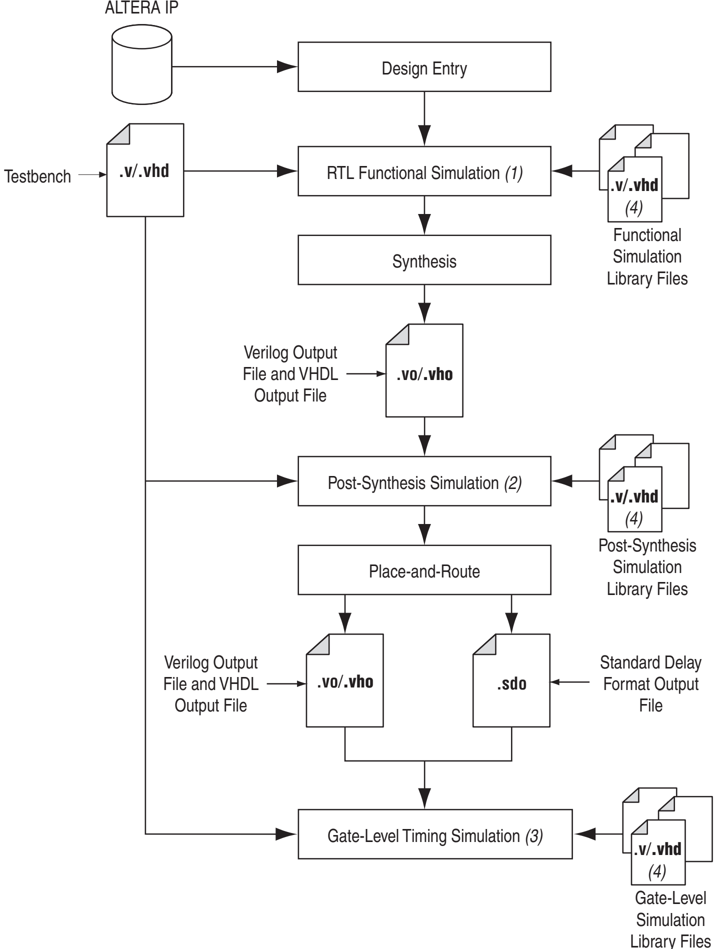
Note to Table 2–2:

(1) Updated ModelSim-Altera pre-compiled libraries are available for download on Altera's website for each release of the Quartus II service pack.

Altera Design Flow with ModelSim-Altera or ModelSim Software

Figure 2–1 illustrates an Altera design flow using the Mentor Graphics ModelSim-Altera software or the ModelSim software.

Figure 2–1. Altera Design Flow with ModelSim-Altera Software, ModelSim Software, and Quartus II Software



Notes to Figure 2–1:

(1) An RTL functional simulation is performed before a gate-level timing simulation or post-synthesis simulation. RTL functional simulation verifies the functionality of the design before synthesis and place-and-route. If you are performing an RTL functional simulation through NativeLink, you must complete Analysis and Elaboration first.

(2) A post-synthesis simulation verifies the functionality of a design after synthesis has been performed.

(3) Gate-level timing simulation is a post place-and-route simulation to verify the operation of the design after timing delays have been calculated.

(4) In the ModelSim-Altera software, you do not have to compile the simulation library files, as they are already precompiled for you.

Simulation Libraries

Simulation model libraries are required to run a simulation whether you are running an RTL functional simulation, post-synthesis simulation, or gate-level timing simulation. In general, running an RTL functional simulation requires the RTL functional simulation model libraries, while running a post-synthesis or gate-level timing simulation requires the gate-level timing simulation model libraries. You must compile the necessary library files before you can run the simulation.

However, there are a few exceptions where you are also required to compile gate-level timing simulation library files to perform RTL functional simulation. For example, the following list shows some of the Altera megafunctions' gate-level libraries required to perform an RTL functional simulation using third-party simulators:

- ALTCLKBUF
- ALTCLKCTRL
- ALTDQS
- ALTDQ
- ALTDDIO_IN
- ALTDDIO_OUT
- ALTDDIO_BIDIR
- ALTUFM_NONE
- ALTUFM_PARALLEL
- ALTUFM_SPI
- ALTMEMMULT
- ALTREMOTE_UPDATE

To identify which type of simulation libraries are required to run the simulation for a certain Altera megafunction, refer to the last page in the Altera megafunction MegaWizard™ Plug-In Manager. This explains which simulation library files are required to perform an RTL functional simulation for that particular megafunction.

Simulating the Transceiver Megafunction (for example, ALT2GXB) is also another exception that requires the gate-level libraries to perform RTL functional simulation and vice-versa.

For detailed, step-by-step instructions about how to simulate the Transceiver Megafunction, refer to "Simulating Designs that Include Transceivers" on page 2–64.

Pre-Compiled Simulation Libraries in the ModelSim-Altera Software

In the ModelSim-Altera software, the pre-compiled libraries for both functional and gate-level simulations are available. You do not have to explicitly compile these library files before running the simulation directly.

It is important that the pre-compiled libraries provided in <*ModelSim Altera path*>**/altera**> must be compatible with the version of the Quartus II software that is used to create the simulation netlist. To check whether the pre-compiled libraries are compatible with your version of the Quartus II software, refer to the <*ModelSim Altera path*>**/altera/version.txt** file. This file shows which version and build of the Quartus II software was used to create the pre-compiled libraries.

RTL Functional Simulation Libraries

RTL functional simulation libraries include the LPM simulation model, Altera megafunction simulation model, and the low-level primitive simulation model. Table 2–3 shows the pre-compiled library name and the location in the ModelSim-Altera software for all RTL functional simulation models in VHDL.

Table 2–3. Pre-Compiled RTL Functional Simulation Libraries in the ModelSim-Altera Software (VHDL)

RTL Simulation Model	Pre-Compiled Library Name	Location in ModelSim-Altera
LPM	lpm	<*ModelSim-Altera installation directory*>**\altera\vhdl\220model**
Altera Megafunction	altera_mf	<*ModelSim-Altera installation directory*>**\altera\vhdl\altera_mf**
Low-level Primitives	altera	<*ModelSim-Altera installation directory*>**\altera\vhdl\altera**
ALTGXB Megafunction (Stratix GX)	altgxb	<*ModelSim-Altera installation directory*>**\altera\vhdl\altgxb**

Low-Level Primitives	alt_vtl	<*ModelSim-Altera installation directory*>**\altera\vhdl\alt_vtl**

Table 2–4 shows the pre-compiled library name and the location in the ModelSim-Altera software for all RTL functional simulation models in Verilog HDL.

Table 2–4. Pre-Compiled RTL Functional Simulation Libraries in the ModelSim-Altera Software (Verilog HDL)

RTL Simulation Model	Pre-Compiled Library Name	Location in ModelSim-Altera
LPM	lpm_ver	<*ModelSim-Altera installation directory*>**\altera\verilog\220model**
Altera Megafunction	altera_mf_ver	<*ModelSim-Altera installation directory*>**\altera\verilog\altera_mf**
Low-level Primitives	altera_ver	<*ModelSim-Altera installation directory*>**\altera\verilog\altera**
ALTGXB Megafunction (Stratix GX)	altgxb_ver	<*ModelSim-Altera installation directory*>**\altera\verilog\altgxb**
High-Level Primitives	sgate_ver	<*ModelSim-Altera installation directory*>**\altera\verilog\sgate**
Low-Level Primitives	alt_ver	<*ModelSim-Altera installation directory*>**\altera\verilog\alt_vtl**

Gate-Level Simulation Libraries

Gate-level simulation libraries include the supported Altera device atom simulation models. Table 2–5 shows the pre-compiled library name and location in the ModelSim-Altera software for all gate-level simulation models in VHDL.

Table 2–5. Pre-Compiled Gate-Level Simulation Libraries in the ModelSim-Altera Software (VHDL) (Part 1 of 2)

Device Simulation Model	Pre-Compiled Library Name	Location in ModelSim-Altera
Arria® II (without transceiver block)	arriaii	<*ModelSim-Altera installation directory*>**\altera\vhdl\arriaii**
Arria II (with transceiver block)	arriaii_hssi	<*ModelSim-Altera installation directory*>**\altera\vhdl\arriaii_hssi**

Simulation Library Files in the Quartus II Software

In ModelSim SE/PE, no pre-compiled libraries are available. You must compile the necessary libraries to perform RTL functional or gate-level simulation. The following sections show the location of these library files in the Quartus II directory structure. You can refer to these library files for a particular simulation model.

RTL Functional Simulation Library Files

Table 2–7 shows the VHDL RTL simulation model location in the Quartus II directory.

Table 2–7. RTL Functional Simulation Library Files in the Quartus II Directory (VHDL)

RTL Simulation Model	VHDL Libraries

Simulation Netlist Files

Simulation netlist files are required to perform post-synthesis simulation or gate-level timing simulation. These simulation netlist files are generated from the EDA Netlist Writer.

If you are performing post-synthesis simulation, the Verilog HDL Output File (***.vo**) or VHDL Output File (***.vho**) is required. For the steps to generate post-synthesis simulation netlist files for ***.vo** or ***.vho** files, refer to "Generate Post-Synthesis Simulation Netlist Files" on page 2–13.

If you are performing gate-level timing simulation, the ***.vo** file or ***.vho** file and the Standard Delay Format Output File (***.sdo**) are also required. The ***.sdo** file is used to annotate the delay for the elements found in the ***.vo** or ***.vho** file. The section "Generate Gate-Level Timing Simulation Netlist Files" on page 2–14 shows you the steps to generate simulation netlist files for ***.vo** or ***.vho**, and ***.sdo** files.

 © March 2009 Altera Corporation

Generate Post-Synthesis Simulation Netlist Files

The following steps describe the process of generating post-synthesis simulation netlist files in the Quartus II software:

1. Perform Analysis and Synthesis. On the Processing menu, point to **Start** and click **Start Analysis & Synthesis** (you can also perform this after step 2).
2. Turn on the **Generate Netlist for Functional Simulation Only** option by performing the following steps:
   a. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
   b. In the **Category** list, expand **EDA Tool Settings** and click **Simulation**. The **Simulation** page appears.
   c. In the **Tool name** list:
      - If you are using the ModelSim-Altera software, select **ModelSim-Altera**.
      - If you are using the Mentor Graphics ModelSim software, select **ModelSim**.
   d. Under **EDA Netlist Writer options**, in the **Format for output netlist** list, select **VHDL** or **Verilog**. You can also modify where you want the post-synthesis netlist to be generated by editing or browsing to a directory in the **Output directory** box.
   e. Click **More EDA Netlist Writer Settings**. The **More EDA Netlist Writer Settings** dialog box appears.
   f. In the **Existing options settings** list, click **Generate netlist for functional simulation only**.
   g. In the **Setting** list under **Options**, select **On**.
   h. Click **OK**.
   i. In the **Settings** dialog box, click **OK**.
3. Run the EDA Netlist Writer. On the Processing menu, point to **Start** and click **Start EDA Netlist Writer**.

During the EDA Netlist Writer stage, the Quartus II software produces a ***.vo** file or ***.vho** file that can be used for post-synthesis simulations in the ModelSim software. This netlist file is mapped to architecture-specific primitives. No timing information is included at this stage. The resulting netlist is located in the output directory you specified in the **Settings** dialog box, which defaults to the <*project directory*>**/simulation/modelsim** directory.

If you want to generate a post-synthesis simulation netlist with just the cell delays, you can generate an ***.sdo** file without running the Fitter. In this case, the ***.sdo** file includes all timing values for only the device cells. Interconnect delays are not included because fitting (placement and routing) has not been performed. To generate the post-synthesis netlist and the ***.sdo** file, type the following commands at a command prompt:

- `quartus_map <project name> -c <revision name>` ↵

- `quartus_sta <project name> -c <revision name> --post_map ↵`

  or

  ```
  quartus_tan <project name> -c <revision name> --post_map \
  --zero_ic_delays ↵
  ```

- ```
  quartus_eda <project name> -c <revision name> --simulation \
  --tool= <3rd party EDA tool> --format=<HDL language> ↵
  ```

For more information about the **–format** and **–tool** options, type the following command at a command prompt:

```
quartus_eda --help=<options> ↵
```

Generate Gate-Level Timing Simulation Netlist Files

To perform gate-level timing simulation, the ModelSim or ModelSim-Altera software requires information about how the design was placed into device-specific architectural blocks. The Quartus II software provides this information in the form of a ***.vo** file for Verilog HDL designs and a ***.vho** file for VHDL designs. The accompanying timing information is stored in the ***.sdo** file, which annotates the delay for the elements found in the ***.vo** file or ***.vho** file.

To generate a gate-level timing simulation netlist in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, click the "+" icon to expand **EDA Tool Settings** and select **Simulation**. The **Simulation** page appears.
3. In the **Tool name** list:
   - If you are using the ModelSim-Altera software, select **ModelSim-Altera**.
   - If you are using the Mentor Graphics ModelSim software, select **ModelSim**.
4. Under **EDA Netlist Writer options**, in the **Format for output netlist** list, select **VHDL** or **Verilog**. You can also modify where you want the post-synthesis netlist to be generated by editing or browsing to a directory in the **Output directory** box.
5. Click **OK**.
6. In the **Settings** dialog box, click **OK**.
7. If you have not run a full compilation, perform a full compilation. On the Processing menu, click **Start Compilation**.
8. If you have already run a full compilation, run the EDA Netlist Writer. On the Processing menu, point to **Start** and click **Start EDA Netlist Writer**.

   During the full compilation or EDA Netlist Writer stage, the Quartus II software produces a ***.vo** file, ***.vho** file, and a ***.sdo** file used for gate-level timing simulations in the ModelSim software. This netlist file is mapped to architecture-specific primitives. The timing information for the netlist is included in the *.**sdo** file. The resulting netlist is located in the output directory you specified in the **Settings** dialog box, which defaults to the *<project directory>***/simulation/modelsim** directory.
```

Generating Timing Simulation Netlist Files with Different Timing Models

In Stratix III and later devices (for example, Cyclone III and Stratix IV), you can specify different temperature and voltage parameters to generate the timing simulation netlist files. If you enable the Quartus II Classic Timing Analyzer or Quartus II TimeQuest Timing Analyzer when generating the timing simulation netlist files (***.vo** or ***.vho** and ***.sdo**), different timing models for different operating conditions are used by default. Multi-corner timing analysis is run by default during the full compilation.

Table 2–11 shows an example of default-available operating conditions (model, voltage, and temperature) for Stratix III and Cyclone III devices.

Table 2–11. Default Available Operating Conditions for Stratix III and Cyclone III Devices

Device Family	Model	Voltage	Temperature (°C)
Stratix III	Slow	1100 mV	85°
	Slow	1100 mV	0°
	Fast	1100 mV	0°
Cyclone III	Slow	1200 mV	85°
	Slow	1200 mV	0°
	Fast	1200 mV	0°

If multi-corner timing analysis is not run during full compilation, perform the following steps to manually generate the simulation netlist files (***.vo** or ***.vho** and ***.sdo**) for the three different operating conditions listed in Table 2–11:

1. Generate all the available corner models at all operating conditions. Type the following command at a command prompt:

```
quartus_sta <project name> --multicorner ↵
```

2. Generate the timing simulation netlist files for all three corners specified in Table 2–11. Perform steps 2 through 8 in "Generate Gate-Level Timing Simulation Netlist Files" on page 2–14. The output files are generated in the simulation output directory.

The following examples show the timing simulation netlist files generated for the operating conditions of the preceding steps, when **Verilog** is selected as the output netlist format:

First slow corner (slow, 1100 mV, 85° C):

- **.vo** file—<*revision name*>**.vo**
- **.sdo** file—<*revision name*>**_v.sdo**

The <*revision_name*>**.vo** and <*revision name*>**_v.sdo** are generated for backward compatibility in case there are existing scripts that still use them.

- **.vo** file—<*revision name*>_<*speedgrade*>_1100mv_85c_slow**.vo**
- **.sdo** file—<*revision name*>_<*speedgrade*>_1100mv_85c_v_slow**.sdo**

Second slow corner (slow, 1100 mV, 0° C):

- **.vo** file—<*revision name*>_<*speedgrade*>_1100mv_0c_slow**.vo**
- **.sdo** file—<*revision name*>_<*speedgrade*>_1100mv_0c_v_slow**.sdo**

Fast corner (fast, 1100 mV, 0° C):

- **.vo** file—<*revision name*>_min_1100mv_0c_fast**.vo**
- **.sdo** file—<*revision name*>_min_1100mv_0c_v_fast**.sdo**

For older devices, a slow-corner (worst case) timing model is used by default. There are only two timing models available: slow-corner and fast-corner. To generate the timing simulation netlist files using a different timing model, you must run the Quartus II Classic Timing Analyzer or the Quartus II TimeQuest Timing Analyzer with a different timing model before you start the EDA Netlist Writer.

To run the Quartus II Classic Timing Analyzer with the best-case model, on the Processing menu, point to **Start** and click **Start Classic Timing Analyzer (Fast Timing Model)**. After timing analysis is complete, the Compilation Report appears.

You can also type the following command at a command prompt:

```
quartus_tan <project_name> --fast_model=on ↵
```

To run the Quartus II TimeQuest Timing Analyzer with a best-case model, use the `-fast_model` option after you create the timing netlist.

The following command enables the fast timing models:

```
create_timing_netlist --fast_model ↵
```

After running the Quartus II Classic or Quartus II TimeQuest Timing Analyzer, perform steps 2 through 8 in "Generate Gate-Level Timing Simulation Netlist Files" on page 2–14 to generate the timing simulation netlist file. For fast corner timing models, the `-fast` post fix is added to the ***.vo** or ***.vho** and ***.sdo** file (for example, **my_project_fast.vo** or **my_project_fast.vho** and **my_project_fast.sdo**).

For more information about running multi-corner timing analysis, refer to the *Quartus II Classic Timing Analyzer* or the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Disable Timing Violation on Registers

In certain situations, a timing violation can be ignored and you might want to disable timing violations on registers. For example, timing violations that occur in internal synchronization registers used for asynchronous clock domain crossing.

By default, the **x_on_violation_option logic** option is **On**, which means simulation shows "**x**" whenever a timing violation occurs. To disable showing the timing violation on certain registers, set the **x_on_violation_option logic** option to **Off** on those registers. The following command is the Quartus II Tcl Command to disable timing violation on registers. This Tcl command is also stored in the **.qsf** file.

```
set_instance_assignment -name X_ON_VIOLATION_OPTION OFF -to <register_name>
```

Compile Libraries Using the EDA Simulation Library Compiler

The EDA Simulation Library Compiler is used to compile Verilog HDL and VHDL simulation libraries for all Altera devices and supported third-party simulators. You can use this tool to compile all libraries required by RTL and gate-level simulation.

When the compilation targets third-party simulation tools such as ModelSim and NC-Sim, the compiled libraries are kept in either the directory you set or the default directory. When you perform the simulation using these simulators, you can use or re-use the compiled libraries and avoid the overhead associated with redundant library compilations.

However, if the Synopsys VCS or VCS-MX software performs the compilation while running the EDA Simulation Library Compiler, the option files (**simlib_comp.vcs**) are generated after compilation. You can then include your design and testbench files in the option files and invoke them with the `vcs` command.

Before using this option, ensure the appropriate simulation tools are already installed and their paths are specified. To specify the path, refer to "Setting Up NativeLink" on page 2–70.

Run the EDA Simulation Library Compiler through the GUI

Starting with the Quartus II software 9.0 release, the EDA Simulation Library Compiler contains a GUI. To compile libraries with the EDA Simulation Library Compiler GUI, perform the following steps:

1. On the Tools menu, click **EDA Simulation Library Compiler**. The **EDA Simulation Library Compiler** dialog box appears.
2. In the **Tool name** entry box under **EDA simulation tool**, select a simulation tool.

   The **Executable location** box displays location of the simulation tool you specified. This location must be set before running the EDA Simulation Library Compiler.
3. Under **Library families**, select one or more device families for your design compilation and move them to the **Selected families** box.
4. Under **Library language**, select **VHDL**, **Verilog**, or both.
5. In the **Output directory** field, specify a location in which to store the compiled libraries or option files.
6. Click **Start Compilation**.

For example, if you want to simulate a Verilog HDL design on a Stratix II device in the ModelSim simulator, do the following:

- Select **ModelSim** in the **Tool name** field.
- Move **Stratix II** from the **Available families** list to the **Selected families** list.
- Select **Verilog** in the **Library language** field.
- Specify a location in the **Output directory** field in which to keep the user-compiled libraries.
- Click **Start Compilation**.

When the EDA Simulation Library Compiler finishes, all required libraries are compiled and stored in the output location you specified. The next time you perform simulation in ModelSim, you only have to compile your design and testbench files. You do not have to compile the Altera libraries again.

The EDA Simulation Library Compiler supports only ModelSim SE/PE. It does not support ModelSim-Altera, because ModelSim-Altera already contains precompiled libraries.

If you use NativeLink to run the simulation, refer to "Using the NativeLink Feature with ModelSim-Altera or ModelSim Software" on page 2–70.

Run EDA Simulation Library Compiler In Command Line

To run the EDA Simulation Library Compiler in the command line, type the following command:

```
quartus_sh --simlib_comp -family <device> -tool <simulation tool name>
-language <language> -directory <directory> ↵
```

For more information about the command's options and how to define them, type the following command:

```
quartus_sh --help=simlib_comp ↵
```

Perform Simulation Using the ModelSim-Altera Software

Simulation of Verilog HDL or VHDL designs with ModelSim-Altera software can be done at various levels to verify designs from different aspects. Simulation is divided into three categories: RTL functional simulation, post-synthesis simulation, and gate-level timing simulation. Simulation helps you verify your designs and debug them against any possible errors in the designs.

You can perform the simulation through the GUI or on the command line. The following sections provide step-by-step instructions to perform the simulation through the GUI and on the command line.

For high-speed simulation, you must select **ps** in the **Resolution** list for your simulator resolutions. If you choose slower than **ps**, the high-speed simulation may fail.

Simulating the VHDL Designs through the GUI

Simulating the VHDL design using the ModelSim-Altera GUI is user-friendly. You do not have to remember the commands to compile the libraries, or load and simulate the VHDL design files. You can use the ModelSim-Altera GUI to perform RTL functional simulation, post-synthesis simulation, and gate-level timing simulation. The following sections show how to perform simulation at various levels through the ModelSim-Altera GUI.

Perform RTL Functional Simulation

RTL functional simulation is typically performed to verify the syntax of the code and to check the functionality of the design. The following sections show how to perform RTL functional simulation in the ModelSim-Altera software for VHDL designs.

Use the following instructions to perform an RTL functional simulation for VHDL designs in the ModelSim-Altera software.

The ModelSim-Altera software includes pre-compiled simulation libraries. Creating simulation libraries and compiling simulation models are not required.

Compile Testbench and Design Files into the Work Library

The following instructions show you how to compile your testbench and design files into the work library using the ModelSim-Altera GUI.

1. In the ModelSim-Altera software, on the File menu, click **Change Directory**. The **Choose Folder** dialog box appears.
2. Browse to the directory where your designs are located.
3. Click **OK**.

To create the work library, perform the following steps:

1. In the ModelSim-Altera software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.
3. In the **Library Name** box, type the library name `Work` in the text box.
4. Click **OK**.

To compile the testbench and design files into the work library, perform the following steps:

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library **Work**. The design files and testbench file should be compiled into the **Work** library.
3. Select the design files and testbench file, and click **Compile**.
4. Click **Done**.

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, perform the following steps:

1. On the Simulate menu, click **Start Simulation**. The **Start Simulation** dialog box appears.
2. In the **Start Simulation** dialog box, click the **Design** tab. In the **Resolution** list, select **ps**.
3. In the **Library** list, select and expand the **Work** library.
4. Select the top-level design unit (your testbench).
5. In the **Resolution** list, select **ps**.

6. For VHDL designs, if you have not included the libraries' mapped name in your design files or sub-files, perform the following steps:
   a. Click the **Libraries** tab.
   b. In the **Search Libraries** text box, click the **Add** button.
   c. Browse to the required pre-compiled library in the ModelSim-Altera software. You can either click **Browse** and go to the path <*ModelSim-Altera installation directory*>**/altera/vhdl/**<*pre-compiled library*> or you can just click the arrow button to select the <*pre-compiled library mapped name*>.

      Examples of <*pre-compiled library*> or <*pre-compiled library mapped name*> are **altera_mf** and **lpm**. The functional RTL simulation libraries are usually required for performing RTL functional simulation. For the complete set of libraries, refer to "Pre-Compiled Simulation Libraries in the ModelSim-Altera Software" on page 2–5.
   d. Click **OK** to add the libraries to the **Search Libraries** text box.
7. Click **OK**.

Running the Simulation

To run a simulation, perform the following steps:

1. On the View menu, point to **Debug Windows** and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to **Debug Windows** and click **Wave**.
3. Drag signals to monitor from the Objects window and drop them into the Wave window.
4. On the Processing menu, point to **Run** and click **Run 100 ps** to run the simulation for 100 ps.

Perform Post-Synthesis Simulation

Post-synthesis simulation verifies that functionality of the design is not lost after synthesis. You can create the post-synthesis netlist in the Quartus II software and use the netlist to perform post-synthesis simulation with the ModelSim-Altera software.

Before running post-synthesis simulation, generate post-synthesis simulation netlist files. Refer to the instructions in "Generate Post-Synthesis Simulation Netlist Files" on page 2–13.

The following sections help you perform a post-synthesis simulation for a VHDL design in the ModelSim-Altera software.

The ModelSim-Altera software includes pre-compiled simulation libraries. Creating simulation libraries and compiling simulation models are not required.

Compile Testbench and VHDL Output File into the Work Library

The following instructions show how you can compile your testbench and ***.vho** file into the work library using the ModelSim-Altera GUI.

To change to the simulation output directory, perform the following steps:

1. In the ModelSim-Altera software, on the File menu, click **Change Directory**. The **Choose Folder** dialog box appears.
2. Browse to the directory where your testbench or ***.vho** file is located. By default, the ***.vho** file is located in <*project directory*>**/simulation/modelsim**.
3. Click **OK**.

To create the work library, perform the following steps:

1. In the ModelSim-Altera software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.
3. In the **Library Name** box, type the library name `Work` in the text box.
4. Click **OK**.

To compile the testbench and VHDL output (***.vho**) files into the work library, perform the following steps:

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library **Work**. The testbench and VHDL output (***.vho**) files should be compiled into the **Work** library.
3. Select the testbench and ***.vho** design files and click **Compile**.
4. Click **Done**.

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, perform the following steps:

1. On the Simulate menu, click **Start Simulation**. The **Start Simulation** dialog box appears.
2. In the **Start Simulation** dialog box, click the **Design** tab. In the **Resolution** list, select **ps**.
3. In the **Library** list, select and expand the **Work** library.
4. Select the top-level design unit (your testbench).
5. In the **Resolution** list, select **ps**.

6. For VHDL designs, if you have not included the libraries' mapped name in your design files or sub-files, perform the following steps:
   a. Click the **Libraries** tab.
   b. In the **Search Libraries** text box, click the **Add** button.
   c. Browse to the required pre-compiled library in the ModelSim-Altera software. You can either click **Browse** and go to the path <*ModelSim-Altera installation directory*>**/altera/vhdl/**<*pre-compiled library*> or you can just click the arrow button to select the <*pre-compiled library mapped name*>.

      Examples of <*pre-compiled library*> or <*pre-compiled library mapped name*> are **stratixiii** and **cycloneiii**. The gate-level simulation libraries are usually required for performing post-synthesis simulation. For the complete set of libraries, refer to "Pre-Compiled Simulation Libraries in the ModelSim-Altera Software" on page 2–5.
   d. Click **OK** to add the libraries to the **Search Libraries** text box.
7. Click **OK**.

Running the Simulation

To run a simulation, perform the following steps:

1. On the View menu, point to **Debug Windows** and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to **Debug Windows** and click **Wave**.
3. Drag signals to monitor from the Objects window and drop them into the Wave window.
4. On the Processing menu, point to **Run** and click **Run 100 ps** to run the simulation for 100 ps.

Perform Gate-Level Simulation

Gate-level simulation is a very important step in ensuring that the FPGA device's functionality is still correct and meets all required timing requirements after the design was placed and routed. You can create the gate-level netlist in the Quartus II software and use the netlist to perform gate-level simulation with the ModelSim-Altera software.

Before running gate-level simulation, generate gate-level timing simulation netlist files. Refer to the instructions in "Generate Gate-Level Timing Simulation Netlist Files" on page 2–14.

The following sections help you perform a gate-level simulation for a VHDL design in the ModelSim-Altera software.

The ModelSim-Altera software includes pre-compiled simulation libraries. Creating simulation libraries and compiling simulation models are not required.

Compile Testbench and VHDL Output File into the Work Library

The following instructions show how you can compile your testbench and ***.vho** file into the work library using the ModelSim-Altera GUI.

© March 2009 Altera Corporation

To change to the simulation output directory, perform the following steps:

1. In the ModelSim-Altera software, on the File menu, click **Change Directory**. The **Choose Folder** dialog box appears.
2. Browse to the directory where your testbench or ***.vho** file is located. By default, the ***.vho** file is located in *<project directory>***/simulation/modelsim**.
3. Click **OK**.

To create the work library, perform the following steps:

1. In the ModelSim-Altera software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.
3. In the **Library Name** box, type the library name `Work` in the text box.
4. Click **OK**.

To compile the testbench and VHDL output (***.vho**) files into the work library, perform the following steps:

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library **Work**. The testbench and VHDL output (***.vho**) files should be compiled into the **Work** library.
3. Select the testbench and VHDL output (***.vho**) design files, and click **Compile**.
4. Click **Done**.

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, perform the following steps:

1. On the Simulate menu, click **Start Simulation**. The **Start Simulation** dialog box appears.
2. Click the **SDF** tab, and click **Add**. The **Add SDF Entry** dialog box appears.
3. In the **Add SDF Entry** dialog box, click **Browse** and select the ***.sdo** file. By default, the ***.sdo** file is located in *<project directory>***/simulation/modelsim**.
4. In the **Apply to Region** dialog box, type the instance path to which the ***.sdo** file is to be applied. For example, if you are using a testbench exported into the Quartus II software from a Vector Waveform File, the instance path is set to **/i1**.

You do not have to choose from the **Delay** list because the Quartus II EDA Netlist Writer generates the ***.sdo** file using the same value for the triplet (minimum, typical, and maximum timing values).

5. Click **OK**.
6. In the **Start Simulation** dialog box, click the **Design** tab. In the **Resolution** list, select **ps**.
7. In the **Library** list, select and expand the **Work** library.

8. Select the top-level design unit (your testbench).
9. In the **Resolution** list, select **ps**.
10. For VHDL designs, if you have not included the libraries' mapped name in your design files or sub-files, perform the following steps:
    a. Click the **Libraries** tab.
    b. In the **Search Libraries** text box, click the **Add** button.
    c. Browse to the required pre-compiled library in the ModelSim-Altera software. You can either click **Browse** and go to the path <*ModelSim-Altera installation directory*>**/altera/vhdl/**<*pre-compiled library*> or you can just click the arrow button to select the <*pre-compiled library mapped name*>.

       Examples of <*pre-compiled library*> or <*pre-compiled library mapped name*> are **stratixiii** and **cycloneiii**. The gate-level simulation libraries are usually required for performing gate-level simulation. For the complete set of libraries, refer to "Pre-Compiled Simulation Libraries in the ModelSim-Altera Software" on page 2–5.
    d. Click **OK** to add the libraries to the **Search Libraries** text box.
11. Click **OK**.

Running the Simulation

To run a simulation, perform the following steps:

1. On the View menu, point to **Debug Windows** and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to **Debug Windows** and click **Wave**.
3. Drag signals to monitor from the Objects window and drop them into the Wave window.
4. On the Processing menu, point to **Run** and click **Run 100 ps** to run the simulation for 100 ps.

Simulating Verilog HDL Designs through the GUI

Simulating the Verilog HDL design using the ModelSim-Altera GUI is user-friendly. You do not have to remember the commands to compile the libraries or load and simulate the Verilog HDL design files. You can use the ModelSim-Altera GUI to perform RTL functional simulation, post-synthesis simulation, and gate-level timing simulation. The following sections show how to perform simulation at various levels through the ModelSim-Altera GUI.

Perform RTL Functional Simulation

RTL functional simulation is typically performed to verify the syntax of the code and to check the functionality of the design. The following sections show how to perform RTL functional simulation in ModelSim-Altera for Verilog HDL designs.

Use the following instructions to perform an RTL functional simulation for Verilog HDL designs in the ModelSim-Altera software.

The ModelSim-Altera software includes pre-compiled simulation libraries. Creating simulation libraries and compiling simulation models are not required.

Compile Testbench and Design Files into the Work Library

The followings instructions show you how to compile your testbench and design files into the work library using the ModelSim-Altera GUI.

To change to the design directory, perform the following steps:

1. In the ModelSim-Altera software, on the File menu, click **Change Directory**. The **Choose Folder** dialog box appears.
2. Browse to the directory where your designs are located.
3. Click **OK**.

To create the work library, perform the following steps:

1. In the ModelSim-Altera software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.
3. In the **Library Name** box, type the library name `Work` in the text box.
4. Click **OK**.

To compile the testbench and design files into the work library, perform the following steps:

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library **Work**. The design files and testbench file should be compiled into the **Work** library.
3. Select the design files and testbench file and click **Compile**.
4. Click **Done**.

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, perform the following steps:

1. On the Simulate menu, click **Start Simulation**. The **Start Simulation** dialog box appears.
2. In the **Start Simulation** dialog box, click the **Design** tab. In the **Resolution** list, select **ps**.
3. In the **Library** list, select and expand the **Work** library.
4. Select the top-level design unit (your testbench).
5. In the **Resolution** list, select **ps**.
6. Click the **Libraries** tab.
7. In the **Search Libraries** text box, click the **Add** button.

8. Browse to the required pre-compiled library in the ModelSim-Altera software. You can either click **Browse** and go to the path <*ModelSim-Altera installation directory*>**/altera/verilog/**<*pre-compiled library*> or you can just click the arrow button to select the <*pre-compiled library mapped name*>.

   Examples of <*pre-compiled library*> or <*pre-compiled library mapped name*> are **altera_mf_ver** and **lpm_ver**. The RTL simulation libraries are usually required for performing RTL functional simulation. For the complete set of libraries, refer to "Pre-Compiled Simulation Libraries in the ModelSim-Altera Software" on page 2–5.

9. Click **OK** to add the libraries to the **Search Libraries** text box.
10. Click **OK**.

Running the Simulation

To run a simulation, perform the following steps:

1. On the View menu, point to **Debug Windows** and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to **Debug Windows** and click **Wave**.
3. Drag signals to monitor from the Objects window and drop them into the Wave window.
4. On the Processing menu, point to **Run** and click **Run 100 ps** to run the simulation for 100 ps.

Perform Post-Synthesis Simulation

Post-synthesis simulation can be performed to verify that functionality of the design is not lost after synthesis. You can create the post-synthesis netlist in the Quartus II software and use the netlist to perform post-synthesis simulation with the ModelSim-Altera software.

Before running post-synthesis simulation, generate post-synthesis simulation netlist files. Refer to the instructions in "Generate Post-Synthesis Simulation Netlist Files" on page 2–13.

The following sections help you perform a post-synthesis simulation for a Verilog HDL design in the ModelSim-Altera software.

The ModelSim-Altera software includes pre-compiled simulation libraries. Creating simulation libraries and compiling simulation models are not required.

Compile Testbench and Verilog HDL Output File into the Work Library

The following instructions show how you can compile your testbench and Verilog HDL output file (***.vo**) into the work library using the ModelSim-Altera GUI.

To change to the simulation output directory, perform the following steps:

1. In the ModelSim-Altera software, on the File menu, click **Change Directory**. The **Choose Folder** dialog box appears.
2. Browse to the directory where your testbench or ***.vo** file is located. By default, the ***.vho** file is located in <*project directory*>**/simulation/modelsim**.

3. Click **OK**.

To create the work library, perform the following steps:

1. In the ModelSim-Altera software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.
3. In the **Library Name** box, type the library name `Work` in the text box.
4. Click **OK**.

To compile the testbench and Verilog HDL output (***.vo**) files into the work library, perform the following steps:

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library **Work**. The testbench and Verilog HDL output (***.vo**) files should be compiled into the **Work** library.
3. Select the testbench and ***.vo** design files, and click **Compile**.
4. Click **Done**.

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, perform the following steps:

1. On the Simulate menu, click **Start Simulation**. The **Start Simulation** dialog box appears.
2. In the **Start Simulation** dialog box, click the **Design** tab. In the **Resolution** list, select **ps**.
3. In the **Library** list, select and expand the **Work** library.
4. Select the top-level design unit (your testbench).
5. In the **Resolution** list, select **ps**.
6. Click the **Libraries** tab.
7. In the **Search Libraries** text box, click the **Add** button.
8. Browse to the required pre-compiled library in the ModelSim-Altera software. You can either click **Browse** and go to the path <*ModelSim-Altera installation directory*>**/altera/verilog/**<*pre-compiled library*> or you can just click the arrow button to select the <*pre-compiled library mapped name*>.

   Examples of <*pre-compiled library*> or <*pre-compiled library mapped name*> are **stratixiii_ver** and **cycloneiii_ver**. The gate-level simulation libraries are usually required for performing post-synthesis simulation. For the complete set of libraries, refer to "Pre-Compiled Simulation Libraries in the ModelSim-Altera Software" on page 2–5.
9. Click **OK** to add the libraries to the **Search Libraries** text box.
10. Click **OK**.

Running the Simulation

To run a simulation, perform the following steps:

1. On the View menu, point to **Debug Windows** and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to **Debug Windows** and click **Wave**.
3. Drag signals to monitor from the Objects window and drop them into the Wave window.
4. On the Processing menu, point to **Run** and click **Run 100 ps** to run the simulation for 100 ps.

Perform Gate-Level Simulation

Gate-level simulation is a very important step in ensuring that the FPGA device's functionality is still correct and meets all required timing requirements after the design was placed and routed. You can create the gate-level netlist in the Quartus II software and use the netlist to perform gate-level simulation with the ModelSim-Altera software.

Before running gate-level simulation, generate gate-level timing simulation netlist files. Refer to the instructions in "Generate Gate-Level Timing Simulation Netlist Files" on page 2–14.

The following sections help you perform a gate-level simulation for a Verilog HDL design in the ModelSim-Altera software.

The ModelSim-Altera software includes pre-compiled simulation libraries. Creating simulation libraries and compiling simulation models are not required.

Compile Testbench and Verilog HDL Output File into the Work Library

The following instructions show how you can compile your testbench and ***.vo** file into the work library using the ModelSim-Altera GUI.

To change to the simulation output directory, perform the following steps:

1. In the ModelSim-Altera software, on the File menu, click **Change Directory**. The **Choose Folder** dialog box appears.
2. Browse to the directory where your testbench or ***.vo** file is located. By default, the ***.vo** file is located in <*project directory*>**/simulation/modelsim**.
3. Click **OK**.

To create the work library, perform the following steps:

1. In the ModelSim-Altera software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.
3. In the **Library Name** box, type the library name `Work` in the text box.
4. Click **OK**.

To compile the testbench and ***.vo** files into the work library, perform the following steps:

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library **Work**. The testbench and ***.vo** files should be compiled into the **Work** library.
3. Select the testbench and ***.vo** design files, and click **Compile**.
4. Click **Done**.

Resolve compile-time errors before proceeding to the next section.

Loading the Design

When simulating in Verilog HDL, the ***.sdo** file does not have to be manually specified. In the **$sdf_annotate** task, when the Quartus II software generates the ***.vo** file, the ModelSim-Altera software looks for the ***.sdo** file in the folder in which the VSIM was run. If your ***.sdo** file is not in the same directory in which you ran VSIM, copy the ***.sdo** file into your current directory.

To load a design, perform the following steps:

1. On the Simulate menu, click **Start Simulation**. The **Start Simulation** dialog box appears.
2. In the **Start Simulation** dialog box, click the **Design** tab. In the **Resolution** list, select **ps**.
3. In the **Library** list, select and expand the **Work** library.
4. Select the top-level design unit (your testbench).
5. In the **Resolution** list, select **ps**.
6. Click the **Libraries** tab.
7. In the **Search Libraries** text box, click the **Add** button.
8. Browse to the required pre-compiled library in the ModelSim-Altera software. You can either click **Browse** and go to the path <*ModelSim-Altera installation directory*>**/altera/verilog/**<*pre-compiled library*> or you can just click the arrow button to select the <*pre-compiled library mapped name*>.

   Examples of <*pre-compiled library*> are **altera_mf_ver** and **lpm_ver**. The gate-level simulation libraries are usually required for performing gate-level simulation. For the complete set of libraries, refer to "Pre-Compiled Simulation Libraries in the ModelSim-Altera Software" on page 2–5.
9. Click **OK** to add the libraries to the **Search Libraries** text box.
10. Click **OK**.

Running the Simulation

To run a simulation, perform the following steps:

1. On the View menu, point to **Debug Windows** and click **Objects**. This command displays all objects in the current scope.

2. On the View menu, point to **Debug Windows** and click **Wave**.
3. Drag signals to monitor from the Objects window and drop them into the Wave window.
4. On the Processing menu, point to **Run** and click **Run 100 ps** to run the simulation for 100 ps.

Simulating the VHDL Designs at the Command Line

Simulating VHDL designs using the ModelSim-Altera command line gives you more flexibility and control to compile the libraries, and load and simulate the VHDL design files. All simulation commands are Tcl commands, which can be put into the ModelSim Macros file (***.do**). Using the ***.do** file allows you to run simulation in batch mode. You only have to execute the ***.do** file and the ModelSim-Altera tool automatically executes all commands in the ***.do** script macro file.

You can use the ModelSim-Altera command line to perform RTL functional simulation, post-synthesis simulation, and gate-level simulation. The following sections show how to perform simulation at various levels through the ModelSim-Altera command line.

Perform RTL Functional Simulation

RTL functional simulation is typically performed to verify the syntax of the code and to check the functionality of the design. The following sections show how to perform RTL functional simulation in ModelSim-Altera for VHDL designs.

The ModelSim-Altera software includes pre-compiled simulation libraries. Creating simulation libraries and compiling simulation models are not required.

Compile Testbench and Design Files into the Work Library

The following commands show how to compile your testbench and design files into the work library in the ModelSim-Altera command prompt.

To change to the design library, type the following command:

```
cd <your_design_directory> ↵
```

(for example, *cd:/designs*)

To create the work library, type the following commands:

```
vlib work ↵
vmap work work ↵
```

To compile the testbench and design files into the work library, type the following command:

```
vcom -work work <my_testbench.vhd> <my_design_files.vhd> ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, type the following command:

```
vsim -t ps -L <pre-compiled-library1> -L <pre-compiled-library2> work.<my_testbench> ↵
```

The <*pre-compiled-library1*> and <*pre-compiled-library2*> variables are the libraries required to compile your testbench. If you have multiple libraries, use the `-L` option for each library in the `vsim` command.

Examples of <*pre-compiled library*> are **altera_mf** and **lpm**. The functional RTL simulation libraries are usually required for performing RTL functional simulation. For the complete set of libraries, refer to "Pre-Compiled Simulation Libraries in the ModelSim-Altera Software" on page 2–5.

You can choose not to invoke `-L` in the `vsim` command for VHDL designs if you have already included the libraries' mapped name in your design files or sub-files.

Running the Simulation

To run a simulation, type the following commands:

```
add wave <signal name> ↵
run <time period> ↵
```

To add all signals in your testbench hierarchy, type the following command:

```
add wave * ↵
```

To run the simulation for 100 ps, type the following command:

```
run 100 ps ↵
```

Perform Post-Synthesis Simulation

Post-synthesis simulation can be performed to verify that functionality of the design is not lost after synthesis. You can create the post-synthesis netlist in the Quartus II software and use the netlist to perform post-synthesis simulation with the ModelSim-Altera software.

The following sections help you perform a post-synthesis simulation for a VHDL design in the ModelSim-Altera software.

The ModelSim-Altera software includes pre-compiled simulation libraries. Creating simulation libraries and compiling simulation models are not required.

Compile Testbench and VHDL Output File into the Work Library

Before running post-synthesis simulation, generate post-synthesis simulation netlist files. Refer to the instructions in "Generate Post-Synthesis Simulation Netlist Files" on page 2–13.

The following instructions show how to compile your testbench and ***.vho** file into the work library using the ModelSim-Altera GUI.

To change to the simulation output directory, type the following command:

```
cd <simulation_output_directory> ↵
```

(for example, **cd:/designs/modelsim/simulation**)

This directory contains the ***.vho** file, which is generated by the netlist writer.

To create the work library, type the following commands:

```
vlib work ↵
vmap work work ↵
```

To compile the testbench and ***.vho** files into the work library, type the following command:

```
vcom -work work <my_testbench.vhd> <my_design_netlists.vho> ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, type the following command:

```
vsim -t ps -L <pre-compiled-library1> -L <pre-compiled-library2> work.<my_testbench> ↵
```

The <*pre-compiled-library1*> and <*pre-compiled-library2*> variables are the libraries required to compile your testbench. If you have multiple libraries, use the `-L` option for each library in the `vsim` command.

Examples of <*pre-compiled library*> are **stratixiii** and **cycloneiii**. The gate-level simulation libraries are usually required for performing post-synthesis simulation. For the complete set of libraries, refer to "Pre-Compiled Simulation Libraries in the ModelSim-Altera Software" on page 2–5.

You can choose not to invoke `-L` in the `vsim` command for VHDL designs if you have already included the libraries' mapped name in your design files or sub-files.

Running the Simulation

To run a simulation, type the following commands:

```
add wave <signal name> ↵
run <time period> ↵
```

To add all signals in your testbench hierarchy, type the following command:

```
add wave * ↵
```

To run the simulation for 100 ps, type the following command:

```
run 100 ps ↵
```

Perform Gate-Level Simulation

Gate-level simulation is a very important step in ensuring that the FPGA device's functionality is still correct and meets all required timing requirements after the design was placed and routed. You can create the gate-level netlist in the Quartus II software and use the netlist to perform gate-level simulation with the ModelSim-Altera software.

The following sections help you perform a gate-level simulation for a VHDL design in the ModelSim-Altera software.

The ModelSim-Altera software includes pre-compiled simulation libraries. Creating simulation libraries and compiling simulation models are not required.

Compile Testbench and VHDL Output File into the Work Library

Before running gate-level simulation, generate gate-level timing simulation netlist files. Refer to the instructions in "Generate Gate-Level Timing Simulation Netlist Files" on page 2–14.

The following instructions show how to compile your testbench and ***.vho** file into the work library using the ModelSim-Altera GUI.

To change to the simulation output directory, type the following command:

```
cd <simulation_output_directory> ↵
```

(for example, **cd:/designs/modelsim/simulation**)

☞ This directory contains the ***.vho** file, which is generated by the netlist writer.

To create the work library, type the following commands:

```
vlib work ↵
vmap work work ↵
```

To compile the testbench and ***.vho** files into the work library, type the following command:

```
vcom -work work <my_testbench.vhd> <my_design_netlists.vho> ↵
```

☞ Resolve compile-time errors before proceeding to the next section.

Loading the Design

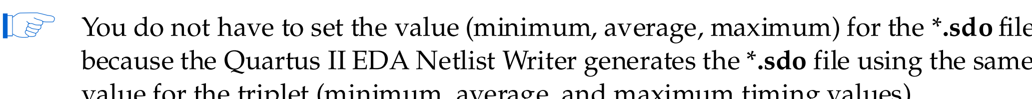
To load a design, type the following command:

```
vsim -t ps -sdftyp <design instance> = <path to *.sdo file> -L \
<pre-compiled-library1> -L <pre-compiled-library2> work.<my_testbench> ↵
```

The *<pre-compiled-library1>* and *<pre-compiled-library2>* variables are the libraries required to compile your testbench. If you have multiple libraries, use the `-L` option for each library in the `vsim` command.

Examples of *<pre-compiled library>* are **stratixiii** and **cycloneiii**. The gate-level simulation libraries are usually required for performing gate-level simulation. For the complete set of libraries, refer to "Pre-Compiled Simulation Libraries in the ModelSim-Altera Software" on page 2–5.

You can choose not to invoke `-L` in the `vsim` command for VHDL designs if you have already included the libraries' mapped name in your design files or sub-files.



☞ You do not have to set the value (minimum, average, maximum) for the ***.sdo** file because the Quartus II EDA Netlist Writer generates the ***.sdo** file using the same value for the triplet (minimum, average, and maximum timing values).

☞ If your design under test is instantiated in the testbench file under the `i1` label, the *<design instance>* should be "`i1`" (for example, **/i1=<*my design*>.sdo**).

Running the Simulation

To run a simulation, type the following commands:

```
add wave <signal name> ↵
run <time period> ↵
```

To add all signals in your testbench hierarchy, type the following command:

```
add wave * ↵
```

To run the simulation for 100 ps, type the following command:

```
run 100 ps ↵
```

Simulating the Verilog HDL Designs at the Command Line

Simulating Verilog HDL design using the ModelSim-Altera command line gives you more flexibility and control to compile the libraries, and load and simulate the Verilog HDL design files. All simulation commands are Tcl commands which can be put into the ModelSim Macros file (***.do**). Using the ***.do** file allows you to run simulation in batch mode. You only have to execute the ***.do** file and the ModelSim-Altera tool automatically executes all the commands in the ***.do** script macro file.

You can use the ModelSim-Altera command line to perform the RTL functional simulation, post-synthesis simulation, and gate-level simulation. The following sections show how to perform simulation at various levels on the ModelSim-Altera command line.

Perform RTL Functional Simulation

RTL functional simulation is typically performed to verify the syntax of the code and to check the functionality of the design. The following sections show how to perform RTL functional simulation in ModelSim-Altera for Verilog HDL designs.

The ModelSim-Altera software includes pre-compiled simulation libraries. Creating simulation libraries and compiling simulation models are not required.

Compile Testbench and Design Files into the Work Library

The following commands compile your testbench and design files into the work library at the ModelSim-Altera command prompt.

To change to the design library, type the following command:

```
cd <your_design_directory> ↵
```

(for example, **cd:/designs**)

To create the work library, type the following commands:

```
vlib work ↵
vmap work work ↵
```

To compile the testbench and design files into the work library, type the following command:

```
vlog -work work <my_testbench.v> <my_design_files.v> ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, type the following command:

```
vsim -t ps -L <library1> -L <library2> work.<my_testbench> ↵
```

The <*library1*> and <*library2*> variables are the required libraries to compile your testbench. If you have multiple libraries, use the `-L` option multiple times in the `vsim` command.

Examples of <*pre-compiled library*> are **altera_mf_ver** and **lpm_ver**. The functional RTL simulation libraries are usually required for performing RTL functional simulation. For the complete set of libraries, refer to "Pre-Compiled Simulation Libraries in the ModelSim-Altera Software" on page 2–5.

Running the Simulation

To run a simulation, type the following commands:

```
add wave <signal name> ↵
run <time period> ↵
```

To add all signals in your testbench hierarchy, type the following command:

```
add wave * ↵
```

To run the simulation for 100 ps, type the following command:

```
run 100 ps ↵
```

Perform Post-Synthesis Simulation

Post-synthesis simulation can be done to verify that functionality of the design is not lost after synthesis. You can create the post-synthesis netlist in the Quartus II software and use the netlist to perform post-synthesis simulation with the ModelSim-Altera software.

The following sections help you perform a post-synthesis simulation for a Verilog HDL design in the ModelSim-Altera software.

The ModelSim-Altera software includes pre-compiled simulation libraries. Creating simulation libraries and compiling simulation models are not required.

Compile Testbench and Verilog Output File into the Work Library

Before running post-synthesis simulation, generate post-synthesis simulation netlist files. Refer to the instructions in "Generate Post-Synthesis Simulation Netlist Files" on page 2–13.

The following instructions show how to compile your testbench and ***.vo** file into the work library using the ModelSim-Altera software.

To change to the simulation output directory, type the following command:

```
cd <simulation_output_directory> ↵
```

(for example, **cd:/designs/modelsim/simulation**)

This directory contains the ***.vo** file, which is generated by the netlist writer.

To create the work library, type the following commands:

```
vlib work ↵
vmap work work ↵
```

To compile the testbench and ***.v** files into the work library, type the following command:

```
vlog -work work <my_testbench.v> <my_design_netlists.vo> ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, type the following command:

```
vsim -t ps -L <library1> -L <library2> work.<my_testbench> ↵
```

The <*library1*> and <*library2*> variables are the required libraries to compile your testbench. Examples of <*pre-compiled library*> are **stratixiii_ver**, **stratixii_ver**, and **stratixiigx_ver**. Gate-level libraries are usually required for performing post-synthesis simulation. If you have multiple libraries, use the `-L` option multiple times in the `vsim` command. For the complete set of libraries, refer to "Pre-Compiled Simulation Libraries in the ModelSim-Altera Software" on page 2–5.

Running the Simulation

To run a simulation, type the following commands:

```
add wave <signal name> ↵
run <time period> ↵
```

To add all signals in your testbench hierarchy, type the following command:

```
add wave * ↵
```

To run the simulation for 100 ps, type the following command:

```
run 100 ps ↵
```

Perform Gate-Level Simulation

Gate-level simulation is a very important step in ensuring that the FPGA device's functionality is still correct and meets all required timing requirements after the design was placed and routed. You can create the gate-level netlist in the Quartus II software and use the netlist to perform gate-level simulation with the ModelSim-Altera software.

The following sections help you perform a gate-level simulation for a Verilog HDL design in the ModelSim-Altera software.

The ModelSim-Altera software includes pre-compiled simulation libraries. Creating simulation libraries and compiling simulation models are not required.

Compile Testbench and Verilog Output File into the Work Library

Before running gate-level simulation, generate gate-level timing simulation netlist files. Refer to the instructions in "Generate Gate-Level Timing Simulation Netlist Files" on page 2–14.

The following instructions show how to compile your testbench and ***.vo** file into the work library using the ModelSim-Altera software.

To change to the simulation output directory, type the following command:

```
cd <simulation_output_directory> ↵
```

(for example, **cd:/designs/modelsim/simulation**)

This directory contains the ***.vho** file, which is generated by the netlist writer.

To create the work library, type the following commands:

```
vlib work ↵
vmap work work ↵
```

To compile the testbench and VHDL output (***.vho**) files into the work library, type the following command:

```
vlog -work work <my_testbench.v> <my_design_netlists.vo> ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

When simulating in Verilog HDL, the ***.sdo** file does not have to be manually specified. In the **$sdf_annotate** task, when the Quartus II software generates the ***.vo** file, the ModelSim-Altera software looks for the ***.sdo** file in the folder in which the VSIM was run. If your ***.sdo** file is not in the same directory in which you ran VSIM, copy the ***.sdo** file into your current directory.

To load a design, type the following command:

```
vsim -t ps -L <library1> -L <library2> work.<my_testbench> ↵
```

The <*library1*> and <*library2*> variables are the required libraries to compile your testbench. Examples of pre-compiled libraries are **stratixiii_ver**, **stratixii_ver**, and **stratixiigx_ver**. Gate-level libraries are usually required for performing gate-level timing simulation. If you have multiple libraries, use the `-L` option multiple times in the `vsim` command. For the complete set of libraries, refer to "Pre-Compiled Simulation Libraries in the ModelSim-Altera Software" on page 2–5.

Running the Simulation

To run a simulation, type the following commands:

```
add wave <signal name> ↵
run <time period> ↵
```

To add all signals in your testbench hierarchy, type the following command:

```
add wave * ↵
```

To run the simulation for 100 ps, type the following command:

```
run 100 ps ↵
```

Perform Simulation Using the ModelSim Software

Simulation of Verilog HDL or VHDL designs with ModelSim software can be done at various levels to verify designs from different aspects. Simulation is divided into three categories: RTL functional simulation, post-synthesis simulation, and gate-level simulation. Simulation helps you verify your designs and debug them against any possible errors in the designs.

You can perform the simulation through the GUI or command line. The following sections provide step-by-step instructions to perform the simulation through the GUI and the command line. You can proceed to the specific section that meets your needs.

For high-speed simulation, you must select **ps** in the **Resolution** list for your simulator resolutions. If you choose slower than **ps**, the high-speed simulation may fail.

Simulating the VHDL Designs Using the GUI

Simulating VHDL design using the ModelSim GUI is user-friendly. You do not have to remember the commands to compile the libraries or load and simulate the VHDL design files. You can use the ModelSim GUI to perform RTL functional simulation, post-synthesis simulation, and gate-level timing simulation. The following sections show how to perform simulation at various levels through the ModelSim GUI.

Perform RTL Functional Simulation

RTL functional simulation is typically performed to verify the syntax of the code and to check the functionality of the design. The following sections show how to perform RTL functional simulation in ModelSim for VHDL designs.

Use the following instructions to perform an RTL functional simulation for VHDL designs in the ModelSim software.

Create Simulation Libraries

Simulation libraries are required to simulate a design that contains an Altera primitive, LPM function, or Altera megafunction. Depending on your design, you must create the required simulation libraries and link them to your design correctly.

To change to the design directory, perform the following steps:

1. In the ModelSim software, on the File menu, click **Change Directory**. The **Choose Folder** dialog box appears.
2. Browse to the directory where your designs are located.
3. Click **OK**.

If you are not using the EDA Simulation Library Compiler, perform the following steps to create the simulation library. (If you are using this utility, you can skip these steps.)

1. In the ModelSim software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.
3. In the **Library Name** box, type the library name of the newly created library.

For example, the library name for Altera megafunctions is **altera_mf**, and the library name for LPM is **lpm**. To see all the functional simulation library files, refer to "RTL Functional Simulation Libraries" on page 2–6.

4. Click **OK**.

Compile Simulation Models into Simulation Libraries

If you are not using the Altera Simulation Library Compiler, perform the following steps to compile simulation models into simulation libraries. (If you are using this utility, you can skip these steps.)

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library that you created (for example, **altera_mf**, **lpm**).
3. Browse to the <*Quartus II installation directory*>**/eda/sim_lib** and add the necessary simulation model files to your project. Select the simulation model files and click **Compile**.

The **altera_mf_components.vhd** and **altera_mf.vhd** model files should be compiled into the **altera_mf** library. The **220pack.vhd** and **220model.vhd** model files should be compiled into the **lpm** library.

4. Repeat step 2 and step 3 to compile other simulation models.
5. Click **Done**.

Compile Testbench and Design Files into the Work Library

The following instructions show you how to compile your testbench and design files into the work library using the ModelSim GUI.

To create the work library, perform the following steps:

1. In the ModelSim software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.
3. In the **Library Name** box, type the library name `Work` in the text box.
4. Click **OK**.

To compile the testbench and design files into the work library, perform the following steps:

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library **Work**. The design files and testbench file should be compiled into the **Work** library.
3. Select the design files and the testbench file and click **Compile**.
4. Click **Done**.

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, perform the following steps:

1. On the Simulate menu, click **Start Simulation**. The **Start Simulation** dialog box appears.
2. In the **Start Simulation** dialog box, click the **Design** tab. In the **Resolution** list, select **ps**.
3. In the **Library** list, select and expand the **Work** library.
4. Select the top-level design unit (your testbench).
5. In the **Resolution** list, select **ps**.
6. For VHDL designs, if you have not included the libraries' mapped name in your design files or sub-files, perform the following steps:
   a. Click the **Libraries** tab.
   b. In the **Search Libraries** (-L) text box, click the **Add** button.
   c. Browse to the required simulation library that you previously compiled (for example, **altera_mf, lpm**, or **altera**).
   d. Click **OK** to add the libraries to the **Search Libraries** (-L) text box.
7. Click **OK**.

Running the Simulation

To run a simulation, perform the following steps:

1. On the View menu, point to **Debug Windows** and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to **Debug Windows** and click **Wave**.
3. Drag signals to monitor from the Objects window and drop them into the Wave window.
4. On the Processing menu, point to **Run** and click **Run 100 ps** to run the simulation for 100 ps.

Perform Post-Synthesis Simulation

Post-synthesis simulation can be performed to verify that functionality of the design is not lost after synthesis. You can create the post-synthesis netlist in the Quartus II software and use the netlist to perform post-synthesis simulation with the ModelSim software.

Before running post-synthesis simulation, generate post-synthesis simulation netlist files. Refer to the instructions in "Generate Post-Synthesis Simulation Netlist Files" on page 2–13.

The following sections help you perform a post-synthesis simulation for a VHDL design in the ModelSim software.

Create Simulation Libraries

Simulation libraries are required to simulate a design that is mapped to post-synthesis primitives. Depending on the device family you are using, you must create the required simulation libraries and link them to your design correctly.

To change to the simulation output directory, perform the following steps:

1. In the ModelSim software, on the File menu, click **Change Directory**. The **Choose Folder** dialog box appears.
2. Browse to the directory where your testbench or ***.vho** file is located. By default, the ***.vho** file is located in *<project directory>/simulation/modelsim*.
3. Click **OK**.

If you are not using the EDA Simulation Library Compiler, perform the following steps to create the simulation library. (If you are using this utility, you can skip these steps.)

1. In the ModelSim software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.
3. In the **Library Name** box, type the library name of the newly created library.

For example, the library name for Stratix III family is **stratixiii**. To see all the gate-level timing simulation library files, refer to "Gate-Level Simulation Library Files" on page 2–10.

4. Click **OK**.

Compile Simulation Models into Simulation Libraries

If you are not using the Altera Simulation Library Compiler, perform the following steps to compile simulation models into simulation libraries. (If you are using this utility, you can skip these steps.)

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library that you created (for example, **stratixiii**).
3. Browse to the *<Quartus II installation directory>***/eda/sim_lib** and add the necessary simulation model files to your project. Select the simulation model files and click **Compile**.

The **stratixiii_components.vhd** and **stratixiii.vhd** model files are compiled into the **stratixiii** library.

4. Repeat step 2 and step 3 to compile other simulation models.
5. Click **Done**.

Compile Testbench and VHDL Output File into the Work Library

The following instructions show you how to compile your testbench and ***.vho** file into the work library using the ModelSim GUI.

To create the work library, perform the following steps:

1. In the ModelSim software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.
3. In the **Library Name** box, type the library name `Work` in the text box.
4. Click **OK**.

To compile the testbench file and ***.vho** file into the work library, perform the following steps:

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library **Work**. The testbench and ***.vho** file should be compiled into the **Work** library.
3. Select the testbench and ***.vho** file design files and click **Compile**.
4. Click **Done**.

Loading the Design

To load a design, perform the following steps:

1. On the Simulate menu, click **Start Simulation**. The **Start Simulation** dialog box appears.
2. In the **Start Simulation** dialog box, click the **Design** tab. In the **Resolution** list, select **ps**.
3. In the **Library** list, select and expand the **Work** library.
4. Select the top-level design unit (your testbench).
5. In the **Resolution** list, select **ps**.
6. For VHDL designs, if you have not included the libraries' mapped name in your design files or sub-files, perform the following steps:
   a. Click the **Libraries** tab.
   b. In the **Search Libraries** (-L) text box, click the **Add** button.
   c. Browse to the required simulation library that you previously compiled (for example, **stratixii, stratixiii**, or **cycloneiii**).
   d. Click **OK** to add the libraries to the **Search Libraries** (-L) text box.
7. Click **OK**.

Running the Simulation

To run a simulation, perform the following steps:

1. On the View menu, point to **Debug Windows** and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to **Debug Windows** and click **Wave**.
3. Drag signals to monitor from the Objects window and drop them into the Wave window.

4. On the Processing menu, point to **Run** and click **Run 100 ps** to run the simulation for 100 ps.

Perform Gate-Level Simulation

Gate-level simulation is a very important step in ensuring that the FPGA device's functionality is still correct and meets all required timing requirements after the design was placed and routed. You can create the gate-level netlist in the Quartus II software and use the netlist to perform gate-level simulation with the ModelSim software.

Before running gate-level simulation, generate gate-level timing simulation netlist files. Refer to the instructions in "Generate Gate-Level Timing Simulation Netlist Files" on page 2–14.

The following sections help you perform a gate-level simulation for a VHDL design in the ModelSim software.

Create Simulation Libraries

Simulation libraries are required to simulate a design that is mapped to post-synthesis primitives. Depending on the device family you are using, you must create the required simulation libraries and link them to your design correctly.

To change to the simulation output directory, perform the following steps:

1. In the ModelSim software, on the File menu, click **Change Directory**. The **Choose Folder** dialog box appears.
2. Browse to the directory where your testbench or ***.vho** file is located. By default, the ***.vho** file is located in <*project directory*>*/simulation/modelsim*>.
3. Click **OK**.

If you are not using the EDA Simulation Library Compiler, perform the following steps to compile simulation models into simulation libraries. (If you are using this utility, you can skip these steps.)

1. In the ModelSim software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.
3. In the **Library Name** box, type the library name of the newly created library.

For example, the library name for Stratix III family is **stratixiii**. To see all gate-level timing simulation library files, refer to "Gate-Level Simulation Libraries" on page 2–6.

4. Click **OK**.

Compile Simulation Models into Simulation Libraries

If you are not using the Altera Simulation Library Compiler, perform the following steps to compile simulation models into simulation libraries. (If you are using this utility, you can skip these steps.)

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library that you created (for example, **stratixiii**).

3. Browse to the <*Quartus II installation directory*>**/eda/sim_lib** and add the necessary simulation model files to your project. Select the simulation model files and click **Compile**.

The **stratixiii_components.vhd** and **stratixiii.vhd** model files should be compiled into the **stratixiii** library.

4. Repeat step 2 and step 3 to compile other simulation models.
5. Click **Done**.

Compile Testbench and Design Files into the Work Library

The following instructions show you how to compile your testbench and ***.vho** file into the work library using the ModelSim GUI.

To create the work library, perform the following steps:

1. In the ModelSim software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.
3. In the **Library Name** box, type the library name `Work` in the text box.
4. Click **OK**.

To compile the testbench file and ***.vho** file into the work library, perform the following steps:

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library **Work**. The testbench and ***.vho** file should be compiled into the **Work** library.
3. Select the testbench and ***.vho** design files and click **Compile**.
4. Click **Done**.

Loading the Design

To load a design, perform the following steps:

1. On the Simulate menu, click **Start Simulation**. The **Start Simulation** dialog box appears.
2. Click the **SDF** tab and click **Add**.
3. In the **Add SDF Entry** dialog box, click **Browse** and select the ***.sdo** file. By default, the ***.sdo** file is located in <*project directory*>**/simulation/modelsim**.
4. In the **Apply to Region** dialog box, type in the instance path to which the ***.sdo** file is to be applied. For example, if you are using a testbench exported into the Quartus II software from a Vector Waveform File, the instance path is set to `/i1`.

   You do not have to choose from the **Delay** list because the Quartus II EDA Netlist Writer generates the ***.sdo** file using the same value for the triplet (minimum, typical, and maximum timing values).

5. Click **OK**.

6. Click the **Design** tab. In the **Resolution** list, select **ps**.
7. In the **Library** list, select the **Work** library.
8. In the **Start Simulation** dialog box, expand the **Work** library.
9. Select the top-level design unit (your testbench).
10. In the **Resolution** list, select **ps**.
11. For VHDL designs, if you have not included the libraries' mapped name in your design files or sub-files, perform the following steps:
    a. Click the **Libraries** tab.
    b. In the **Search Libraries** (-L) text box, click the **Add** button.
    c. Browse to the required simulation library that you previously compiled (for example, **stratixii, stratixiii**, or **cycloneiii**).
    d. Click **OK** to add the libraries to the **Search Libraries** (-L) text box.
12. Click **OK**.

Running the Simulation

To run a simulation, perform the following steps:

1. On the View menu, point to **Debug Windows** and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to **Debug Windows** and click **Wave**.
3. Drag signals to monitor from the Objects window and drop them into the Wave window.
4. On the Processing menu, point to **Run** and click **Run 100 ps** to run the simulation for 100 ps.

Simulating the Verilog HDL Designs Using the GUI

Simulating Verilog HDL design using the ModelSim GUI is user-friendly. You do not have to remember the commands to compile the libraries or load and simulate the Verilog HDL design files. You can use the ModelSim GUI to perform RTL functional simulation, post-synthesis simulation, and gate-level timing simulation. The following sections show how to perform simulation at various levels through the ModelSim GUI.

Perform RTL Functional Simulation

RTL functional simulation is typically performed to verify the syntax of the code and to check the functionality of the design. The following sections show how to perform RTL functional simulation in ModelSim for Verilog HDL designs.

Use the following instructions to perform an RTL functional simulation for Verilog HDL designs in the ModelSim software.

Create Simulation Libraries

Simulation libraries are required to simulate a design that contains an Altera primitive, LPM function, or Altera megafunction. Depending on your design, you must create the required simulation libraries and link them to your design correctly.

If you are not using the Altera Simulation Library Compiler, perform the following steps to compile simulation models into simulation libraries. (If you are using this utility, you can skip these steps.)

1. In the ModelSim software, on the File menu, click **Change Directory**. The **Choose Folder** dialog box appears.
2. Browse to the directory where your designs are located.
3. Click **OK**.

To create the simulation library, perform the following steps:

1. In the ModelSim software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.
3. In the **Library Name** box, type the library name of the newly created library.

For example, the library name for Altera megafunctions is **altera_mf_ver**, and the library name for LPM is **lpm_ver**. To see all the functional simulation library files, refer to "RTL Functional Simulation Libraries" on page 2–6.

4. Click **OK**.

Compile Simulation Models into Simulation Libraries

If you are not using the EDA Simulation Library Compiler, perform the following steps to compile simulation models into simulation libraries. (If you are using this utility, you can skip these steps.)

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library that you created (for example, **altera_mf_ver** or **lpm_ver**).
3. Browse to the <*Quartus II installation directory*>**/eda/sim_lib** and add the necessary simulation model files to your project. Select the simulation model files and click **Compile**.

The **altera_mf.v** model files should be compiled into the **altera_mf_ver** library. The **220model.v** model files should be compiled into the **lpm_ver** library.

4. Repeat step 2 and step 3 to compile other simulation models.
5. Click **Done**.

Compile Testbench and Design Files into the Work Library

The following instructions show you how to compile your testbench and design files into the work library using the ModelSim GUI.

To change to the design directory, perform the following steps:

1. In the ModelSim software, on the File menu, click **Change Directory**. The **Choose Folder** dialog box appears.
2. Browse to the directory where your designs are located.
3. Click **OK**.

To compile the testbench and design files into the work library, perform the following steps:

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library **Work**. The design files and testbench file should be compiled into the **Work** library.
3. Select the design files and the testbench file and click **Compile**.
4. Click **Done**.

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, perform the following steps:

1. On the Simulate menu, click **Start Simulation**. The **Start Simulation** dialog box appears.
2. Click the **Design** tab. In the **Resolution** list, select **ps**.
3. In the **Library** list, select and expand the **Work** library.
4. Select the top-level design unit (your testbench).
5. In the **Resolution** list, select **ps**.
6. Click the **Libraries** tab.
7. In the **Search Libraries** (-L) text box, click the **Add** button to browse to the required simulation library that you previously compiled (for example, **altera_mf_ver**, **lpm_ver**, or **altera_ver**) and click **OK** to add them into the **Search Libraries** (-L) text box.
8. Click **OK**.

Running the Simulation

To run a simulation, perform the following steps:

1. On the View menu, point to **Debug Windows** and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to **Debug Windows** and click **Wave**.
3. Drag signals to monitor from the Objects window and drop them into the Wave window.
4. On the Processing menu, point to **Run** and click **Run 100 ps** to run the simulation for 100 ps.

Perform Post-Synthesis Simulation

Post-synthesis simulation can be performed to verify that functionality of the design is not lost after synthesis. You can create the post-synthesis netlist in the Quartus II software and use the netlist to perform post-synthesis simulation with the ModelSim software.

Before running post-synthesis simulation, generate post-synthesis simulation netlist files. Refer to the instructions in "Generate Post-Synthesis Simulation Netlist Files" on page 2–13.

The following sections help you perform a post-synthesis simulation for a Verilog HDL design in the ModelSim software.

Create Simulation Libraries

Simulation libraries are required to simulate a design that is mapped to post-synthesis primitives. Depending on the device family you are using, you must create the required simulation libraries and link them to your design correctly.

To change to the simulation output directory, perform the following steps:

1. In the ModelSim software, on the File menu, click **Change Directory**. The **Choose Folder** dialog box appears.
2. Browse to the directory where your testbench or ***.vo** file is located. By default, the ***.vo** file is located in <*project directory*>**/simulation/modelsim**.
3. Click **OK**.

To create the simulation library, perform the following steps:

1. In the ModelSim software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.
3. In the **Library Name** box, type the library name of the newly created library.

For example, the library name for Stratix III family is **stratixiii**. To see all the gate-level timing simulation library files, refer to "Gate-Level Simulation Library Files" on page 2–10.

4. Click **OK**.

Compile Simulation Models into Simulation Libraries

If you are not using the EDA Simulation Library Compiler, perform the following steps to compile simulation models into simulation libraries. (If you are using this utility, you can skip these steps.)

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library that you created (for example, **stratixiii_ver**).
3. Browse to the <*Quartus II installation directory*>**/eda/sim_lib** and add the necessary simulation model files to your project. Select the simulation model files and click **Compile**.

The **stratixiii_atoms.v** model files should be compiled into the **stratixiii_ver** library.

4. Repeat step 2 and step 3 to compile other simulation models, if needed.
5. Click **Done**.

Compile Testbench and Verilog Output File into the Work Library

The following instructions show you how to compile your testbench and ***.vo** into the work library using the ModelSim GUI.

To create the work library, perform the following steps:

1. In the ModelSim software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.
3. In the **Library Name** box, type the library name `Work` in the text box.
4. Click **OK**.

To compile the testbench file and ***.vo** file into the work library, perform the following steps:

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library **Work**. The testbench and ***.vo** file should be compiled into the **Work** library.
3. Select the testbench and ***.vo** design files, and click **Compile**.
4. Click **Done**.

Loading the Design

To load a design, perform the following steps:

1. On the Simulate menu, click **Start Simulation**. The **Start Simulation** dialog box appears.
2. Click the **Design** tab. In the **Resolution** list, select **ps**.
3. In the **Library** list, select the **Work** library.
4. In the **Start Simulation** dialog box, expand the **Work** library.
5. Select the top-level design unit (your testbench).
6. In the **Resolution** list, select **ps**.
7. Click the **Libraries** tab.
8. In the **Search Libraries** (-L) text box, click the **Add** button to browse to the required simulation library that you previously compiled (for example, **stratixiii_ver** or **stratixiiigx_ver**) and click **OK** to add them into the **Search Libraries** (-L) text box.
9. Click **OK**.

Running the Simulation

To run a simulation, perform the following steps:

1. On the View menu, point to **Debug Windows** and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to **Debug Windows** and click **Wave**.
3. Drag signals to monitor from the Objects window and drop them into the Wave window.
4. On the Processing menu, point to **Run** and click **Run 100 ps** to run the simulation for 100 ps.

Perform Gate-Level Simulation

Gate-level simulation is a very important step in ensuring that the FPGA device's functionality is still correct and meets all required timing requirements after the design was placed and routed. You can create the gate-level netlist in the Quartus II software and use the netlist to perform gate-level simulation with the ModelSim software.

Before running gate-level simulation, generate gate-level timing simulation netlist files. Refer to the instructions in "Generate Gate-Level Timing Simulation Netlist Files" on page 2–14.

The following sections help you perform a gate-level simulation for a Verilog HDL design in the ModelSim software.

Create Simulation Libraries

Simulation libraries are required to simulate a design that contains an Altera primitive, LPM function, or Altera megafunction. Depending on your design, you must create the required simulation libraries and link them to your design correctly.

To change to the design directory, perform the following steps:

1. In the ModelSim software, on the File menu, click **Change Directory**. The **Choose Folder** dialog box appears.
2. Browse to the directory where your designs are located.
3. Click **OK**.

To change to the simulation output directory, perform the following steps:

1. In the ModelSim software, on the File menu, click **Change Directory**. The **Choose Folder** dialog box appears.
2. Browse to the directory where your testbench or ***.vo** file is located. By default, the ***.vo** file is located in <*project directory*>**/simulation/modelsim**.
3. Click **OK**.

If you are not using the EDA Simulation Library Compiler, perform the following steps to create the simulation library. (If you are using the utility, you can skip these steps.)

1. In the ModelSim software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.

3. In the **Library Name** box, type the library name of the newly created library.

For example, the library name for Stratix III family is **stratixiii**. To see all the gate-level timing simulation library files, refer to "Gate-Level Simulation Library Files" on page 2–10.

4. Click **OK**.

Compile Simulation Models into Simulation Libraries

If you are not using the Altera Simulation Library Compiler, perform the following steps to compile simulation models into simulation libraries. (If you are using this utility, you can skip these steps.)

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library that you created (for example, **stratixiii_ver**).
3. Browse to the <*Quartus II installation directory*>**/eda/sim_lib** and add the necessary simulation model files to your project. Select the simulation model files and click **Compile**.

The **stratixiii_atoms.v** model files should be compiled into the **stratixiii_ver** library.

4. Repeat step 2 and step 3 to compile other simulation models, if needed.
5. Click **Done**.

Compile Testbench and Verilog Output File into the Work Library

The following instructions show you how to compile your testbench and ***.vo** file into the work library using the ModelSim GUI.

To create the work library, perform the following steps:

1. In the ModelSim software, on the File menu, point to **New** and click **Library**. The **Create a New Library** dialog box appears.
2. Select a new library and a logical mapping to it.
3. In the **Library Name** box, type the library name `Work` in the text box.
4. Click **OK**.

To compile the testbench file and Verilog HDL output file (***.vo**) into the work library, perform the following steps:

1. On the Compile menu, click **Compile**. The **Compile Source Files** dialog box appears.
2. Select the library **Work**. The testbench and ***.vo** file should be compiled into the **Work** library.
3. Select the testbench and ***.vo** design files and click **Compile**.
4. Click **Done**.

Resolve compile-time errors before proceeding to the next section.

Loading the Design

When simulating in Verilog HDL, the ***.sdo** file does not have to be manually specified. In the **$sdf_annotate** task, when the Quartus II software generates the ***.vo** file, the ModelSim-Altera software looks for the ***.sdo** file in the folder in which the VSIM was run. If your ***.sdo** file is not in the same directory in which you ran VSIM, copy the ***.sdo** file into your current directory.

To load a design, perform the following steps:

1. On the Simulate menu, click **Start Simulation**. The **Start Simulation** dialog box appears.
2. Click the **Design** tab. In the **Resolution** list, select **ps**.
3. In the **Library** list, select and expand the **Work** library.
4. Select the top-level design unit (your testbench).
5. In the **Resolution** list, select **ps**.
6. Click the **Libraries** tab.
7. In the **Search Libraries** (-L) text box, click the **Add** button to browse to the required simulation library that you previously compiled (for example, **stratixiii_ver** or **stratixiiigx_ver**) and click **OK** to add them into the **Search Libraries** (-L) text box.
8. Click **OK**.

Running the Simulation

To run a simulation, perform the following steps:

1. On the View menu, point to **Debug Windows** and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to **Debug Windows** and click **Wave**.
3. Drag signals to monitor from the Objects window and drop them into the Wave window.
4. On the Processing menu, point to **Run** and click **Run 100 ps** to run the simulation for 100 ps.

Simulating the VHDL Designs at the Command Line

Simulating VHDL design using the ModelSim command line gives you more flexibility and control to compile the libraries and load and simulate the VHDL design files. All simulation commands are Tcl commands which can be put into the ModelSim Macros file (***.do**). Using the ***.do** file allows you to run simulation in batch mode. You only have to execute the ***.do** file and the ModelSim tool automatically executes all the commands in the ***.do** script macro file.

You can use the ModelSim command line to perform RTL functional simulation, post-synthesis simulation, and gate-level simulation. The following sections show how to perform simulation at various levels through the ModelSim command line.

Perform RTL Functional Simulation

RTL functional simulation is typically performed to verify the syntax of the code and to check the functionality of the design. The following sections show how to perform RTL functional simulation in ModelSim for VHDL designs.

Create Simulation Libraries

Simulation libraries are required to simulate a design that contains an Altera primitive, LPM function, or Altera megafunction. Depending on your design, you must create the required simulation libraries and link them to your design correctly.

To change to the design library, type the following command:

```
cd <your_design_directory> ↵
```

(for example, **cd:/designs**)

To create the simulation libraries, type the following commands:

```
vlib <library_name> ↵
vmap <logical_library_name> <library_name> ↵
```

For example, the library name for Altera megafunction is **altera_mf**, and the library name for LPM is **lpm**. To see all the functional simulation library files, refer to "RTL Functional Simulation Library Files" on page 2–9.

To create simulation libraries for **altera_mf**, **lpm**, and **altera**, type the following commands:

```
vlib altera_mf ↵
vmap altera_mf altera_mf ↵
vlib lpm ↵
vmap lpm lpm ↵
vlib altera ↵
vmap altera altera ↵
```

Compile Simulation Models into Simulation Libraries

To compile simulation models into simulation libraries, type the following command:

```
vcom -work <simulation_library> <Quartus II installation directory> \
/eda/sim_lib/<simulation_library_files> ↵
```

For example, the **altera_mf_components.vhd** and **altera_mf.vhd** model files should be compiled into the **altera_mf** library. The **220pack.vhd** and **220model.vhd** model files should be compiled into the **lpm** library.

Use Example 2–1 to compile the simulation model files to the simulation libraries for **altera_mf, lpm,** and **altera**.

Example 2–1.

```
vcom -work altera_mf <Quartus II installation directory> \
/eda/sim_lib/altera_mf_components.v <Quartus II installation directory> \
/eda/sim_lib/altera_mf.vhd ↵

vcom -work lpm <Quartus II installation directory>/eda/sim_lib/220model.vhd \
<Quartus II installation dir>/eda/sim_lib/220model.vhd ↵

vcom -work altera <Quartus II installation directory> \
/eda/sim_lib/altera_primitives_components.vhd \
<Quartus II installation directory>/eda/sim_lib/altera_primitives.vhd ↵
```

If you are using the EDA Simulation Library Compiler, skip the steps for creating and compiling the simulation libraries.

Compile Testbench and Design Files into the Work Library

The following commands show how to compile your testbench and design files into the work library using the ModelSim software.

To create the work library, type the following commands:

```
vlib work ↵
vmap work work ↵
```

To compile the testbench and design files into the work library, type the following command:

```
vcom -work work <my_testbench.vhd> <my_design_files.vhd> ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, type the following command:

```
vsim -t ps -L <compiled-library1> -L <compiled-library2> work.<my_testbench> ↵
```

The *<compiled-library1>* and *<compiled-library2>* variables are the libraries you compiled previously (for example, **altera_mf** or **lpm**) that are required to compile your testbench. RTL libraries are usually required for performing RTL simulation. If you have multiple libraries, use the `-L` option for each library in the `vsim` command.

Running the Simulation

To run a simulation, type the following commands:

```
add wave <signal name> ↵
run <time period> ↵
```

To add all signals in your testbench hierarchy, type the following command:

```
add wave * ↵
```

To run the simulation for 100 ps, type the following command:

```
run 100 ps ↵
```

Perform Post-Synthesis Simulation

Post-synthesis simulation can be performed to verify that functionality of the design is not lost after synthesis. You can create the post-synthesis netlist in the Quartus II software and use the netlist to perform post-synthesis simulation with the ModelSim software.

Before running post-synthesis simulation, generate post-synthesis simulation netlist files. Refer to the instructions in "Generate Post-Synthesis Simulation Netlist Files" on page 2–13.

The following sections help you perform a post-synthesis simulation for a VHDL design in the ModelSim software.

Create Simulation Libraries

Simulation libraries are required to simulate a design that is mapped to post-synthesis primitives. Depending on the device family you are using, you must create the required simulation libraries and link them to your design correctly.

To change to the simulation output directory, type the following command:

```
cd <simulation_output_directory> ↵
```

(for example, **cd:/designs/modelsim/simulation**)

To create the simulation libraries, type the following commands:

```
vlib <library_name> ↵
vmap <logical_library_name> <library_name> ↵
```

For example, the library name for the Stratix III family is **stratixiii**. To see all the gate-level timing simulation library files, refer to "Gate-Level Simulation Libraries" on page 2–6.

To create simulation libraries for **stratixiii**, type the following commands:

```
vlib stratixiii ↵
vmap stratixiii stratixiii ↵
```

Compile Simulation Models into Simulation Libraries

To compile simulation models into simulation libraries, type the following command:

```
vcom -work <simulation_library> <Quartus II installation directory> \
/eda/sim_lib/<simulation_library_files> ↵
```

For example, the **stratixiii_atoms_components.vhd** and **stratixiii_atoms.vhd** model files should be compiled into the **stratixiii** library.

Use Example 2–2 to compile the simulation model files to the simulation libraries for **stratixiii**:

Example 2–2.

```
vcom -work stratixiii <Quartus II installation directory> \
/eda/sim_lib/stratixiii_atoms_components.vhd <Quartus II installation directory> \
/eda/sim_lib/stratixiii_atoms.vhd ↵
```

If you are using the EDA Simulation Library Compiler, skip the steps for creating and compiling the simulation libraries.

Compile Testbench and VHDL Output Files into the Work Library

The following commands show how to compile your testbench and ***.vho** file into the work library using the ModelSim software.

To create the work library, type the following commands:

```
vlib work ↵
vmap work work ↵
```

To compile the testbench and ***.vho** file into the work library, type the following command:

```
vcom -work work <my_testbench.vhd> <my_design_files.vho> ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, type the following command:

```
vsim -t ps -L <compiled-library1> -L <compiled-library2> work.<my_testbench> ↵
```

The <*compiled-library1*> and <*compiled-library2*> variables are the libraries you compiled previously (for example, **stratixiii** or **cycloneiii**) that are required to compile your testbench. Gate-level libraries are usually required for performing post-synthesis simulation. If you have multiple libraries, use the `-L` option for each library in the `vsim` command.

Running the Simulation

To run a simulation, type the following commands:

```
add wave <signal name> ↵
run <time period> ↵
```

To add all signals in your testbench hierarchy, type the following command:

```
add wave * ↵
```

To run the simulation for 100 ps, type the following command:

```
run 100 ps ↵
```

Perform Gate-Level Simulation

Gate-level simulation is a very important step in ensuring that the FPGA device's functionality is still correct and meets all required timing requirements after the design was placed and routed. You can create the gate-level netlist in the Quartus II software and use the netlist to perform gate-level simulation with the ModelSim software.

Before running gate-level simulation, generate gate-level timing simulation netlist files. Refer to the instructions in "Generate Gate-Level Timing Simulation Netlist Files" on page 2–14.

The following sections help you perform a gate-level simulation for a VHDL design in the ModelSim software.

Create Simulation Libraries

Simulation libraries are required to simulate a design that is mapped to post-synthesis primitives. Depending on the device family that you are using, you must create the required simulation libraries and link them to your design correctly.

To change to the simulation output directory, type the following command:

```
cd <simulation_output_directory> ↵
```

(for example, **cd:/designs/modelsim/simulation**)

To create the simulation libraries, type the following commands:

```
vlib <library_name> ↵
vmap <logical_library_name> <library_name> ↵
```

For example, the library name for the Stratix III family is **stratixiii**. To see all the gate-level timing simulation library files, refer to "Gate-Level Simulation Libraries" on page 2–6.

To create simulation libraries for **stratixiii**, type the following commands:

```
vlib stratixiii ↵
vmap stratixiii stratixiii ↵
```

Compile Simulation Models into Simulation Libraries

To compile simulation models into simulation libraries, type the following command:

```
vcom -work <simulation_library> <Quartus II installation directory> \
/eda/sim_lib/<simulation_library_files> ↵
```

For example, the **stratixiii_atoms_components.vhd** and **stratixiii_atoms.vhd** model files should be compiled into the **stratixiii** library.

Use Example 2–3 to compile the simulation model files to the simulation libraries for **stratixiii**.

Example 2–3.

```
vcom -work stratixiii <Quartus II installation directory> \
/eda/sim_lib/stratixiii_atoms_components.vhd <Quartus II installation directory> \
/eda/sim_lib/stratixiii_atoms.vhd ↵
```

Be sure that the user-compiled libraries are stored using the same path as the design and testbench files you want to compile.

Compile Testbench and VHDL Output Files into the Work Library

The following commands show how to compile your testbench and ***.vho** file into the work library using the ModelSim GUI.

To create the work library, type the following commands:

```
vlib work ↵
vmap work work ↵
```

To compile the testbench and ***.vho** file into the work library, type the following command:

```
vcom -work work <my_testbench.vht> <my_design_files.vho>  ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, type the following command:

```
vsim -t ps -sdftyp <design instance> = <path to *.sdo file> -L <compiled-library1> \
-L <compiled-library2> work.<my_testbench> ↵
```

The *<compiled-library1>* and *<compiled-library2>* variables are the libraries you compiled previously (for example, **stratixiii** or **cycloneiii**) that are required to compile your testbench. Gate-level libraries are usually required for performing gate-level simulation. If you have multiple libraries, use the `-L` option for each library in the `vsim` command.

You do not have to set the value (minimum, average, maximum) for the ***.sdo** file because the Quartus II EDA Netlist Writer generates the ***.sdo** file using the same value for the triplet (minimum, average, and maximum timing values).

If your design under test is instantiated in the testbench file under the `i1` label, the *<design instance>* should be "`i1`" (for example, `/i1=`*<my design>***.sdo**).

Running the Simulation

To run a simulation, type the following commands:

```
add wave <signal name> ↵
run <time period> ↵
```

To add all signals in your testbench hierarchy, type the following command:

```
add wave * ↵
```

To run the simulation for 100 ps, type the following command:

```
run 100 ps ↵
```

Simulating the Verilog HDL Designs at the Command Line

Simulating Verilog HDL design using the ModelSim command line gives you more flexibility and control to compile the libraries, and load and simulate the Verilog HDL design files. All simulation commands are Tcl commands which can be put into the ***.do** file. Using the ***.do** file allows you to run simulation in batch mode. You only have to execute the ***.do** file and the ModelSim tool automatically executes all the commands in the ***.do** script macro file.

You can use the ModelSim command line to perform RTL functional simulation, post-synthesis simulation, and gate-level simulation. The following sections show how to perform simulation at various levels through the ModelSim command line.

Perform RTL Functional Simulation

RTL functional simulation is typically performed to verify the syntax of the code and to check the functionality of the design. The following sections show how to perform RTL functional simulation in ModelSim for Verilog HDL designs.

Create Simulation Libraries

Simulation libraries are required to simulate a design that contains an Altera primitive, LPM function, or Altera megafunction. Depending on your design, you must create the required simulation libraries and link them to your design correctly.

To change to the design library, type the following command:

```
cd <your_design_directory> ↵
```

(for example, **cd:/designs**)

To create the simulation libraries, type the following commands:

```
vlib <library_name> ↵
vmap <logical_library_name> <library_name> ↵
```

For example, the library name for Altera megafunction is **altera_mf_ver**, and the library name for LPM is **lpm_ver**. To see all the functional simulation library files, refer to "RTL Functional Simulation Library Files" on page 2–9.

To create simulation libraries for **altera_mf**, **lpm_ver**, and **altera_ver**, type the following commands:

```
vlib altera_mf_ver ↵
vmap altera_mf altera_mf_ver ↵
vlib lpm_ver ↵
vmap lpm lpm_ver ↵
vlib altera_ver ↵
vmap altera altera_ver ↵
```

Compile Simulation Models into Simulation Libraries

To compile simulation models into simulation libraries, type the following command:

```
vlog -work <simulation_library> <Quartus II installation directory>\
/eda/sim_lib/<simulation_library_files> ↵
```

For example, the **altera_mf.v** model files should be compiled into the **altera_mf_ver** library. The **220model.v** model files should be compiled into the **lpm_ver** library.

To compile the simulation model files to the simulation libraries for **altera_mf_ver**, **lpm_ver**, and **altera_ver**, type the following commands:

```
vlog -work altera_mf_ver \
<Quartus II installation directory>/eda/sim_lib/altera_mf.v ↵

vlog -work lpm_ver \
<Quartus II installation directory>/eda/sim_lib/220model.v ↵

vlog -work altera_ver \
<Quartus II installation directory>/eda/sim_lib/altera_primitives.v ↵
```

Compile Testbench and Design Files into the Work Library

The following commands show how to compile your testbench and design files into the work library in the ModelSim command prompt.

To create the work library, type the following commands:

```
vlib work ↵
vmap work work ↵
```

To compile the testbench and design files into the work library, type the following command:

```
vlog -work work <my_testbench.v> <my_design_files.v>  ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, type the following command:

```
vsim -t ps -L <library1> -L <library2> work.<my_testbench> ↵
```

The <*library1*> and <*library2*> variables are the required libraries to compile your testbench. If you have multiple libraries, use the `-L` option multiple times in the `vsim` command.

Running the Simulation

To run a simulation, type the following commands:

```
add wave <signal name> ↵
run <time period> ↵
```

To add all signals in your testbench hierarchy, type the following command:

```
add wave * ↵
```

To run the simulation for 100 ps, type the following the command:

```
run 100 ps ↵
```

Perform Post-Synthesis Simulation

Post-synthesis simulation can be done to verify that functionality of the design is not lost after synthesis. You can create the post-synthesis netlist in the Quartus II software and use the netlist to perform post-synthesis simulation with the ModelSim software.

Before running post-synthesis simulation, generate post-synthesis simulation netlist files. Refer to the instructions in "Generate Post-Synthesis Simulation Netlist Files" on page 2–13.

The following sections help you perform a post-synthesis simulation for a Verilog HDL design in the ModelSim software.

Create Simulation Libraries

Simulation libraries are required to simulate a design that is mapped to post-synthesis primitives. Depending on the device family you are using, you must create the required simulation libraries and link them to your design correctly.

To change to the simulation output directory, type the following command:

```
cd <simulation_output_directory> ↵
```

(for example, **cd:/designs/modelsim/simulation**)

© March 2009 Altera Corporation

To create the simulation libraries, type the following commands:

```
vlib <library_name> ↵
vmap <logical_library_name> <library_name> ↵
```

For example, the library name for the Stratix III family is **stratixiii_ver**. To see all the gate-level timing simulation library files, refer to "Gate-Level Simulation Libraries" on page 2–6.

To create simulation libraries for **stratixiii_ver**, type the following commands:

```
vlib stratixiii_ver ↵
vmap stratixiii_ver stratixiii_ver ↵
```

If you are using the EDA Simulation Library Compiler, skip the steps for creating and compiling the simulation libraries.

Compile Simulation Models into Simulation Libraries

To compile simulation models into simulation libraries, type the following command:

```
vlog -work <simulation_library> <Quartus II installation dir> \
/eda/sim_lib/<simulation_library_files> ↵
```

For example, the **stratixiii_atoms.v** model files should be compiled into the **stratixiii_ver** library.

To compile the simulation model files to the simulation libraries for **stratixiii_ver**, type the following command:

```
vlog -work stratixiii_ver <Quartus II installation directory> \
/eda/sim_lib/stratixiii_atoms.v ↵
```

If you are using the Altera Simulation Library Compiler, skip the steps for creating and compiling the simulation libraries.

Compile Testbench and Verilog Output Files into the Work Library

The following commands show how to compile your testbench and ***.vo** file into the work library using the ModelSim software.

To create the work library, type the following commands:

```
vlib work ↵
vmap work work ↵
```

To compile the testbench and ***.vo** file into the work library, type the following command:

```
vlog -work work <my_testbench.vt> <my_design_netlists.vo> ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, type the following command:

```
vsim -t ps -L <library1> -L <library2> work.<my_testbench> ↵
```

The <*library1*> and <*library2*> variables are the libraries you compiled previously (for example, **stratixiii** or **stratixiigx**) that are required to compile your testbench. Gate-level libraries are usually required for performing post-synthesis simulation. If you have multiple libraries, use the `-L` option multiple times in the `vsim` command.

Running the Simulation

To run a simulation, type the following commands:

```
add wave <signal name> ↵
run <time period> ↵
```

To add all signals in your testbench hierarchy, type the following command:

```
add wave * ↵
```

To run the simulation for 100 ps, type the following the command:

```
run 100 ps ↵
```

Perform Gate-Level Simulation

Gate-level simulation is a very important step in ensuring that the FPGA device's functionality is still correct and meets all required timing requirements after the design was placed and routed. You can create the gate-level netlist in the Quartus II software and use the netlist to perform gate-level simulation with the ModelSim software.

Before running gate-level simulation, generate gate-level timing simulation netlist files. Refer to the instructions in "Generate Gate-Level Timing Simulation Netlist Files" on page 2–14.

The following sections help you perform a gate-level simulation for a Verilog HDL design in the ModelSim software.

Create Simulation Libraries

Simulation libraries are required to simulate a design that is mapped to post-synthesis primitives. Depending on the device family that you are using, you must create the required simulation libraries and link them to your design correctly.

To change to the simulation output directory, type the following command:

```
cd <simulation_output_directory> ↵
```

(for example, **cd:/designs/modelsim/simulation**)

This directory contains the ***.vo** file, which is generated by the netlist writer.

To create the simulation libraries, type the following commands:

```
vlib <library_name> ↵
vmap <logical_library_name> <library_name> ↵
```

For example, the library name for the Stratix III family is **stratixiii_ver**. To see all the gate-level timing simulation library files, refer to "Gate-Level Simulation Libraries" on page 2–6.

To create simulation libraries for **stratixiii_ver**, type the following commands:

```
vlib stratixiii_ver ↵
vmap stratixiii_ver stratixiii_ver ↵
```

© March 2009 Altera Corporation

Compile Simulation Models into Simulation Libraries

To compile simulation models into simulation libraries, type the following command:

```
vlog -work <simulation_library> <Quartus II installation directory> \
/eda/sim_lib/<simulation_library_files> ↵
```

For example, the **stratixiii_atoms.v** model files should be compiled into the **stratixiii_ver** library.

Use the following example to compile the simulation model files to the simulation libraries for **stratixiii_ver**:

```
vlog -work stratixiii <Quartus II installation directory> \
/eda/sim_lib/stratixiii_atoms.v ↵
```

If you are using the EDA Simulation Library Compiler, skip the steps for creating and compiling the simulation libraries.

Compile Testbench and Verilog Output Files into the Work Library

The following commands show how to compile your testbench and ***.vo** file into the work library using the ModelSim command line.

To create the work library, type the following commands:

```
vlib work ↵
vmap work work ↵
```

To compile the testbench and ***.vo** files into the work library, type the following command:

```
vlog -work work <my_testbench.v> <my_design_netlists.vo>  ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

When simulating in Verilog HDL, the ***.sdo** file does not have to be manually specified. In the **$sdf_annotate** task, when the Quartus II software generates the ***.vo** file, the ModelSim-Altera software looks for the ***.sdo** file in the folder in which the VSIM was run. If your ***.sdo** file is not in the same directory in which you ran VSIM, copy the ***.sdo** file into your current directory.

To load a design, type the following command:

```
vsim -t ps -L <library1> -L <library2> work.<my_testbench> ↵
```

The *<library1>* and *<library2>* variables are the libraries you compiled previously (for example, **stratixiii_ver** or **stratixiigx_ver**) that are required to compile your testbench. Gate-level libraries are usually required for performing gate-level timing simulation. If you have multiple libraries, use the `-L` option multiple times in the `vsim` command.

Running the Simulation

Perform the following commands to run a simulation:

```
add wave <signal name> ↵
run <time period> ↵
```

To add all signals in your testbench hierarchy, type the following command:

```
add wave * ↵
```

To run the simulation for 100 ps, type the following the command:

```
run 100 ps ↵
```

Simulating Designs that Include Transceivers

If your design includes a Stratix GX, Stratix II GX, Stratix IV, Arria II GX, or Arria GX transceiver, you must compile additional library files to perform RTL functional or gate-level timing simulations. The following example shows how to perform simulation on designs that include transceivers in Stratix GX and Stratix II GX devices.

Performing simulation with transceivers in Arria GX and Stratix II GX are very similar. You only have to replace **stratixiigx_atoms** and **stratixiigx_hssi_atoms** model files with **arriagx_atoms** and **arriagx_hssi_atoms** model files.

For high-speed simulation, you must select **ps** in the **Resolution** list for your simulator resolutions. If you choose slower than **ps**, the high-speed simulation may fail.

Stratix GX RTL Functional Simulation

To perform an RTL functional simulation of your design that instantiates the ALTGXB megafunction, which enables the gigabit transceiver block on Stratix GX devices, compile the **stratixgx_mf** model file into the **altgxb** library.

The **stratixiigx_mf** model file references the **lpm** and **sgate** libraries. If you are using ModelSim PE/SE, you must create these libraries to perform a simulation.

Perform RTL Functional Simulation for Stratix GX in VHDL

If you are using the ModelSim-Altera software, compiling the libraries is not necessary. You can simulate the design directly by typing the commands in Example 2–4.

Example 2–4.

```
vcom -work <my design>.vhd <my testbench>.vhd ↵
vsim -L lpm -L altera_mf -L sgate -L altgxb work.<my testbench> ↵
```

If you are using ModelSim SE/PE, you must compile the necessary libraries before you can simulate the designs. To compile and simulate the design, type the commands in Example 2–5 at the ModelSim command prompt.

Example 2–5.

```
vcom -work altera_mf altera_mf_components.vhd altera_mf.vhd ↵
vcom -work lpm 220pack.vhd 220model.vhd ↵
vcom -work sgate sgate_pack.vhd sgate.vhd ↵
vcom -work altgxb stratixgx_mf.vhd stratixgx_mf_components.vhd ↵
vcom -work <my design>.vhd <my testbench>.vhd ↵
vsim -L lpm -L altera_mf -L sgate -L altgxb work.<my testbench> ↵
```

Perform RTL Functional Simulation for Stratix GX in Verilog HDL

If you are using the ModelSim-Altera software, compiling the libraries is not necessary. You can simulate the design directly by typing the commands in Example 2–6.

Example 2–6.

```
vlog -work <my design>.v <my testbench>.v ↵
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L altgxb work.<my testbench> ↵
```

If you are using ModelSim SE/PE, you must compile the necessary libraries before you can simulate the designs. To compile and simulate the design, type the commands in Example 2–7 at the ModelSim command prompt.

Example 2–7.

```
vlib work_ver ↵
vlib lpm_ver ↵
vlib altera_mf_ver ↵
vlib sgate_ver ↵
vlib altgxb_ver ↵
vlog -work lpm_ver 220model.v ↵
vlog -work altera_mf_ver altera_mf.v ↵
vlog -work sgate_ver sgate.v ↵
vlog -work altgxb_ver stratixgx_mf.v ↵
vlog -work <my design>.v <my testbench>.v ↵
vsim -L lpm_ver -L sgate_ver-L altgxb_ver work.<my testbench> ↵
```

Stratix GX Gate-Level Timing Simulation

Perform a gate-level timing simulation of your design that includes a Stratix GX transceiver by compiling the **stratixgx_atoms** and **stratixgx_hssi_atoms** model files into the **stratixgx** and **stratixgx_gxb** libraries, respectively.

The **stratixgx_hssi_atoms** model file references the **lpm** and **sgate** libraries. If you are using ModelSim PE/SE, you must create these libraries to perform a simulation.

Perform Gate-Level Timing Simulation for Stratix GX in VHDL

If you are using the ModelSim-Altera software, compiling the libraries is not necessary. You can simulate the design directly by typing the commands in Example 2–8.

Example 2–8.

```
vcom -work <my design>.vho <my testbench>.vhd ↵
vsim -L lpm -L altera_mf -L sgate -L stratixgx -L stratixgx_gxb \
-sdftyp <design instance>=<path to .sdo file>.sdo work.<my testbench> \
-t ps - +transport_int_delays+transport_path_delays ↵
```

If you are using ModelSim SE/PE, you must compile the necessary libraries before you can simulate the designs. To compile and simulate the design, type the commands in Example 2–9 at the ModelSim command prompt.

Example 2–9.

```
vcom -work lpm 220pack.vhd 220model.vhd ↵
vcom -work altera_mf altera_mf_components.vhd altera_mf.vhd ↵
vcom -work sgate sgate_pack.vhd sgate.vhd ↵
vcom -work stratixgx stratixgx_atoms.vhd stratixgx_components.vhd ↵
vcom -work stratixgx_gxb stratixgx_hssi_atoms.vhd \
stratixgx_hssi_components.vhd ↵
vcom -work <my design>.vho <my testbench>.vhd ↵
vsim -L lpm -L altera_mf -L sgate -L stratixgx -L stratixgx_gxb \
-sdftyp <design instance>=<path to .sdo file>.sdo work.<my testbench> \
-t ps +transport_int_delays +transport_path_delays ↵
```

Perform Gate-Level Timing Simulation for Stratix GX in Verilog HDL

If you are using the ModelSim-Altera software, compiling the libraries is not necessary. You can simulate the design directly by typing the command in Example 2–10.

Example 2–10.

```
vlog -work <my design>.vo <my testbench>.v ↵
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L stratixgx_ver -L \
stratixgx_gxb_ver work.<my testbench> -t ps +transport_int_delays \
+transport_path_delays ↵
```

If you are using ModelSim SE/PE, you must compile the necessary libraries before you can simulate the designs. To compile and simulate the design, type the commands in Example 2–11 at the ModelSim command prompt.

Example 2–11.

```
vlog -work lpm_ver 220model.v ↵
vlog -work altera_mf_ver altera_mf.v ↵
vlog -work sgate_ver sgate.v ↵
vlog -work stratixgx_ver stratixgx_atoms.v ↵
vlog -work stratixgx_gxb_ver stratixgx_hssi_atoms.v ↵
vlog -work <my design>.vo <my testbench>.v ↵
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L stratixgx_ver \
-L stratixgx_gxb_ver work.<my testbench> -t ps +transport_int_delays \
+transport_path_delays ↵
```

Stratix II GX RTL Functional Simulation

Stratix II GX function simulation is similar to Arria GX functional simulation. The following example shows only the functional simulation for designs that include transceivers in Stratix II GX devices. To simulate transceivers in Arria GX devices, you only have to replace the **stratixiigx_hssi** model file with the **arriagx_hssi** model file.

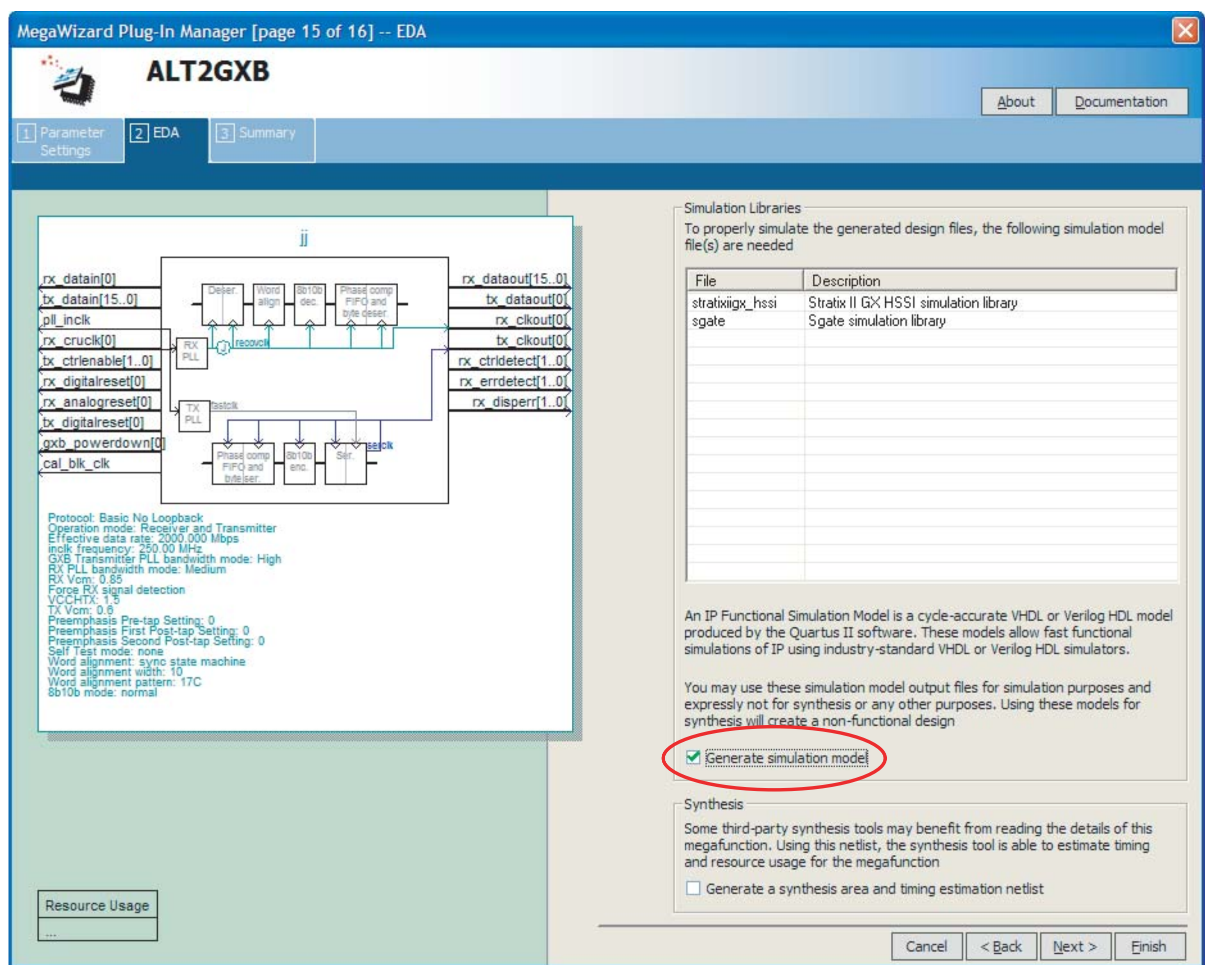
To perform a functional simulation of your design that instantiates the ALT2GXB megafunction, which enables the gigabit transceiver block on Stratix II GX devices, compile the **stratixiigx_hssi** model file into the **stratixiigx_hssi** library.

The **stratixiigx_hssi_atoms** model file references the **lpm** and **sgate** libraries. If you are using ModelSim PE/SE, you must create these libraries to perform a simulation.

Generate a functional simulation netlist by turning on **Generate Simulation Model** in the **Simulation Library** tab of the ALT2GXB MegaWizard Plug-In Manager (Figure 2–2). The <*alt2gxb entity name*>**.vho** or <*alt2gxb module name*>**.vo** is generated in the current project directory.

The Quartus II-generated ALT2GXB functional simulation library file references `stratixiigx_hssi` wysiwyg atoms.

Figure 2–2. ALT2GXB MegaWizard Plug-In Manager, Generate Simulation Model



Perform RTL Functional Simulation for Stratix II GX in VHDL

If you are using the ModelSim-Altera software, compiling the libraries is not necessary. You can simulate the design directly by typing the commands in Example 2–12.

Example 2–12.

```
vcom -work work <alt2gxb entity name>.vho ↵
vcom -work <my design>.vhd <my testbench>.vhd ↵
vsim -L lpm -L altera_mf -L sgate -L stratixgx_hssi work.<my design> ↵
```

If you are using ModelSim SE/PE, you must compile the necessary libraries before you can simulate the designs. To compile and simulate the design, type the commands in Example 2–13 at the ModelSim command prompt.

Example 2–13.

```
vcom -work lpm 220pack.vhd 220model.vhd ↵
vcom -work altera_mf altera_mf_components.vhd altera_mf.vhd ↵
vcom -work sgate sgate_pack.vhd sgate.vhd ↵
vcom -work stratixiigx_hssi stratixiigx_hssi_components.vhd \
stratixiigx_hssi_atoms.vhd ↵
vcom -work work <alt2gxb entity name>.vho ↵
vcom -work <my design>.vhd <my testbench>.vhd ↵
vsim -L lpm -L altera_mf -L sgate -L stratixgx_hssi work.<my testbench> ↵
```

Perform RTL Functional Simulation for Stratix II GX in Verilog HDL

If you are using the ModelSim-Altera software, compiling the libraries is not necessary. You can simulate the design directly by typing the commands in Example 2–14.

Example 2–14.

```
vlog -work work <alt2gxb module name>.vo ↵
vlog -work <my design>.v <my testbench>.v ↵
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L stratixgx_hssi_ver \
work.<my testbench> ↵
```

If you are using ModelSim SE/PE, you must compile the necessary libraries before you can simulate the designs. To compile and simulate the design, type the commands in Example 2–15 at the ModelSim command prompt.

Example 2–15.

```
vlog -work lpm_ver 220model.v ↵
vlog -work altera_mf_ver altera_mf.v ↵
vlog -work sgate_ver sgate.v ↵
vlog -work stratixiigx_hssi_ver stratixiigx_hssi_atoms.v ↵
vlog -work work <alt2gxb module name>.vo ↵
vlog -work <my design>.v <my testbench>.v ↵
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L stratixgx_hssi_ver \
work.<my testbench> ↵
```

Stratix II GX Gate-Level Timing Simulation

Stratix II GX gate-level timing simulation is similar to Arria GX gate-level timing simulation. The following example shows only the gate-level timing simulation for designs that include transceivers in Stratix II GX devices. To simulate transceivers in Arria GX devices, you only have to replace the **stratixiigx_hssi** model file with the **arriagx_hssi** model file.

To perform a gate-level timing simulation of your design that includes a Stratix II GX transceiver, compile **stratixiigx_atoms** and **stratixiigx_hssi_atoms** into the **stratixiigx** and **stratixiigx_hssi** libraries, respectively.

The **stratixiigx_hssi_atoms** model file references the **lpm** and **sgate** libraries. If you are using ModelSim PE/SE, you must create these libraries to perform a simulation.

Perform Gate-Level Timing Simulation for Stratix II GX in VHDL

If you are using the ModelSim-Altera software, compiling the libraries is not necessary. You can simulate the design directly by typing the commands in Example 2–16.

Example 2–16.

```
vcom -work <my design>.vho <my testbench>.vhd ↵
vsim -L lpm -L altera_mf -L sgate -L stratixiigx -L stratixiigx_hssi \
-sdftyp <design instance>=<path to .sdo file>.sdo work.<my testbench> \
-t ps +transport_int_delays +transport_path_delays ↵
```

If you are using ModelSim SE/PE, you must compile the necessary libraries before you can simulate the designs. To compile and simulate the design, type the commands in Example 2–17 at the ModelSim command prompt.

Example 2–17.

```
vcom -work lpm 220pack.vhd 220model.vhd ↵
vcom -work altera_mf altera_mf_components.vhd altera_mf.vhd ↵
vcom -work sgate sgate_pack.vhd sgate.vhd ↵
vcom -work stratixiigx stratixiigx_atoms.vhd \
stratixiigx_components.vhd ↵
vcom -work stratixiigx_hssi stratixiigx_hssi_components.vhd \
stratixiigx_hssi_atoms.vhd ↵
vcom -work <my design>.vho <my testbench>.vhd ↵
vsim -L lpm -L altera_mf -L sgate -L stratixiigx -L stratixiigx_hssi \
-sdftyp <design instance>=<path to .sdo file>.sdo work.<my testbench> \
-t ps +transport_int_delays +transport_path_delays ↵
```

Perform Gate-Level Timing Simulation for Stratix II GX in Verilog HDL

If you are using the ModelSim-Altera software, compiling the libraries is not necessary. You can simulate the design directly by typing the commands in Example 2–18.

Example 2–18.

```
vlog -work <my design>.vo <my testbench>.v ↵
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L stratixiigx_ver \
-L stratixiigx_hssi_ver work.<my testbench> -t ps \
+transport_int_delays +transport_path_delays ↵
```

If you are using ModelSim SE/PE, you must compile the necessary libraries before you can simulate the designs. To compile and simulate the design, type the commands in Example 2–19 at the ModelSim command prompt.

Example 2–19.

```
vlog -work lpm_ver 220model.v ↵
vlog -work altera_mf_ver altera_mf.v ↵
vlog -work sgate_ver sgate.v ↵
vlog -work stratixiigx_ver stratixiigx_atoms.v ↵
vlog -work stratixiigx_hssi_ver stratixiigx_hssi_atoms.v ↵
vlog -work <my design>.vo <my testbench>.v ↵
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L stratixiigx_ver \
-L stratixiigx_hssi_ver work.<my testbench> -t ps \
+transport_int_delays +transport_path_delays ↵
```

Transport Delays

By default, the ModelSim software filters out all pulses that are shorter than the propagation delay between primitives. Turning on the transport delay options in the ModelSim software prevents the simulation tool from filtering out these pulses. Use the following options to ensure that all signal pulses are seen in the simulation results.

+transport_path_delays

Use this option when the pulses in your simulation are shorter than the delay within a gate-level primitive.

+transport_int_delays

Use this option when the pulses in your simulation are shorter than the interconnect delay between gate-level primitives.

The **+transport_path_delays** and **+transport_int_delays** options are also used by default in the NativeLink feature for gate-level timing simulation.

For more information about either of these options, refer to the ModelSim-Altera Command Reference installed with the ModelSim software.

The following ModelSim software command shows the command line syntax to perform a gate-level timing simulation with the device family library:

```
vsim -t 1ps -L stratixii -sdftyp /i1=filtref_vhd.sdo work.filtref_vhd_vec_tst \
+transport_int_delays +transport_path_delays
```

Using the NativeLink Feature with ModelSim-Altera or ModelSim Software

The NativeLink feature in the Quartus II software facilitates the seamless transfer of information between the Quartus II software and EDA tools and allows you to run ModelSim within the Quartus II software.

Setting Up NativeLink

To run ModelSim automatically from the Quartus II software using the NativeLink feature, you must specify the path to your simulation tool by performing the following steps:

1. On the Tools menu, click **Options**. The **Options** dialog box appears.
2. In the **Category** list, select **EDA Tool Options**.
3. Double-click the entry under **Location of executable** beside the name of your EDA Tool.
4. Type or browse to the directory containing the executables of your EDA tool.

For ModelSim-Altera software and ModelSim SE/PE, executable files are stored in the **win32aloem** and **win32** directories, respectively.

c:\\<*ModelSim-Altera installation path***>\\win32aloem**

c:\\<*ModelSim installation path***>\\win32**

5. Click **OK**.

You can also specify the path to the simulator's executables by using the `set_user_option` Tcl command:

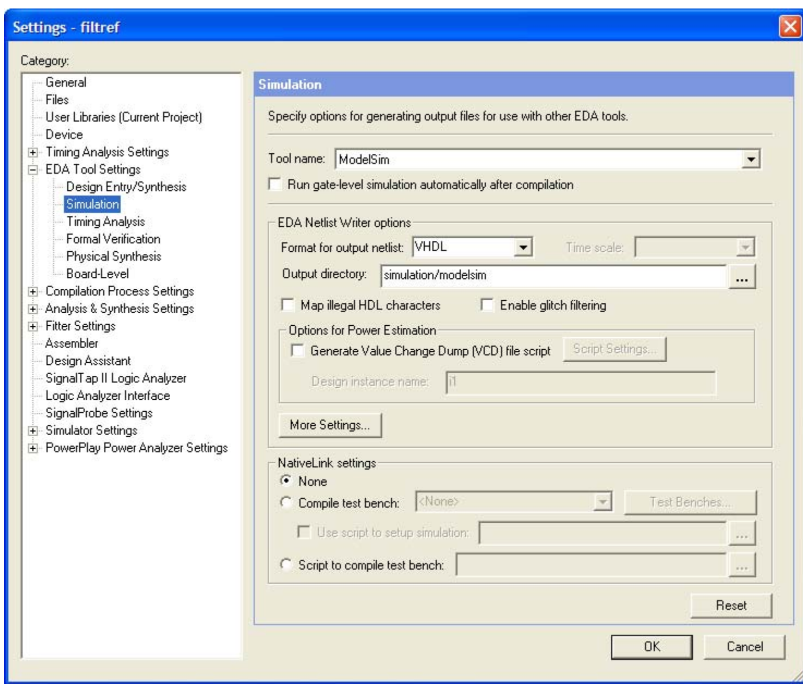
```
set_user_option -name EDA_TOOL_PATH_MODELSIM <path to executables> ↵
set_user_option -name EDA_TOOL_PATH_MODELSIM_ALTERA <path to executables> ↵
```

Perform an RTL Simulation Using NativeLink

To run an RTL functional simulation with the ModelSim software in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears (Figure 2–3).

Figure 2–3. Simulation Page in the Settings Dialog Box



3. In the **Tool name** list, select one of the following options:
   - **ModelSim**
   - **ModelSim-Altera**

4. If your design is written entirely in Verilog HDL or VHDL, the NativeLink feature automatically chooses the correct language and Altera simulation libraries. If your design is written with mixed languages, the NativeLink feature uses the default language specified in the **Format for output netlist** list. To change the default language when there is a mixed language design, under **EDA Netlist Writer options**, in the **Format for output netlist** list, select **VHDL** or **Verilog**. Table 2–12 shows the design languages for output netlists and simulation models.

Table 2–12. NativeLink Design Languages

Design File	Format for Output Netlist	Simulation Models Used
Verilog HDL	Any	Verilog HDL
VHDL	Any	VHDL
Mixed	Verilog HDL	Verilog HDL
Mixed	VHDL	VHDL

For mixed language simulation, choose the same language that was used to generate your megafunctions to ensure correct parameter passing between the megafunctions and the Altera libraries. For example, if your ALTSYNCRAM megafunction was generated in VHDL, choose **VHDL** as the format for the output netlist.

When creating mixed language designs, it is important to be aware of the following:

- EDA simulation tools do not allow seamless passing of parameters when a VHDL entity is instantiated in Verilog HDL designs.
- The ModelSim and ModelSim-Altera software does not allow the use of Verilog User Defined Primitives (UDPs) to be instantiated in VHDL designs.

5. If you have testbench files or macro scripts, enter the information under **NativeLink settings**.

   For more information about setting up a testbench file with NativeLink, refer to "Setting Up a Testbench" on page 2–75.

6. If you have compiled libraries using the EDA Simulation Library Compiler, perform the following steps:

   a. On the **Simulation** page, click **More EDA Netlist Writer Settings**. The **More EDA Netlist Writer Settings** dialog box appears.

   b. Under **Existing option settings**, click **Location of user compiled simulation library**.

   c. In the **Setting** field, type the path that contains the user-compiled libraries that are generated from the EDA Simulation Library Compiler; for example, **c:**<*design_path*>**/simulation/modelsim**.

For more information about the EDA Simulation Library Compiler, refer to "Compile Libraries Using the EDA Simulation Library Compiler" on page 2–17.

7. Click **OK.**

8. On the Processing menu, point to **Start** and click **Start Analysis & Elaboration** to perform an Analysis and Elaboration. This command collects all your file name information and builds your design hierarchy in preparation for simulation.
9. On the Tools menu, point to **Run EDA Simulation Tool** and click **EDA RTL Simulation** to automatically run ModelSim, compile all necessary design files, and complete a simulation.
10. If you want to run ModelSim in command-line mode when running it automatically after full compilation, perform the following steps:
    a. On the **Simulation** page, click **More NativeLink Settings**. The **More NativeLink Settings** dialog box appears.
    b. Under **Existing option settings**, click **Launch third-party EDA tool in command-line mode**.
    c. In the **Setting** field, select **On**.
    d. Click **OK**.
11. If you want to generate only the **.do** script without launching ModelSim during the NativeLink process, you can perform the following steps:
    a. On the **Simulation** page, click **More NativeLink Settings**. The **More NativeLink Settings** dialog box appears.
    b. Under **Existing option settings**, click **Generate third-party EDA tool command scripts without running the EDA tool**.
    c. In the **Setting** field, select **On**.

    If you turn this option on and run NativeLink, the **.do** file for ModelSim simulation is generated without launching ModelSim. You can then run the simulation by typing the following command:

    ```
    do <your_design_name>_run_msim_rtl_level_<verilog/vhdl>.do
    ```

Perform a Gate-Level Simulation Using NativeLink

To run a gate-level timing simulation with the ModelSim software in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears (Figure 2–3 on page 2–71).
3. In the **Tool name** list, select one of the following options:
    - **ModelSim**
    - **ModelSim-Altera**
4. Under **EDA Netlist Writer options**, in the **Format for output netlist** list, choose **VHDL** or **Verilog**. You can also modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
5. To run a gate-level simulation after each full compilation, turn on **Run gate-level simulation automatically after compilation**.

6. If you have testbench files or macro scripts, enter the information under **NativeLink settings**.
7. If you have compiled libraries using the EDA Simulation Library Compiler, perform the following steps:
   a. On the **Simulation** page, click **More EDA Netlist Writer Settings**. The **More EDA Netlist Writer Settings** dialog box appears.
   b. Under **Existing option settings**, click **Location of user compiled simulation library**.
   c. In the **Setting** field, type the path that contains the pre-compiled libraries that are generated from the EDA Simulation Library Compilation tool; for example, **c:**<*design_path*>**/simulation/modelsim**.
8. Click **OK**.
9. On the Processing menu, point to **Start** and click **Start EDA Netlist Writer** to generate a simulation netlist of your design.

   If you must run full compilation after you set the **EDA Tool Settings**, the **Start EDA Netlist Writer** command is not required.

10. On the Tools menu, point to **Run EDA Simulation Tool** and click **EDA Gate Level Simulation** to automatically run ModelSim, compile all necessary design files, and complete a simulation.

    If multi-corner Timing Analysis is performed, a dialog box appears, asking you to select the timing corner to run simulation. Select the timing corner and click **Run**.

    A ***.do** file is generated in the <*project_directory*>**\simulation\modelsim** directory while running NativeLink. You can perform a simulation with the ***.do** file directly from ModelSim when you rerun a simulation without using NativeLink. To perform the simulation directly without NativeLink, type the following command in the ModelSim console:
    do <*generated_do_file*>**.do**.

11. If you want to run ModelSim in command-line mode when running it automatically after full compilation, you can perform the following steps:
    a. On the **Simulation** page, click **More NativeLink Settings**. The **More NativeLink Settings** dialog box appears.
    b. Under **Existing option settings**, click **Launch third-party EDA tool in command-line mode**.
    c. In the **Setting** field, select **On**.
    d. Click **OK**.

12. If you want to generate only the **.do** script without launching ModelSim during the NativeLink process, you can perform the following steps:

    a. On the **Simulation** page, click **More NativeLink Settings**. The **More NativeLink Settings** dialog box appears.

    b. Under **Existing option settings**, click **Generate third-party EDA tool command scripts without running the EDA tool**.

    c. In the **Setting** field, select **On**.

    If you turn this option on and run the NativeLink, the **.do** file for the simulation process is generated without showing the results in the GUI. You can then run the simulation by typing the following command:

    ```
    do <your_design_name>_run_msim_rtl_level_<verilog/vhdl>.do
    ```

Setting Up a Testbench

You can use NativeLink to compile your design files and testbench files, and run an EDA simulation tool to automatically perform a simulation.

To set up NativeLink for simulation, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, click the "+" icon to expand **EDA Tool Settings** and select **Simulation**. The **Simulation** page appears.
3. Under **NativeLink settings**, select **None**, **Compile test bench**, or **Script to compile test bench** (Table 2–13).

Table 2–13. NativeLink Settings

Settings	Description
None	Compile simulation models and design files.
Compile test bench	NativeLink compiles simulation models, design files, testbench files, and starts simulation.
Script to compile test bench	NativeLink compiles the simulation models and design files. The script you provide is sourced after design files compile. Use this option when you want to create your own script to compile your testbench and perform simulation.

4. If you select **Compile test bench**, select your testbench setup from the **Compile test bench** list. You can use different testbench setups to specify different test scenarios. If there are no testbench setups entered, create a testbench setup by performing the following steps:
   a. Click **Test Benches**. The **Test Benches** dialog box appears.
   b. Click **New**. The **New Test Bench Settings** dialog box appears.
   c. In the **Test Bench name** box, type in the testbench setup name that identifies the different testbench setups.
   d. In the **Test level module** box, type in the top-level testbench entity name. For example, for a Quartus II-generated VHDL testbench, type in <*Vector Waveform File name*>`_vhd_vec_tst`.
   e. In the **Instance** box, type in the full instance path to the top level of your FPGA design. For example, for a Quartus II-generated VHDL testbench, type in `i1`.
   f. Under **Simulation period**, select **Run simulation until all vector stimuli are used** or specify the end time of the simulation.
   g. Under **Test bench files**, browse and add all your testbench files in the **File name** box. Use the **Up** and **Down** button to reorder your files. The script used by NativeLink compiles the files in order from top to bottom.

You can also specify the library name and HDL version to compile the testbench file. NativeLink compiles the testbench to a library name using the specified HDL version.

   h. Click **OK**.
   i. In the **Test Benches** dialog box, click **OK**.
5. Under **NativeLink settings**, turn on **Use script to set up simulation** and browse to your script. Your script is executed to set up and run simulation after loading the design using the `vsim` command.
6. If you choose **Script to compile test bench**, browse to your script and click **OK**.

Creating a Testbench

In the Quartus II software, you can create a Verilog HDL or VHDL testbench from a Vector Waveform File. The generated testbench includes the behavior of the input stimulus and applies it to your instantiated top-level FPGA design.

1. On the File menu, click **Open**. The **Open** dialog box appears.
2. Click the **Files of type** arrow and select **Waveform/Vector Files**. Select your Vector Waveform File.
3. Click **Open**.
4. On the File menu, click **Export**. The **Export** dialog box appears.
5. Click the **Save as type** arrow and select **VHDL Test Bench File (*.vht)** or **Verilog Test Bench File (*.vt)**.
6. Turn on **Add self-checking code to file** to check your simulation results against your Vector Waveform File.

7. Click **Export**. Your VHDL or Verilog HDL testbench file is generated in your project directory.

Generate Simulation Script from EDA Netlist Writer

In the Quartus II software version 9.0 and later, you can generate the simulation script (including the **.do** file, Tcl script, and option file) when you run the EDA Netlist Writer. You can use the simulation script to run your simulation in the preferred simulator in stand-alone mode.

To generate a simulation script with the EDA Netlist Writer, perform the following steps:

1. On the **Simulation** page, click **More EDA Netlist Writer Settings**. The **More EDA Netlist Writer Settings** dialog box appears.
2. Under **Existing option settings**, click **Generate third-party EDA tool command script for RTL simulation** (if you want to generate an RTL simulation script) or click **Generate third-party EDA tool command script for Gate-Level simulation** (if you want to generate a Gate-Level simulation script).
3. In the **Setting** field, select **On**.
4. Click **OK**.
5. Follow the steps in "Generate Gate-Level Timing Simulation Netlist Files" on page 2–14.

In the command-line, to generate the simulation script with the EDA Netlist Writer, type the following command:

```
quartus_eda --simulation --tools=<Your decided tool> --format=<vhdl or verilog>
    --gen_script=<rtl or gate_level> <Project Name> -c <Revision name>
```

ModelSim Error Message Verification

ModelSim error and warning messages are tagged with a `vsim` or `vcom` code. To find out the cause and resolution for a `vsim` or `vcom` error or warning, use the `verror` command.

For example, ModelSim may display the following error message:

```
# ** Error:
C:/altera_trn/DUALPORT_TRY/simulation/modelsim/DUALPORT_TRY.vho(31):
(vcom-1136) Unknown identifier "stratixiii".
```

In this case, type the following command:

```
verror 1136 ↵
```

At that point, the error message appears as follows:

```
# vcom Message # 1136:
# The specified name was referenced but was not found. This indicates
# that either the name specified does not exist or is not visible at
# this point in the code.
```

Generating a Timing VCD File for PowerPlay

To generate a timing Value Change Dump (***.vcd**) file for PowerPlay, you must first generate a ***.vcd** script file in the Quartus II software and run the ***.vcd** script file from the ModelSim or ModelSim-Altera software to generate a timing ***.vcd** file. This timing ***.vcd** file can then be used by PowerPlay for power estimation. The following instructions show you step-by-step how to generate a timing ***.vcd** file.

To generate timing VCD Scripts in the Quartus II software, perform the following steps:

1. In the Quartus II software, on the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, under **EDA Tool Settings**, select **Simulation**. The **Simulation** page appears.
3. Choose the appropriate third-party simulation tool (ModelSim or ModelSim-Altera) in the **Tool name** list. Turn on the **Generate Value Change Dump (VCD) file script** option.
4. To generate the ***.vcd** script file, perform a full compilation.

To generate a timing ***.vcd** file in the ModelSim-Altera or ModelSim software, perform the following steps:

1. In the ModelSim or ModelSim-Altera software, before simulating your design, source the `<`*revision_name*`>_dump_all_vcd_nodes.tcl` script. To source the Tcl script, run the following command before running the `vsim` command. For example:

   ```
   source <revision_name>_dump_all_vcd_nodes.tcl ↵
   ```

2. Continue to run the simulation as usual until the end of the simulation. Exit the ModelSim or ModelSim-Altera software. If you do not exit the software, the ModelSim software may end the writing process of the timing ***.vcd** files improperly, resulting in a corrupted timing ***.vcd** file.

For more information about using the timing ***.vcd** file for power estimation, refer to the *PowerPlay Power Analysis* chapter in volume 3 of the *Quartus II Handbook*.

Viewing a Waveform from a .wlf File

A **.wlf** file is automatically generated when your simulation is done. The **.wlf** file is not readable. It is used for generating the waveform view through ModelSim.

To view a waveform from a **.wlf** file through ModelSim, perform the following steps:

1. Type `vsim` on a command line. The **ModelSim** dialog box appears.
2. On the View menu, click **Datasets**. The **Datasets Browser** dialog box appears.
3. Click **Open** and browse to the directory that contains your **.wlf** file.
4. If you have found your **.wlf** file, click **Open**, then click **OK**.
5. Click **Done**.
6. In the Object browser, select the signals that you want to observe.

7. On the Add menu, click **Wave** and then click **Selected Signals**.

You cannot view a waveform from a **.vcd** file in ModelSim directly. The **.vcd** file must first be converted to a **.wlf** file.

1. Use the `vcd2wlf` command to convert the file. For example, type the following on a command-line:

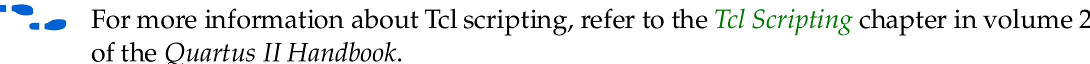
```
vcd2wlf <example>.vcd <example>.wlf ↵
```

2. After you convert the **.vcd** file to a **.wlf** file, follow the procedures for viewing a waveform from a **.wlf** file through ModelSim.

You can also convert your **.wlf** file to a **.vcd** file by using the `wlf2vcd` command.

Scripting Support

You can run procedures and create settings described in this chapter in a Tcl script. You can also run some procedures at the command line prompt.



For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*.

For more information about command line scripting, refer to the *Command Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

For detailed information about scripting command options, refer to the `Qhelp` command line and Tcl API help browser. To access this information, type the following command to start the Qhelp browser:

```
quartus_sh --qhelp ↵
```

Generating a Post-Synthesis Simulation Netlist for ModelSim

You can use the Quartus II software to generate a post-synthesis simulation netlist with Tcl commands or with a command at the command-line prompt. The following example assumes that you are selecting ModelSim (Verilog HDL output from the Quartus II software).

Tcl Commands

Use the following Tcl commands to set the output format to Verilog HDL, the simulation tool to ModelSim for Verilog HDL, and to generate a functional netlist:

```
set_global_assignment-name EDA_SIMULATION_TOOL "ModelSim (Verilog)" ↵
set_global_assignment-name EDA_GENERATE_FUNCTIONAL_NETLIST ON ↵
```

Command Prompt

Use the following command to generate a simulation output file for the ModelSim simulator. Specify VHDL or Verilog HDL for the format:

```
quartus_eda <project name> --simulation=on --format=<format> \
--tool=ModelSim --functional ↵
```

Generating a Gate-Level Timing Simulation Netlist for ModelSim

Use the Quartus II software to generate a gate-level timing simulation netlist with Tcl commands or with a command at the command prompt.

Tcl Commands

Use one of the following Tcl commands:

- `set_global_assignment -name EDA_SIMULATION_TOOL \`
  `"ModelSim-Altera (Verilog)"` ↵
- `set_global_assignment -name EDA_SIMULATION_TOOL \`
  `"ModelSim-Altera (VHDL)"` ↵
- `set_global_assignment -name EDA_SIMULATION_TOOL \`
  `"ModelSim (Verilog)"` ↵
- `set_global_assignment -name EDA_SIMULATION_TOOL \`
  `"ModelSim (VHDL)"` ↵

Command Line

Generate a simulation output file for the ModelSim simulator by specifying VHDL or Verilog HDL for the format by typing the following command at the command prompt:

```
quartus_eda <project name> --simulation=on --format=<format> \
--tool=ModelSim ↵
```

Software Licensing and Licensing Setup in ModelSim-Altera Subscription Edition

License the ModelSim-Altera Subscription Edition software subscription with a parallel port FIXEDPC license, or a network FLOATNET or FLOATPC license. Each Altera software subscription includes a license for both VHDL and Verilog HDL. The ModelSim-Altera Subscription Edition software supports both VHDL and Verilog HDL, but the software does not support mixed language simulation.

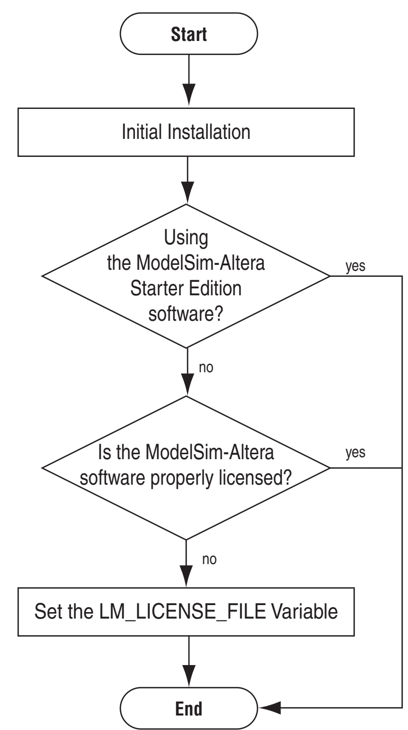
The USB software guard is not supported by versions earlier than Mentor Graphics ModelSim software 5.8d.

You can obtain a license for the ModelSim-Altera Subscription Edition software from the Altera website at www.altera.com. Get licensing information for the Mentor Graphics ModelSim software directly from Mentor Graphics. Refer to Figure 2–4 for the set-up process.

For ModelSim-Altera software versions prior to 5.5b, use the **PCLS** utility included with the software to set up the license.

For the Quartus II software version 8.1 and later, the no-cost entry level of the ModelSim-Altera software does not require a license file. However, you must request a license file to use the ModelSim-Altera Subscription Edition software.

Figure 2–4. ModelSim-Altera Subscription Edition Software Licensing Set Up Process



LM_LICENSE_FILE Variable

Altera recommends setting the `LM_LICENSE_FILE` environment variable to the location of the license file. For example, the value for the `LM_LICENSE_FILE` environment variable should point to <*path to license file*>**\license.dat.**

For more information about setting up the license for ModelSim-Altera Subscription Edition software, refer to *AN 340: Altera Software Licensing*.

Conclusion

Using the ModelSim and ModelSim-Altera simulation software within the Altera FPGA design flow enables Altera software users to easily and accurately perform RTL functional simulations, post-synthesis simulations, and gate-level simulations on their designs. Proper verification of designs at the functional, post-synthesis, and post place-and-route stages using the ModelSim and ModelSim-Altera software helps ensure design functionality and success and, ultimately, a quick time-to-market.

3. Synopsys VCS and VCS-MX Support

QII53002-9.0.0

Introduction

This chapter is an overview of using the Synopsys VCS and VCS-MX software to simulate designs that target Altera® FPGAs. It provides a step-by-step explanation of how to perform register transfer level (RTL) functional simulations, post-synthesis simulations, and gate-level timing simulations using the VCS and VCS-MX software.

Verilog HDL design simulation is the same in both the VCS and VCS-MX software. In this chapter, VCS-MX is used in VHDL design simulation examples.

This chapter discusses the following topics:

- "Software Requirements"
- "Using the VCS or VCS-MX Software in the Quartus II Design Flow" on page 3–2
- "Common VCS and VCS-MX Software Compiler Options" on page 3–17
- "Using VirSim" on page 3–18
- "Using DVE" on page 3–18
- "Debugging Support Command-Line Interface" on page 3–19
- "Simulating Designs that Include Transceivers" on page 3–19
- "Transport Delays" on page 3–22
- "Using NativeLink with the VCS or VCS-MX Software" on page 3–22
- "Generating a Simulation Script from the EDA Netlist Writer" on page 3–27
- "Generating a Timing .vcd File for PowerPlay" on page 3–28
- "Viewing a Waveform from a .vpd or .vcd File" on page 3–28
- "Scripting Support" on page 3–29

Software Requirements

To simulate your design using the Synopsys VCS software, you must first set up the Altera libraries. These libraries are installed with the Quartus® II software.

Table 3–1 shows the compatibility between versions of the Quartus II software and the Synopsys VCS software.

Table 3–1. Supported Quartus II and VCS Software Version Compatibility (Part 1 of 2)

Synopsys	Altera
VCS and VCS-MX software version Y-2006-06-SP1	Quartus II software version 9.0
VCS software version Y-2006-06-SP1	Quartus II software version 8.1
VCS software version Y-2006.06-SP1	Quartus II software version 7.2 and 8.0
VCS software version 2006.06	Quartus II software version 7.1
VCS software version 2005.06-SP2	Quartus II software version 7.0 and 6.1
VCS software version 2005.06-SP1	Quartus II software version 6.0

Table 3–1. Supported Quartus II and VCS Software Version Compatibility (Part 2 of 2)

Synopsys	Altera
VCS software version 7.2	Quartus II software version 5.1
VCS software version 7.2	Quartus II software version 5.0
VCS software version 7.1.1	Quartus II software version 4.2

For more information about installing the software and the directories created during the Quartus II software installation, refer to the *Quartus II Installation and Licensing for Windows* or the *Quartus II Installation and Licensing for UNIX and Linux Workstation* manuals.

Using the VCS or VCS-MX Software in the Quartus II Design Flow

You can perform the following types of simulations using the VCS and VCS-MX software:

- RTL Functional Simulation
- Post-synthesis Simulation
- Gate-level timing Simulation

Figure 3–1 shows the VCS, VCS-MX, and Quartus II software design flow.

Gate-Level Simulation Library Files

Notes to Figure 3–1:

(1) RTL functional simulation is performed before a gate-level timing simulation or post-synthesis simulation. RTL functional simulation verifies the functionality of the design before synthesis and place-and-route. If you are performing a functional simulation through NativeLink, you must complete analysis and elaboration first.

(2) A post-synthesis simulation verifies the functionality of a design after synthesis has been performed.

(3) Gate-level timing simulation is a post place-and-route simulation to verify the operation of the design after the timing delays have been calculated.

(4) All these simulation libraries are located at <*quartus installation directory*>**\eda\sim_lib**.

Compile Libraries Using the EDA Simulation Library Compiler

The EDA Simulation Library Compiler is used to compile Verilog HDL and VHDL simulation libraries for all Altera devices and supported third-party simulators. You can use this tool to compile all libraries required by RTL and gate-level simulation.

When you use this tool to perform compilation by targeting third-party simulation tools, such as ModelSim, NC-Sim, VCS_MX, Active-HDL, and Riviera-PRO, the compiled libraries are kept in either the directory you set or the default directory after compilation. When you perform the simulation using these simulators, you can reuse the compiled libraries and avoid the overhead associated with redundant library compilations.

However, if you targeted the Synopsys VCS software to perform compilation while running the EDA Simulation Library Compiler, the option file (**simlib_comp.vcs**) is generated after compilation. You can then include your design and test bench files into the option file and invoke it with the VCS command.

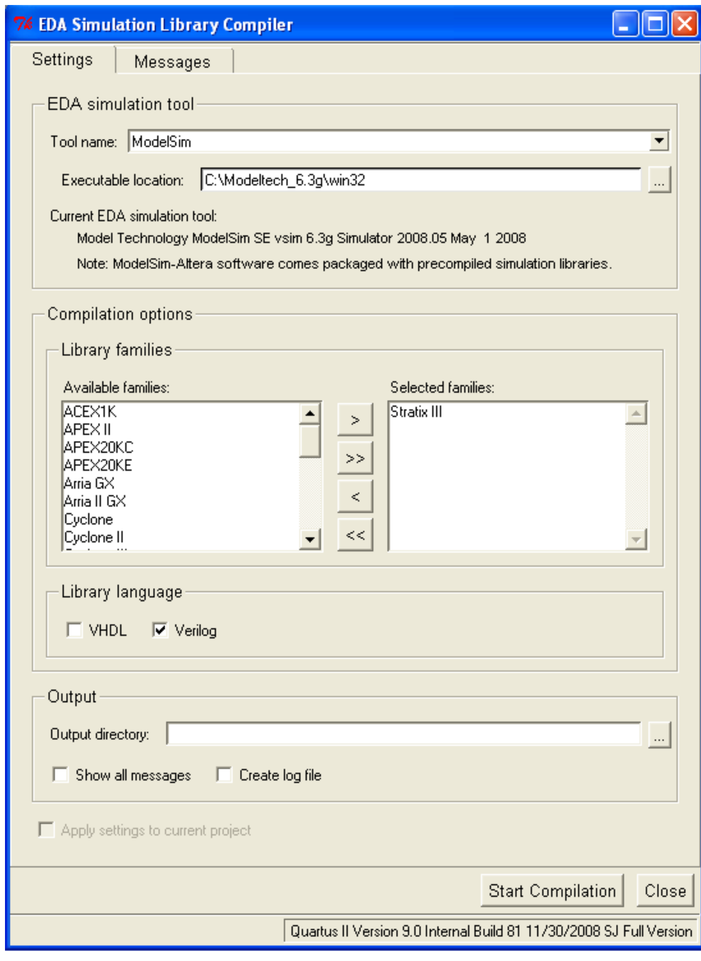
Before using this option, ensure the appropriate simulation tools are already installed with the paths specified. To specify the path, refer to "Setting Up the EDA Tool Executable Location" on page 3–22.

Using the EDA Simulation Library Compiler GUI

Beginning with the Quartus II software version 9.0, the EDA Simulation Library Compiler contains a GUI. To compile libraries using the EDA Simulation Library Compiler GUI, perform the following steps:

1. On the Tools menu, click **EDA Simulation Library Compiler**. The **EDA Simulation Library Compiler** dialog box appears (Figure 3–2).

Figure 3–2. EDA Simulation Library Compiler Dialog Box



2. In the **Tool name** entry box, select the third-party simulation tool you want to use.

   After you have selected the simulation tool, the location of the tool is displayed in the **Executable location** entry box.

3. Select one or more device families for your design compilation from the list in the **Available families** entry box. Click **>** to move them into the **Selected families** box.
4. In the Library language field, turn on **VHDL**, **Verilog**, or both.
5. In the **Output directory** entry box, specify the directory in which to store the compiled libraries or option files.
6. Turn on the **Show all messages** option, **Create log file** option, or both, if desired.
7. Turn on the **Apply settings to current project** option, if desired.
8. Click **Start Compilation**.

Verilog HDL example

To run a simulation for your Verilog HDL design with a Stratix® II device in the VCS simulator, do the following:

- Select **VCS** in the **Tool name** entry box
- Move **Stratix II** from the **Available families** list to **Selected families**
- Turn on **Verilog** in the **Library language** box
- Specify the location of the **Output directory**
- Click **Start Compilation**

After you run the EDA Simulation Library Compiler, an option file (**simlib_comp.vcs**) is generated and stored in the output location you specified. The option file is shown in Example 3–1.

Example 3–1.

```
+cli+1 -line -timescale=1ps/1ps \
-v /apps/quartus/9.0/quartus/eda/sim_lib/altera_primitives.v \
-v /apps/quartus/9.0/quartus/eda/sim_lib/220model.v \
-v /apps/quartus/9.0/quartus/eda/sim_lib/sgate.v \
-v /apps/quartus/9.0/quartus/eda/sim_lib/altera_mf.v \
-v /apps/quartus/9.0/quartus/eda/sim_lib/stratixii_atoms.v \
 +incdir+/apps/quartus/9.0/quartus/eda/sim_lib
```

If you manually run a simulation using the Synopsys VCS simulator, you must include your design file and test bench file in the option file, as shown in Example 3–2:

Example 3–2.

```
+cli+1 -line -timescale=1ps/1ps design_file.v test_bench_file.vt\
-v /apps/quartus/9.0/quartus/eda/sim_lib/altera_primitives.v \
-v /apps/quartus/9.0/quartus/eda/sim_lib/220model.v \
-v /apps/quartus/9.0/quartus/eda/sim_lib/sgate.v \
-v /apps/quartus/9.0/quartus/eda/sim_lib/altera_mf.v \
-v /apps/quartus/9.0/quartus/eda/sim_lib/stratixiii_atoms.v \
 +incdir+/apps/quartus/9.0/quartus/eda/sim_lib
```

To compile all of the libraries, design files, and test bench files, type the following command:

```
vcs -f simlib_comp.vcs ↵
```

VHDL example

To run a simulation for your VHDL design with a Stratix II device in the VCS-MX simulator, do the following:

- Select **VCSMX** in the **Tool name** entry box
- Move **Stratix II** from the **Available families** list to **Selected families**
- Turn on **VHDL** in the **Library language** box
- Specify the location of the **Output directory**
- Click **Start Compilation**

After you run the EDA Simulation Library Compiler, all of the required libraries are compiled and stored in the output location you specified.

If you use NativeLink to run the simulation, refer to "Using NativeLink with the VCS or VCS-MX Software" on page 3–22.

Using the EDA Simulation Library Compiler in the Command Line

To run the EDA Simulation Library Compiler in the command line, type the following:

```
quartus_sh --simlib_comp -family <device> -tool <simulation tool name>
-language <language> -directory <directory> ↵
```

For more information about the command line options and how to define them, you can type the command:

```
quartus_sh --help=simlib_comp ↵
```

RTL Functional Simulations

RTL functional simulations verify the functionality of the design before synthesis, placement, and routing. These simulations are independent of any Altera FPGA architecture implementation. After the HDL designs are verified to be functionally correct, the next step is to synthesize the design and use the Quartus II software to place-and-route the design in an Altera device.

To functionally simulate an Altera FPGA design in the VCS or VCS-MX software that uses Altera intellectual property (IP) megafunctions or a library of parameterized modules (LPM) functions, you must include certain libraries during the compilation. Table 3–2 summarizes the Verilog HDL library files that are required to compile LPM functions and Altera megafunctions.

Table 3–2. Altera Verilog HDL Functional/Behavioral Simulation Library Files

RTL Simulation Model	Verilog HDL Libraries
ALTGX Megafunction (Stratix IV GX)	<*path to Quartus II installation*>/eda/sim_lib/stratixiv_hssi_atoms.v *(1)*
LPM	<*path to Quartus II installation*>/eda/sim_lib/220model.v
Altera Megafunction	<*path to Quartus II installation*>/eda/sim_lib/altera_mf.v
ALTGXB Megafunction (Stratix GX)	<*path to Quartus II installation*>/eda/sim_lib/stratixgx_mf.v *(1)*
ALT2GXB Megafunction (Stratix II GX)	<*path to Quartus II installation*>/eda/sim_lib/stratixiigx_hssi_atoms.v *(1)* <*path to Quartus II installation*>/eda/sim_lib/arriagx_hssi_atoms.v *(1)*
High-Level Primitives	<*path to Quartus II installation*>/eda/sim_lib/sgate.v
Low-Level Primitives	<*path to Quartus II installation*>/eda/sim_lib/altera_primitives.v

Note to Table 3–2:

(1) The **stratixgx_mf.v**, **stratixiigx_hssi_atoms.v**, **arriagx_hssi_atoms.v**, and **stratixiv_hssi_atoms.v** library files require the LPM and SGATE libraries.

Table 3–3 summarizes the VHDL library files that are required to compile LPM functions and Altera megafunctions.

Table 3–3. Altera VHDL Functional/Behavioral Simulation Library Files

RTL Simulation Model	VHDL Libraries
ALTGX Megafunction (Stratix IV GX)	<*path to Quartus II installation*>/eda/sim_lib/stratixiv_hssi_components.vhd <*path to Quartus II installation*>/eda/sim_lib/stratixiv_hssi_atoms.vhd *(1)*
LPM	<*path to Quartus II installation*>/eda/sim_lib/220pack.vhd <*path to Quartus II installation*>/eda/sim_lib/220model.vhd <*path to Quartus II installation*>/eda/sim_lib/220model_87.vhd
Altera Megafunction	<*path to Quartus II installation*>/eda/sim_lib/altera_mf_components.vhd <*path to Quartus II installation*>/eda/sim_lib/altera_mf.vhd <*path to Quartus II installation*>/eda/sim_lib/altera_mf_87.vhd
ALTGXB Megafunction (Stratix GX)	<*path to Quartus II installation*>/eda/sim_lib/stratixgx_mf_components.vhd <*path to Quartus II installation*>/eda/sim_lib/stratixgx_mf.vhd *(1)*
ALT2GXB Megafunction (Stratix II GX)	<*path to Quartus II installation*>/eda/sim_lib/stratixiigx_hssi_components.vhd <*path to Quartus II installation*>/eda/sim_lib/stratixiigx_hssi_atoms.vhd *(1)* <*path to Quartus II installation*>/eda/sim_lib/arriagx_hssi_components.vhd <*path to Quartus II installation*>/eda/sim_lib/arriagx_hssi_atoms.vhd *(1)*
High-Level Primitives	<*path to Quartus II installation*>/eda/sim_lib/sgate_pack.vhd <*path to Quartus II installation*>/eda/sim_lib/sgate.vhd
Low-Level Primitives	<*path to Quartus II installation*>/eda/sim_lib/altera_primitives_components.vhd <*path to Quartus II installation*>/eda/sim_lib/altera_primitives.vhd

Note to Table 3–3:

(1) The **stratixgx_mf.vhd**, **stratixiigx_hssi_atoms.vhd**, **arriagx_hssi_atoms.vhd**, and **stratixiv_hssi_atoms.vhd** library files require the LPM and SGATE libraries.

RTL Functional Simulation (Verilog HDL Designs)

The following VCS command performs an RTL functional simulation for Verilog HDL designs with one of the libraries in Table 3–2:

```
vcs -R <testbench>.v <design name>.v -v <library file1>.v -v <library file 2>.v ↵
```

If you have already generated the option file (**simlib_comp.vcs**) from the EDA Simulation Library Compiler, type the following command:

```
vcs -f simlib_comp.vcs ↵
```

Be sure to include the design files and testbench files in **simlib_comp.vcs**.

Alternatively, you can use the following commands to perform RTL functional simulation for Verilog HDL designs:

```
# Create Libraries Directories
mkdir <Directory_to_store_compiled_library1>
mkdir <Directory_to_store_compiled_library2>
# Create Work Directory
mkdir <Directory_to_store_compiled_design_and_testbench_files>
# Compilation
# (Before this step, make sure the mapped file ".synopsys_vss.setup" is created.)
# Libraries Compilation
vlogan -work <library1_name> <library1>.v
vlogan -work <library2_name> <library2>.v
# Design and Test bench files Compilation
vlogan -work <work_library_name> <design>.v <test_bench>.v
# Eleboration
vcs -debug_all <work_library_name>.<testbench_top_level_module>
# Run Simulation
simv -gui
```

.synopsys_vss.setup contains the following mapping commands to map the libraries:

```
<library1_name> : <Directory_to_store_compiled_library1>
<library2_name> : <Directory_to_store_compiled_library2>
<work_library_name> : <Directory_to_store_compiled_design_and_testbench_files>
```

RTL Functional Simulation (VHDL Designs)

For VHDL designs, you need to use VCS-MX software to perform all types of simulations. The following commands are for performing an RTL functional simulation for VHDL designs with one of the libraries in Table 3–3 on page 3–8:

```
# Create Libraries Directories
mkdir <Directory_to_store_compiled_library1>
mkdir <Directory_to_store_compiled_library2>
# Create Work Directory
mkdir <Directory_to_store_compiled_design_and_testbench_files>
# Compilation
# (Before this step, make sure the mapped file ".synopsys_vss.setup" is created.)
# Libraries Compilation
vhdlan -work  <library1_name> <library1>.vhd
vhdlan -work  <library2_name> <library2>.vhd
# Design and Test bench files Compilation
vhdlan -work <work_library_name> <design>.vhd <test_bench>.vhd
# Eleboration
scs -debug_all <work_library_name>.<testbench_top_level_module>
# Run Simulation
scsim -gui
```

.synopsys_vss.setup contains the following mapping commands to map the libraries:

```
<library1_name> : <Directory_to_store_compiled_library1>
<library2_name> : <Directory_to_store_compiled_library2>
<work_library_name> : <Directory_to_store_compiled_design_and_testbench_files>
```

If you have generated the Altera libraries with the EDA Simulation Library Compiler, ignore the steps **# Create Libraries Directories** and **# Libraries Compilation**.

Post-Synthesis Simulation

A post-synthesis simulation verifies the functionality of a design after synthesis has been performed. You can create a post-synthesis netlist in the Quartus II software and use this netlist to perform a post-synthesis simulation in the VCS or VCS-MX software. When the post-synthesis version of the design has been verified, the next step is to place-and-route the design in the target architecture using the Quartus II software.

Generating a Post-Synthesis Simulation Netlist

The following steps describe the process of generating a post-synthesis simulation netlist in the Quartus II software:

1. Perform Analysis and Synthesis. On the Processing menu, point to **Start** and click **Start Analysis & Synthesis**.

2. Turn on the **Generate Netlist for Functional Simulation Only** option by performing the following steps:
   a. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
   b. In the **Category** list, under **EDA Tool Settings,** select **Simulation**. The **Simulation** dialog box appears.
   c. In the **Tool name** list, select **VCS or VCS MX**.
   d. You can modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
   e. Click **More EDA Netlist Writer Settings**. The **More EDA Netlist Writer Settings** dialog box appears.
   f. In the **Existing option settings** list, click **Generate netlist for functional simulation only**.
   g. Under **Option**, from the **Setting** list, select **On**.
   h. Click **OK**.
   i. In the **Settings** dialog box, click **OK**.
3. Run the EDA Netlist Writer. On the Processing menu, point to **Start** and click **Start EDA Netlist Writer**.

During the EDA Netlist Writer stage, the Quartus II software produces a Verilog Output File (**.vo**) or VHDL Output File (**.vho**) that can be used for post-synthesis simulation in the VCS software. This netlist file is mapped to architecture-specific primitives. No timing information is included at this stage.

The resulting netlist is located in the output directory you specified in the **Settings** dialog box, which defaults to the <*project directory*>**/simulation/vcs** directory for VCS or to the <*project directory*>**/simulation/scsim** directory for VCS-MX. This netlist, along with the device family library listed in Table 3–4 and Table 3–5, can be used to perform a post-synthesis simulation in the VCS or VCS-MX software.

Table 3–4. Altera Gate-Level Timing Simulation Library Files (Verilog HDL) (Part 1 of 2)

Device Simulation Model	Location in Quartus II Directory Structure

FLEX 6000	<*Quartus II installation directory*>\eda\sim_lib\flex6000_components.vhd <*Quartus II installation directory*>\eda\sim_lib\flex6000_atoms.vhd
FLEX 10KE ACEX 1K	<*Quartus II installation directory*>\eda\sim_lib\flex10ke_components.vhd <*Quartus II installation directory*>\eda\sim_lib\flex10ke_atoms.vhd

Post-Synthesis Simulations (Verilog HDL)

The following VCS command shows the command-line syntax used to perform a post-synthesis simulation with the appropriate device family library listed in Table 3–4:

```
vcs -R <testbench> <post synthesis netlist> -v <Altera device family library> ↵
```

If you have already generated the option file (**simlib_comp.vcs**) from the EDA Simulation Library Compiler, type the following command:

```
vcs -f simlib_comp.vcs ↵
```

Be sure to include the post synthesis netlist file and testbench files in **simlib_comp.vcs**.

Alternatively, you can use the following commands to perform Post-Synthesis simulation for Verilog HDL designs:

```
# Create Libraries Directories
mkdir <Directory_to_store_compiled_library1>
mkdir <Directory_to_store_compiled_library2>
# Create Work Directory
mkdir <Directory_to_store_compiled_post_synthesis_netlist_and_testbench_files>
# Compilation
# (Before this step, make sure that mapped file ".synopsys_vss.setup" is created.)
# Libraries Compilation
vlogan -work  <library1_name> <library1>.v
vlogan -work  <library2_name> <library2>.v
# Design and Test bench files Compilation
vlogan -work <work_library_name> <post_synthesis_netlist>.vo <test_bench>.v
# Eleboration
vcs -debug_all <work_library_name>.<testbench_top_level_module>
# Run Simulation
simv -gui
```

The **.synopsys_vss.setup** file contains the following commands to map the libraries:

```
<library1_name> : <Directory_to_store_compiled_library1>
<library2_name> : <Directory_to_store_compiled_library2>
<work_library_name> :
   <Directory_to_store_compiled_post_synthesis_netlist_and_testbench_files>
```

Post-Synthesis Simulations (VHDL)

The following VCS-MX software commands show the command-line syntax used to perform a post-synthesis simulation with the appropriate device family library listed in Table 3–5:

```
# Create Libraries Directories
mkdir <Directory_to_store_compiled_library1>
mkdir <Directory_to_store_compiled_library2>
# Create Work Directory
mkdir <Directory_to_store_compiled_post_synthesis_netlist_and_testbench_files>
# Compilation
#(Before this step, make sure that mapped file ".synopsys_vss.setup" is created.)
# Libraries Compilation
vhdlan -work  <library1_name> <library1>.vhd
vhdlan -work  <library2_name> <library2>.vhd
# Design and Test bench files Compilation
vhdlan -work <work_library_name> <post_synthesis_netlist>.vho <test_bench>.vhd
# Eleboration
scs -debug_all <work_library_name>.<testbench_top_level_module>
# Run Simulation
scsim -gui
```

The **.synopsys_vss.setup** file contains the following commands to map the libraries:

```
<library1_name> : <Directory_to_store_compiled_library1>
<library2_name> : <Directory_to_store_compiled_library2>
<work_library_name> :
   <Directory_to_store_compiled_post_synthesis_netlist_and_testbench_files>
```

If you have generated the Altera libraries with EDA Simulation Library Compiler, ignore the steps **# Create Libraries Directories** and **# Libraries Compilation**.

Gate-Level Timing Simulation

A gate-level timing simulation verifies the functionality of the design after place-and-route. You can create a post-fit netlist in the Quartus II software and use this netlist to perform a gate-level timing simulation in the VCS or VCS-MX software.

Generating a Gate-Level Timing Simulation Netlist

To perform gate-level timing simulation, the VCS or VCS-MX software requires information about how the design was placed into device-specific architectural blocks. The Quartus II software provides this information in the form of a **.vo** file for Verilog HDL designs or a **.vho** file for VHDL designs. The accompanying timing information is stored in the Standard Delay Output (**.sdo**) file, which annotates the delay for the elements found in the **.vo** or **.vho** file.

To generate a gate-level timing simulation netlist in the Quartus II software, perform the following steps:

1. Perform a full compilation. On the Processing menu, click **Start Compilation**.
2. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
3. In the **Category** list, under **EDA Tool Settings**, select **Simulation**. The **Simulation** dialog box appears.
4. In the **Tool name** list, select **VCS** or **VCS MX**.
5. You can modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
6. Click **OK**.
7. In the **Settings** dialog box, click **OK**.
8. Run the EDA Netlist Writer. On the Processing menu, point to **Start** and click **Start EDA Netlist Writer**.

During the EDA Netlist Writer stage, the Quartus II software produces a **.vo** file that can be used for post-synthesis simulations in the VCS software or a **.vho** file that can be used for post-synthesis simulations in the VCS-MX software. This netlist file is mapped to architecture-specific primitives. No timing information is included at this stage. The resulting netlist is located in the output directory you specified in the **Settings** dialog box, which defaults to the <*project directory*>**/simulation/vcs** directory for Verilog HDL designs or the <*project directory*>**/simulation/scsim** directory for VHDL designs.

Generating a Timing Netlist with Different Timing Models

In Stratix III and later devices (for example, Cyclone III and Stratix IV devices) you can specify different temperature and voltage parameters to generate the timing netlist. If you enable the Quartus II Classic Timing Analyzer or the Quartus II TimeQuest Timing Analyzer when generating the simulation netlist files (***.vo** or ***.vho** and ***.sdo**), different timing models for different operating conditions are used by default. The multi-corner timing analysis is run by default during the full compilation.

Table 3–6 shows examples of default available operating conditions (model, voltage, and temperature) for Stratix III and Cyclone III devices.

Table 3–6. Default Available Operating Condition for Stratix III and Cyclone III Devices

Device Family	Model	Voltage	Temperature (C)
Stratix III	Slow	1100 mV	85°
	Slow	1100 mV	0°
	Fast	1100 mV	0°
Cyclone III	Slow	1200 mV	85°
	Slow	1200 mV	0°
	Fast	1200 mV	0°

If the multi-corner timing analysis is not run during full compilation, you should perform the following steps to manually generate the simulation netlist files (***.vo** or ***.vho** and ***.sdo**) for the three different operating conditions listed in Table 3–6:

1. Generate all the available corner models at all operating conditions. Type the following command at a command prompt:

```
quartus_sta <project name> --multicorner ↵
```

2. Generate the simulation output files for all three corners specified in Table 3–6. Perform steps 2 through 8 in “Generating a Gate-Level Timing Simulation Netlist” on page 3–14. The output files are generated in the simulation output directory.

The following example shows all of the generated simulation netlist files for the three operating conditions of the preceding steps, when **Verilog** is selected as the output netlist format:

First slow corner (slow, 1100 mV, 85° C):

.vo file— *<revision name>***.vo**

.sdo file— *<revision name>***_v.sdo**

The *<revision_name>***.vo** and *<revision name>***_v.sdo** are generated for backward compatibility in case there are existing scripts that still use them.

.vo file— *<revision name>*_*<speedgrade>***_1100mv_85c_slow.vo**

.sdo file— *<revision name>*_*<speedgrade>***_1100mv_85c_v_slow.sdo**

Second slow corner (slow, 1100 mV, 0° C):

.vo file— *<revision name>*_*<speedgrade>***_1100mv_0c_slow.vo**

.sdo file— *<revision name>*_*<speedgrade>***_1100mv_0c_v_slow.sdo**

Fast corner (fast, 1100 mV, 0° C):

.vo file— *<revision name>***_min_1100mv_0c_fast.vo**

.sdo file— *<revision name>***_min_1100mv_0c_v_fast.sdo**

For all other older device families (for example, Stratix II and Stratix devices), a slow-corner (worst case) timing model is used by default. There are only two timing models available, the slow-corner and fast-corner timing models. To generate the **.sdo** file using a different timing model, you must run the Quartus II Classic Timing Analyzer or the Quartus II TimeQuest Timing Analyzer with a different timing model before you start the EDA Netlist Writer.

To run the Quartus II Classic Timing Analyzer with the best-case model, on the Processing menu, point to **Start** and click **Start Classic Timing Analyzer (Fast Timing Model)**. After the timing analysis is complete, the Compilation Report appears. You can also type the following command at a command prompt:

```
quartus_tan <project_name> --fast_model=on ↵
```

To run the Quartus II TimeQuest Timing Analyzer with a best-case model, use the **-fast_model** option after you create the timing netlist. The following command enables the fast timing models:

```
create_timing_netlist --fast_model ↵
```

After you run the Quartus II Classic Timing Analyzer or Quartus II TimeQuest Timing Analyzer, you can perform steps 2 through 8 in "Generating a Gate-Level Timing Simulation Netlist" on page 3–14 to generate the ***.sdo** file. For fast-corner timing models, the `-fast` post fix is added to the ***.vo** or ***.vho** and ***.sdo** files (for example, **my_project_fast.vo** or **my_project_fast.vho** and **my_project_fast.sdo**).

For more information about generating the timing netlist with different timing models, refer to the *Quartus II Classic Timing Analyzer* chapter or the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Gate-Level Timing Simulations (Verilog HDL)

For gate-level timing simulation, follow the steps in "Post-Synthesis Simulations (Verilog HDL)" on page 3–13.

You do not need to specify the ***.sdo** file because it is already specified in the ***.vo** file. However, the ***.sdo** file must be in same directory in which the `simv` command is running.

Gate-Level Timing Simulations (VHDL)

For gate-level timing simulation, follow the steps in "Post-Synthesis Simulations (VHDL)" on page 3–13.

For VHDL, the ***.sdo** file must be specified in the `scsim` command as follows:

```
scsim -gui -sdf typ:<design_instance>:<design>.sdo ↵
```

Disable Timing Violation on Registers

In certain situations, the timing violations can be ignored and you want to disable the timing violation on registers (for example, timing violations that occur in internal synchronization registers used for asynchronous clock-domain crossing).

By default, the **x_on_violation_option logic** option is **On**, which means simulation shows "**X**" whenever a timing violation occurs. To disable showing the timing violation on certain registers, you can set the **x_on_violation_option logic** option to **Off** for those registers. The following command is an example of the Quartus II Settings file (**.qsf**):

```
set_instance_assignment -name X_ON_VIOLATION_OPTION OFF -to <register_name> ↵
```

Perform Timing Simulation Using the Post-Synthesis Netlist

You can perform a timing simulation using the post-synthesis netlist instead of using a gate-level netlist, and you can generate an **.sdo** file without running the fitter. In this case, the **.sdo** file includes all timing values for the device cells only. Interconnect delays are not included because fitting (placement and routing) has not been performed.

To generate the post-synthesis netlist and the **.sdo** file, type the following commands at a command prompt:

```
quartus_map <project name> -c <revision name> ↵
quartus_tan <project name> -c <revision name> --post_map \
--zero_ic_delays ↵
quartus_eda <project name> -c <revision name> --simulation \
--tool= <third-party EDA tool> --format=<HDL language> ↵
```

For more information about the `-format` and `-tool` options, type the following command:

```
quartus_eda -help=<options> command ↵
```

Common VCS and VCS-MX Software Compiler Options

The VCS software has options that help you simulate your design. Table 3–7 lists some of the available options.

Table 3–7. VCS Software Compiler Options (Part 1 of 2)

Library	Description
`-R`	Runs the executable file immediately.
`-RI`	After the compile has completed, instructs the VCS software to automatically launch VirSim.
`-v <library filename>`	Specifies a Verilog HDL library file (for example, **220model.v** or **altera_mf.v**). The VCS software looks in this file for module definitions that are found in the source code. Only the relevant library files are compiled based on the modules found.
`-y <library directory>`	Specifies a Verilog HDL library directory. The VCS software looks for library files in this folder that contain module definitions that are instantiated in the source code.
`+compsdf`	Indicates that the VCS software compiler includes the back-annotated Standard Delay File (**.sdf**) file in the compilation.
`+cli`	The VCS software enters Command-Line Interface (CLI) mode upon successful compilation completion.

Table 3–7. VCS Software Compiler Options (Part 2 of 2)

Library	Description
`+race`	Specifies that the VCS software generate a report that indicates all of the race conditions in the design. The default report name is race.out.
`-P`	Compiles user-defined Programming Language Interface (PLI) table files.
`-q`	Indicates the VCS software runs in quiet mode. All messages are suppressed.

For more information about VCS software options, refer to the *VCS User Guide*.

Using VirSim

VirSim is the graphical debugging system for the VCS software. This tool is included with the VCS software and can be run by using the `-RI` compile-time compiler option when compiling a design. The following VCS software command shows the command-line syntax for compiling and loading a timing simulation in VirSim:

```
vcs -RI <testbench>.v <design name>.vo -v <path to Quartus II installation> \
   \eda\sim_lib\<device family>_atoms.v +compsdf ↵
```

For more information about using VirSim, refer to the *VirSim User Guide* included in the VCS software installation.

Using DVE

DVE is the graphical debugging system for the VCS and VCS-MX software. This tool is included with the VCS-MX software. It can be run by using the `-gui` (simulating option) when running a simulation.

The following VCS or VCS-MX software commands show the command-line syntax for simulating in DVE:

`simv -gui` (for Verilog HDL simulation)

`scsim -gui` (for VHDL simulation)

However, to open the GUI with these commands, you must enable the use of UCLI and DVE when performing elaboration. To enable UCLI and DVE, enter the following commands:

`vcs -debug_all` (for Verilog HDL simulations)

`scs -debug_all` (for VHDL simulations)

For more information about using DVE, refer to the *DVE User Guide* included in the VCS-MX software installation.

Debugging Support Command-Line Interface

The Synopsys VCS software has an interactive non-graphical debugging capability that is very similar to other UNIX debuggers such as the GNU debugger (GDB). The VCS software CLI can be used to halt simulations at user-defined break points, force registers with values, and display register values.

Enable the non-graphical capability by using the `+cli` run-time option. Use the VCS software CLI to debug your Altera FPGA design by typing the following command:

```
vcs -R <testbench>.v <design name>.vo -v <path to Quartus II \
installation> \eda\sim_lib\<device family>_atoms.v +compsdf +cli ↵
```

The `+cli` command takes an optional number argument that specifies the level of debugging capability. As the optional debugging capability is increased, the overhead incurred by the simulation is increased, resulting in an increase in simulation time.

For more information about the `+cli` options, refer to the *VCS User Guide* included in the VCS software installation.

For the design examples to run gate-level timing simulation in VHDL or Verilog HDL language, refer to www.altera.com/support/examples/vcs/exm-vcs.html.

Simulating Designs that Include Transceivers

If your design includes a Stratix IV, Stratix II GX, Stratix GX, Arria II GX, or Arria GX transceiver, you must compile additional library files to perform functional RTL or gate-level timing simulations.

Stratix GX RTL Functional Simulation

To perform an RTL functional simulation of your design that instantiates the ALTGXB megafunction, enabling the gigabit transceiver block gigabit transceiver block on Stratix GX devices, you should compile the **stratixgx_mf** model file into the **altgxb** library.

The **stratixiigx_mf** model file references the **lpm** and **sgate** libraries; you must create these libraries to perform a simulation.

Compiling Library Files for Functional Stratix GX Simulation in Verilog HDL

To compile the libraries necessary for functional simulation of a Verilog HDL design targeting a Stratix GX device, at the VCS command prompt, type the following command:

```
vcs -R <testbench>.v <design files>.v -v stratixgx_mf.v -v sgate.v \
-v 220model.v -v altera_mf.v ↵
```

Stratix GX Gate-Level Timing Simulation

Perform a gate-level timing simulation of your design that includes a Stratix GX transceiver by compiling the **stratixgx_atoms** and **stratixgx_hssi_atoms** model files into the **stratixgx** and **stratixgx_gxb** libraries, respectively.

The **stratixgx_hssi_atoms** model file references the **lpm** and **sgate** libraries; you must create these libraries to perform a simulation.

Compiling Library Files for Timing Stratix GX Simulation in Verilog HDL

To compile the libraries necessary for timing simulation of a Verilog HDL design targeting a Stratix GX device, at the VCS command prompt, type the following command:

```
vcs -R <testbench>.v <gate-level netlist>.vo -v stratixgx_atoms.v -v \
stratixgx_hssi_atoms.v -v sgate.v -v 220model.v -v altera_mf.v +transport_int_delays \
+pulse_int_e/0 +pulse_int_r/0 +transport_path_delays +pulse_e/0 +pulse_r/0 ↵
```

Stratix II GX RTL Functional Simulation

Stratix II GX RTL functional simulation is similar to Arria GX RTL functional simulation. The following example shows only the RTL functional simulation for designs that include transceivers in Stratix II GX. To simulate the transceiver in Arria GX, you only have to replace the **stratixiigx_hssi** model file with the **arriagx_hssi** model file.

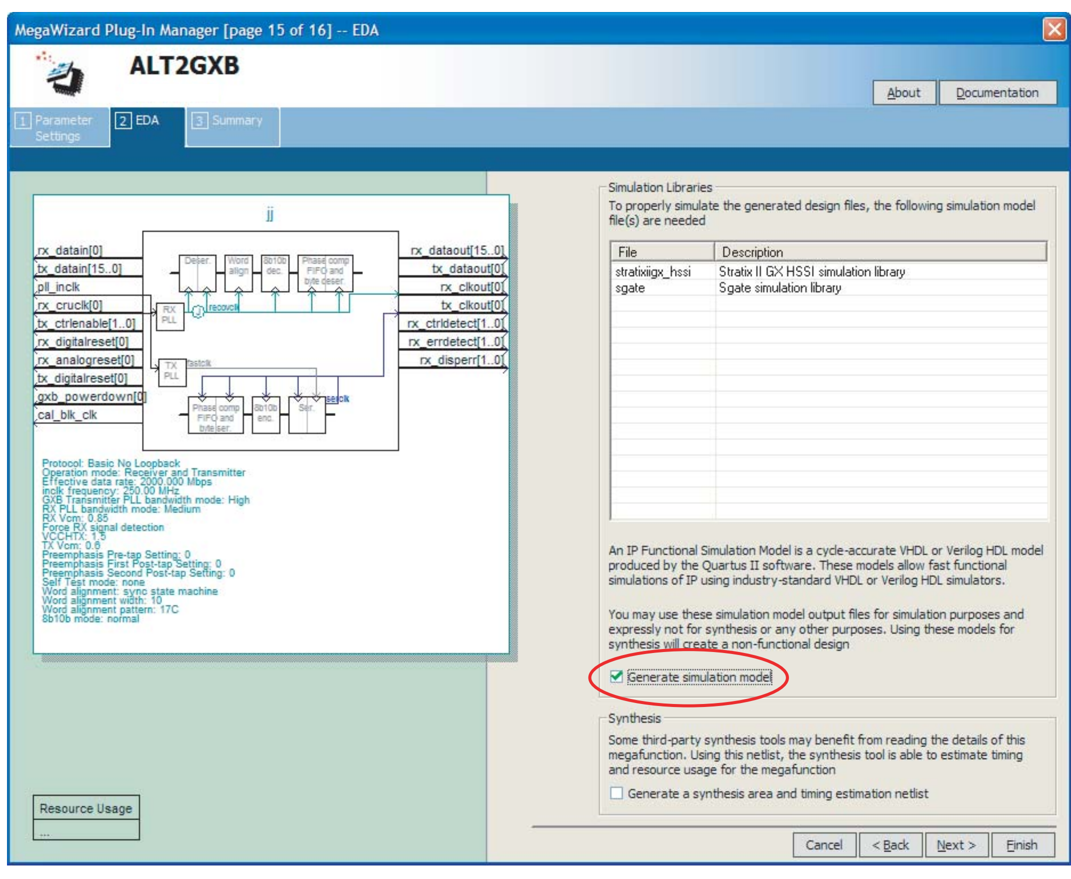
To perform an RTL functional simulation of your design that instantiates the ALT2GXB megafunction, enabling the gigabit transceiver block gigabit transceiver block on Stratix II GX devices, you should compile the **stratixiigx_hssi** model file into the **stratixiigx_hssi** library.

The **stratixiigx_hssi_atoms** model file references the **lpm** and **sgate** libraries; you must create these libraries to perform a simulation.

Generate a functional simulation netlist by turning on **Generate Simulation Model in the Simulation Library** in the ALT2GXB MegaWizard™ Plug-In Manager (Figure 3–3). The <*alt2gxb entity name*>**.vho** file or <*alt2gxb module name*>**.vo** file is generated in the current project directory.

The Quartus II-generated ALT2GXB functional simulation library file references **stratixiigx_hssi wysiwyg atoms**.

Figure 3–3. ALT2GXB MegaWizard Plug-In Manager, Generate Simulation Model



Compiling Library Files for Stratix II GX RTL Functional Simulation in Verilog HDL

To compile the libraries necessary for functional simulation of a Verilog HDL design targeting a Stratix II GX device, type the following command at the VCS command prompt:

```
vcs -R <testbench>.v <alt2gxb simulation netlist>.vo -v \
stratixgx_hssi_atoms.v -v sgate.v -v 220model.v -v altera_mf.v ↵
```

Stratix II GX Gate-Level Timing Simulation

Stratix II GX gate-level timing simulation is similar to Arria GX gate-level timing simulation. The following example shows only the gate-level timing simulation for designs that include transceivers in Stratix II GX. To simulate the transceiver in Arria GX, you only have to replace the **stratixiigx_hssi** model file with the **arriagx_hssi** model file.

To perform a gate-level timing simulation of your design that includes a Stratix II GX transceiver, compile `stratixiigx_atoms` and `stratixiigx_hssi_atoms` into the **stratixiigx** and **stratixiigx_hssi** libraries, respectively.

The **stratixiigx_hssi_atoms** model file references the **lpm** and **sgate** libraries; so you must create these libraries to perform a simulation.

Compiling Library Files for Stratix II GX Gate-Level Timing Simulation in Verilog HDL

To compile the libraries necessary for timing simulation of a Verilog HDL design targeting a Stratix II GX device, type the following command at the VCS command prompt:

```
vcs -R <testbench>.v <gate-level netlist>.vo -v stratixiigx_atoms.v -v \
stratixiigx_hssi_atoms.v -v sgate.v -v 220model.v -v altera_mf.v \
+transport_int_delays +pulse_int_e/0 +pulse_int_r/0 \
+transport_path_delays +pulse_e/0 +pulse_r/0 ↵
```

Transport Delays

By default, the VCS software filters out all pulses that are shorter than the propagation delay between primitives. Turning on the transport delay options in the VCS software prevents the simulation tool from filtering out these pulses. Use the following options to ensure that all signal pulses are seen in the simulation results.

+transport_path_delays

Use this option when the pulses in your simulation are shorter than the delay within a gate-level primitive. You must include the `+pulse_e/number` and `+pulse_r/number` options.

+transport_int_delays

Use this option when the pulses in your simulation are shorter than the interconnect delay between gate-level primitives. You must include the `+pulse_int_e/number` and `+pulse_int_r/number` options. The `+transport_path_delays` and `+transport_int_delays` options are also used by default in the NativeLink feature for gate-level timing simulation.

For more information about either of these options, refer to the *VCS User Guide* installed with the VCS software.

The following VCS software command shows the command-line syntax to perform a post-synthesis simulation with the device family library:

```
vcs -R <testbench>.v <gate-level netlist>.v -v <Altera device family library>.v \
+transport_int_delays +pulse_int_e/0 +pulse_int_r/0 +transport_path_delays \
+pulse_e/0 +pulse_r/0 ↵
```

Using NativeLink with the VCS or VCS-MX Software

The NativeLink feature in the Quartus II software facilitates the seamless transfer of information between the Quartus II software and EDA tools and allows you to run VCS or VCS-MX within the Quartus II software.

Setting Up the EDA Tool Executable Location

Before using the NativeLink feature, you must specify the path to your simulation tool. To specify the path, perform the following steps:

1. On the Tools menu, click **Options.** The **Options** dialog box appears.

2. In the **Category** list, select **EDA Tool Options**. The **EDA Tool Options** dialog box appears.
3. Double-click the entry under the **Location of Executable** column.
4. Type or browse to the directory containing the executables of your EDA tool. For the VCS simulator tool, the executable path is at <*VCS_Installed_Directory*>**/bin**. For the VCS-MX simulator tool, the executable path is at <*VCS-MX_Installed_Directory*>**/bin**.
5. Click **OK**.

You can also specify the path to the simulator's executables by using the `set_user_option` Tcl command:

```
set_user_option -name EDA_TOOL_PATH_VCS <path to executables> ↵
```

Performing an RTL Simulation Using NativeLink

To run an RTL functional simulation automatically with the VCS or VCS-MX software in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, under **EDA Tool Settings**, select **Simulation**. The **Simulation** dialog box appears.
3. In the **Tool name** list, select **VCS or VCS MX**. You can also modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
4. If you have testbench files or macro scripts, enter the information under **NativeLink settings**.

   For more information about setting up a testbench with NativeLink, refer to "Setting Up a Testbench" on page 3–26.
5. (For VCS-MX only) If you have compiled libraries using the EDA Simulation Library Compiler, perform the following steps:
   a. On the **Simulation** page, click **More EDA Netlist Writer Settings**. The **More EDA Netlist Writer Settings** dialog box appears.
   b. Under **Existing option settings**, click **Location of User-Compiled Simulation Library**.
   c. Under **Setting**, type the path that contains the pre-compiled libraries that are generated from the EDA Simulation Library Compilation tool; for example, <*design_path*>**/simulation/scsim**.
6. Click **OK.**
7. On the Processing menu, point to **Start** and click **Start Analysis & Elaboration** to perform an analysis and elaboration. This command collects all your file name information and builds your design hierarchy in preparation for simulation.
8. On the Tools menu, point to **Run EDA Simulation Tool** and click **EDA RTL Simulation** to automatically launch the VCS or VCS-MX software, compile all necessary design files, and complete a simulation.

9. If you want to generate only the Tcl script without using the GUI after the NativeLink process, perform the following steps:

   a. On the **Simulation** page, click **More NativeLink Settings**. The **More NativeLink Settings** dialog box appears.

   b. Under **Existing option settings**, click **Generate third-party EDA tool command scripts without running the EDA tool**.

   c. Under **Setting**, click **On**.

   For VCS software, if you turn on this option and run NativeLink, files such as **script_file.sh** and the option file (<*revision_name*>**_rtl.vcs**) are generated without showing the result in the GUI. You can then run the simulation by typing the following command:

   ```
   sh script_file.sh ↵
   ```

   For VCS-MX software, if you turn on this option and run NativeLink, the file <*project_name*>**_vcsmx_rtl_**<*vhdl/verilog*>**.tcl** is generated without showing the result in the GUI. You can then run the simulation by typing the following command:

   ```
   quartus_sh -t <project_name>_vcsmx_rtl_<vhdl/verilog>.tcl ↵
   ```

Performing a Gate-Level Timing Simulation Using NativeLink

To automatically run a gate-level timing simulation with the VCS or VCS-MX software in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears.
3. In the **Tool name** list, select **VCS** or **VCS MX**.
4. You can modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
5. To perform a gate level simulation after each full compilation, turn on **Run gate-level simulation automatically after compilation**.
6. If you have testbench files or macro scripts, enter the information under **NativeLink settings**.
7. (For VCS-MX only) If you have compiled libraries using the EDA Simulation Library Compiler, perform the following steps:

   a. On the **Simulation** page, click **More EDA Netlist Writer Settings**. The **More EDA Netlist Writer Settings** dialog box appears.

   b. Under **Existing option settings**, click **Location of User-Compiled Simulation Library**.

   c. Under **Setting**, type the path that contains the pre-compiled libraries that are generated from the EDA Simulation Library Compilation tool; for example, <*design_path*>**/simulation/scsim**.

8. Click **OK**.
9. Perform a full compilation. On the Processing menu, click **Start Compilation**.

10. On the Processing menu, point to **Start** and click **Start EDA Netlist Writer** to generate a simulation netlist of your design.

If you have run full compilation after you set the EDA Tool Settings, the **Start EDA Netlist Writer** step is not required.

11. On the Tools menu, point to **Run EDA Simulation Tool** and click **EDA Gate Level Simulation** to automatically launch the VCS or VCS-MX software, compile all necessary design files, and complete a simulation.

    If multi-corner Timing Analysis is performed, a dialog box appears, asking you to select the timing corner to run simulation. Select the timing corner and click **Run**.

12. If you want to run VCS or VCS-MX in command-line mode when running it automatically after full compilation, perform the following steps:
    a. On the Simulation page, click **More NativeLink Settings**. The **More NativeLink Settings** dialog box appears.
    b. Under **Existing option settings**, click **Launch third-party EDA tool in command-line mode**.
    c. Under Setting, click **On**.
    d. Click **OK**.
13. If you want to generate only the Tcl script without using the GUI after the NativeLink process, you can perform the following steps:
    a. On the **Simulation** page, click **More NativeLink Settings**. The **More NativeLink Settings** dialog box appears.
    b. Under **Existing option settings**, click **Generate third-party EDA tool command scripts without running the EDA tool**.
    c. Under **Setting**, click **On**.

    For VCS software, if you turn on this option and run NativeLink, files such as **script_file.sh** and the option file (<*revision_name*>**_gate.vcs**) are generated without showing the result in the GUI. You can then run the simulation by typing the following command:

    ```
    sh script_file.sh ↵
    ```

    For VCS-MX software, if you turn on this option and run NativeLink, the file <*project_name*>**_vcsmx_gate_**<*vhdl/verilog*>**.tcl** is generated without showing the result in the GUI. You can then run the simulation by typing the following command:

    ```
    quartus_sh -t <project_name>_vcsmx_gate_<vhdl/verilog>.tcl ↵
    ```

Setting Up a Testbench

You can automatically launch your EDA simulator tool, compile your design files and testbench files, and perform a simulation automatically using the NativeLink feature.

To set up NativeLink with a testbench, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. Click the "+" icon to expand **EDA Tool Settings** and select **Simulation**. The **Simulation** page appears.
3. Under **NativeLink settings**, select **None** or **Compile test bench**. Table 3–8 shows the NativeLink settings.

Table 3–8. NativeLink Settings

Settings	Description
None	Compile simulation models and design files.
Compile test bench	NativeLink compiles simulation models, design files, testbench files, and starts simulation.

4. If you select **Compile test bench**, select your testbench setup from the **Compile test bench** list. You can use different testbench setups to specify different testbench files for different test scenarios. If there are no testbench setups entered, create a testbench setup by performing the following steps:
   a. Click **Test Benches**. The **Test Benches** dialog box appears.
   b. Click **New**. The **New Test Bench Settings** dialog box appears.
   c. In the **Test bench name** box, type in the testbench setup name, which is used to identify the different testbench setups.
   d. In the **Top level module** box, type in the top-level entity name. For example, for a Quartus II generated Verilog HDL testbench, type <*Vector Waveform File name*>`_vlg_vec_tst`.
   e. In the **Instance** box, type the full instance path to the top level of your FPGA design. For example, for a Quartus II generated Verilog HDL testbench, type `i1`.
   f. Under **Simulation period**, select **Run simulation until all vector stimuli are used**. If you select **End simulation at**, specify the simulation end time and the time unit.
   g. Under **Test bench files**, browse and add all your testbench files in the **File name** box. Use the **Up** and **Down** buttons to reorder your files. The script used by NativeLink compiles the files in order from top to the bottom.

You can also specify the library name and the HDL version to compile the testbench file. NativeLink compiles the testbench to the library name of the HDL specified version.

   h. Click **OK**.
   i. In the **Test Benches** dialog box, click **OK**.

Creating a Testbench

In the Quartus II software, you can create a Verilog HDL or VHDL testbench from a Vector Waveform File (**.vwf**). The generated testbench includes the behavior of the input stimulus and applies it to your instantiated top-level FPGA design. To create a Verilog HDL or VHDL testbench, perform the following steps:

1. On the File menu, click **Open**. The **Open** dialog box appears.
2. Click the **Files of type** arrow and select **Waveform/Vector Files**. Select your file.
3. Click **Open**.
4. On the File menu, click **Export**. The **Export** dialog box appears.
5. Click the **Save as type** arrow and select **VHDL Test Bench File (*.vht)** or **Verilog Test Bench File (*.vt)**.
6. You can turn on **Add self-checking code to file** to check your simulation results against your **.vwf** file.
7. Click **Export**.

Generating a Simulation Script from the EDA Netlist Writer

Beginning in the Quartus II software version 9.0, you can generate the simulation script (such as the DO file, Tcl script, and option file) when you run the EDA Netlist Writer. You can use the simulation script to run your simulation at the stated simulator in stand-alone.

For generating the simulation script via EDA Netlist Writer, perform the following steps:

1. Click **More EDA Netlist Writer Settings**. The **More EDA Netlist Writer Settings** dialog box appears.
2. In the **Existing options** list, click **Generate third-party EDA tool command script for RTL simulation** (if you want to generate an RTL simulation script) or click **Generate third-party EDA tool command script for Gate-Level simulation** (if you want to generate a Gate-Level simulation script).
3. Under **Setting**, click **On**.
4. Click **OK**.
5. Follow the steps in "Generating a Post-Synthesis Simulation Netlist for VCS" on page 3–29.

To generate the simulation script with the EDA Netlist Writer, type the following command in the command line:

```
quartus_eda --simulation --tools=<Your decided tool> --format=<vhdl or verilog>
--gen_script=<rtl or gate_level> <Project Name> -c <Revision name> ↵
```

Generating a Timing .vcd File for PowerPlay

To generate a timing Value Change Dump (***.vcd**) file for PowerPlay, you must first generate a VCD script in the Quartus II software, and then run the VCD script from the VCS software. This timing **.vcd** file can then be used by PowerPlay for power estimation.

Perform the following steps to generate timing VCD scripts in the Quartus II software:

1. In the Quartus II software, on the Assignments menu, click **Settings**. The Settings database appears.
2. In the **Settings** dialog box, on the **Simulator Settings** page, in the **Tool Name** list, choose the appropriate third-party simulation tool (for example, VCS), and turn the **Generate Value Change Dump File Script** option on.
3. To generate the VCD script file, perform a full compilation.

Perform the following steps to generate a timing **.vcd** file in the VCS software:

1. In the VCS software, before compiling and simulating your design, include the script in your testbench file where the design under test (DUT) is instantiated:

```
include <revision_name>_dump_all_vcd_nodes.v ↵
```

Include the script within the testbench module block. If you include the script outside of the testbench module block, syntax errors occur during compilation.

2. Run the simulation using the VCS command as usual. Exit the VCS software when the simulation is done and the *<revision_name>***.vcd** file is generated in the simulation directory.

For more detailed information about using the timing **.vcd** file for power estimation, refer to the *PowerPlay Power Analysis* chapter in volume 3 of the *Quartus II Handbook*.

Viewing a Waveform from a .vpd or .vcd File

A **.vpd** file is automatically generated when your simulation is done. The **.vpd** file is not readable. It is used for generating the waveform view through VirSim or DVE. You can view your waveform result in VirSim or DVE if you have created a **.vpd** or **.vcd** file.

To view a waveform from a **.vpd** file through VirSim, perform the following steps:

1. Type `virsim` on a command line. The **VirSim Hierarchy** dialog box appears.
2. On the File menu, click **Open**. The **Open File** dialog box appears.
3. In the **Directories** field, browse to the directory that contains your **.vpd** file (for example, **inter.vpd**).
4. Double-click the **.vpd** file.
5. On the Window menu, click **Waveform**. The **VirSim Waveform** dialog box appears.

6. Move the signals that you want to observe from the **VirSim Hierarchy** dialog box to the **VirSim Waveform** dialog box. View the waveform.

To view a waveform from a **.vpd** file through DVE, perform the following steps:

1. Type `dve` on a command line. The **DVE** dialog box appears.
2. On the File menu, click **Open Database**. The **Open Database** dialog box appears.
3. Browse to the directory that contains your **.vpd** file (for example, **inter.vpd**).
4. Double-click the **.vpd** file.
5. In the **DVE** dialog box, select the signals that you want to observe from the Hierarchy.
6. On the Signal menu, click **Add To Waves**.
7. Click **New Wave View**. The waveform appears.

You cannot view a waveform from a **.vcd** file in VirSim or DVE directly. The **.vcd** file must first be converted to a **.vpd** file. Perform the following steps:

1. Use the `vcd2vpd` command to convert the file. For example, type the following on a command-line:

```
vcd2vpd <example>.vcd <example>.vpd ↵
```

2. After you convert the **.vcd** file to a **.vpd** file, follow the procedures for viewing a waveform from a **.vpd** file through VirSim or DVE.

You can also convert your **.vpd** file to a **.vcd** file by using the `vpd2vcd` command.

Scripting Support

You can run procedures and create settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

For detailed information about scripting command options, refer to the Qhelp utility.

To start the **Qhelp** utility, type this command:

```
quartus_sh --qhelp ↵
```

Generating a Post-Synthesis Simulation Netlist for VCS

You can use the Quartus II software to generate a post-synthesis simulation netlist with Tcl commands or with a command at a command prompt.

Tcl Commands

Type the following Tcl commands to generate a post-synthesis simulation netlist:

```
set_global_assignment -name EDA_SIMULATION_TOOL "VCS" ↵
set_global_assignment -name EDA_GENERATE_FUNCTIONAL_NETLIST ON ↵
```

Command Prompt

Type the following command to generate a simulation output file for the VCS software simulator; specify VHDL or Verilog HDL for the format:

```
quartus_eda <project name> --simulation=on --format=<format> \
--tool=vcs --functional ↵
```

Generating a Gate-Level Timing Simulation Netlist for VCS

You can use the Quartus II software to generate a gate-level timing simulation netlist with Tcl commands or with a command at a command prompt.

Tcl Commands

Type the following Tcl command to generate a gate-level timing simulation netlist:

```
set_global_assignment -name EDA_SIMULATION_TOOL "VCS" ↵
```

Command Prompt

Type the following command to generate a simulation output file for the VCS software simulator. Specify VHDL or Verilog HDL for the format.

```
quartus_eda <project name> --simulation=on --format=<format> --tool=vcs ↵
```

Conclusion

You can use the Synopsys VCS or VCS-MX software in your Altera FPGA design flow to easily and accurately perform RTL functional simulations, post-synthesis simulations, and gate-level functional timing simulations. The seamless integration of the Quartus II software and VCS or VCS-MX software make this simulation flow an ideal method for fully verifying an FPGA design.

Document Revision History

Table 3–9 shows the revision history for this chapter.

Table 3–9. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Added support for Synopsys VCS-MX software. ■ Changed chapter title to "Synopsys VCS and VCS-MX Support". ■ Major revision to "Compile Libraries Using the EDA Simulation Library Compiler" on page 3–4. ■ Major revision to "RTL Functional Simulations" on page 3–7. ■ Added Table 3–4 on page 3–10 and Table 3–5 on page 3–11. ■ Added new section "Using DVE" on page 3–18. ■ Added new section "Generating a Simulation Script from the EDA Netlist Writer" on page 3–27. ■ Added new section "Viewing a Waveform from a .vpd or .vcd File" on page 3–28.	Updated for the Quartus II software version 9.0 release.
November 2008 v8.1.0	■ Added "Compile Libraries Using the EDA Simulation Library Compiler" on page 3–3. ■ Added information about the `--simlib_comp` utility. ■ Updated entire chapter using 8½" × 11" chapter template. ■ Minor editorial updates.	Updated for the Quartus II software version 8.1 release.
May 2008 v8.0.0	■ Updated Table 3–1. ■ Updated Figure 3–1. ■ Updated Table 3–3. ■ Updated "Generating a Timing Netlist with Different Timing Models" on page 3–7. ■ Added "Disable Timing Violation on Registers" on page 3–8. ■ Updated "Simulating Designs that Include Transceivers" on page 3–10. ■ Updated "Performing a Gate-Level Timing Simulation Using NativeLink" on page 3–15. ■ Added "Generating a Timing VCD File for PowerPlay" on page 3–17.	Updated for the Quartus II software version 8.0.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

4. Cadence NC-Sim Support

QII53003-9.0.0

Introduction

This chapter is a "getting started" guide to using the Cadence Incisive verification platform software in Altera® FPGA design flows. The Incisive verification platform software includes NC-Sim, NC-Verilog, NC-VHDL, Verilog HDL, and VHDL desktop simulators. This chapter provides step-by-step explanations of the basic NC-Sim, NC-Verilog, and NC-VHDL functional, post-synthesis, and gate-level timing simulations. It also describes the location of the simulation libraries and how to automate simulations.

This chapter contains the following topics:

- "Software Requirements"
- "Simulation Flow Overview" on page 4–2
- "RTL Functional Simulation" on page 4–7
- "Post-Synthesis Simulation" on page 4–17
- "Gate-Level Timing Simulation" on page 4–19
- "Simulating Designs that Include Transceivers" on page 4–24
- "Using the NativeLink Feature with NC-Sim" on page 4–29
- "Generating a Timing VCD File for PowerPlay" on page 4–35
- "Viewing a Waveform from a .trn File" on page 4–36
- "Scripting Support" on page 4–37

Software Requirements

You must first install the Quartus® II software before using it with the Cadence Incisive verification platform software. The Cadence interface is installed automatically when you install the Quartus II software on your computer.

Table 4–1 shows the Cadence NC simulator versions compatible with specific Quartus II software versions.

Table 4–1. Compatibility Between Software Versions (Part 1 of 2)

Quartus II Software	Cadence NC Simulators (UNIX)	Cadence NC Simulators (PC)	Cadence NC Simulators (Linux)
Version 9.0	Version 6.2	—	Version 6.2
Version 8.1	Version 6.2	—	Version 6.2
Version 8.0	Version 6.2	—	Version 6.2
Version 7.2	Version 6.1 p001	—	Version 6.1 p001
Version 7.1	Version 5.83 p003	—	Version 5.83 p003
Version 7.0	Version 5.82 p001	—	Version 5.82 p001
Version 6.1	Version 5.82 p001	Version 5.4 s011	Version 5.82 p001

Version 4.0	Version 5.0 s005	Version 5.0 s006	Version 5.0 p001

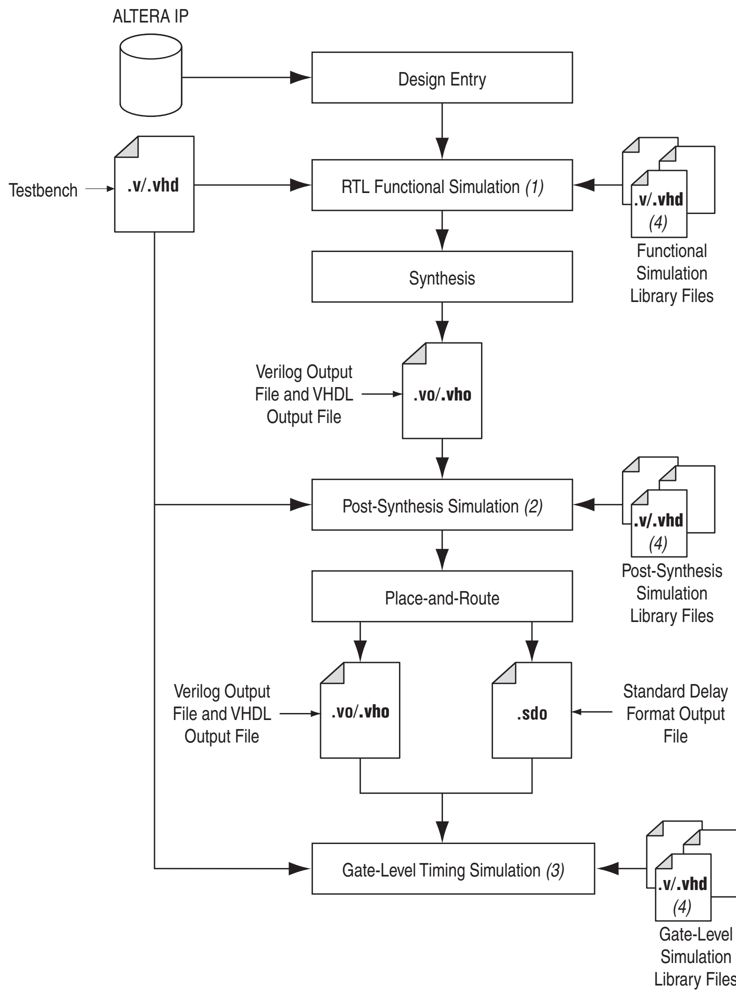
Simulation Flow Overview

The Incisive platform software supports the following simulation flows:

- RTL Functional Simulation
- Post-Synthesis Simulation
- Gate-Level Timing Simulation
- Using the NativeLink Feature with NC-Sim

Figure 4–1 shows the Quartus II software and Cadence design flow.

Figure 4–1. Quartus II Software Design Flow with Cadence NC Simulators *(Note 1)*, *(2)*, *(3)*, *(4)*



Notes to Figure 4–1:

(1) RTL functional simulation is performed before a gate-level timing simulation or post-synthesis simulation. RTL functional simulation verifies the functionality of the design before synthesis and place-and-route. If you are performing a functional simulation with NativeLink, you must complete analysis and elaboration first.

(2) A post-synthesis simulation verifies the functionality of a design after synthesis has been performed.

(3) Gate-level timing simulation is a post place-and-route simulation to verify the operation of the design after the worst-case timing delays have been calculated.

(4) All of these simulation libraries are located at *<quartus installation directory>***eda\sim_lib**.

RTL functional simulation verifies the functionality of your design. When you perform an RTL functional simulation with Cadence Incisive simulators, you use your design files (Verilog HDL or VHDL) and the models provided with the Quartus II software. These Quartus II models are required if your design uses the library of parameterized modules (LPM) functions or Altera-specific megafunctions. Refer to "RTL Functional Simulation" on page 4–7 for more information about how to perform this simulation.

A post-synthesis simulation verifies the functionality of a design after synthesis has been performed. You can create a post-synthesis netlist (**.vo** or **.vho**) in the Quartus II software and use this netlist to perform a post-synthesis simulation with the Incisive simulator. Refer to "Post-Synthesis Simulation" on page 4–17 for more information about how to perform this simulation.

After performing place-and-route, the Quartus II software generates a Verilog Output File (**.vo**) or VHDL Output File (**.vho**) and a Standard Delay Output file (**.sdo**) for gate-level timing simulation. The netlist files map your design to architecture-specific primitives. The **.sdo** file contains the delay information of each architecture primitive and routing element specific to your design. Together, these files provide an accurate simulation of your design with the selected Altera FPGA architecture. Refer to "Gate-Level Timing Simulation" on page 4–19 for more information about how to perform this simulation.

Operation Modes

In the NC simulators, you can use either the GUI mode or the command-line mode to simulate your design.

To start the Incisive simulators in GUI mode in a PC or a UNIX environment, at a command prompt, type the following:

```
nclaunch ↵
```

To simulate in command-line mode, use the programs shown in Table 4–2.

Table 4–2. Command-Line Programs

Program	Function
ncvlog or **ncvhdl**	NC-Verilog (**ncvlog**) compiles your Verilog HDL code into a Verilog Syntax Tree (**.vst**) file. **ncvlog** also performs syntax and static semantics checks. NC-VHDL (**ncvhdl**) compiles your VHDL code into a VHDL Syntax Tree (**.ast**) file. **ncvhdl** also performs syntax and static semantics checks.
ncelab	NC-Elab (**ncelab**) elaborates the design. **ncelab** constructs the design hierarchy and establishes signal connectivity. This program also generates a Signature File (**.sig**) and a Simulation SnapShot File (**.sss**).
ncsim	NC-Sim (**ncsim**) performs mixed-language simulation. This program is the simulation kernel that performs event scheduling and executes the simulation code.

Quartus II Software and NC Simulation Flow Overview

This section provides an overview of the Quartus II software and Cadence NC simulation flow. More detailed information is provided in "RTL Functional Simulation" on page 4–7, "Post-Synthesis Simulation" on page 4–17, and "Gate-Level Timing Simulation" on page 4–19.

For high-speed simulation, you must select **ps** in the **Resolution** list for your simulator resolutions. If you choose slower than **ps**, the high-speed simulation might fail.

Perform the following steps:

1. Set up your working environment (UNIX only).

   You must set several environment variables in UNIX to establish an environment that facilitates entering and processing designs.

2. Create user libraries.

   Create a file that maps logical library names to their physical locations. These library mappings include your working directory and any design-specific libraries; for example, Altera LPM functions or megafunctions.

3. Compile source code and testbenches.

   Compile your design files at the command-line using **ncvlog** (Verilog HDL files) or **ncvhdl** (VHDL files) or, on the Tools menu, click **Verilog Compiler** or **VHDL Compiler** in NCLaunch. During compilation, the NC software performs syntax and static semantic checks. If no errors are found, compilation produces an internal representation for each HDL design unit in the source files. By default, these intermediate objects are stored in a single, packed, library database file in your working directory.

4. Elaborate your design.

   Before you can simulate your model, you must define the design hierarchy in a process called "elaboration". Use **ncelab** in command-line mode or, on the Tools menu in NCLaunch, click **Elaborator**.

5. Add signals to your waveform.

   Before simulating, specify which signals to view in your waveform using a simulation history manager (SHM) database.

6. Simulate your design.

   Run the simulator with the **ncsim** program (command-line mode) or by clicking **Run** in the SimVision Console window.

Compile Libraries Using the EDA Simulation Library Compiler

The EDA Simulation Library Compiler is used to compile Verilog HDL and VHDL simulation libraries for all Altera devices and supported third-party simulators. You can use this tool to compile all libraries required by RTL and gate-level simulation.

When the compilation targets third-party simulation tools such as ModelSim, VCS-MX, Active-HDL, Riviera-PRO, and NC-Sim, the compiled libraries are kept in either the directory you set or the default directory. When you perform the simulation using these simulators, you can use or re-use the compiled libraries and avoid the overhead associated with redundant library compilations.

However, if the Synopsys VCS software performs the compilation while running the EDA Simulation Library Compiler, the option files (**simlib_comp.vcs**) are generated after compilation. You can then include your design and testbench files in the option files and invoke them with the `vcs` command.

Before using this option, ensure the appropriate simulation tools are already installed and their paths are specified. To specify the path, refer to "Setting Up NativeLink" on page 4–29.

Run the EDA Simulation Library Compiler through the GUI

Starting with the Quartus II software 9.0 release, the EDA Simulation Library Compiler contains a GUI. To compile libraries with the EDA Simulation Library Compiler GUI, perform the following steps:

1. On the Tools menu, click **EDA Simulation Library Compiler**. The **EDA Simulation Library Compiler** dialog box appears.
2. In the **Tool name** entry box under **EDA simulation tool**, select a simulation tool.

   The **Executable location** box displays the location of the simulation tool you specified. This location must be set before running the EDA Simulation Library Compiler.
3. Under **Library families**, select one or more device families for your design compilation and move them to **Selected families** box.
4. Under **Library language**, select **VHDL**, **Verilog**, or both.
5. In the **Output directory** field, specify a location in which to store the compiled libraries or option files.
6. Click **Start Compilation**.

For example, if you want to simulate a Verilog HDL design on a Stratix® II device in the NC-Sim simulator, do the following:

- Select **NC-Sim** in the **Tool name** field.
- Move **Stratix II** from the **Available families** list to the **Selected families** list.
- Select **Verilog** in the **Library language** field.
- Specify a location in the **Output directory** field in which to keep the option file.
- Click **Start Compilation**.

When the EDA Simulation Library Compiler finishes, all required libraries are compiled and stored in the output location you specified. The next time you perform simulation in NC-Sim, you only have to compile your design and testbench files. You do not have to compile the Altera libraries again.

If you use NativeLink to run the simulation, refer to "Using the NativeLink Feature with NC-Sim" on page 4–29.

Run EDA Simulation Library Compiler In Command Line

You can run the EDA Simulation Library Compiler in the command line. Type the following command:

```
quartus_sh --simlib_comp -family <device> -tool <simulation tool name>
-language <language> -directory <directory> ↵
```

For more information about the command's options and how to define them, type the following command:

```
quartus_sh --help=simlib_comp ↵
```

RTL Functional Simulation

The following sections provide detailed instructions for performing RTL functional simulation using the Quartus II software and the Cadence Incisive platform software tools.

Create Libraries

Before simulating with the Incisive simulator, you must set up libraries with a file named **cds.lib**. The **cds.lib** file is an ASCII text file that maps logical library names—for example, your working directory or the location of resource libraries such as models for LPM functions—to their physical directory paths. When you run the Incisive simulator, the tool reads **cds.lib** to determine which libraries are accessible and where they are located. There is also a default **cds.lib** file, which you can modify for your project settings.

You can use more than one **cds.lib** file. For example, you can have a project-wide **cds.lib** file that contains library settings specific to a project, such as technology or cell libraries and a user **cds.lib** file.

The following sections describe how to create and edit a **cds.lib** file:

- "Basic Library Setup" on page 4–7
- "LPM Functions, Altera Megafunctions, and Altera Primitive Library Setup" on page 4–9

Basic Library Setup

You can create a **cds.lib** file with any text editor. The following examples show how you use the `DEFINE` statement to bind a library name to its physical location. The logical and physical names can be the same or you can select different names. The `DEFINE` statement usage is:

```
DEFINE <library name> <physical directory path>
```

A simple **cds.lib** file for Verilog HDL contains the lines shown in Example 4–1.

Example 4–1. cds.lib File for Verilog HDL

```
DEFINE lib_std /usr1/libs/std_lib
DEFINE worklib ../worklib
```

Using Multiple cds.lib Files

Use the `INCLUDE` or `SOFTINCLUDE` statement to reference another **cds.lib** file within a **cds.lib** file. The syntax is:

```
INCLUDE <path to another cds.lib>
```

or

```
SOFTINCLUDE <path to another cds.lib>
```

For VHDL or mixed-language simulation, in addition to the `DEFINE` statements, you must include the default **cds.lib** file (included with NC-Sim). The syntax for including the default **cds.lib** file is:

```
INCLUDE <path to NC installation>/tools/inca/files/cds.lib
```

or

```
INCLUDE $CDS_INST_DIR/tools/inca/files/cds.lib
```

The default **cds.lib** file, provided with NC tools, contains a `SOFTINCLUDE` statement to include other **cds.lib** files, such as **cdsvhdl.lib** and **cdsvlog.lib**. These files contain library definitions for IEEE libraries and Synopsys libraries.

Create a cds.lib File in Command-Line Mode

To create a **cds.lib** file at the command prompt, perform the following steps:

1. Create a directory for the work library and any other libraries you require by typing the following at a command prompt:

   ```
   mkdir <library name> ↵
   ```

   For example: `mkdir worklib` ↵

2. Using a text editor, create a **cds.lib** file and add the following line to it:

   ```
   DEFINE <library name> <physical directory path>
   ```

   For example: `DEFINE worklib ./worklib` ↵

Create a cds.lib File in GUI Mode

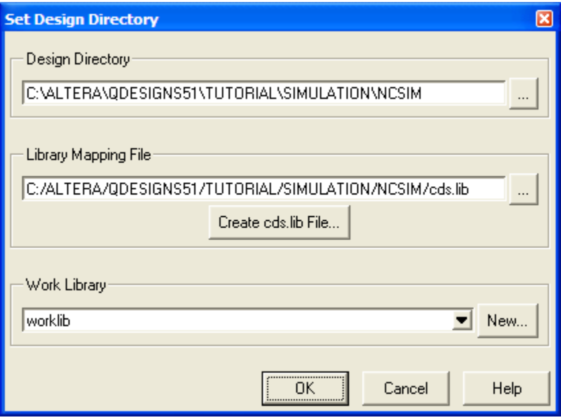
To create a **cds.lib** file using the GUI, perform the following steps:

1. To run the GUI, at the command line, type the following command:

   ```
   nclaunch ↵
   ```

2. If the NCLaunch window is not in multiple step mode, on the File menu, click **Switch to Multiple Step**.
3. Change your design directory. On the File menu, click **Set Design Directory**. The **Set Design Directory** dialog box appears (Figure 4–2).

Figure 4–2. Creating a Work Directory in GUI Mode



4. To navigate to your design directory, click **Browse**.
5. Click **Create cds.lib File**. In the **New cds.lib File** dialog box, click **Save** and choose the libraries to include.
6. Under **Work Library**, click **New**.
7. Enter your new work library name; for example, `worklib`.

8. Click **OK**. The new library is displayed under **Work Library**. Figure 4–2 shows an example using the directory name **worklib**.
9. Repeat steps 7 and 8 for each functional simulation library. For example: `lpm`, `altera_mf`, `altera`.
10. In the **Set Design Directory** dialog box, click **OK**.

You can edit your libraries by editing the **cds.lib** file. To edit the **cds.lib** file, in the right side of the window, right-click the **cds.lib** filename and choose **Edit**.

LPM Functions, Altera Megafunctions, and Altera Primitive Library Setup

Altera provides behavioral descriptions for LPM functions, Altera-specific megafunctions, and Altera primitives. You can implement the megafunctions in a design using the Quartus II MegaWizard™ Plug-In Manager, or by instantiating them directly from your design file. If your design uses LPM functions, Altera megafunctions, or Altera primitives, you must set up resource libraries so you can simulate your design in the Incisive simulator.

Many LPM functions and Altera megafunctions use memory files. You must convert the memory files into a format the Incisive tools can read before simulating. To covert the memory files, follow the instructions in “Compile Source Code and Testbenches” on page 4–11.

Altera provides megafunction behavioral descriptions in the files shown in Table 4–3. These library files are located in the <*path to Quartus II installation*>/**eda**/**sim_lib** directory.

For more information about LPM functions and Altera megafunctions, refer to the Quartus II Help.

Table 4–3. Megafunction Behavioral Description Files (Part 1 of 2)

Library Description	Verilog HDL	VHDL
LPM	**220model.v**	**220model.vhd** *(1)* **220model_87.vhd** *(2)* **220pack.vhd**
Altera megafunction	**altera_mf.v**	**altera_mf.vhd** *(1)* **altera_mf_87.vhd** *(2)* **altera_components.vhd**
Altera primitives	**altera_primitives.v**	**altera_primitives.vhd** *(1)* **altera_primitives_components.vhd**
IP functional simulation models	**sgate.v**	**sgate.vhd** **sgate_pack.vhd**
ALTGXB	**stratixgx_mf.v** *(3)*	**stratixgx_mf.vhd** *(3)* **stratixgx_mf_components.vhd** *(3)*

Table 4–3. Megafunction Behavioral Description Files (Part 2 of 2)

Library Description	Verilog HDL	VHDL
ALT2GXB	**stratixiigx_hssi_atoms.v**, **arriagx_hssi_atoms.v** *(3)*, *(4)*	**stratixiigx_hssi_atoms.vhd** **stratixiigx_hssi_components.vhd** **arriagx_hssi_atoms.vhd** **arriagx_hssi_components.vhd** *(3)*, *(4)*
ALTGX	**stratixiv_hssi_atoms.v**	**stratixiv_hssi_atoms.vhd** **stratixiv_hssi_components.vhd**

Notes to Table 4–3:

(1) Use this model with VHDL 93.

(2) Use this model with VHDL 87.

(3) The ALT2GXB and ALTGXB library files require the **lpm** and **sgate** libraries.

(4) You must generate a functional simulation netlist for simulation.

If an `lpm` library does not exist, set up a library for LPM functions. Create a new directory and add the following line to your **cds.lib** file:

```
DEFINE lpm <path>/<directory name>
```

If an `altera_mf` library does not exist, set up a library for Altera megafunctions. Add the following line to your **cds.lib** file:

```
DEFINE altera_mf <path>/<directory name>
```

Megafunctions Requiring Atom Libraries

The following Altera megafunctions require device atom libraries to perform a functional simulation in a third-party simulator:

- ALTCLKBUF
- ALTCLKCTRL
- ALTDQ
- ALTDQS
- ALTDDIO_IN
- ALTDDIO_OUT
- ALTDDIO_BIDIR
- ALTUFM_NONE
- ALTUFM_PARALLEL
- ALTUFM_SPI
- ALTMEMMULT
- ALTREMOTE_UPDATE

For more information about these megafunctions, refer to the Literature: Megafunctions section of the Altera website.

The device atom library files are located in the following directory:

*<path to Quartus II installation>***/eda/sim_lib**

Compile Source Code and Testbenches

Compile your testbench and design files with **ncvlog** (for Verilog HDL files) and **ncvhdl** (for VHDL files). Both **ncvlog** and **ncvhdl** perform syntax checks and static semantic checks. A successful compilation produces an internal representation for each HDL design unit in the source files. By default, these intermediate objects are stored in a single, packed, library database file in your work library directory.

Compilation in Command-Line Mode

To compile from the command line, use one of the following commands:

- Verilog HDL:

  ncvlog <*options*> -work <*library name*> <*design files*> ↵

- VHDL:

  ncvhdl <*options*> -work <*library name*> <*design files*> ↵

You must create a work library before compiling.

If your design uses LPM, Altera megafunctions, or Altera primitives, you must also compile the Altera-provided functional models. The commands in Example 4–2 and Example 4–3 show an example of each.

Example 4–2. Creating a Work Directory in GUI Mode in Verilog HDL

```
ncvlog -WORK lpm 220model.v
ncvlog -WORK altera_mf altera_mf.v
ncvlog -WORK altera altera_primitives.v
```

Example 4–3. ncvlog -WORK altera altera_primitives.v in VHDL

```
ncvhdl -V93 -WORK lpm 220pack.vhd
ncvhdl -V93 -WORK lpm 220model.vhd
ncvhdl -V93 -WORK altera_mf altera_mf_components.vhd
ncvhdl -V93 -WORK altera_mf altera_mf.vhd
ncvhdl -V93 -WORK altera altera_primitives_components.vhd
ncvhdl -V93 -WORK altera altera_primitives.vhd
```

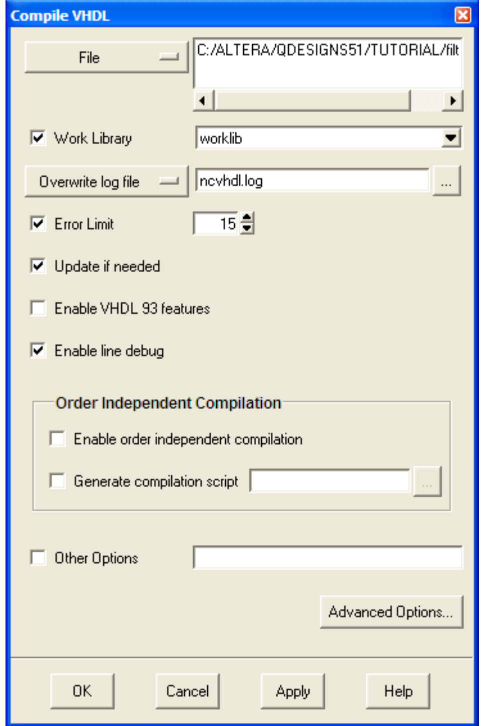
Compilation in GUI Mode

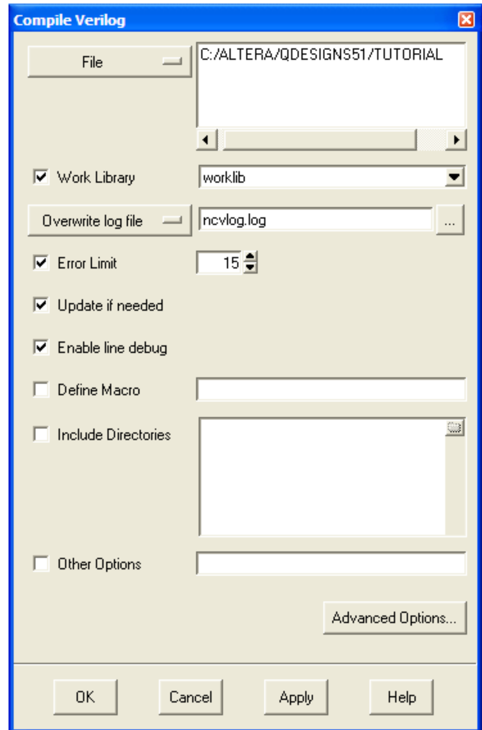
To compile using the NCLaunch GUI, perform the following steps:

1. In the NCLaunch window, right-click a library filename and click **NCVlog** (Verilog HDL) or **NCVhdl** (VHDL).

   Alternatively, on the Tools menu, click **Verilog Compiler** or **VHDL Compiler**. Figure 4–3 shows the **Compile Verilog** and **Compile VHDL** dialog boxes.

Figure 4–3. Compiling Verilog HDL and VHDL Files





2. To begin compilation, in the **Compile Verilog** or **Compile VHDL** dialog box, select the file. Click **OK**. The dialog box closes and returns you to **NCLaunch**.

The command-line equivalent argument is shown at the bottom of the **NCLaunch** window.

Elaborate Your Design

Before you can simulate your design, you must define the design hierarchy in a process called elaboration. When you use the Incisive simulator, you use the language-independent **ncelab** program to elaborate your design. The **ncelab** program constructs a design hierarchy based on the design's instantiation and configuration information, establishes signal connectivity, and computes initial values for all objects in the design. The elaborated design hierarchy is stored in a simulation snapshot, which is the representation of your design that the simulator uses to run the simulation. The snapshot is stored in the library database file, along with the other intermediate objects generated by the compiler and elaborator.

If you are running the NC-Verilog simulator with the single-step invocation method (`ncverilog`), and want to compile your source files and elaborate the design with one command, use the `+elaborate` option to stop the simulator after elaboration; for example:

```
ncverilog +elaborate test.v ↵
```

© March 2009 Altera Corporation

Elaboration in Command-Line Mode

To elaborate your Verilog HDL or VHDL design from the command line, use the following command:

```
ncelab [options][<library>.]<cell>[:<view>] ↵
```

You can set your simulation timescale using the `-TIMESCALE` <*arguments*> option. The following example elaborates a dual-port RAM with the time scale option:

```
ncelab -TIMESCALE 1ps/1ps worklib.lpm_ram_dp_test:entity ↵
```

If you specified a timescale of 1 ps in the Verilog HDL testbench, the `TIMESCALE` option is not necessary. Using a ps resolution ensures the correct simulation of your design.

If your design includes high speed signals, you might have to add the following pulse reject options with the `ncelab` command.

```
ncelab -TIMESCALE 1ps/1ps worklib.mydesign:entity -PULSE_R 0 -PULSE_INT_R 0 ↵
```

For more information about the pulse reject options, refer to the *SDF Annotate Guide* from Cadence.

To list the elements in your library and the available views, use the **ncls** program. The following command displays all of the cells and their views in your current **worklib** directory:

```
ncls -library worklib ↵
```

For more information about the **ncls** program, refer to the Cadence NC-Verilog Simulator Help or Cadence NC-VHDL Simulator Help.

Elaboration in GUI Mode

To elaborate using the GUI, perform the following steps:

1. In the right side of the NCLaunch window, expand your current work library.
2. Select and (if necessary) expand the entity or module name you want to elaborate.
3. Right-click the view you want to display. Click **NCElab**. The **Elaborate** dialog box appears. Optionally, on the Tools menu, click **Elaborator**.
4. In the **Other Options** box, set the simulation timescale by typing the following command :

   ```
   -TIMESCALE 1ps/1ps ↵
   ```

5. To begin elaboration, in the **Elaborate** dialog box, click **OK**. The dialog box closes and returns you to **NCLaunch**.

Add Signals to View

The SHM database is a Cadence proprietary waveform database that stores selected signals for viewing. To specify which signal to view, you must create a database. To create this database, add commands to your code, or create a Verilog Value Change Dump File (**.vcd**) to store the simulation history.

For more information about using a **.vcd** file, refer to the *Cadence NC-Sim User Manual* from Cadence included in the installation package.

Adding Signals in Command-Line Mode

To create an SHM database, specify the system tasks described in Table 4–4 in your Verilog HDL code.

For VHDL, you can use the Tcl command interface or C function calls to add signals to a database. Refer to the Cadence documentation included in the installation package for details.

Table 4–4. SHM Database System Tasks

System Task	Description
`$shm_open("<filename>.shm");`	Opens a database. If you do not specify a filename, the default **waves.shm** database opens. If a database with the specified name does not exist, it is created for you.
`$shm_probe("[A|S|C]");`	Probe signals. You can specify the signals to probe; if you do not specify signals, the default is all ports in the current scope. `A` probes all nodes in the current scope. `S` probes all nodes below the current scope. `C` probes all nodes below the current scope and in libraries.
`$shm_save;`	Saves the database.
`$shm_close;`	Closes the database.

Example 4–4 shows an example of how to add signals to an SHM database.

Example 4–4. Elaborating the Design

```
initial
   begin
      $shm_open ("waves.shm");
      $shm_probe ("AS");
    end
```

You can insert this code sample into your Verilog HDL file. It is applicable only for Verilog HDL files. For more information about these system tasks, refer to the *Cadence NC-Sim User Manua*l included in the installation.

Adding Signals in GUI Mode

To add signals in GUI mode, perform the following steps:

1. In the NC-Sim software, load the design.

   a. In the **NCLaunch** window, click the "**+**" icon to expand the **Snapshots** directory.

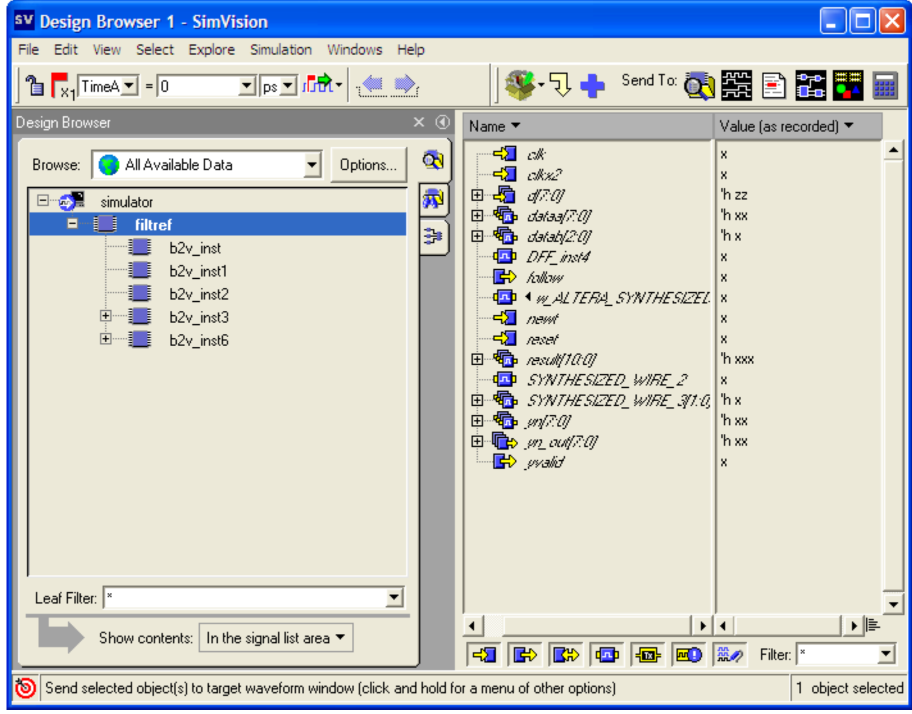
   b. Right-click the **lib.cell:view** you want to simulate. Click **NCSim**.

   c. In the **Simulate** dialog box, click **OK**.

   After you load the design, the SimVision Console and SimVision Design Browser windows appear. Figure 4–4 shows the SimVision Design Browser window.

2. To display the signal names, in the Design Browser window, on the left side of the window select a module (Figure 4–4).

Figure 4–4. SimVision Design Browser



3. To send the selected signals to the Waveform Viewer, perform one of the following steps:

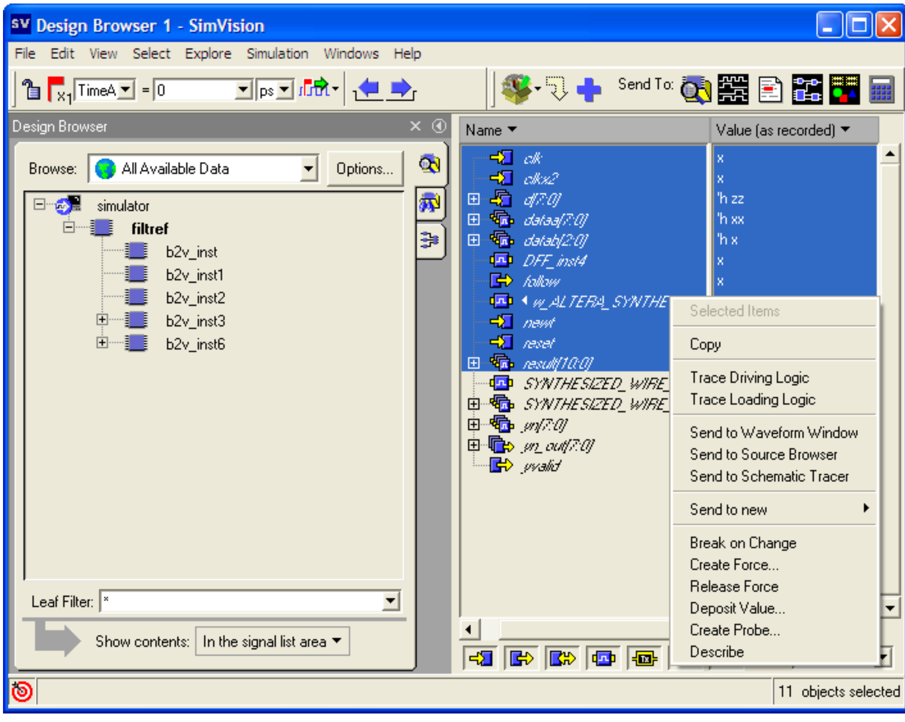
   Select a group of signals from the right side of the Design Browser window. In the **Send To** toolbar (the upper-right area of the Design Browser window), click the Send to Waveform Viewer icon.

   or

   Right-click the signals and click **Send to Waveform Window** (Figure 4–5).

   A waveform window showing all of your signals appears. You are now ready to simulate your testbench and design.

Figure 4–5. Selecting Signals in the Design Browser Window



Simulate the Design

After you have compiled and elaborated your design, you can simulate it using **ncsim**. The **ncsim** program loads the file or snapshot generated by **ncelab** as its primary input. It then loads other intermediate objects referenced by the snapshot. If you enable interactive debugging, it might also load HDL source files and script files. The simulation output is controlled by the model or debugger. The output can include result files generated by the model, SHM database, or **.vcd** file.

RTL Functional Simulation in Command-Line Mode

To perform RTL functional simulation of your Verilog HDL or VHDL design at the command line, type the following command:

```
ncsim [options][<library>.]<cell>[:<view>] ↵
```

For example:

```
ncsim worklib.lpm_ram_dp:syn ↵
```

Table 4–5 shows some of the options you can use with **ncsim**.

Table 4–5. ncsim Options

Options	Description
`-gui`	Launch GUI mode
`-batch`	Used for non-interactive mode
`-tcl`	Used for interactive mode (not required when using `–gui`)

RTL Functional Simulation in GUI Mode

You can run and step through simulation of your Verilog HDL or VHDL design in the GUI. In the Design Browser window, on the Simulation menu, click **Run** to begin the simulation.

You must load the design before simulating. If you have not done so, refer to step 1 in "Adding Signals in GUI Mode" on page 4–14 for instructions.

Post-Synthesis Simulation

The following sections provide detailed instructions for performing post-synthesis simulation using Quartus II output files, simulation libraries, and the Incisive platform software.

Quartus II Simulation Output Files

After performing synthesis with either a third-party synthesis tool or with Quartus II integrated synthesis, you must generate a simulation netlist for functional simulations. To generate a simulation netlist for functional simulation, perform the following steps in the Quartus II software:

1. Perform Analysis and Synthesis. On the Processing menu, point to **Start** and click **Start Analysis & Synthesis**.
2. Turn on the **Generate Netlist for Functional Simulation Only** option by performing the following steps:
   a. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
   b. In the **Category** list, click the "+" symbol to expand the **EDA Tool Settings** list.
   c. Under **EDA Tool Settings**, click **Simulation**.
   d. In the **Tool name** list, from the pull-down menu, select **NCSim**.
   e. Under **EDA Netlist Writer options**, in the **Format for output netlist** list, select **VHDL** or **Verilog**.

      You can also modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
   f. Click the **More EDA Netlist Writer Settings** button. The **More EDA Netlist Writer Settings** dialog box appears.
   g. In the **Existing options settings list**, click **Generate Netlist for Functional Simulation Only**.
   h. From the **Setting** list under **Option**, from the pull-down list, click **On**.
   i. Click **OK**.
   j. In the **Settings** dialog box, click **OK**.
3. Run the EDA Netlist Writer. On the Processing menu, point to **Start** and click **Start EDA Netlist Writer**.

During the EDA Netlist Writer stage, the Quartus II software produces a **.vo** file or **.vho** file that can be used for post-synthesis simulations in the NC-Sim software. This netlist file is mapped to architecture-specific primitives. No timing information is included at this stage. The resulting netlist is located in the output directory you specified in the **Settings** dialog box, which defaults to the *<project directory>***/simulation/NCSim** directory.

Create Libraries

Create the following libraries for your simulation:

- Work library
- Device family library targeting your design targets using the following files in the *<path to Quartus II installation>***/eda/sim_lib** directory:
  - *<device_family>***_atoms.v**
  - *<device_family>***_atoms.vhd**
  - *<device_family>***_components.vhd**

Compile Project Files and Libraries

Compile the project files and libraries into your work directory using the **ncvlog** or **ncvhdl** programs or the GUI. Include the following files:

- Testbench file
- The Quartus II software functional output netlist file (**.vo** file or **.vho** file)
- Atom library file for the device family *<device family>***_atoms.***<v | vhd>*
- For VHDL, *<device family>***_components.vhd**

Refer to the section "Compile Source Code and Testbenches" on page 4–11 for instructions about compiling.

Elaborate Your Design

Elaborate your design using the **ncelab** program as described in "Elaboration in GUI Mode" on page 4–13.

Add Signals to the View

Refer to the section "Add Signals to View" on page 4–13 for information about adding signals to the view.

Simulate Your Design

Simulate your design using the **ncsim** program as described in "Simulate the Design" on page 4–16.

Gate-Level Timing Simulation

The following sections provide detailed instructions for performing timing simulation using the Quartus II output files, simulation libraries, and Cadence NC tools.

Generating a Gate-Level Timing Simulation Netlist

To perform gate-level timing simulation, the NC-Sim software requires information about how the design was placed into device-specific architectural blocks. The Quartus II software provides this information in the form of a **.vo** file for Verilog HDL designs and a **.vho** file for VHDL designs. The accompanying timing information is stored in the **.sdo** file, which annotates the delay for the elements found in the **.vo** file or **.vho** file.

To generate the **.vo** or **.vho** file and the **.sdo** file, perform the following steps:

1. Perform a full compilation. On the Processing menu, click **Start Compilation**.
2. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
3. In the **Category** list, select **Simulation**. The **Simulation** page appears.
4. In the **Tool name** list, select **NCSim**.
5. Under **EDA Netlist Writer options**, in the **Format for output netlist** list, select **VHDL** or **Verilog**. You can also modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
6. Click **OK**.
7. Run the EDA Netlist Writer. On the Processing menu, point to **Start** and click **Start EDA Netlist Writer**.

During the EDA Netlist Writer stage, the Quartus II software produces a **.vo** file, **.vho** file, and an **.sdo** file used for gate-level timing simulations in the NC-Sim software. This netlist file is mapped to architecture-specific primitives. The timing information for the netlist is included in the **.sdo** file. The resulting netlist is located in the output directory you specified in the **Settings** dialog box, which defaults to the <*project directory*>**/simulation/ncsim** directory.

Generating a Timing Netlist with Different Timing Models

To generate the timing netlist in Stratix III and later devices (for example, Cyclone® III and Stratix IV), you can specify different temperature and voltage parameters. Using the Quartus II Classic or Quartus II TimeQuest Timing Analyzer when generating the simulation netlist files (***.vo** or ***.vho** and ***.sdo**), produces different timing models for different operating conditions. The multi-corner timing analysis is run by default during the full compilation.

Table 4–6 shows the example of default available operation conditions (model, voltage, and temperature) for Stratix III and Cyclone III devices.

Table 4–6. Default Available Operating Condition for Stratix III and Cyclone III Devices

Device Family	Model	Voltage	Temperature (°C)
Stratix III	Slow	1100 mV	85°
	Slow	1100 mV	0°
	Fast	1100 mV	0°
Cyclone III	Slow	1200 mV	85°
	Slow	1200 mV	0°
	Fast	1200 mV	0°

If the multi-corner timing analysis is not run during full compilation, you should perform the following steps to manually generate the simulation netlist files (***.vo** or *.**vho** and *.**sdo**) for the three different operating conditions listed in Table 4–6:

1. Generate all the available corner models at all operating conditions. Type the following command at a command prompt:

```
quartus_sta <project name> --multicorner ↵
```

2. Generate the simulation output files for all three corners specified in Table 4–6. Perform steps 2 through 7 in “Generating a Gate-Level Timing Simulation Netlist” on page 4–19. The output files are generated in the simulation output directory.

The following example shows all generated simulation netlist files for the three operating conditions of the preceding steps, when selecting **Verilog** as the output netlist format:

First slow corner (slow, 1100 mV, 85° C)

.vo file— <*revision name*>**.vo**

.sdo file— <*revision name*>**_v.sdo**

The <*revision_name*>**.vo** and <*revision name*>**_v.sdo** are generated for backward compatibility in case there are existing scripts that still use them.

.vo file— <*revision name*>_<*speedgrade*>**_1100mv_85c_slow.vo**

.sdo file— <*revision name*>_<*speedgrade*>**_1100mv_85c_v_slow.sdo**

Second slow corner (slow, 1100 mV, 0° C)

.vo file— <*revision name*>_<*speedgrade*>**_1100mv_0c_slow.vo**

.sdo file— <*revision name*>_<*speedgrade*>**_1100mv_0c_v_slow.sdo**

Fast corner (fast, 1100 mV, 0° C)

.vo file— <*revision name*>**_min_1100mv_0c_fast.vo**

.sdo file— <*revision name*>**_min_1100mv_0c_v_fast.sdo**

For all other older families, a slow-corner (worst case) timing model is used by default. There are only two timing models available: slow-corner and fast-corner. To generate the **.sdo** file using a different timing model, you must run the Quartus II Classic or the Quartus II TimeQuest Timing Analyzer with a different timing model before you start the EDA Netlist Writer.

To run the Quartus II Classic Timing Analyzer with the best-case model, on the Processing menu, point to **Start** and click **Start Classic Timing Analyzer (Fast Timing Model)**. After the timing analysis is complete, the Compilation Report appears. You can also type the following command at a command prompt:

```
quartus_tan <project_name> --fast_model=on ↵
```

To run the Quartus II TimeQuest Timing Analyzer with a best-case model, use the **-fast_model** option after you create the timing netlist. The following command enables the fast timing models:

```
create_timing_netlist --fast_model ↵
```

After you run the Quartus II Classic or Quartus II TimeQuest Timing Analyzer, you can perform steps 2 through 7 in "Generating a Gate-Level Timing Simulation Netlist" on page 4–19 to generate the ***.sdo** file. For fast corner timing models, the **-fast** post fix is added to the ***.vo** or ***.vho** and ***.sdo** files (for example, **my_project_fast.vo** or **my_project_fast.vho**, and **my_project_fast.sdo**).

For more information about generating a timing netlist with different timing models, refer to the *Quartus II Classic Timing Analyzer* or the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Disable Timing Violation on Registers

In certain situations, the timing violations can be ignored and you can disable the timing violation on registers. For example, timing violations that occur in internal synchronization registers used for asynchronous clock-domain crossing.

By default, the **x_on_violation_option logic** option is **On**, which means the simulation shows "**X**" whenever a timing violation occurs. To disable showing the timing violation on certain registers, you can set the **x_on_violation_option logic** option to **Off** for those registers. The following command is the Quartus II Tcl command to disable timing violation on registers. This Tcl command is also stored in the **.qsf** file.

```
set_instance_assignment -name X_ON_VIOLATION_OPTION OFF -to \
<register_name>
```

Perform Timing Simulation Using Post-Synthesis Netlist

You can perform a timing simulation using the post-synthesis netlist instead of using a gate-level netlist and you can generate a **.sdo** file without running the Fitter. In this case, the **.sdo** file includes all timing values for the device cells only. Interconnect delays are not included because fitting (placement and routing) has not been performed.

To generate the post-synthesis netlist and the **.sdo** file, type the following at a command prompt:

```
quartus_map <project name> -c <revision name> ↵
quartus_tan <project name> -c <revision name> --post_map --zero_ic_delays ↵
quartus_eda <project name> -c <revision name> --simulation --tool=<3rd party EDA tool> \
--format=<HDL language> ↵
```

For more information about the `-format` and `-tool` options, type the following command at a command prompt:

```
quartus_eda -help=<options> command ↵
```

Quartus II Timing Simulation Libraries

Altera device simulation library files are provided in the <*Quartus II installation*>/**eda**/**sim_lib** directory. The **.vo** file or **.vho** file requires the library for the device your design targets. For example, the Stratix device family requires the following library files:

- **stratix_atoms.v**
- **stratix_atoms.vhd**
- **stratix_components.vhd**

If your design targets a Stratix device, you must set up the appropriate mappings in your **cds.lib** file. Refer to "Create Libraries" for more information.

Create Libraries

Create the following libraries for your simulation:

- Work library
- Device family libraries targeting using the following files in the <*path to Quartus II installation*>/**eda**/**sim_lib** directory:
  - <*device_family*>**_atoms.v**
  - <*device_family*>**_atoms.vhd**
  - <*device_family*>**_components.vhd**

For instructions for creating libraries, refer to "Basic Library Setup" on page 4–7 and "LPM Functions, Altera Megafunctions, and Altera Primitive Library Setup" on page 4–9.

Compile the Project Files and Libraries

Compile the project files and libraries into your work directory using the **ncvlog** or **ncvhdl** programs or the GUI. Include the following files:

- Testbench file
- The Quartus II software functional output netlist file (**.vo** file or **.vho** file)
- Atom library file for the device family <*device family*>**_atoms.**<*v* | *vhd*>
- For VHDL, <*device family*>**_components.vhd**

For instructions about compiling, refer to "Compile Source Code and Testbenches" on page 4–11.

Elaborate Your Design

When performing elaboration with the Quartus II-generated Verilog HDL netlist file, the Standard Delay Format Output File is read automatically. When you run **ncelab**, it recognizes the embedded system task `$sdf_annotate` and automatically compiles and annotates the Standard Delay Format Output File (runs **ncsdfc** automatically).

The Standard Delay Format Output File should be located in the same directory where you invoke an elaboration or simulation, because the `$sdf_annotate` task references the Standard Delay Format Output File without using a full path. If you are invoking an elaboration or simulation from a different directory, you can either comment out the `$sdf_annotate` and annotate the Standard Delay Format Output File with the GUI, or add the full path of the Standard Delay Format Output File.

Refer to "Elaborate Your Design" on page 4–12 for instructions for elaboration.

For VHDL, the Quartus II software-generated VHDL netlist file does not contain system task calls to locate your **.sdf** file; therefore, you must compile the Standard Delay Format Output File manually. For information about compiling the Standard Delay Format Output File, refer to "Compiling the Standard Delay Output File (VHDL Only) in Command-Line Mode" and "Compiling the Standard Delay Output File (VHDL Only) in GUI Mode".

Compiling the Standard Delay Output File (VHDL Only) in Command-Line Mode

To annotate the Standard Delay Format Output File timing data from the command line, perform the following steps:

1. Compile the Standard Delay Format Output File using the **ncsdfc** program by typing the following command at the command prompt:

   ```
   ncsdfc <project name>_vhd.sdo -output <output name> ↵
   ```

   The **ncsdfc** program generates an *<output name>***.sdf.X** compiled **.sdo** file.

   If you do not specify an output name, **ncsdfc** uses *<project name>***.sdo.X**.

2. Specify the compiled **.sdf** file for the project by adding the following command to an ASCII SDF command file for the project:

   ```
   COMPILED_SDF_FILE = "<project name>.sdf.X" SCOPE = <instance path>
   ```

Example 4–5 shows an example of an SDF command file.

Example 4–5. SDF Command File

```
// SDF command file sdf_file
COMPILED_SDF_FILE = "lpm_ram_dp_test_vhd.sdo.X",
SCOPE = :tb,
MTM_CONTROL = "TYPICAL",
SCALE_FACTORS = "1.0:1.0:1.0",
SCALE_TYPE = "FROM_MTM";
```

After you compile the **.sdf** file, type the following command to elaborate the design:

```
ncelab worklib.<project name>:entity -SDF_CMD_FILE <SDF Command File> ↵
```

Compiling the Standard Delay Output File (VHDL Only) in GUI Mode

To annotate the **.sdo** file timing data in the GUI, in the **NCLaunch** window, perform the following steps:

1. On the Tools menu, click **SDF Compiler**. The **Compile SDF** dialog box appears.
2. In the **SDF File** box, type the name of the **.sdo** file for the project.

3. Click **OK**.

   When the **.sdo** file compilation is complete, you can elaborate the design. Refer to "Elaboration in GUI Mode" on page 4–13 for instructions.

   If you perform a VHDL gate-level timing simulation, you must create an SDF command file before you begin elaboration. To create the SDF command file, continue the procedure.

4. On the Tools menu, click **Elaborator**. The **Elaborate** dialog box appears.
5. Click **Advanced Options**.
6. Click **Annotation**.
7. Turn on **Use SDF File**.
8. Click **Edit**.
9. Browse to the location of the SDF command file name.
10. Click **Add** and browse to the location of the **.sdo** file in the **Compiled SDF File** box and click **OK**.
11. Click **OK** to save and exit the **SDF Command File** dialog box.

Add Signals to View

Refer to the section "Add Signals to View" on page 4–13 for information about adding signals to view.

Simulate Your Design

Simulate your design using the **ncsim** program as described in "Simulate the Design" on page 4–16.

For the design examples to run gate-level timing simulation, refer to the Cadence NC-Sim Simulation Design Example web page.

Simulating Designs that Include Transceivers

If your design includes a Stratix IV, Stratix II GX, Stratix GX, Arria® II GX, or Arria GX transceiver, you must compile additional library files to perform RTL functional or gate-level timing simulations.

For high-speed simulation, you must select **ps** in the **Resolution** list for your simulator resolutions. If you choose slower than **ps**, the high-speed simulation might fail.

Stratix GX RTL Functional Simulation

To perform an RTL functional simulation of your design that instantiates the ALTGXB megafunction, enabling the gigabit transceiver block (GXB) on Stratix GX devices, compile the **stratixgx_mf** model file into the **altgxb** library.

The **stratixgx_mf** model file references the **lpm** and **sgate** libraries, so you must create these libraries to perform a simulation.

Compiling Library Files for Functional Stratix GX Simulation in VHDL

To compile the libraries necessary for functional simulation of a VHDL design targeting a Stratix GX device, type the commands shown in Example 4–6 at the NC-Sim command prompt.

Example 4–6. Compile Libraries Commands for Functional Simulation in VHDL

```
ncvhdl -work lpm 220pack.vhd 220model.vhd
ncvhdl -work altera_mf altera_mf_components.vhd altera_mf.vhd
ncvhdl -work sgate sgate_pack.vhd sgate.vhd
ncvhdl -work altgxb stratixgx_mf.vhd stratixgx_mf_components.vhd
ncsim work.<my design>
```

Compiling Library Files for Functional Stratix GX Simulation in Verilog HDL

To compile the libraries necessary for a functional simulation of a Verilog HDL design targeting a Stratix GX device, type the commands shown in Example 4–7 at the NC-Sim command prompt.

Example 4–7. Compile Libraries Commands for Functional Simulation in Verilog HDL

```
ncvlog -work lpm 220model.v
ncvlog -work altera_mf altera_mf.v
ncvlog -work sgate sgate.v
ncvlog -work altgxb stratixgx_mf.v
ncsim work.<my design>
```

Stratix GX Gate-Level Timing Simulation

To perform a gate-level timing simulation of your design that includes a Stratix GX transceiver, compile the **stratixgx_atoms** and **stratixgx_hssi_atoms** model files into the **stratixgx** and **stratixgx_gxb** libraries, respectively.

You must create these libraries to perform a simulation because the **stratixgx_hssi_atoms** model file references the **lpm** and **sgate** libraries.

Compiling Library Files for Timing Stratix GX Simulation in VHDL

To compile the libraries necessary for timing simulation of a VHDL design targeting a Stratix GX device, type the commands shown in Example 4–8 at the NC-Sim command prompt.

Example 4–8. Compile Libraries Commands for Timing Simulation in VHDL

```
ncvhdl -work lpm 220pack.vhd 220model.vhd
ncvhdl -work altera_mf altera_mf_components.vhd altera_mf.vhd
ncvhdl -work sgate sgate_pack.vhd sgate.vhd
ncvhdl -work stratixgx stratixgx_atoms.vhd stratixgx_components.vhd
ncvhdl -work stratixgx_gxb stratixgx_hssi_atoms.vhd \
stratixgx_hssi_components.vhd
ncelab work.<my design> -TIMESCALE 1ps/1ps -PULSE_R 0 -PULSE_INT_R 0
```

Compiling Library Files for Timing Stratix GX Simulation in Verilog HDL

To compile the libraries necessary for timing simulation of a Verilog HDL design targeting a Stratix GX device, type the commands shown in Example 4–9 at the NC-Sim command prompt.

Example 4–9. Compile Libraries Commands for Timing Simulation in Verilog HDL

```
ncvlog -work lpm 220model.v
ncvlog -work altera_mf altera_mf.v
ncvlog -work sgate sgate.v
ncvlog -work stratixgx stratixgx_atoms.v
ncvlog -work stratixgx_gxb stratixgx_hssi_atoms.v
ncelab work.<my design> -TIMESCALE 1ps/1ps -PULSE_R 0 -PULSE_INT_R 0
```

Stratix II GX RTL Functional Simulation

Stratix II GX functional simulation is similar to Arria GX functional simulation. Example 4–10 shows only the RTL functional simulation for designs that include transceivers in Stratix II GX. To simulate transceivers in Arria GX, replace the **stratixiigx_hssi** model file with the **arriagx_hssi** model file.

To perform an RTL functional simulation of your design that instantiates the ALT2GXB megafunction, edit your **cds.lib** file so all of the libraries point to the work library, and compile the **stratixiigx_hssi** model file into the **stratixiigx_hssi** library. When compiling the library files, you can safely ignore the following warning message:

```
"Multiple logical libraries mapped to a single location"
```

Example 4–10 shows the **cds.lib** file.

Example 4–10. cds.lib File

```
SOFTINCLUDE ${CDS_INST_DIR}/tools/inca/files/cdsvhdl.lib
SOFTINCLUDE ${CDS_INST_DIR}/tools/inca/files/cdsvlog.lib
DEFINE work ./ncsim_work
DEFINE stratixiigx_hssi ./ncsim_work
DEFINE stratixiigx ./ncsim_work
DEFINE lpm ./ncsim_work
DEFINE sgate ./ncsim_work
```

The **stratixiigx_hssi_atoms** model file references the **lpm** and **sgate** libraries, so you must create these libraries to perform a simulation.

Generate a functional simulation netlist by turning on **Create a simulation library for this design** in the last page of the ALT2GXB MegaWizard Plug-In Manager (Figure 4–6). The *<alt2gxb entity name>***.vho** or *<alt2gxb module name>***.vo** is generated in the current project directory.

Figure 4–6. ALT2GXB MegaWizard Plug-In Manager: Generate Simulation Model

The Quartus II generated ALT2GXB functional simulation library file references **stratixiigx_hssi** WYSIWYG atoms.

Compiling Library Files for Functional Stratix II GX Simulation in VHDL

To compile the libraries necessary for functional simulation of a VHDL design targeting a Stratix II GX device, type the commands shown in Example 4–11 at the NC-Sim command prompt.

Example 4–11. Compile Libraries Commands for Functional Simulation in VHDL

```
ncvhdl -work lpm 220pack.vhd 220model.vhd
ncvhdl -work altera_mf altera_mf_components.vhd altera_mf.vhd
ncvhdl -work sgate sgate_pack.vhd sgate.vhd
ncvhdl -work stratixiigx_hssi stratixiigx_hssi_components.vhd \
stratixiigx_hssi_atoms.vhd
ncvhdl -work work <alt2gxb entity name>.vho
ncelab work.<my design>
```

Compiling Library Files for Functional Stratix II GX Simulation in Verilog HDL

To compile the libraries necessary for functional simulation of a Verilog HDL design targeting a Stratix II GX device, type the commands shown in Example 4–12 at the NC-Sim command prompt.

Example 4–12. Compile Libraries Commands for Functional Simulation in Verilog HDL

```
ncvlog -work lpm 220model.v
ncvlog -work altera_mf altera_mf.v
ncvlog -work sgate sgate.v
ncvlog -work stratixiigx_hssi stratixiigx_hssi_atoms.v
ncvlog -work work <alt2gxb module name>.vo
ncelab work.<my design>
```

Stratix II GX Gate-Level Timing Simulation

Stratix II GX functional simulation is similar to Arria GX functional simulation. Example 4–13 shows only the gate-level timing simulation for designs that include transceivers in Stratix II GX. To simulate transceivers in Arria GX, replace the **stratixiigx_hssi** model file with the **arriagx_hssi** model file.

To perform a post-fit timing simulation of your design that includes the ALT2GXB megafunction, edit your **cds.lib** file so that all the libraries point to the work library and compile `stratixiigx_atoms` and `stratixiigx_hssi_atoms` into the **stratixiigx** and **stratixiigx_hssi** libraries, respectively. When compiling the library files, you can safely ignore the following warning message:

```
"Multiple logical libraries mapped to a single location"
```

For an example of a **cds.lib** file, refer to "Stratix II GX RTL Functional Simulation" on page 4–26.

The **stratixiigx_hssi_atoms** model file references the **lpm** and **sgate** libraries, so you must create these libraries to perform a simulation.

Compiling Library Files for Timing Stratix II GX Simulation in VHDL

To compile the libraries necessary for timing simulation of a VHDL design targeting a Stratix II GX device, type the commands shown in Example 4–13 at the NC-Sim command prompt.

Example 4–13. Compile Libraries Commands for Timing Simulation in VHDL

```
ncvhdl -work lpm 220pack.vhd 220model.vhd
ncvhdl -work altera_mf altera_mf_components.vhd altera_mf.vhd
ncvhdl -work sgate sgate_pack.vhd sgate.vhd
ncvhdl -work stratixiigx stratixiigx_atoms.vhd \
stratixiigx_components.vhd
ncvhdl -work stratixiigx_hssi stratixiigx_hssi_components.vhd \
stratixiigx_hssi_atoms.vhd
ncvhdl -work work <alt2gxb>.vho
ncelab work.<my design> -TIMESCALE 1ps/1ps -PULSE_R 0 -PULSE_INT_R 0
```

Compiling Library Files for Timing Stratix II GX Simulation in Verilog HDL

To compile the libraries necessary for timing simulation of a Verilog HDL design targeting a Stratix II GX device, type the commands shown in Example 4–14 at the NC-Sim command prompt.

Example 4–14. Compile Libraries Commands for Timing Simulation in Verilog HDL

```
ncvlog -work lpm 220model.v
ncvlog -work altera_mf altera_mf.v
ncvlog -work sgate sgate.v
ncvlog -work stratixiigx stratixiigx_atoms.v
ncvlog -work stratixiigx_hssi stratixiigx_hssi_atoms.v
ncelab work.<my design> -TIMESCALE 1ps/1ps -PULSE_R 0 -PULSE_INT_R 0
```

Pulse Reject Delays

By default, the NC-Sim software filters out all pulses that are shorter than the propagation delay between primitives. Setting the pulse reject delays (similar to transport delays) options in the NC-Sim software prevents the simulation tool from filtering out these pulses. Use the following options to ensure that all signal pulses are seen in the simulation results.

-PULSE_R

Use this option when the pulses in your simulation are shorter than the delay within a gate-level primitive. The argument is the percentage of delay for pulse reject limit for the path.

-PULSE_INT_R

Use this option when the pulses in your simulation are shorter than the interconnect delay between gate-level primitives. The argument is the percentage of delay for pulse reject limit for the path. The `-PULSE_R` and `-PULSE_INT_R` options are also used by default in the NativeLink feature for gate-level timing simulation.

The following NC-Sim software command describes the command-line syntax to perform a gate-level timing simulation with the device family library:

```
ncelab worklib.<project name>:entity -SDF_CMD_FILE <SDF Command File> \
-TIMESCALE 1ps/1ps -PULSE_R 0 -PULSE_INT_R 0
```

Using the NativeLink Feature with NC-Sim

The NativeLink feature in the Quartus II software facilitates the seamless transfer of information between the Quartus II software and EDA tools and allows you to run NC-Sim within the Quartus II software.

Setting Up NativeLink

To run NC-Sim automatically from the Quartus II software using the NativeLink feature, you must specify the path to your simulation tool by performing the following steps:

1. On the Tools menu, click **Options**. The **Options** dialog box appears.
2. In the **Category** list, select **EDA Tool Options**. The **EDA Tool Options** page appears.

3. Double-click the entry under the **Location of executable** column beside the name of your **EDA Tool**, and type or browse to the directory containing the executables of your EDA tool.

   For example, if NCSim is installed in the **/tools/ncsim** directory, enter the location as **/tools/ncsim/tools.lnx86/bin**.

4. Click **OK**.

You can also specify the path to the simulator's executables by using the `set_user_option` Tcl command:

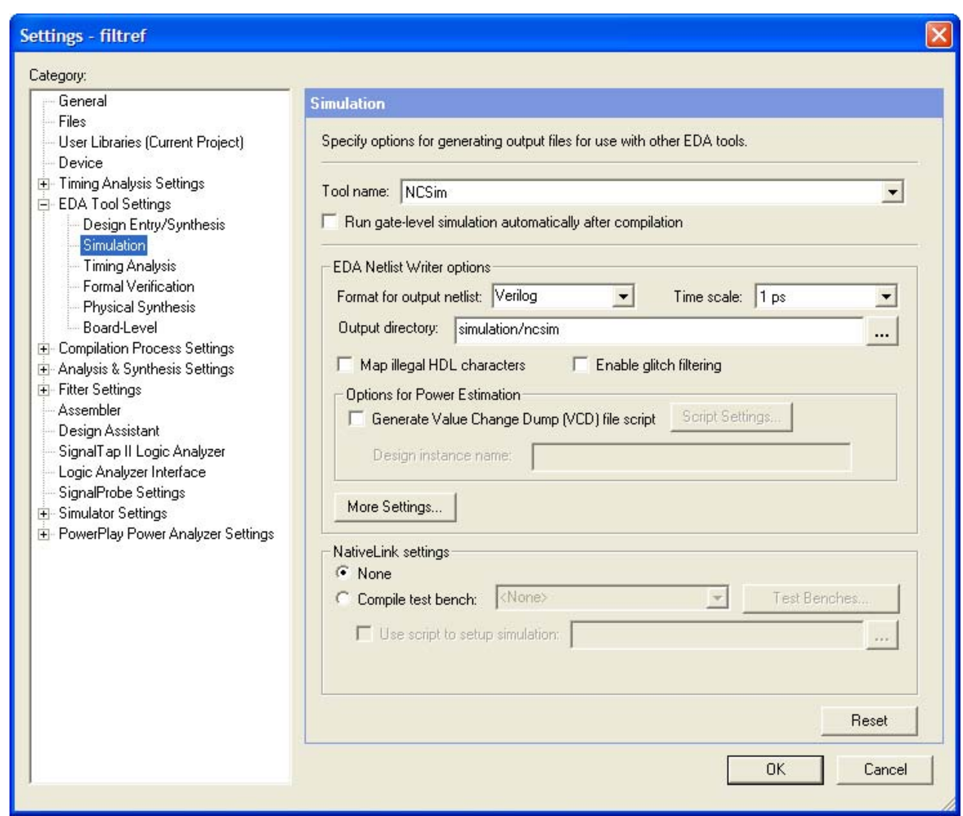
```
set_user_option -name EDA_TOOL_PATH_NCSIM <path to executables>
```

Performing an RTL Simulation Using NativeLink

To run an RTL functional simulation with the NC-Sim software automatically in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears (Figure 4–7).

Figure 4–7. Simulation Page in the Settings Dialog Box



3. In the **Tool name** pull-down list, select **NCSim**.

4. If your design is written entirely in Verilog HDL or in VHDL, the NativeLink feature automatically chooses the correct language and Altera simulation libraries. If your design is written with mixed languages, the NativeLink feature uses the default language specified in the **Format for output netlist** list. To change the default language when there is a mixed language design, under **EDA Netlist Writer options**, in the **Format for output netlist** list, select **VHDL** or **Verilog**. Table 4–7 shows the design languages for output netlists and simulation models.

Table 4–7. NativeLink Design Languages

Design File	Format for Output Netlist	Simulation Models Used
Verilog HDL	Any	Verilog HDL
VHDL	Any	VHDL
Mixed	Verilog HDL	Verilog HDL
Mixed	VHDL	VHDL

For mixed-language simulation, choose the same language that was used to generate the megafunctions to ensure correct parameter passing between the megafunctions and the Altera libraries. For example, if your ALTSYNCRAM megafunction was generated in VHDL, choose VHDL as the format for output netlist.

For mixed-language simulations, it is important to be aware of the following conditions:

- VHDL designs instantiating Verilog HDL user-defined primitives (UDPs) are not supported.
- Parameters cannot be passed in Verilog HDL modules that instantiate VHDL components.

5. If you have testbench files or macro scripts, enter the information under **NativeLink settings**.

   For more information about setting up a testbench with NativeLink, refer to the section “Setting Up a Testbench” on page 4–33.

6. If you have compiled libraries using the EDA Simulation Library Compiler, perform the following steps:

   a. On the **Simulation** page, click **More EDA Netlist Writer Settings**. The **More EDA Netlist Writer Settings** dialog box appears.

   b. Under **Existing option settings**, click **Location of User-Compiled Simulation Library**.

   c. Under **Setting**, type the path that contains the user-compiled libraries that are generated from the EDA Simulation Library Compiler; for example, **c:**<*design_path*>**/simulation/ncsim**.

7. Click **OK.**

8. On the Processing menu, point to **Start** and click **Start Analysis and Elaboration** to perform an analysis and elaboration. This command collects all your file name information and builds your design hierarchy in preparation for simulation.

9. To automatically run NC-Sim, compile all necessary design files, and complete a simulation, on the Tools menu, point to **Run EDA Simulation Tool** and click **EDA RTL Simulation**.

Performing a Gate-Level Simulation Using NativeLink

To run a gate-level timing simulation with the NC-Sim software in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears (Figure 4–7 on page 4–30).
3. In the **Tool name** list, select **NCSim**.
4. Under **EDA Netlist Writer options**, in the **Format for output netlist** list, choose **VHDL** or **Verilog**. You can also modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
5. To perform a gate level simulation after each full compilation, turn on **Run Gate Level Simulation automatically after compilation**.
6. If you have testbench files or macro scripts, enter the information under **NativeLink settings**.
7. If you have compiled libraries using the EDA Simulation Library Compiler, perform the following steps:
   a. On the **Simulation** page, click **More EDA Netlist Writer Settings**. The **More EDA Netlist Writer Settings** dialog box appears.
   b. Under **Existing option settings**, click **Location of User-Compiled Simulation Library**.
   c. Under **Setting**, type the path that contains the pre-compiled libraries that are generated from the EDA Simulation Library Compiler; for example, **c:**<*design_path*>**/simulation/modelsim**.
8. Click **OK**.
9. On the Processing menu, point to **Start** and click **Start EDA Netlist Writer** to generate a simulation netlist of your design.

☞ If you have run full compilation after you set the **EDA Tool Settings**, the **Start EDA Netlist Writer** step is not required.

10. To automatically run NC-Sim, compile all necessary design files, and complete a simulation, on the Tools menu, point to **Run EDA Simulation Tool** and click **EDA Gate Level Simulation**.

☞ If multi-corner Timing Analysis is performed, a dialog box appears asking you to select the timing corner to run simulation. Select the timing corner and click **Run**.

A Tcl File (***.tcl**) is generated in the <*project_directory*>**\simulation\ncsim** directory when you run NativeLink. This **.tcl** file enables you to simulate the design without using NativeLink, with the following command:

```
quartus_sh -t <project_directory>\simulation\ncsim\<generated_do_file>.tcl ↵
```

1. To generate only the Tcl script without using the GUI after the NativeLink process, perform the following steps:
   a. On the **Simulation** page, click **More NativeLink Settings**. The **More NativeLink Settings** dialog box appears.
   b. Under **Existing option settings**, click **Generate third-party EDA tool command scripts without running the EDA tool**.
   c. Under **Setting**, click **On**.

   If you turn this option on and run NativeLink, the **.tcl** file for the simulation process will be generated without showing the results in the GUI. You can then run the simulation by typing the following command:

```
quartus_sh -t <your_design_name>_ncsim_gate_level_<verilog/vhdl>.tcl
```

Setting Up a Testbench

You can compile your design files and testbench files, and run EDA simulation tools to perform a simulation automatically using the NativeLink feature.

To setup NativeLink with a testbench, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears.
3. Under **NativeLink settings**, select **None** or **Compile test bench** (Table 4–8).

Table 4–8. NativeLink Settings

Settings	Description
None	Compile simulation models and design files.
Compile test bench	NativeLink compiles simulation models, design files, testbench files, and starts simulation.

4. If you select **Compile test bench**, select your testbench setup from the **Compile test bench** list. You can use different testbench setups to specify different testbench files for different test scenarios. If there are no testbench setups entered, create a testbench setup by performing the following steps:

   a. Click **Test Benches**. The **Test Benches** dialog box appears.

   b. Click **New**. The **New Test Bench Settings** dialog box appears.

   c. In the **Test Bench name** box, type in the testbench setup name which is used to identify the different testbench setups.

   d. In the **Test level module** box, type in the top-level entity name. For example, for a Quartus II generated VHDL testbench, type `filtref_vhd_vec_tst`.

   e. In the **Instance** box, type in the full instance path to the top level of your FPGA design. For example, for a Quartus II generated VHDL testbench, type `i1`.

   f. Under **Simulation period**, select **Run simulation until all vector stimuli are used**. If you select **End simulation at**, specify the simulation end time and the time unit.

   g. Under **Test bench files**, browse and add all your testbench files in the **File name** box. Use the **Up** and **Down** button to reorder your files. The script used by NativeLink compiles the files in order from top to the bottom.

   You can also specify the library name and the HDL version to compile the testbench file. NativeLink compiles the testbench to the library name of the HDL specified version.

   h. Click **OK**.

   i. In the **Test Benches** dialog box, click **OK**.

5. Under **NativeLink settings**, you can turn on **Use script to setup simulation** and browse to your script. You can write a script to set up your waveforms before running the simulation.

The script should be a valid NC-Sim Tcl script. NativeLink passes the script to **ncsim** command with command-line arguments to set up and run simulation.

Creating a Testbench

In the Quartus II software, you can create a Verilog HDL or VHDL testbench from a Vector Waveform File (**.vwf**). The generated testbench includes the behavior of the input stimulus and applies it to your instantiated top-level FPGA design.

1. On the File menu, click **Open**. The **Open** dialog box appears.
2. In the Files of type list, **Files of type** arrow and select **Waveform/Vector Files**. Select your file.
3. Click **Open**.
4. On the File menu, click **Export**. The **Export** dialog box appears.
5. In the **Save as type** list, select **VHDL Test Bench File (*.vht)** or **Verilog Test Bench File (*.vt)**.

6. You can turn on **Add self-checking code to file** to check your simulation results against your Vector Waveform File.
7. Click **Export**.

Generate Simulation Script from EDA Netlist Writer

In the Quartus II software version 9.0 and later, you can generate the simulation script (including the **.do** file, Tcl script, and option file) when you run the EDA Netlist Writer. You can use the simulation script to run your simulation in the preferred simulator in stand-alone mode.

To generate a simulation script with the EDA Netlist Writer, perform the following steps:

1. On the **Simulation** page, click **More EDA Netlist Writer Settings**. The **More EDA Netlist Writer Settings** dialog box appears.
2. Under **Existing option settings**, click **Generate third-party EDA tool command script for RTL simulation** (if you want to generate an RTL simulation script) or click **Generate third-party EDA tool command script for Gate-Level simulation** (if you want to generate a Gate-Level simulation script).
3. Under **Setting**, click **On**.
4. Click **OK**.
5. Follow the steps in "Quartus II Simulation Output Files" on page 4–17.

In the command-line, to generate the simulation script with the EDA Netlist Writer, type the following command:

```
quartus_eda --simulation --tools=<Your decided tool> --format=<vhdl or verilog>
    --gen_script=<rtl or gate_level> <Project Name> -c <Revision name> ↵
```

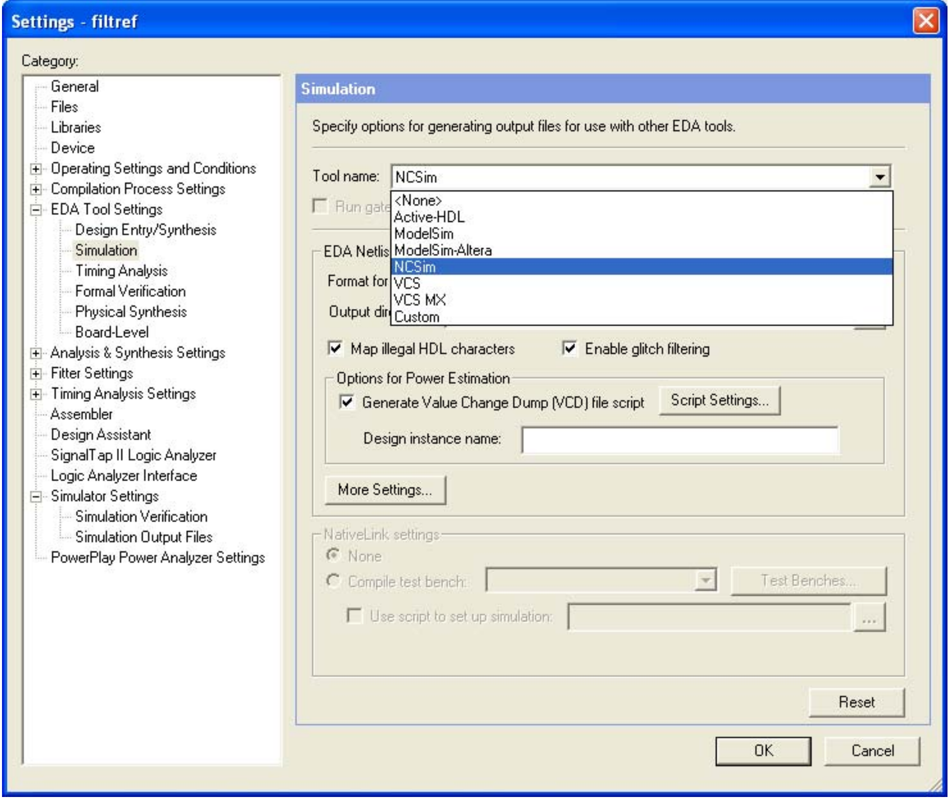
Generating a Timing VCD File for PowerPlay

To generate a timing **.vcd** file for PowerPlay, you must first generate a VCD script in the Quartus II software and run the VCD script from the NC-Sim software to generate a timing **.vcd** file. This timing **.vcd** file can then be used by the PowerPlay Early Power Estimator for power estimation. The following instructions show you how to generate a timing **.vcd** file.

Perform the following steps to generate timing VCD scripts in the Quartus II software:

1. In the Quartus II software, on the Assignments menu, click **Settings**. The **Settings** dialog box appears (Figure 4–8).
2. In the **Category** list, click the "+" icon to expand **EDA Tool SEttings**.
3. Click **Simulation**.
4. From the **Tool Name** pull-down list, click your required third-party simulation tool.
5. Turn on the **Generate Value Change Dump (VCD) File Script** option.

Figure 4–8. Simulation Settings Dialog Box



6. Click **OK**.
7. To generate the VCD script file, perform a full compilation.

Perform the following steps to generate a timing **.vcd** file in NC-Sim:

1. In the NC-Sim software, before simulating your design, source the *<revision_name>***_dump_all_vcd_nodes.tcl** script. To source the **.tcl** script, you should use the **–input** switch while running the **nssim** command. For example:

```
ncsim -input <revision_name>_dump_all_vcd_nodes.tcl <my design>
```

2. Continue to run the simulation until simulation finishes. Exit the **ncsim** and the *<revision_name>***.vcd** is generated in the simulation directory.

For more detailed information about using the timing **.vcd** file for power estimation, refer to the *PowerPlay Power Analysis* chapter in volume 3 of the *Quartus II Handbook*.

Viewing a Waveform from a .trn File

A **.trn** file is automatically generated when your simulation is done. The **.trn** file is not readable. It is used for generating the waveform view through SimVision.

To view a waveform from a **.trn** file through SimVision, perform the following steps:

1. Type `simvision` on a command line. The **Design Browser** dialog box appears.
2. On the File menu, click **Open Database**. The **Open File** dialog box appears.

3. In the **Directories** field, browse to the directory that contains your **.trn** file.
4. Double-click the **.trn** file.
5. In the **Design Browser** dialog box, select the signals that you want to observe from the Hierarchy.
6. Right-click the selected signals and click **Send to Waveform Window**.

You cannot view a waveform from a **.vcd** file in SimVision and the **.vcd** file cannot be converted to a **.trn** file.

Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt.

For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser.

To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ↵
```

The *Quartus II Scripting Reference Manual* includes the same information in PDF format.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. For information about all settings and constraints in the Quartus II software, refer to the *Quartus II Settings File Manual*. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Generate NC-Sim Simulation Output Files

You can generate **.vo** files and **.sdo** simulation output files with Tcl commands or at a command prompt.

For more information about generating **.vo** simulation output files and **.sdo** file simulation output files, refer to "Quartus II Simulation Output Files" on page 4–17.

Tcl Commands

The following three assignments cause a Verilog HDL netlist to be written out when you run the Quartus II netlist writer. The netlist has a 1 ps timing resolution for the NC-Sim simulation software.

```
set_global_assignment -name EDA_OUTPUT_DATA_FORMAT VERILOG -section_id eda_simulation
set_global_assignment -name EDA_TIME_SCALE "1 ps" -section_id eda_simulation
set_global_assignment -name EDA_SIMULATION_TOOL "NC-Verilog (Verilog)"
```

Use the following Tcl command to run the Quartus II Netlist Writer:

```
execute_module -tool eda
```

Command Prompt

Use the following command to generate a simulation output file for the Cadence NC-Sim software simulator. Specify Verilog HDL or VHDL for the format.

```
quartus_eda <project name> --simulation --format=<verilog|vhdl> --tool=ncsim ↵
```

Conclusion

The Cadence NC family of simulators work within an Altera FPGA design flow to perform RTL functional, post-synthesis, and gate-level timing simulation, easily and accurately.

Altera provides functional models of LPM and Altera-specific megafunctions that you can compile with your testbench or design. For timing simulation, use the atom netlist file generated by Quartus II compilation.

The seamless integration of the Quartus II software and Cadence NC tools make this simulation flow an ideal method for fully verifying an FPGA design.

Document Revision History

Table 4–9 shows the revision history for this chapter.

Table 4–9. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Removed "Compile Libraries Using the Altera Simulation Library Compiler". ■ Added "Compile Libraries Using the EDA Simulation Library Compiler" on page 4–5. ■ Added "Generate Simulation Script from EDA Netlist Writer" on page 4–35. ■ Added "Viewing a Waveform from a .trn File" on page 4–36. ■ Minor editorial updates.	Updated for the Quartus II software version 9.0 release.
November 2008 v8.1.0	■ Added "Compile Libraries Using the Altera Simulation Library Compiler" on page 4–5. ■ Added information about the `--simlib_comp` utility. ■ Minor editorial updates. ■ Updated entire chapter using 8½" × 11" chapter template.	Updated for the Quartus II software version 8.1 release.
May 2008 v8.0.0.0	■ Updated Table 4–1. ■ Updated Figure 4–1. ■ Updated "Compilation in Command-Line Mode" on page 4–9. ■ Updated "Generating a Timing Netlist with Different Timing Models" on page 4–18. ■ Added "Disable Timing Violation on Registers" on page 4–20. ■ Updated "Simulating Designs that Include Transceivers" on page 4–23. ■ Updated "Performing a Gate Level Simulation Using NativeLink" on page 4–30. ■ Added "Generating a Timing VCD File for PowerPlay" on page 4–33. ■ Added hyperlinks to referenced documents throughout the chapter. ■ Minor editorial updates.	Updated for the Quartus II software version 8.0 release.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

5. Aldec Active-HDL Support

QII53023-9.0.0

Introduction

This chapter provides an overview of how to use the Active-HDL software to simulate designs that target Altera® FPGAs. It provides a step-by-step explanation of how to perform register transfer level (RTL) functional simulations, post-synthesis simulations, and gate-level timing simulations for Verilog HDL or VHDL designs using Active-HDL software. This chapter also describes the location of the simulation library files, how to compile these library files, and how to load the design and testbench.

The Quartus® II software version 9.0 and later supports Aldec's Riviera-PRO tool. For more information about this simulator, refer to the manual that is provided with installation. The manual is located at <*Riviera-PRO Installation Directory*>**/help/riviera.pdf**.

This chapter contains the following topics:

- "Software Compatibility"
- "Using Active-HDL Software in Quartus II Design Flows" on page 5–2
- "Simulation Libraries" on page 5–3
- "Simulation Netlist Files" on page 5–6
- "Perform Simulation Using the Active-HDL Software (GUI Mode)" on page 5–12
- "Perform Simulation Using the Active-HDL Software (Batch Mode)" on page 5–28
- "Simulating Designs that Include Transceivers" on page 5–39
- "Using the NativeLink Feature in Active-HDL Software" on page 5–45
- "Generating VCD Files for PowerPlay" on page 5–51
- "Scripting Support" on page 5–52

Software Compatibility

To simulate your design using the Active-HDL software, you must first set up the Altera libraries. These libraries are installed with the Quartus II software. Table 5–1 shows the compatibility between versions of the Quartus II software and the Aldec Active-HDL software.

Table 5–1. Supported Quartus II and Active-HDL Software Version Compatibility

Aldec	Altera
Active-HDL software version 8.1	Quartus II software version 9.0
Active-HDL software version 7.3sp1	Quartus II software version 8.1
Active-HDL software version 7.3	Quartus II software version 8.0
Active-HDL software version 7.3	Quartus II software version 7.2

For more information about installing the software and directories created during the Quartus II software installation, refer to the *Quartus II Installation and Licensing for Windows* manual or the *Quartus II Installation and Licensing for UNIX and Linux Workstations* manual.

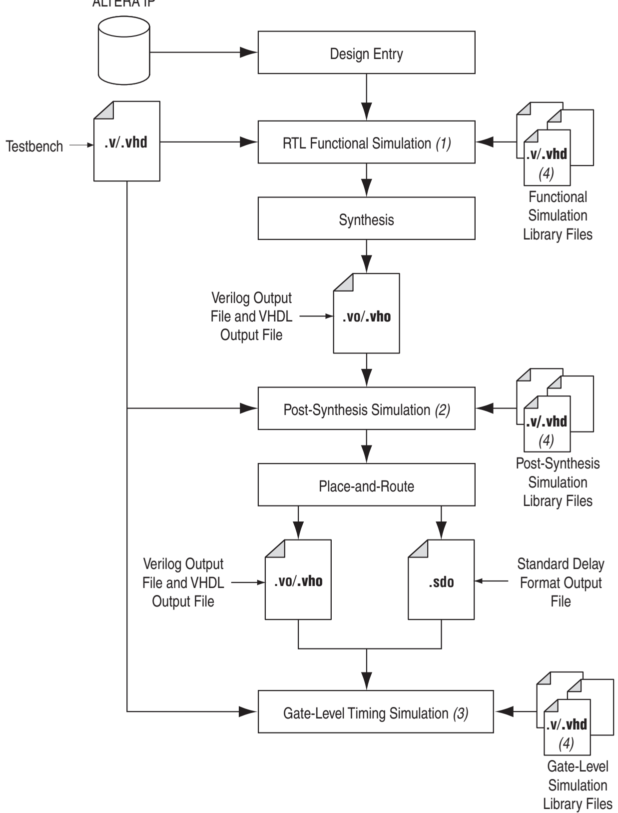
Using Active-HDL Software in Quartus II Design Flows

You can perform the following types of simulations using the Active-HDL software:

- RTL Functional Simulation
- Post-synthesis Simulation
- Gate-level Timing Simulation

Figure 5–1 illustrates the Active-HDL software used in the Altera Quartus II design flow.

Figure 5–1. Using the Active-HDL Software in an Altera Quartus II Design



Notes to Figure 5–1:

(1) RTL functional simulation is performed before a gate-level timing simulation or post-synthesis simulation. RTL functional simulation verifies the functionality of the design before synthesis and place-and-route. If you are performing an RTL functional simulation through NativeLink, you must complete analysis and elaboration first.

(2) A post-synthesis simulation verifies the functionality of a design after synthesis has been performed.

(3) Gate-level timing simulation is a post place-and-route simulation to verify the operation of the design after the worst-case timing delays have been calculated.

(4) In Active-HDL software, you must compile the simulation library files to perform RTL functional, post-synthesis, and gate-level timing simulation. All these simulation libraries are located at *<quartus installation directory>***eda\sim_lib**. If you already have the precompiled simulation libraries that come with the Active-HDL software, compiling the simulation library files is not required.

Simulation Libraries

Simulation model libraries are required to run a simulation whether you are running an RTL functional simulation, post-synthesis simulation, or gate-level timing simulation. In general, running an RTL functional simulation requires the RTL functional simulation model libraries and running a post-synthesis or gate-level timing simulation requires the gate-level timing simulation model libraries. You must compile the necessary library files before you can run the simulation.

However, there are a few exceptions where you are also required to compile gate-level timing simulation library files to perform RTL functional simulation. For example, the following are some of the Altera megafunctions gate-level libraries required to perform an RTL functional simulation in third-party simulators:

- ALTCLKBUF
- ALTCLKCTRL
- ALTDQS
- ALTDQ
- ALTDDIO_IN
- ALTDDIO_OUT
- ALTDDIO_BIDIR
- ALTUFM_NONE
- ALTUFM_PARALLEL
- ALTUFM_SPI
- ALTMEMMULT
- ALTREMOTE_UPDATE

To identify what type of simulation libraries are required to run the simulation for a certain Altera megafunction, refer to the last page in the Altera MegaWizard™ Plug-In Manager. It tells you what simulation library files are required to perform an RTL functional simulation for that particular megafunction.

Simulating the transceiver megafunction (for example, ALT2GXB) is also another exception that requires the gate-level libraries to perform RTL functional simulation and vice-versa. For detailed, step-by-step instructions about how to simulate the transceiver megafunction, refer to "Simulating Designs that Include Transceivers" on page 5–39.

Simulation Library Files in the Quartus II Software

In Active-HDL software, you must compile the necessary libraries to perform RTL functional, post-synthesis functional, or gate-level timing simulation. The following sections show the location of these library files in the Quartus II directory structure. You can refer to these library files for any particular simulation model that you are looking for.

RTL Functional Simulation Library Files

Table 5–2 shows the VHDL RTL simulation model location in the Quartus II directory.

Table 5–2. RTL Functional Simulation Library Files in the Quartus II Software (VHDL)

RTL Simulation Model	Location in Quartus II Directory Structure
LPM	*<Quartus II installation directory>***\eda\sim_lib\220pack.vhd** *<Quartus II installation directory>***\eda\sim_lib\220model.vhd** *<Quartus II installation directory>***\eda\sim_lib\220model_87.vhd** *(1)*
Altera Megafunction	*<Quartus II installation directory>***\eda\sim_lib\altera_mf_components.vhd** *<Quartus II installation directory>***\eda\sim_lib\altera_mf.vhd** *<Quartus II installation directory>***\eda\sim_lib\altera_mf_87.vhd** *(1)*
Low-Level Primitives	*<Quartus II installation directory>* **\eda\sim_lib\altera_primitives_components.vhd** *<Quartus II installation directory>***\eda\sim_lib\altera_primitives.vhd**
ALTGXB Megafunction (Stratix® GX)	*<Quartus II installation directory>* **\eda\sim_lib\stratixgx_mf_components.vhd** *<Quartus II installation directory>***\eda\sim_lib\stratixgx_mf.vhd**

Note to Table 5–2:

(1) Simulating a design that uses VHDL-1987.

Table 5–3 shows the Verilog RTL simulation model location in the Quartus II directory.

Table 5–3. RTL Functional Simulation Library Files in the Quartus II Software (Verilog)

RTL Simulation Model	Location in Quartus II Directory Structure
LPM	*<Quartus II installation directory>***\eda\sim_lib\220model.v**
Altera Megafunction	*<Quartus II installation directory>***\eda\sim_lib\altera_mf.v**
Low-Level Primitives	*<Quartus II installation directory>***\eda\sim_lib\altera_primitives.v**
ALTGXB Megafunction (Stratix GX)	*<Quartus II installation directory>***\eda\sim_lib\stratixgx_mf.v**

Gate-Level Timing Simulation Library Files

Table 5–4 shows the VHDL gate-level timing simulation model location in the Quartus II directory.

Table 5–4. Gate-Level Timing Simulation Library Files in the Quartus II Software (VHDL) (Part 1 of 2)

Simulation Netlist Files

Simulation netlist files are required to perform post-synthesis simulation or gate-level timing simulation. These simulation netlist files are generated from the EDA Netlist Writer.

If you are performing post-synthesis simulation, the Verilog Output File (***.vo**) or VHDL Output File (***.vho**) is required. The section "Generate Post-Synthesis Simulation Netlist Files" on page 5–7 shows you the steps to generate post-synthesis simulation netlist files for ***.vo** or ***.vho** files.

If you are performing gate-level timing simulation, not only is the ***.vo** file or ***.vho** file required, but the Standard Delay Format Output File (*.**sdo**) is also required. The ***.sdo** file is used to annotate the delay for the elements found in the ***.vo** or ***.vho** file. The section "Generate Gate-Level Timing Simulation Netlist Files" on page 5–8 shows you how to generate gate-level timing simulation netlist files (that is, ***.vo** or ***.vho** files and ***.sdo** files).

Generate Post-Synthesis Simulation Netlist Files

The following steps describe the process for generating post-synthesis simulation netlist files in the Quartus II software:

1. Perform Analysis and Synthesis. On the Processing menu, point to **Start** and click **Start Analysis and Synthesis** (you can also do this after step 2).
2. Turn on the **Generate Netlist for Functional Simulation Only** option by performing the following steps:
   a. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
   b. In the **Category** list, click the "+" icon to expand **EDA Tools Settings** and select **Simulation**. The **Simulation** page appears.
   c. In the **Tool name** list, select **Active-HDL**.
   d. Under **EDA Netlist Writer options**, in the **Format for output netlist** list, select **VHDL** or **Verilog**. You can also modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
   e. Click **More EDA Netlist Writer Settings**. The **More EDA Netlist Writer Settings** dialog box appears.
   f. In the **Existing option settings** list, click **Generate netlist for functional simulation only**.
   g. Under **Options**, from the **Setting** list, select **On**.
   h. Click **OK**.
   i. In the **Settings** dialog box, click **OK**.
3. Run the EDA Netlist Writer. On the Processing menu, point to **Start** and click **Start EDA Netlist Writer**.

During the EDA Netlist Writer stage, the Quartus II software produces a **.vo** or **.vho** file that can be used for post-synthesis simulations in the Active-HDL software. This netlist file is mapped to architecture-specific primitives. No timing information is included at this stage. The resulting netlist is located in the output directory you specified in the **Settings** dialog box, which defaults to the *<project directory>***/simulation/activehdl** directory.

If you want to generate a post-synthesis simulation netlist with just the cell delays, you can generate the ***.sdo** file without running the Fitter. In this case, the ***.sdo** file includes all timing values for only the device cells. Interconnect delays are not included because fitting (placement and routing) has not been performed. To generate the post-synthesis netlist and ***.sdo** file, type the following commands at a command prompt:

```
quartus_map <project name> -c <revision name> ↵
quartus_sta <project name> -c <revision name> --post_map --zero_ic_delays ↵
```

or

```
quartus_tan <project name> -c <revision name> --post_map --zero_ic_delays ↵
quartus_eda <project name> -c <revision name> --simulation --tool= <3rd party EDA tool> \
--format=<HDL language> ↵
```

For more information about the **–format** and **–tool** options, type the following command at a command prompt:

```
quartus_eda -help=<options> ↵
```

Generate Gate-Level Timing Simulation Netlist Files

To perform gate-level timing simulation, the Active-HDL software requires information about how the design was placed into device-specific architectural blocks. The Quartus II software provides this information in the form of a ***.vo** file for Verilog HDL designs and a ***.vho** file for VHDL designs. The accompanying timing information is stored in the **.sdo** file, which annotates the delay for the elements found in the Verilog Output file or VHDL Output file.

Perform he following steps describe to generate a gate-level timing simulation netlist file in the Quartus II software:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, click the "+" icon to expand **EDA Tool Settings** and select **Simulation**. The **Simulation** page appears.
3. In the **Tool name** list, select **Active-HDL**.
4. Under **EDA Netlist Writer options**, in the **Format for output netlist** list, select **VHDL** or **Verilog**. You can also modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
5. Click **OK**.
6. In the **Settings** dialog box, click **OK**.
7. If you have not run a full compilation, perform a full compilation. On the Processing menu, click **Start Compilation**.
8. If you have already run a full compilation, run the EDA Netlist Writer. On the Processing menu, point to **Start** and click **Start EDA Netlist Writer**.

   During the full compilation or EDA Netlist Writer stage, the Quartus II software produces a ***.vo** file, a ***.vho** file, and a ***.sdo** file used for gate-level timing simulations in the Active-HDL software. This netlist file is mapped to architecture-specific primitives. The timing information for the netlist is included in the *.**sdo** file. The resulting netlist is located in the output directory you specified in the **Settings** dialog box, which defaults to *<project directory>***/simulation/activehdl**.

Generating Different Timing Models

In Stratix III and later devices (for example, Cyclone III and Stratix IV), you can specify different temperature and voltage parameters to generate the timing netlist. If you enable the Quartus II Classic or Quartus II TimeQuest Timing Analyzer when generating the simulation netlist files (***.vo** or ***.vho** and ***.sdo**), different timing models for different operating conditions are used by default. Multicorner timing analysis is run by default during the full compilation.

Table 5–6 shows an example of available default operation conditions (model, voltage, and temperature) for Stratix III and Cyclone III devices.

Table 5–6. Default Available Operating Condition for Stratix III and Cyclone III Devices

Device Family	Model	Voltage	Temperature (°C)
Stratix III	Slow	1100 mV	85°
	Slow	1100 mV	0°
	Fast	1100 mV	0°
Cyclone III	Slow	1200 mV	85°
	Slow	1200 mV	0°
	Fast	1200 mV	0°

If multicorner timing analysis is not run during full compilation, perform the following steps to manually generate the simulation netlist files (***.vo** or ***.vho** and ***.sdo**) for the three different operating conditions listed in Table 5–6:

1. Generate all the available corner models at all operating conditions. Type the following command at a command prompt:

   ```
   quartus_sta <project name> --multicorner ↵
   ```

2. Generate the simulation output files for all three corners specified in Table 5–6. Perform steps 2 through 8 in "Generate Gate-Level Timing Simulation Netlist Files" on page 5–8. The output files are generated in the simulation output directory.

The following examples show all the simulation netlist files generated for the three operating conditions in Table 5–6, when **Verilog** is selected as the output netlist format:

First Slow Corner (Slow, 1100 mV, 85° C):

.vo file— <*revision name*>**.vo**
.sdo file— <*revision name*>**_v.sdo**

The <*revision_name*>**.vo** and <*revision name*>**_v.sdo** are generated for backward compatibility issues in case there are existing scripts that still use them.

.vo file— <*revision name*>_<*speedgrade*>_1100mv_85c_slow**.vo**
.sdo file— <*revision name*>_<*speedgrade*>_1100mv_85c_v_slow**.sdo**

Second Slow Corner (Slow, 1100 mV, 0° C):

.vo file— <*revision name*>_<*speedgrade*>_1100mv_0c_slow**.vo**
.sdo file— <*revision name*>_<*speedgrade*>_1100mv_0c_v_slow**.sdo**

Fast Corner (Fast, 1100 mV, 0° C):

.vo file— <*revision name*>_min_1100mv_0c_fast**.vo**
.sdo file— <*revision name*>_min_1100mv_0c_v_fast**.sdo**

For older devices, a slow-corner (worst case) timing model is used by default. There are only two timing models available: the slow-corner and the fast-corner timing model. To generate the ***.sdo** file using a different timing model, you must run the Quartus II Classic or the Quartus II TimeQuest Timing Analyzer with a different timing model before you start the EDA Netlist Writer.

To run the Quartus II Classic Timing Analyzer with the best-case model, on the Processing menu, point to **Start** and click **Start Classic Timing Analyzer (Fast Timing Model)**. After timing analysis is complete, the Compilation Report appears. You can also type the following command at a command prompt:

```
quartus_tan <project_name> --fast_model=on ↵
```

To run the Quartus II TimeQuest Timing Analyzer with a best-case model, use the **-fast_model** option after you create the timing netlist. The following command enables fast timing models:

```
create_timing_netlist --fast_model ↵
```

After you run the Quartus II Classic or Quartus II TimeQuest Timing Analyzer, perform steps 2 through 8 in "Generate Gate-Level Timing Simulation Netlist Files" on page 5–8 to generate the ***.sdo** file. For fast corner timing models, the **–fast** post fix is added to the ***.vo** or ***.vho**, and ***.sdo** file (for example, **my_project_fast.vo** or **my_project_fast.vho**, and **my_project_fast.sdo**).

For more information about generating the timing netlist with a different timing model, refer to the *Quartus II Classic Timing Analyzer* or the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Disable Timing Violation on Registers

In certain situations, the timing violation can be ignored and you can disable the timing violation on registers; for example, timing violations that occur in internal synchronization registers used for asynchronous clock-domain crossing.

By default, the **x_on_violation_option logic** option is **On**, which means the simulation shows "x" whenever a timing violation occurs. To disable showing the timing violation on certain registers, set the **x_on_violation_option logic** option to **Off** on those registers. The following command is an example of the QSF file:

```
set_instance_assignment -name X_ON_VIOLATION_OPTION OFF -to <register_name>
```

Compile Libraries Using the EDA Simulation Library Compiler

The EDA Simulation Library Compiler is used to compile Verilog HDL and VHDL simulation libraries for all Altera devices and supported third-party simulators. You can use this tool to compile all libraries required by RTL and gate-level simulation.

When the compilation targets third-party simulation tools such as ModelSim, VCS-MX, Active-HDL, Riviera-PRO, and NC-Sim, the compiled libraries are kept in either the directory you set or the default directory. When you perform the simulation using these simulators, you can use or re-use the compiled libraries and avoid the overhead associated with redundant library compilations.

However, if the Synopsys VCS software performs the compilation while running the EDA Simulation Library Compiler, the option files (**simlib_comp.vcs**) are generated after compilation. You can then include your design and test bench files in the option files and invoke them with the `vcs` command.

Before using this option, ensure the appropriate simulation tools are already installed and their paths are specified. To specify the path, refer to "Setting Up NativeLink" on page 5–45.

Run the EDA Simulation Library Compiler through the GUI

Starting with the Quartus II software 9.0 release, the EDA Simulation Library Compiler contains a GUI. To compile libraries with the EDA Simulation Library Compiler GUI, perform the following steps:

1. On the Tools menu, click **EDA Simulation Library Compiler**. The **EDA Simulation Library Compiler** dialog box appears.
2. In the **Tool name** entry box under **EDA simulation tool**, select a simulation tool.

   The **Executable location** box displays the location of the simulation tool you specified. This location must be set before running the EDA Simulation Library Compiler.
3. Under **Library families**, select one or more device families for your design compilation and move them to **Selected families** box.
4. Under **Library language**, select **VHDL**, **Verilog**, or both.
5. In the **Output directory** field, specify a location in which to store the compiled libraries or option files.
6. Click **Start Compilation**.

For example, if you want to simulate a Verilog HDL design on a Stratix II device in the Active-HDL simulator, do the following:

- Select **Active-HDL** in the **Tool name** field.
- Move **Stratix II** from the **Available families** list to the **Selected families** list.
- Select **Verilog** in the **Library language** field.
- Specify a location in the **Output directory** field in which to keep the option file.
- Click **Start Compilation**.

When the EDA Simulation Library Compiler finishes, all required libraries are compiled and stored in the output location you specified. The next time you perform simulation in Active-HDL, you only have to compile your design and testbench files. You do not have to compile the Altera libraries again.

Run EDA Simulation Library Compiler In Command Line

You can run the EDA Simulation Library Compiler in the command line. Type the following command:

```
quartus_sh --simlib_comp -family <device> -tool <simulation tool name>
-language <language> -directory <directory> ↵
```

For more information about the command’s options and how to define them, type the following command:

```
quartus_sh --help=simlib_comp ↵
```

Perform Simulation Using the Active-HDL Software (GUI Mode)

Perform simulation of Verilog HDL or VHDL designs with Active-HDL software at various levels to verify designs from different aspects. There are three types of simulation:

- RTL functional simulation
- Post-synthesis simulation
- Gate-level timing simulation

Simulation helps you verify your designs and debug them against any possible errors the designs may have. The following sections provide step-by-step instructions to perform the simulation through the GUI.

For high-speed simulation, you must select **ps** in the **Resolution** list for your simulator resolutions. If you choose slower than **ps**, the high-speed simulation may fail.

Workspace creation is the mandatory first step to start working in the Active-HDL GUI. You must create a new workspace to add the simulation model files, design files, and testbench file before you can compile them.

Simulating VHDL Designs

Simulation of a VHDL design using the Active-HDL GUI is user friendly. You do not have to remember the commands to compile the libraries or load and simulate the VHDL design files. You can use the Active-HDL GUI to perform the RTL functional simulation, post-synthesis simulation, and gate-level timing simulation. The following sections show you how to perform simulation at various levels through the Active-HDL GUI.

Perform RTL Functional Simulation

RTL functional simulation is typically performed to verify the syntax of the code and to check the functionality of the design. The following sections show how to perform RTL functional simulation in the Active-HDL software for VHDL designs.

If your Active-HDL software comes with precompiled simulation libraries, creating or compiling simulation libraries is not required and you can skip the following section.

Create and Compile Simulation Libraries

Simulation libraries are required to simulate a design that contains an Altera primitive, lpm function, or Altera megafunction. Different designs require different simulation libraries, and you must create these required simulation libraries before you can run the simulation.

For example, the library name for Altera megafunctions should be **altera_mf** and the library name for LPM should be **lpm**. For a list of all functional simulation library files, refer to "RTL Functional Simulation Library Files" on page 5–4.

Before you start creating simulation libraries (for example, **altera_mf** and **lpm**) ensure that the library with the same name is not present in the Active-HDL software. Perform the following steps:

1. In the Active-HDL software, on the View menu, click **Library Manager.** The Library Manager window appears.
2. Check to see if the simulation libraries (for example, **altera_mf** and **lpm**) that you are going to create are not already present.
3. If the simulation libraries are already present, you must detach them. To detach the simulation libraries, right-click on the library and select **Detach**.

To create and compile the simulation libraries, you must create a new workspace. Perform the following steps to create a new workspace, create a new library, compile the library, and register the library in the **Library Manager**.

1. In the Active-HDL software, on the File menu, point to **New** and click **Design**. The **New Design Wizard** appears.
2. Select **Create an Empty Design** and keep the **Create New Workspace** option selected.
3. Click **Next**. The **Property** page appears.
4. In the **Property** page, click **Next** to proceed to the **Design name** and **Library name** fields.
5. Type the design name (for example, `altera_mf` or `lpm`), select the location of your RTL design in the **Design folder** field, and click **Next**. For simplicity, keep the design name and the library name the same.
6. Click **Finish** to complete the wizard.
7. On the Design menu, click **Add files to Design**.
8. Browse to the <*Quartus II installation directory*>**/eda/sim_lib** and add the necessary simulation model files.

   Compile the **altera_mf_components.vhd** and **altera_mf.vhd** model files into the **altera_mf** library. Compile the **220pack.vhd** and **220model.vhd** model files into the **lpm** library.
9. On the Design menu, click **Compile All** to compile all the files (for example, **altera_mf_components.vhd** and **altera_mf.vhd**) in the design library.
10. On the File menu, click **Close Workspace**.
11. You must register the created library in the Active-HDL software. On the View menu, click **Library Manager**. The Library Manager window appears.
12. On the Library menu, click **Attach Library**.
13. Locate the **.lib** file (for example, **altera_mf.lib** or **lpm.lib**) from the design directory that you created in the previous steps and click **Open**. This action attaches the simulation library as a global library inside your library manager and make it visible for any design in Active-HDL.
14. Repeat this procedure to create and compile another simulation library.

Compile Testbench and Design Files into the Work Library

To compile design files and the testbench into a work library, you must create a new workspace. Perform the following steps to create a new workspace and compile your testbench and design files into the work library:

1. In the Active-HDL software, on the File menu, point to **New** and click **Design**. The **New Design Wizard** appears.
2. Select **Create an Empty Design** and keep the **Create New Workspace** option selected.
3. Click **Next**. The **Property** page appears.
4. In the **Property** page, click **Next** to reach the design name and library name options.
5. Type `work` for the design name and select the location of your RTL design. For simplicity, keep the design name and the library name the same.
6. Click **Finish** to complete the wizard.
7. On the Design menu, click **Add files to Design.**
8. Browse to the RTL design directory and add the testbench and RTL design files.
9. On the Design menu, click **Compile All** to compile the testbench and RTL design files.

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, perform the following steps:

1. In the **Design Browser**, click the **Top-level Selection** pull-down menu. Select the top-level entity, which is your testbench with corresponding architecture.
2. On the Simulation menu, select **Initialize Simulation**. This loads the simulation.
3. The **Design Browser** automatically switches to the **Structure** tab and shows you the design tree.

Running the Simulation

To run a simulation, perform the following steps:

1. On the File menu, point to **New** and click **Waveform**.
2. Drag signals of interest from the **Design Browser** (in the **Structure** tab) to the Waveform window.
3. On the Simulation menu, click **Run Until**. A pop-up window appears.
4. Specify how long you want your simulation to run (for example, 500 ns).

Perform Post-Synthesis Simulation

Perform post-synthesis simulation to verify that functionality of the design is not lost after synthesis. You can create the post-synthesis netlist in the Quartus II software and use the netlist to perform post-synthesis simulation with the Active-HDL software.

Before you run post-synthesis simulation, generate post-synthesis simulation netlist files. Refer to "Generate Post-Synthesis Simulation Netlist Files" on page 5–7.

Use the instructions in the following section to perform a post-synthesis simulation for VHDL designs in the Active-HDL software.

If your Active-HDL software comes with precompiled simulation libraries, creating or compiling simulation libraries is not required, and you can skip the following section.

Create and Compile Simulation Libraries

Simulation libraries are required to simulate a design that is mapped to post-synthesis primitives. Depending on the device family you are using, you must create the required simulation libraries before running the simulation.

Performing post-synthesis simulation requires a gate-level timing simulation library. For example, the library name for the Stratix III family should be **stratixiii**. For a list of all gate-level timing simulation library files, refer to "Gate-Level Timing Simulation Library Files" on page 5–4.

Before you create simulation libraries (for example, **stratixiii**) ensure that a library with the same name is not present in the Active-HDL software. Perform the following steps:

1. In the Active-HDL software, on the View menu, click **Library Manager.** The Library Manager window appears.
2. Check that the simulation libraries (for example, **stratixiii**) you are going to create are not already present.
3. If these simulation libraries are present, you must detach them. To detach these simulation libraries, right-click the library and from the menu list, select **Detach**.

To create and compile the simulation libraries, you must create a new workspace. Perform the following steps to create a new workspace, create a new library, and compile and register the library in the **Library Manager**. Perform the following steps:

1. In the Active-HDL software, on the File menu, point to **New** and click **Design**. The **New Design Wizard** appears.
2. Select **Create an Empty Design** and keep the **Create New Workspace** option selected.
3. Click **Next**. The **Property** page appears.
4. In the **Property** page, click **Next** to reach the design name and library name options.
5. Type the design name (for example, `stratixiii`) and select the location of your RTL design. For simplicity, keep the design name and the library name the same.
6. Click **Finish** to complete the wizard.
7. On the Design menu, click **Add files to Design.**
8. Browse to the <*Quartus II installation directory*>**/eda/sim_lib** and add the necessary simulation model files.

Compile the **stratixiii_atoms_components.vhd** and **stratixiii_atoms.vhd** model files into the **stratixiii** library.

9. On the Design menu, click **Compile All** to compile all the files (for example, **altera_mf_components.vhd** and **altera_mf.vhd**) to the design library.
10. On the File menu, click **Close Workspace**.
11. To register the created library in the Active-HDL software, on the View menu, click **Library Manager**. The Library Manager window appears.
12. On the Library menu, click **Attach Library.**
13. Locate the **.lib** file (for example, **stratixiii.lib**) from the design directory that you created in the previous steps and click **Open**. This attaches the simulation library as a global library inside your library manager and makes it visible for any design in the Active-HDL software.
14. Repeat this procedure to create and compile another simulation library, if necessary.

Compile the Testbench and Design File into the Work Library

To compile design files and the testbench into a work library, you must create a new workspace. Perform the following steps to create a new workspace, and compile your testbench and ***.vho** file into the work library:

1. In the Active-HDL software, on the File menu, point to **New** and click **Design**. The **New Design Wizard** appears.
2. Select **Create an Empty Design** and keep the **Create New Workspace** option selected.
3. Click **Next**. The **Property** page appears.
4. In the **Property** page, click **Next** to reach the design name and library name options.
5. Type `work` for the design name and select the location of your RTL design. For simplicity, keep the design name and the library name the same.
6. Click **Finish** to complete the wizard.
7. On the Design menu, click **Add files to Design**.
8. Browse to the VHDL output file directory (for example, *<project directory>***/simulation/activehdl**) and add the VHDL output file (***.vho**). Browse to the testbench file directory and add the testbench file.
9. On the Design menu, click **Compile All** to compile the testbench and VHDL output netlist files.

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, perform the following steps:

1. In the **Design Browser**, click the **Top-level Selection** list. Select the top-level entity, which is your testbench with corresponding architecture.

2. On the Simulation menu, click **Initialize Simulation**. This loads the simulation.
3. The **Design Browser** automatically switches to the **Structure** tab and displays the design tree.

Running the Simulation

To run the simulation, perform the following steps:

1. On the File menu, point to **New** and click **Waveform**.
2. Drag signals of interest from the **Design Browser** (in the **Structure** tab) to the Waveform window.
3. On the Simulation menu, click **Run Until**.
4. In the pop-up window, specify how long you want your simulation to run (for example, 500 ns).

Perform Gate-Level Timing Simulation

Gate-level timing simulation is a very important step in ensuring that the FPGA's functionality is still correct and meets all the timing requirements after the design was placed and routed. You can create the gate-level netlist in the Quartus II software and use the netlist to perform gate-level simulation with the Active-HDL software.

Before you run gate-level timing simulation, generate gate-level timing simulation netlist files. Refer to "Generate Gate-Level Timing Simulation Netlist Files" on page 5–8.

Use the following instructions to perform a gate-level timing simulation for VHDL designs in the Active-HDL software.

If your Active-HDL software comes with precompiled simulation libraries, creating or compiling simulation libraries is not required, and you can skip the next section.

Create and Compile Simulation Libraries

Simulation libraries are required to simulate a design that is mapped to post-fitting primitives. Depending on the device family you are using, you must create the required simulation libraries before running the simulation.

Performing gate-level timing simulation requires a gate-level timing simulation library. For example, the library name for the Stratix III family should be **stratixiii**. For a list of all gate-level timing simulation library files, refer to "Gate-Level Timing Simulation Library Files" on page 5–4.

Before you create simulation libraries (for example, **stratixiii**), ensure that a library with the same name is not present in the Active-HDL software. Perform the following steps:

1. In the Active-HDL software, on the **View** menu, Click **Library Manager.** The Library Manager window appears.
2. Check to see that the simulation libraries (for example, **stratixiii**) you are going to create are not already present.
3. If these simulation libraries are present, you must detach them. Right-click the library and from the menu list, select **Detach**.

To create and compile simulation libraries, you must create a new workspace. Perform the following steps to create a new workspace, create a new library, and compile and register the library in the **Library Manager**. Do this by performing the following steps:

1. In the Active-HDL software, on the File menu, point to **New** and click **Design**. The **New Design Wizard** appears.
2. Select **Create an Empty Design** and keep the **Create New Workspace** option selected.
3. Click **Next**. The **Property** page appears.
4. In the **Property** page, click **Next** to reach the design name and library name options.
5. Type the design name (for example, `stratixiii`) and select the location of your RTL design. For simplicity, keep the design name and the library name the same.
6. Click **Finish** to complete the wizard.
7. On the Design menu, click **Add files to Design**.
8. Browse to the <*Quartus II installation directory*>**/eda/sim_lib** and add the necessary simulation model files.

   Compile the **statixiii_atoms_components.vhd** and **stratixiii_atoms.vhd** model files into the **stratixiii** library.
9. On the Design menu, click **Compile All** to compile all the files (for example, **altera_mf_components.vhd** and **altera_mf.vhd**) into the design library.
10. On the File menu, click **Close Workspace**.
11. To register the created library in the Active-HDL software, on the **View** menu, click **Library Manager**. The Library Manager window appears.
12. On the Library menu, click **Attach Library**.
13. Locate the **.lib** file (for example, **stratixiii.lib**) from the design directory that you created in the previous steps and click **Open**. This attaches the simulation library as a global library inside your library manager and makes it visible to any design in the Active-HDL software.
14. Repeat this procedure to create and compile another simulation library, if necessary.

Compile the Testbench and Design File into the Work Library

To compile design files and the testbench into a work library, you must create a new workspace. Perform the following steps to create a new workspace and compile your design files into the work library:

1. In the Active-HDL software, on the File menu, point to **New** and click **Design**. The **New Design Wizard** appears.
2. Select **Create an Empty Design** and keep the **Create New Workspace** option selected.
3. Click **Next**. The **Property** page appears.

4. In the **Property** page, click **Next** to reach the design name and library name options.
5. Type `work` for the design name and select the location of your RTL design. For simplicity, keep the design name and the library name the same.
6. Click **Finish** to complete the wizard.
7. On the Design menu, click **Add files to Design**.
8. Browse to the VHDL output file directory (for example, <*project directory*>**/simulation/activehdl**) and add the VHDL output file (***.vho**) and standard output file (***.sdo**). Browse to the testbench file directory and add the testbench file.
9. On the Design menu, click **Compile All** to compile the testbench and VHDL output netlist files.

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, perform the following steps:

1. On the Design menu, click **Settings.** The Design Settings window appears. Expand the **Simulation** category and click **SDF**.

   If there are no **.sdo** files listed, no **.sdo** files have been added to the design. You must add the **.sdo** file before running the timing simulation.

2. In the **Files-Region** dialog box, select the level of the design hierarchy to which the **.sdo** file should be bonded to. For example, if your design under test is instantiated in the testbench file under the **i1** label, the region should be '**i1/**'.
3. In the **SDF** settings box, set **Value** to **Average** and set **Load** to **Yes** so that the simulator loads this file upon simulation start.

You do not have to set the Value (Minimum, Average, Maximum) for the ***.sdo** file, because the Quartus II EDA Netlist Writer generates the ***.sdo** file using the same value for the triplet (minimum, average, and maximum timing values).

4. Click **OK** to close the Design Settings window.
5. In the **Design Browser**, click the **Top-level Selection** list. Select the top-level entity, which is your testbench with corresponding architecture.
6. On the Simulation menu, click **Initialize Simulation**. This loads the simulation.
7. The **Design Browser** automatically switches to the **Structure** tab and shows you the design tree.

Running the Simulation

To run the simulation, perform the following steps:

1. On the File menu, point to **New** and click **Waveform**.
2. Drag signals of interest from the **Design Browser** (in the **Structure** tab) to the Waveform window.

3. On the Simulation menu, click **Run Until**.
4. In the pop-up window, specify how long you want your simulation to run (for example, 500 ns).

Simulating Verilog HDL Designs

Simulation of Verilog HDL designs using the Active-HDL GUI is user friendly. You do not have to remember the commands to compile the libraries or to load and simulate the Verilog HDL design files. You can use the Active-HDL GUI to perform RTL functional simulation, post-synthesis simulation, and gate-level simulation. The following sections show you how to perform simulation at various levels through the Active-HDL GUI.

Perform RTL Functional Simulation

RTL functional simulation is typically performed to verify the syntax of the code and to check the functionality of the design. The following sections show how to perform RTL functional simulation in the Active-HDL software for Verilog HDL designs.

If your Active-HDL software comes with precompiled simulation libraries, creating or compiling simulation libraries is not required, and you can skip the next section.

Create and Compile Simulation Libraries

Simulation libraries are required to simulate a design that contains an Altera primitive, LPM function, or Altera megafunction. Different designs require different simulation libraries, and you must create these required simulation libraries before you can run the simulation.

For example, the library name for Altera megafunctions should be **altera_mf_ver** and the library name for LPM should be **lpm**. For a list of all functional simulation library files, refer to "RTL Functional Simulation Library Files" on page 5–4.

Before you start creating simulation libraries (for example, **altera_mf_ver** or **lpm_ver**), ensure that the library with the same name is not present in the Active-HDL software.

1. In the Active-HDL software, on the View menu, click **Library Manager.** The Library Manager window appears.
2. Check to see if the simulation libraries that you are going to create are not already present.
3. If the simulation libraries are already present, you must detach them. Right-click the library and from the menu list, select **Detach**.

To create and compile simulation libraries, you must create a new workspace. Perform the following steps to create a new workspace, create a new library, compile the library, and register the library in the **Library Manager**.

1. In the Active-HDL software, on the File menu, point to **New** and click **Design**. The **New Design Wizard** appears.
2. Select **Create an Empty Design** and keep the **Create New Workspace** option selected.
3. Click **Next**. The **Property** page appears.

4. In the **Property** page, click **Next** to proceed to the **Design name** and **Library name** fields.
5. Type the design name (for example, `altera_mf_ver` or `lpm_ver`), select the location of your RTL design in the **Design folder** field, and click **Next**. For simplicity, keep the design name and the library name the same.
6. Click **Finish** to complete the wizard.
7. On the Design menu, click **Add files to Design**.
8. Browse to the <*Quartus II installation directory*>**/eda/sim_lib** and add the necessary simulation model files.

   For example, compile the **altera_mf_.v** model files into the **altera_mf_ver** library, and compile the **220model.v** model files into the **lpm_ver** library.
9. On the Design menu, click **Compile All** to compile all the files (for example, **altera_mf.v**) into the design library.
10. On the File menu, click **Close Workspace**.
11. On the View menu, click **Library Manager**. The Library Manager window appears.
12. On the Library menu, click **Attach Library.**
13. Locate the **.lib** file (for example, **altera_mf_ver.lib**) from the design directory that you created in the previous steps and click **Open**. This attaches the simulation library as a global library inside your library manager and makes it visible to any design in Active-HDL.
14. Repeat this procedure to create and compile another simulation library.

Compile the Testbench and Design Files into the Work Library

To compile design files and the testbench into the work library, you must create a new workspace. Perform the following steps to create a new workspace and compile your testbench and design files into the work library:

1. In the Active-HDL software, on the File menu, point to **New** and click **Design**. The **New Design Wizard** appears.
2. Select **Create an Empty Design** and keep the **Create New Workspace** option selected.
3. Click **Next**. The **Property** page appears.
4. In the **Property** page, click **Next** to reach the design name and library name options.
5. Type `work` for the design name and select the location of your RTL design. For simplicity, keep the design name and the library name the same.
6. Click **Finish** to complete the wizard.
7. On the Design menu, click **Add files to Design**.
8. Browse to the RTL design directory and add the testbench and RTL design files.

9. Your design may require simulation libraries that you created previously to compile successfully. For example, the **altera_mf_ver** library is required for compiling designs that use Altera megafunctions. If your design requires these simulation libraries, perform the following steps:

   a. On the Design menu, click **Settings**. The Design Settings window appears. Expand the **Compilation** category and click **Verilog**.

   b. To add the **Verilog Library** settings, click the **Add library** icon (upper-right icon) and click **OK** to insert the required Verilog HDL simulation libraries.

   These simulation libraries are the simulation libraries that you compiled or installed previously (for example, **altera_mf_ver** and **lpm_ver**, **altera_ver**).

10. On the Design menu, click **Compile All** to compile the testbench and RTL design files.

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, perform the following steps:

1. In the **Design Browser**, click the **Top-level Selection** list. Select the top-level module, which is your testbench.
2. To add the required simulation library, on the Design menu, click **Settings.** The Design Settings window appears.

   a. Expand the **Simulation** category and click **Verilog**.

   b. In the **Verilog Libraries** window, click the **Add library** icon (top-right icon) and click **OK** to insert the required Verilog HDL simulation libraries (for example, **altera_mf_ver, lpm_ver**, and **altera_ver**).

3. On the Simulation menu, click **Initialize Simulation**. This loads the simulation.
4. The **Design Browser** automatically switches to the **Structure** tab and shows you the design tree.

Running the Simulation

Perform the following steps to run the simulation:

1. On the File menu, point to **New** and click **Waveform**.
2. Drag signals of interest from the **Design Browser** (in the **Structure** tab) to the Waveform window.
3. On the Simulation menu, click **Run Until.**
4. In the pop-up window, specify how long you want your simulation to run (for example, 500 ns).

Perform Post-Synthesis Simulation

Perform post-synthesis simulation to verify that functionality of the design is not lost after synthesis. You can create the post-synthesis netlist in the Quartus II software and use the netlist to perform post-synthesis simulation with the Active-HDL software.

Before you run post-synthesis simulation, generate post-synthesis simulation netlist files. Refer to "Generate Post-Synthesis Simulation Netlist Files" on page 5–7.

Use the instructions in the following section to perform a post-synthesis simulation for Verilog HDL designs in the Active-HDL software.

If your Active-HDL software comes with precompiled simulation libraries, creating or compiling simulation libraries is not required and you can skip the following section.

Create and Compile Simulation Libraries

Simulation libraries are required to simulate a design that is mapped to post-synthesis primitives. Depending on the device family you are using, you must create the required simulation libraries before running the simulation.

Performing post-synthesis simulation requires a gate-level timing simulation library. For example, the library name for the Stratix III family should be **stratixiii_ver**. For a list of all gate-level timing simulation library files, refer to "Gate-Level Timing Simulation Library Files" on page 5–4.

Before you create simulation libraries (for example, **stratixiii_ver**), ensure that a library with the same name is not present in the Active-HDL software. Perform the following steps:

1. In the Active-HDL software, on the View menu, click **Library Manager.** The Library Manager window appears.
2. Check to see that the simulation libraries you are going to create are not already present.
3. If these simulation libraries are present, you must detach them. Right-click the library and from the menu list, select **Detach**.

To create and compile the simulation libraries, you must create a new workspace. Perform the following steps to create a new workspace, create a new library, and compile and register the library in the **Library Manager**. Perform the following steps:

1. In the Active-HDL software, on the File menu, point to **New** and click **Design**. The **New Design Wizard** appears.
2. Select **Create an Empty Design** and keep the **Create New Workspace** option selected.
3. Click **Next**. The **Property** page appears.
4. In the **Property** page, click **Next**.
5. Type the design name (for example, `stratixiii_ver`) and select the location of your RTL design. For simplicity, keep the design name and the library name the same.
6. Click **Finish** to complete the wizard.
7. On the Design menu, click **Add files to Design**.
8. Browse to <*Quartus II installation directory*>**/eda/sim_lib** and add the necessary simulation model files.

   For example, compile the **statixiii.v** model file into the **stratixiii_ver** library.

9. On the Design menu, click **Compile All** to compile all the files (for example, **stratixiii.v**) to the design library.
10. On the File menu, click **Close Workspace**.
11. On the View menu, click **Library Manager**. The **Library Manager** window appears.
12. On the Library menu, click **Attach Library**.
13. Locate the **.lib** file (for example, **stratixiii.lib**) from the design directory that you created in the previous steps and click **Open**. This attaches the simulation library as a global library inside your library manager and makes it visible to any design in the Active-HDL software.
14. Repeat this procedure to create and compile another simulation library, if necessary.

Compile the Testbench and Design File into the Work Library

To compile design files and the testbench into a work library, you must create a new workspace. Perform the following steps to create a new workspace, and compile your testbench and ***.vo** file into the work library:

1. In the Active-HDL software, on the File menu, point to **New** and click **Design**. The **New Design Wizard** appears.
2. Select **Create an Empty Design** and keep the **Create New Workspace** option selected.
3. Click **Next**. The **Property** page appears.
4. In the **Property** page, click **Next** to reach the design name and library name options.
5. Type `work` for the design name and select the location of your RTL design. For simplicity, keep the design name and the library name the same.
6. Click **Finish** to complete the wizard.
7. On the Design menu, click **Add files to Design**.
8. Browse to the Verilog HDL output file directory (for example, *<project directory>***/simulation/activehdl**) and add the Verilog output file (***.vo**). Browse to the testbench file directory and add the testbench file.
9. Your design may require simulation libraries that you created previously to compile successfully. For example, the **stratixiii** library is required for compiling designs that use Stratix III devices. If your design requires these simulation libraries, perform the following steps:
    a. On the Design menu, click **Settings.** The Design Settings window appears. Expand the **Compilation** category and click **Verilog**.
    b. To add the **Verilog Library** settings, click the **Add library** icon (upper-right icon), and click **OK** to insert the required Verilog HDL simulation libraries.

    ☞ These simulation libraries are the simulation libraries you compiled or installed previously.

10. On the Design menu, click **Compile All** to compile the testbench and ***.vo** files.

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, perform the following steps:

1. In the **Design Browser**, click the **Top-level Selection** list. Select the top-level module, which is your testbench.
2. To add the required simulation library, on the Design menu, click **Settings.** The Design Settings window appears.
   a. Expand the **Simulation** category and click **Verilog**.
   b. In the **Verilog Libraries** window, click the **Add library** icon (top-right icon) and click **OK** to insert the required Verilog HDL simulation libraries (for example, **stratixiii_ver**).
3. On the Simulation menu, click **Initialize Simulation**. This loads the simulation.
4. The **Design Browser** automatically switches to the **Structure** tab and shows you the design tree.

Running the Simulation

Perform the following steps to run a simulation:

1. On the File menu, point to **New** and click **Waveform**.
2. Drag signals of interest from the **Design Browser** (in the **Structure** tab) to the **Waveform** window.
3. On the Simulation menu, click **Run Until**.
4. In the pop-up window, specify how long you want your simulation to run (for example, 500 ns).

Perform Gate-Level Timing Simulation

Gate-level timing simulation is a very important step in ensuring that the FPGA's functionality is still correct and meets all of the timing requirements after the design was placed and routed. You can create the gate-level netlist in the Quartus II software and use the netlist to perform gate-level simulation with the Active-HDL software.

Before you run the gate-level timing simulation, generate gate-level timing simulation netlist files. Refer to "Generate Gate-Level Timing Simulation Netlist Files" on page 5–8.

Use the following instructions to perform a gate-level timing simulation for Verilog HDL designs in the Active-HDL software.

If your Active-HDL software comes with precompiled simulation libraries, creating or compiling simulation libraries is not required, and you can skip the next section.

Create and Compile Simulation Libraries

Simulation libraries are required to simulate a design that is mapped to post-fitting primitives. Depending on the device family you are using, you must create the required simulation libraries before running the simulation.

Performing gate-level timing simulation requires a gate-level timing simulation library. For example, the library name for the Stratix III family should be **stratixiii_ver**. For a list of all gate-level timing simulation library files, refer to "Gate-Level Timing Simulation Library Files" on page 5–4.

Before you create simulation libraries (for example, **stratixiii_ver**), ensure that a library with the same name is not present in the Active-HDL software. Perform the following steps:

1. In the Active-HDL software, on the View menu, click **Library Manager.** The **Library Manager** window appears.
2. Check to see that the simulation libraries (for example, **stratixiii_ver**) you are going to create are not already present.
3. If these simulation libraries are present, you must detach them. Right-click the library and from the menu list, click **Detach**.

To create and compile simulation libraries, you must create a new workspace. Perform the following steps to create a new workspace and a new library, and compile and register the library in the **Library Manager**:

1. In the Active-HDL software, on the File menu, point to **New** and click **Design**. The **New Design Wizard** appears.
2. Select **Create an Empty Design** and keep the **Create New Workspace** option selected.
3. Click **Next**. The **Property** page appears.
4. In the **Property** page, click **Next** to reach the design name and library name options.
5. Type the design name (for example, `stratixiii_ver`) and select the location of your RTL design. For simplicity, keep the design name and the library name the same.
6. Click **Finish** to complete the wizard.
7. On the Design menu, click **Add files to Design**.
8. Browse to <*Quartus II installation directory*>**/eda/sim_lib** and add the necessary simulation model files.

   For example, compile the **statixiii_atoms.v** model files into the **stratixiii_ver** library.
9. On the Design menu, click **Compile All** to compile all the files (for example, **statixiii_atoms.v**) to the design library.
10. On the File menu, click **Close Workspace**.
11. You must now register the created library in the Active-HDL software. On the **View** menu, click **Library Manager**. The Library Manager window appears.
12. On the Library menu, click **Attach Library**.

13. Locate the **.lib** file (for example, **stratixiii.lib**) in your design directory that you created in the previous steps and click **Open**. This attaches the simulation library as a global library inside your library manager and makes it visible for any design in the Active-HDL software.
14. Repeat this procedure to create and compile another simulation library, if necessary.

Compile the Testbench and Design File into the Work Library

To compile design files and the testbench into a work library, you must create a new workspace. Perform the following steps to create a new workspace and compile your testbench and ***.vo** file into the work library:

1. In the Active-HDL software, on the File menu, point to **New** and click **Design**. The **New Design Wizard** appears.
2. Select **Create an Empty Design** and keep the **Create New Workspace** option selected.
3. Click **Next**. The **Property** page appears.
4. In the **Property** page, click **Next** to reach the design name and library name options.
5. Type `work` for the design name and select the location of your RTL design. For simplicity, keep the design name and the library name the same.
6. Click **Finish** to complete the wizard.
7. On the Design menu, click **Add files to Design**.
8. Browse to the Verilog HDL output file directory (for example, *<project directory>***/simulation/activehdl**) and add the ***.vo** file and ***.sdo** file. Browse to the testbench file directory and add the testbench file.
9. On the Design menu, click **Compile All** to compile the testbench and Verilog HDL output netlist files.

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, perform the following steps:

1. In the **Design Browser**, click the **Top-level Selection** list. Select the top-level entity, which is your testbench with corresponding architecture.
2. On the Simulation menu, click **Initialize Simulation**. This loads the simulation.
3. The **Design Browser** automatically switches to the **Structure** tab and shows you the design tree.

Running the Simulation

To run the simulation, perform the following steps:

1. On the File menu, point to **New** and click **Waveform**.
2. Drag signals of interest from the **Design Browser** (in the **Structure** tab) to the Waveform window.

3. On the Simulation menu, click **Run Until.**
4. In the pop-up window, specify how long you want your simulation to run (for example, 500 ns).

Perform Simulation Using the Active-HDL Software (Batch Mode)

Perform simulation of Verilog HDL or VHDL designs with Active-HDL software at various levels to verify designs from different aspects. There are three categories of simulation:

- RTL functional simulation
- Post-synthesis simulation
- Gate-level simulation

Simulation helps you verify your design and debug it against any possible errors in the design.

For high-speed simulation, you must select **ps** in the **Resolution** list for your simulator resolutions. If you choose slower than **ps**, the high-speed simulation may fail.

There are two modes in which the Active-HDL software can operate in the batch mode:

- Shell mode
- Command-line mode

In shell mode, all commands are executed in the Active-HDL shell that is started by **vsimsa.bat**. Commands can be grouped into macro files (***.do**) that are executed within the tool shell.

In command-line mode, standalone commands, such as `vlib`, `vcom`, and `vsim`, are executed in the system shell (for example, `cygwin`). These standalone commands can be grouped into script files (**tcl**, **perl**, **windows batch**) that are run from the system shell.

Before running Active-HDL in a standalone command, make sure that the **Active-HDL/bin** directory is located in PATH environment variables.

If you are running the command from the Active-HDL GUI console, workspace creation is the first step. The following commands create the workspace and open the workspace:

```
createdesign <workspace name> <your design path> ↵
opendesign -a <workspace name>.adf ↵
```

Simulating the VHDL Designs

The following sections show how to perform RTL functional, post-synthesis, and gate-level timing simulations in command-line mode or shell mode of the Active-HDL software.

 © March 2009 Altera Corporation

Perform RTL Functional Simulation

RTL functional simulation is typically performed to verify the syntax of the code and to check the functionality of the design. The following sections show how to perform RTL functional simulation in the Active-HDL software for VHDL designs.

If your Active-HDL software comes with precompiled simulation libraries, creating or compiling simulation libraries is not required and you can skip the following section.

Create Simulation Libraries

Simulation libraries are required to simulate a design that contains an Altera primitive, LPM function, or Altera megafunction. Depending on your design, you must create the required simulation libraries and link them to your design correctly.

Execute the following command to create a simulation library:

```
vlib <library_name> ↵
```

The library name for Altera megafunctions should be **altera_mf** and the library name for LPM should be **lpm**. For a list of all functional simulation library files, refer to "RTL Functional Simulation Library Files" on page 5–4.

For example, to create simulation libraries for **altera_mf, lpm**, and **altera**, type the following commands

```
vlib altera_mf ↵
vlib lpm ↵
vlib altera ↵
```

Compile Simulation Models into Simulation Libraries

Type the following command to compile simulation models into simulation libraries:

```
vcom -work <simulation_library> <Quartus II installation directory>
/eda/sim_lib/<simulation_library_files> ↵
```

For example, compile the **altera_mf_components.vhd** and **altera_mf.vhd** model files into the **altera_mf** library, and the **220pack.vhd** and **220model.vhd** model files into the LPM library.

Use Example 5–1 to compile the simulation model files into the simulation libraries for **altera_mf**, **lpm**, and **altera**:

Example 5–1.

```
vcom -work altera_mf \
<Quartus II installation directory>/eda/sim_lib/altera_mf_components.v <Quartus II \
installation directory>/eda/sim_lib/altera_mf.vhd
vcom -work lpm \
<Quartus II installation directory>/eda/sim_lib/220model.vhd \
<Quartus II installation directory>/eda/sim_lib/220model.vhd
vcom -work altera <Quartus II installation directory> \
/eda/sim_lib/altera_primitives_components.vhd \
<Quartus II installation directory>/eda/sim_lib/altera_primitives.vhd
```

Compile the Testbench and Design Files into the Work Library

The following commands show how to compile your testbench and design files into the work library in the Active-HDL software's batch mode.

Type the following command to create the work library:

```
vlib work ↵
```

Type the following command to compile the testbench and design files into work library:

```
vcom -work work <my_testbench>.vhd <my_design_files>.vhd ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, type the following command:

```
vsim -t ps -L <library1> -L <library2> work .<my_testbench> ↵
```

<library1> and *<library2>* are the required libraries to load the design. If you have multiple libraries, use the `-L` option multiple times with the `vsim` command.

Running the Simulation

Type the following commands to trace the signals and run the simulation:

```
trace <hierarchical signal name> ↵
run <time period> ↵
```

The following commands trace the `DUT/clk1` and `DUT/U1/DATA` signal and run the simulation for 100 ps:

```
trace DUT/clk1 ↵
trace DUT/U1/DATA ↵
....
run 100 ps ↵
```

When the simulation is finished, type the following command to end the simulation:

```
endsim ↵
```

To view the simulation result in the GUI waveform, perform the following command to open the **wave.asdb** file:

```
open -asdb {<your_design_path> \work\src\wave.asdb} ↵
```

Perform Post-Synthesis Simulation

Perform post-synthesis simulation to verify that functionality of the design is not lost after synthesis. You can create the post-synthesis netlist in the Quartus II software and use the netlist to perform post-synthesis simulation with the Active-HDL software.

Before you run post-synthesis simulation, generate post-synthesis simulation netlist files. Refer to "Generate Post-Synthesis Simulation Netlist Files" on page 5–7.

The following sections help you perform a post-synthesis simulation for a VHDL design in the Active-HDL software.

If your Active-HDL software comes with precompiled simulation libraries, creating or compiling simulation libraries is not required, and you can skip the following section.

Create Simulation Libraries

Simulation libraries are required to simulate a design that is mapped to post-synthesis primitives. Depending on the device family you are using, you must create the required simulation libraries and link them to your design correctly.

Execute the following command to create a simulation library:

```
vlib <library_name> ↵
```

For example, the library name for the Stratix III family should be **stratixiii**. For a list of all gate-level timing simulation library files, refer to "Gate-Level Timing Simulation Library Files" on page 5–4.

For example, to create simulation libraries for **stratixiii**, execute:

```
vlib stratixiii ↵
```

Compile Simulation Models into Simulation Libraries

To compile simulation models into simulation libraries, type the following command:

```
vcom -work <simulation_library> \ <Quartus II installation directory> \
/eda/sim_lib/<simulation_library_files> ↵
```

For example, compile the **stratixiii_atoms_components.vhd** and **stratixiii_atoms.vhd** model files into the **stratixiii** library.

Example 5–2 compiles simulation model files into the simulation libraries for **stratixiii**.

Example 5–2.

```
vcom -work stratixiii \
<Quartus II installation directory>/eda/sim_lib/stratixiii_atoms_components.vhd \
<Quartus II installation directory>/eda/sim_lib/stratixiii_atoms.vhd
```

Compile the Testbench and VHDL Output File into the Work Library

The following instructions show how you can compile your testbench ***.vho** files into the work library using the Active-HDL GUI.

Type the following command to create the work library:

```
vlib work ↵
```

Type the following command to compile the testbench and ***.vho** files into the work library:

```
vcom -work work <my_testbench>.vhd <my_vhdl_netlists>.vho ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, perform the following command:

```
vsim -t ps -L <library1> -L <library2> work.<my_testbench>
```

<library1> and *<library2>* are the libraries you compiled previously (for example, **stratixiii and stratixiigx**), which are required to load your design. The gate-level libraries are usually required to perform post-synthesis simulation. If you have multiple libraries, use the `-L` option multiple times with the `vsim` command.

Running the Simulation

Type the following commands to trace the signals and run a simulation:

```
trace <hierarchical signal name> ↵
run <time period> ↵
```

For example, the following commands trace the `DUT/clk1` and `DUT/U1/DATA` signal, and run the simulation for 100 ps.

```
trace DUT/clk1 ↵
trace DUT/U1/DATA ↵
....
run 100 ps ↵
```

When the simulation is finished, type the following command to end the simulation:

```
endsim ↵
```

To view the simulation result in the GUI waveform, perform the following command to open the **wave.asdb** file:

```
open -asdb {<your_design_path> \work\src\wave.asdb} ↵
```

Perform Gate-Level Timing Simulation

Gate-level simulation is a very important step in ensuring that the FPGA's functionality is still correct and meets all required timing requirements after the design was placed and routed. You can create the gate-level netlist in the Quartus II software and use the netlist to perform gate-level timing simulation with the Active-HDL software.

Before you run gate-level timing simulation, generate gate-level timing simulation netlist files. Refer to the instructions in "Generate Gate-Level Timing Simulation Netlist Files" on page 5–8.

The following sections help you perform a gate-level timing simulation for a VHDL design in the Active-HDL software.

If your Active-HDL software comes with precompiled simulation libraries, creating or compiling simulation libraries is not required, and you can skip the Create Simulation Libraries and Compile Simulation Models into Simulation Libraries sections.

Create Simulation Libraries

Simulation libraries are required to simulate a design that is mapped to post-fitting primitives. Depending on the device family you are using, you must create the required simulation libraries and link them to your design correctly.

Type the following commands to create simulation libraries:

```
vlib <library_name> ↵
```

For example, the library name for the Stratix III family should be **stratixiii**. For a list of all gate-level timing simulation library files, refer to "Gate-Level Timing Simulation Library Files" on page 5–4.

To create simulation libraries for **stratixiii**, type the following command:

```
vlib stratixiii ↵
```

Compile Simulation Models into Simulation Libraries

Perform the following command to compile simulation models into simulation libraries:

```
vcom -work <simulation_library> <Quartus II installation \
directory>/eda/sim_lib/<simulation_library_files> ↵
```

For example, compile the **stratixiii_atoms_components.vhd** and **stratixiii_atoms.vhd** model files into the **stratixiii** library.

Example 5–3 compiles the simulation model files to the simulation libraries for **stratixiii**.

Example 5–3.

```
vcom -work stratixiii \
<Quartus II installation directory>/eda/sim_lib/stratixiii_atoms_components.vhd \
<Quartus II installation directory>/eda/sim_lib/stratixiii_atoms.vhd
```

Compile the Testbench and VHDL Output File into the Work Library

The following instructions show how you can compile your testbench and ***.vho** files into the work library using the Active-HDL software.

Type the following command to create the work library:

```
vlib work ↵
```

Type the following command to compile the testbench and ***.vho** files into the work library:

```
vcom -work work <my_testbench>.vhd <my_vhdl_netlists>.vho ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, type the following command:

```
vsim -t ps -L <library1> -L <library2> -sdftyp <instance path to \
design>= <path to SDO file> work.<my_testbench> ↵
```

The *<library1>* and *<library2>* are the libraries that you compiled previously (for example, **stratixiii and stratixiigx**), which are required to load your design. The gate-level libraries are usually required to perform post-synthesis simulation. If you have multiple libraries, use the `-L` option multiple times with the `vsim` command.

You do not have to set the value (**Minimum**, **Average**, **Maximum**) for the ***.sdo** file because the Quartus II EDA Netlist Writer generates the ***.sdo** file using the same value for the triplet (**Minimum**, **Average**, and **Maximum** timing values).

If your design under test is instantiated in the testbench file under the `i1` label, the *<design instance>* should be “`i1/`” (for example, `/i1=`*<my design>***.sdo**).

Running the Simulation

To trace the signals and run a simulation, type the following commands:

```
trace <hierarchical signal name> ↵
run <time period> ↵
```

For example, the following commands trace the DUT/clk1 and DUT/U1/DATA signal, and run the simulation for 100 ps.

```
trace DUT/clk1 ↵
trace DUT/U1/DATA ↵
....
run 100 ps ↵
```

When the simulation is finished, type the following command to end the simulation:

```
endsim ↵
```

To view the simulation result in the GUI waveform, type the following command to open the **wave.asdb** file:

```
open -asdb {<your_design_path> \work\src\wave.asdb} ↵
```

Simulating the Verilog HDL Designs

The following sections show how to perform RTL functional post-synthesis and gate-level timing simulations in the command-line mode of the Active-HDL software.

Perform RTL Functional Simulation

RTL functional simulation is typically performed to verify the syntax of the code and to check the functionality of the design. The following sections show how to perform RTL functional simulation in the Active-HDL software for Verilog HDL designs.

If your Active-HDL software comes with precompiled simulation libraries, creating or compiling simulation libraries is not required, and you can skip the following section.

Create Simulation Libraries

Simulation libraries are required to simulate a design that contains an Altera primitive, LPM function, or Altera megafunction. Depending on your design, you must create the required simulation libraries and link them to your design correctly.

To create a simulation library, type the following command:

```
vlib <library_name> ↵
```

The library name for Altera megafunctions should be **altera_mf_ver** and the library name for LPM should be **lpm_ver**. For a list of all functional simulation library files, refer to "RTL Functional Simulation Library Files" on page 5–4.

To create simulation libraries for **altera_mf**, **lpm**, and **altera**, type the following commands:

```
vlib altera_mf_ver ↵
vlib lpm_ver ↵
vlib altera_ver ↵
```

Compile Simulation Models into Simulation Libraries

To compile simulation models into simulation libraries, type the following command:

```
vlog –work <simulation_library> <Quartus II installation directory> \
/eda/sim_lib/<simulation_library_files> ↵
```

For example, compile the **altera_mf.v** model files into the **altera_mf_ver** library, and compile the **220model.v** model files into the **lpm_ver** library.

Use Example 5–4 to compile the simulation model files to the simulation libraries for **altera_mf_ver**, **lpm_ver**, and **altera_ver**:

Example 5–4.

```
vlog -work altera_mf_ver <Quartus II installation directory>/eda/sim_lib/altera_mf.v
vlog -work lpm_ver <Quartus II installation directory>/eda/sim_lib/220model.v
vlog -work altera_ver \
   <Quartus II installation directory> /eda/sim_lib/altera_primitives.v
```

Compile the Testbench and Design Files into the Work Library

The following commands show how to compile your testbench and design files into the work library in the Active-HDL command-line.

To create the work library, type the following command:

```
vlib work ↵
```

To compile the testbench and design files into the work library, type the following command:

```
vlog -work work <my_testbench>.v <my_design_files>.v ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, type the following command:

```
vsim -t ps -L <library1> -L <library2> work .<my_testbench>.v ↵
```

<library1> and *<library2>* are the required libraries to load your design. If you have multiple libraries, use the `-L` option multiple times with the `vsim` command.

Running the Simulation

To trace the signals and run a simulation, type the following commands:

```
trace <hierarchical signal name> ↵
run <time period>
```

For example, the following commands trace the `DUT/clk1` and `DUT/U1/DATA` signal, and run the simulation for 100 ps:

```
trace DUT/clk1 ↵
trace DUT/U1/DATA ↵
....
run 100 ps ↵
```

When the simulation is finished, type the following command to end the simulation:

```
endsim ↵
```

To view the simulation result in the GUI waveform, type the following command to open the **wave.asdb** file:

```
open -asdb {<your_design_path>\work\src\wave.asdb} ↵
```

Perform Post-Synthesis Simulation

Perform post-synthesis simulation to verify that functionality of the design is not lost after synthesis. You can create the post-synthesis netlist in the Quartus II software and use the netlist to perform Post-Synthesis simulation with the Active-HDL software.

Before you run post-synthesis simulation, generate the post-synthesis simulation netlist files. Refer to "Generate Post-Synthesis Simulation Netlist Files" on page 5–7.

The following sections help you perform a post-synthesis simulation for a Verilog HDL design in the Active-HDL software.

If your Active-HDL software comes with precompiled simulation libraries, creating or compiling simulation libraries is not required, and you can skip the following section.

Create Simulation Libraries

Simulation libraries are required to simulate a design that is mapped to post-synthesis primitives. Depending on the device family you are using, you must create the required simulation libraries and link them to your design correctly.

To create a simulation library, type the following command:

```
vlib <library_name> ↵
```

For example, the library name for the Stratix III family should be **stratixiii_ver**. For a list of all gate-level timing simulation library files, refer to "Gate-Level Timing Simulation Library Files" on page 5–4.

As an example, to create simulation libraries for **stratixiii_ver**, type:

```
vlib stratixiii_ver ↵
```

Compile Simulation Models into Simulation Libraries

To compile simulation models into simulation libraries, type the following command:

```
vlog -work <library_name> <Quartus II installation directory> \
   eda/sim_lib/<simulation_library_files> ↵
```

Compile the **stratixiii_atoms.v** model files into the **stratixiii_ver** library.

Example 5–5 compiles the simulation model files into the simulation libraries for **stratixiii**.

Example 5–5.

```
vlog -work stratixiii_ver \
   <Quartus II installation directory>/eda/sim_lib/stratixiii_atoms.v
```

Compile the Testbench and Verilog Output File into the Work Library

The following instructions show how you can compile your testbench and ***.vo** files into the work library using the Active-HDL command line.

To create the work library, type the following command:

```
vlib work ↵
```

To compile the testbench and ***.vo** files into the work library, type the following command:

```
vlog -work work <my_testbench>.v <design_netlists>.vo ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

To load a design, type the following command:

```
vsim -t ps -L <library1> -L <library2> work.<my_testbench>.v ↵
```

<*library1*> and <*library2*> are the libraries that you compiled previously (for example, **stratixiii_ver** and **stratixiigx_ver**), which are required to load the design. The gate-level libraries are usually required to perform post-synthesis simulation. If you have multiple libraries, use the `-L` option multiple times with the `vsim` command.

Running the Simulation

To trace the signals and run a simulation, type the following command:

```
trace <hierarchical signal name> ↵
run <time period> ↵
```

For example, the following commands trace the `DUT/clk1` and `DUT/U1/DATA` signal, and run the simulation for 100 ps:

```
trace DUT/clk1 ↵
trace DUT/U1/DATA ↵
....
run 100 ps ↵
```

When the simulation is finished, type the following command to end the simulation:

```
endsim ↵
```

To view the simulation result in the GUI waveform, type the following command to open the **wave.asdb** file:

```
open -asdb {<your_design_path> \work\src\wave.asdb} ↵
```

Perform Gate-Level Timing Simulation

Gate-Level timing simulation is a very important step in ensuring that the FPGA's functionality is correct and meets all the timing requirements after the design was placed and routed. You can create the gate-level netlist in the Quartus II software and use the netlist to perform gate-level simulation with the Active-HDL software.

Before you run gate-level timing simulation, generate gate-level timing simulation netlist files. Refer to "Generate Gate-Level Timing Simulation Netlist Files" on page 5–8.

The following sections help you perform a gate-level timing simulation for a Verilog HDL design in the Active-HDL software.

If your Active-HDL software comes with precompiled simulation libraries, creating or compiling simulation libraries is not required, and you can skip the following sections.

Create Simulation Libraries

Simulation libraries are required to simulate a design that is mapped to post-fitting primitives. Depending on the device family you are using, you must create the required simulation libraries and link them to your design correctly.

To create a simulation library, type the following command:

```
vlib <library_name> ↵
```

For example, the library name for the Stratix III family should be **stratixiii_ver**. To see all the gate-level timing simulation library files, refer to "Gate-Level Timing Simulation Library Files" on page 5–4.

As an example, to create simulation libraries for **stratixiii**, type the following command:

```
vlib stratixiii_ver ↵
```

Compile Simulation Models into Simulation Libraries

To compile simulation models into a simulation library, type the following command:

```
vlog -work <simulation_library> <Quartus II installation directory> \
/eda/sim_lib/<simulation_library_files> ↵
```

For example, compile the **stratixiii_atoms.v** model files into the **stratixiii_ver** library.

The following is an example to compile simulation model files to the simulation libraries for **stratixiii**:

```
vlog -work stratixiii_ver <Quartus II installation directory> \
/eda/sim_lib/stratixiii_atoms.v ↵
```

Compile the Testbench and Verilog Output File into the Work Library

The following instructions show how you can compile your testbench and ***.vo** files into the work library using the Active-HDL command line.

To create the work library, type the following command:

```
vlib work ↵
```

To compile the testbench and ***.vo** files into the work library, type the following command:

```
vlog -work work <my_testbench>.v <design_netlist>.vo ↵
```

Resolve compile-time errors before proceeding to the next section.

Loading the Design

When simulating in Verilog HDL, the **.sdo** file does not have to be manually specified, because the Quartus II software generates the **.vo** file with the `$sdf_annotate` task that tells Active-HDL how to load the **.sdo** file. Ensure that the **.sdo** file is located in the same simulation output directory.

To load a design, type the following command:

```
vsim -t ps -L <library1> -L <library2> work.<my_testbench>.v ↵
```

<library1> and the *<library2>* are the libraries that you compiled previously (for example, **stratixiii_ver** and **stratixiigx_ver**), which are required to load the design. The gate-level libraries are usually required for performing gate-level simulation. If you have multiple libraries, use the `-L` option multiple times with the `vsim` command.

Running the Simulation

To trace the signals and run a simulation, type the following command:

```
trace <hierarchical signal name> ↵
run <time period> ↵
```

For example, the following commands trace the `DUT/clk1` and `DUT/U1/DATA` signal, and run the simulation for 100 ps:

```
trace DUT/clk1 ↵
trace DUT/U1/DATA ↵
....
run 100 ps ↵
```

When the simulation is finished, type the following command to end the simulation:

```
endsim ↵
```

To view the simulation result in the GUI waveform, perform the following command to open the **wave.asdb** file:

```
open -asdb {<your_design_path> \work\src\wave.asdb} ↵
```

Simulating Designs that Include Transceivers

If your design includes a Stratix IV, Stratix II GX, Stratix GX, Arria II GX, or Arria GX transceiver, you must compile additional library files to perform RTL functional or gate-level timing simulations. The following example shows how to perform simulation on designs that include Stratix GX and Stratix II GX transceivers.

For high-speed simulation, you must select **ps** in the **Resolution** list for your simulator resolutions. If you choose slower than **ps**, the high-speed simulation may fail.

Performing simulation with transceivers in Arria GX or Stratix II GX is very similar. The only requirement is to replace the **stratixiigx_atoms** and **stratixiigx_hssi_atoms** model files with the **arriagx_atoms** and **arriagx_hssi_atoms** model files.

Stratix GX RTL Functional Simulation

To perform an RTL functional simulation of your design that instantiates the ALTGXB megafunction, which enables the gigabit transceiver block on Stratix GX devices, compile the **stratixgx_mf** model file into the **altgxb** library.

The **stratixgx_mf** model file references the **lpm** and **sgate** libraries, so you must create these libraries to perform a simulation.

Performing RTL Functional Simulation for Stratix GX in VHDL

If you are using Active-HDL software that comes with precompiled simulation libraries, compiling the libraries is not necessary. Simulate the design directly by typing the commands in Example 5–6.

Example 5–6.

```
vcom -work <my design>.vhd <my testbench>.vhd
vsim -L lpm -L altera_mf –L sgate -L altgxb work.<my testbench>
```

If you are using Active-HDL software without precompiled simulation libraries, you must compile the necessary libraries before you can simulation the designs. Type the commands in Example 5–7 to compile and simulate the design.

Example 5–7.

```
vcom -work altera_mf altera_mf_components.vhd altera_mf.vhd
vcom -work lpm 220pack.vhd 220model.vhd
vcom -work sgate sgate_pack.vhd sgate.vhd
vcom -work altgxb stratixgx_mf.vhd stratixgx_mf_components.vhd
vcom -work <my design>.vhd <my testbench>.vhd
vsim -L lpm -L altera_mf -L sgate -L altgxb work.<my testbench>
```

Performing Functional Simulation for Stratix GX in Verilog HDL

If you are using Active-HDL software that comes with precompiled simulation libraries, compiling the libraries is not necessary. You can simulate the design directly by typing the command in Example 5–8.

Example 5–8.

```
vlog -work <my design>.v <my testbench>.v
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L altgxb_ver work.<my testbench>
```

If you are using Active-HDL software without precompiled simulation libraries, you must compile the necessary libraries before you can simulate the designs. Type the commands in Example 5–9 to compile and simulate the design.

Example 5–9.

```
vlib work
vlib lpm_ver
vlib altera_mf_ver
vlib sgate_ver
vlib altgxb_ver
vlog -work lpm_ver 220model.v
vlog -work altera_mf_ver altera_mf.v
vlog -work sgate_ver sgate.v
vlog -work altgxb_ver stratixgx_mf.v
vlog -work <my design>.v <my testbench>.v
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L altgxb_ver work.<my testbench>
```

Stratix GX Gate-Level Timing Simulation

Perform a gate-level timing simulation of your design that includes a Stratix GX transceiver by compiling the **stratixgx_atoms** and **stratixgx_hssi_atoms** model files into the **stratixgx** and **stratixgx_gxb** libraries, respectively.

Performing Timing Simulation for Stratix GX in VHDL

If you are using Active-HDL software that comes with precompiled simulation libraries, compiling the libraries is not necessary. You can simulate the design directly by typing the commands in Example 5–10.

Example 5–10.

```
vcom -work <my design>.vho <my testbench>.vhd
vsim -L lpm -L altera_mf -L sgate -L stratixgx -L stratixgx_gxb \
work.<my testbench> -t ps -sdftyp <design instance>=<path to SDO file>.sdo \
+transport_int_delays+transport_path_delays
```

If you are using Active-HDL software without precompiled simulation libraries, you must compile the necessary libraries before you can simulate the designs. Type the commands in Example 5–11 to compile and simulate the design.

Example 5–11.

```
vcom -work lpm 220pack.vhd 220model.vhd
vcom -work altera_mf altera_mf_components.vhd altera_mf.vhd
vcom -work sgate sgate_pack.vhd sgate.vhd
vcom -work stratixgx stratixgx_atoms.vhd stratixgx_components.vhd
vcom -work stratixgx_gxb stratixgx_hssi_atoms.vhd \
stratixgx_hssi_components.vhd
vcom -work <my design>.vho <my testbench>.vhd
vsim -L lpm -L altera_mf -L sgate -L stratixgx -L stratixgx_gxb work. \
<my testbench> -t ps -sdftyp <design instance>=<path to SDO file>.sdo \
+transport_int_delays +transport_path_delays
```

Performing Gate-Level Timing Simulation for Stratix GX in Verilog HDL

If you are using Active-HDL software that comes with precompiled simulation libraries, compiling the libraries is not necessary. You can simulate the design directly by typing the commands in Example 5–12.

Example 5–12.

```
vlog -work <my design>.v <my testbench>.v
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L stratixgx_ver -L stratixgx_gxb_ver \
work.<my testbench> -t ps +transport_int_delays +transport_path_delays
```

If you are using Active-HDL software without precompiled simulation libraries, you must compile the necessary libraries before you can simulate the designs. Type the commands in Example 5–13 to compile and simulate the design.

Example 5–13.

```
vlog -work lpm_ver 220model.v
vlog -work altera_mf_ver altera_mf.v
vlog -work sgate_ver sgate.v
vlog -work stratixgx_ver stratixgx_atoms.v
vlog -work stratixgx_gxb_ver stratixgx_hssi_atoms.v
vlog -work <my design>.vo <my testbench>.v
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L stratixgx_ver -L stratixgx_gxb_ver \
work.<my testbench> -t ps +transport_int_delays +transport_path_delaysr
```

Stratix II GX RTL Functional Simulation

Stratix II GX RTL functional simulation is similar to Arria GX functional simulation. The following example shows only the RTL functional simulation for designs that include transceivers in Stratix II GX. To simulate transceivers in Arria GX, replace the **stratixiigx_hssi** model file with the **arriagx_hssi** model file.

To perform an RTL functional simulation of your design that instantiates the ALT2GXB megafunction, which enables the gigabit transceiver blocks on Stratix II GX devices, you must generate a functional simulation netlist and compile the **stratixiigx_hssi** model file into the **stratixiigx_hssi** library.

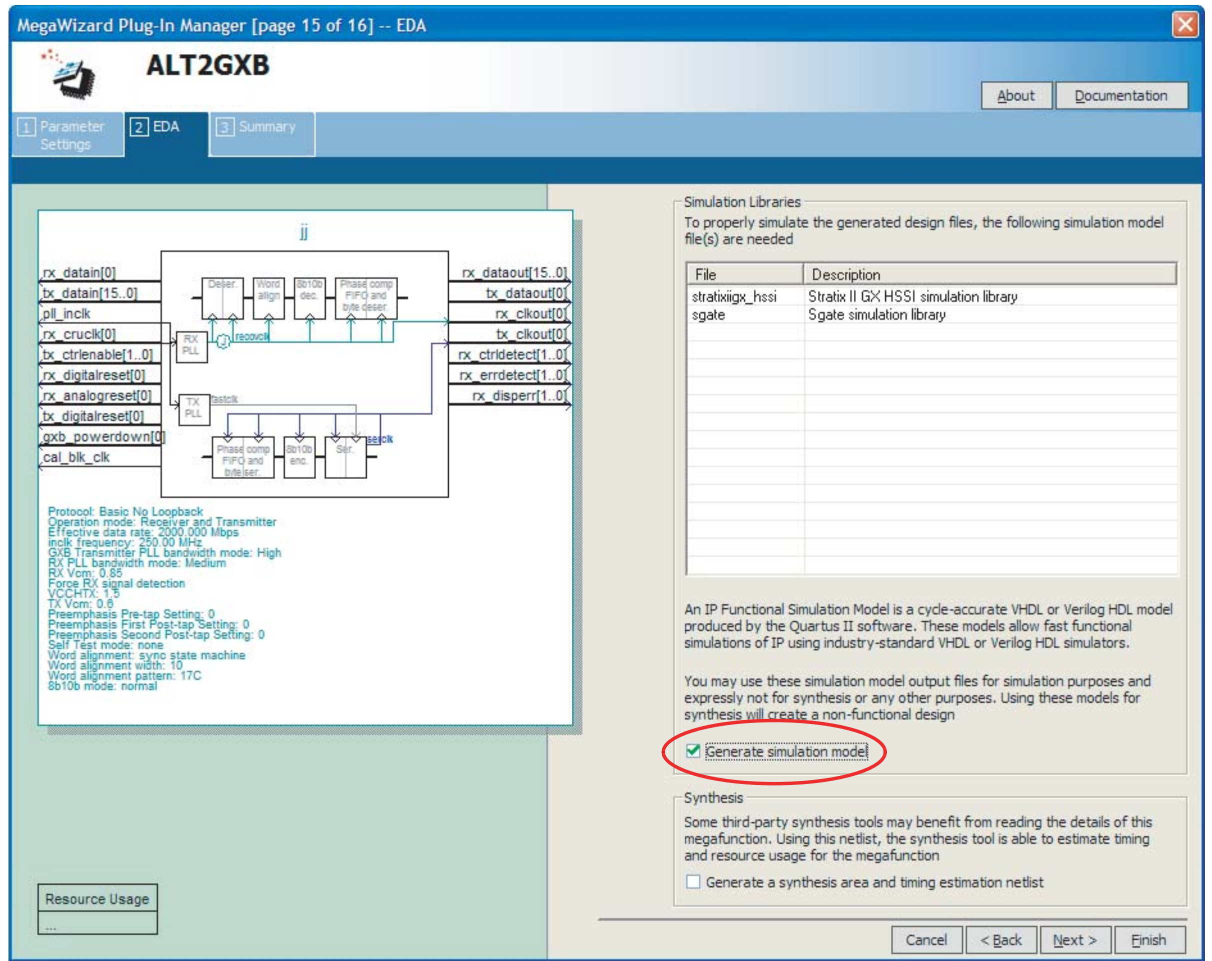
The **stratixgx_hssi_atoms** model file references the **lpm** and **sgate** libraries; you must create these libraries to perform a simulation.

To run the RTL functional simulation, you must generate a functional simulation netlist by turning on **Generate Simulation Model** in the **Simulation Libraries** tab of the ALT2GXB MegaWizard Plug-In Manager (see Figure 5–2).

The <*alt2gxb entity name*>**.vho** or <*alt2gxb module name*>**.vo** is generated in the current project directory.

The Quartus II-generated ALT2GXB functional simulation library file references **stratixiigx_hssi** wysiwyg atoms.

Figure 5–2. ALT2GXB MegaWizard Plug-In Manager



Performing RTL Functional Simulation for Stratix II GX in VHDL

If you are using Active-HDL software that comes with precompiled simulation libraries, compiling the libraries is not necessary. You can simulate the design directly by typing the commands in Example 5–14.

Example 5–14.

```
vcom -work work <alt2gxb entity name>.vho
vcom -work <my design>.vhd <my testbench>.vhd
vsim -L lpm -L altera_mf -L sgate -L stratixgx_hssi work.<my testbench>
```

© March 2009 Altera Corporation

If you are using Active-HDL software without precompiled simulation libraries, you must compile the necessary libraries before you can simulate the designs. Type the commands in Example 5–15 to compile and simulate the design.

Example 5–15.

```
vcom -work lpm 220pack.vhd 220model.vhd
vcom -work altera_mf altera_mf_components.vhd altera_mf.vhd
vcom -work sgate sgate_pack.vhd sgate.vhd
vcom -work stratixiigx_hssi stratixiigx_hssi_components.vhd \
stratixiigx_hssi_atoms.vhd
vcom -work work <alt2gxb entity name>.vho
vcom -work <my design>.vhd <my testbench>.vhd
vsim -L lpm -L altera_mf -L sgate -L stratixgx_hssi work.<my testbench>
```

Performing RTL Functional Simulation for Stratix II GX in Verilog HDL

If you are using Active-HDL software that comes with precompiled simulation libraries, compiling the libraries is not necessary. You can simulate the design directly by typing the commands in Example 5–16.

Example 5–16.

```
vlog -work work <alt2gxb module name>.vo
vlog -work <my design>.v <my testbench>.v
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L stratixgx_hssi_ver \
   work.<my testbench>
```

If you are using Active-HDL software without precompiled simulation libraries, you must compile the necessary libraries before you can simulate the designs. Type the commands in Example 5–17 to compile and simulate the design.

Example 5–17.

```
vlog -work lpm_ver 220model.v
vlog -work altera_mf_ver altera_mf.v
vlog -work sgate_ver sgate.v
vlog -work stratixiigx_hssi_ver stratixiigx_hssi_atoms.v
vlog -work work <alt2gxb module name>.vo
vlog -work <my design>.v <my testbench>.v
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L stratixgx_hssi \
   work.<my testbench>
```

Stratix II GX Gate-Level Timing Simulation

To perform a gate-level timing simulation of your design that includes a Stratix II GX transceiver, you must compile **stratixiigx_atoms** and s**tratixiigx_hssi_atoms** into the **stratixiigx** and **stratixiigx_hssi** libraries, respectively.

Performing Timing Simulation for Stratix II GX in VHDL

If you are using Active-HDL software that comes with precompiled simulation libraries, compiling the libraries is not necessary. You can simulate the design directly by typing the commands in Example 5–18.

Example 5–18.

```
vcom -work <my design>.vho <my testbench>.vhd
vsim -L lpm -L altera_mf -L sgate -L stratixiigx -L stratixiigx_hssi \
work.<my testbench> -t ps -sdftyp <design instance>=<path to SDO file>.sdo \
+transport_int_delays +transport_path_delays
```

If you are using Active-HDL software without precompiled simulation libraries, you must compile the necessary libraries before you can simulate the designs.

Type the commands in Example 5–19 to compile and simulate the design.

Example 5–19.

```
vcom -work lpm 220pack.vhd 220model.vhd
vcom -work altera_mf altera_mf_components.vhd altera_mf.vhd
vcom -work sgate sgate_pack.vhd sgate.vhd
vcom -work stratixiigx stratixiigx_atoms.vhd stratixiigx_components.vhd
vcom -work stratixiigx_hssi stratixiigx_hssi_components.vhd stratixiigx_hssi_atoms.vhd
vcom -work <my design>.vho <my testbench>.vhd
vsim -L lpm -L altera_mf -L sgate -L stratixiigx -L stratixiigx_hssi \
work.<my testbench> -t ps -sdftyp <design instance>=<path to SDO file>.sdo \
+transport_int_delays +transport_path_delays
```

Performing Timing Simulation for Stratix II GX in Verilog HDL

If you are using Active-HDL software that comes with precompiled simulation libraries, compiling the libraries is not necessary. You can simulate the design directly by typing the command in Example 5–20.

Example 5–20.

```
vlog -work <my design>.vo <my testbench>.v
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L stratixiigx_ver -L \
stratixiigx_hssi_ver work.<my design> -t ps +transport_int_delays +transport_path_delays
```

If you are using Active-HDL software without precompiled simulation libraries, you must compile the necessary libraries before you can simulate the designs.

Type the commands in Example 5–21 to compile and simulate the design.

Example 5–21.

```
vlog -work lpm_ver 220model.v
vlog -work altera_mf_ver altera_mf.v
vlog -work sgate_ver sgate.v
vlog -work stratixiigx_ver stratixiigx_atoms.v
vlog -work stratixiigx_hssi_ver stratixiigx_hssi_atoms.v
vlog -work <my design>.vo <my testbench>.v
vsim -L lpm -L altera_mf_ver -L sgate_ver -L stratixiigx_ver -L stratixiigx_hssi_ver \
work.<my testbench> -t ps +transport_int_delays +transport_path_delays
```

Transport Delays

By default, the Active-HDL software filters out all pulses that are shorter than the propagation delay between primitives. Turning on the **transport delay** options in the Active-HDL software prevents the simulation tool from filtering out these pulses. Use the following options to ensure that all signal pulses are visible in the simulation results:

- **+transport_path_delays**

  Use this option when the pulses in your simulation may be shorter than the delay within a gate-level primitive.

- **+transport_int_delays**

  Use this option when the pulses in your simulation may be shorter than the interconnect delay between gate-level primitives.

The **+transport_path_delays** and **+transport_int_delays** options are also used by default in the NativeLink feature for gate-level timing simulation.

For more information about either of these options, refer to the Active-HDL online documentation installed with the Active-HDL software.

Example 5–22 shows an Active-HDL software command in command-line syntax to perform a gate-level timing simulation with the device family library.

Example 5–22.

```
vsim -t 1ps -L stratixii -sdftyp /i1=filtref_vhd.sdo \
work.filtref_vhd_vec_tst +transport_int_delays +transport_path_delays
```

Using the NativeLink Feature in Active-HDL Software

The NativeLink feature in the Quartus II software facilitates the seamless transfer of information between the Quartus II software and EDA tools and allows you to run Active-HDL within the Quartus II software.

Setting Up NativeLink

To run the Active-HDL software automatically from the Quartus II software using the NativeLink feature, you must specify the path to your simulation tool by performing the following steps:

1. On the Tools menu, click **Options**. The **Options** dialog box appears.
2. In the **Category** list, select **EDA Tool Options**.
3. Double-click the entry under **Location of executable** beside the name of your EDA Tool.
4. Type or browse to the directory containing the executables of your EDA tool.

For Active-HDL, the executable files are stored in the **bin** directory (for example, **C:\Program Files\Aldec\Active-HDL X.X\BIN**).

You can also specify the path to the simulator's executables by using the `set_user_option` TCL command:

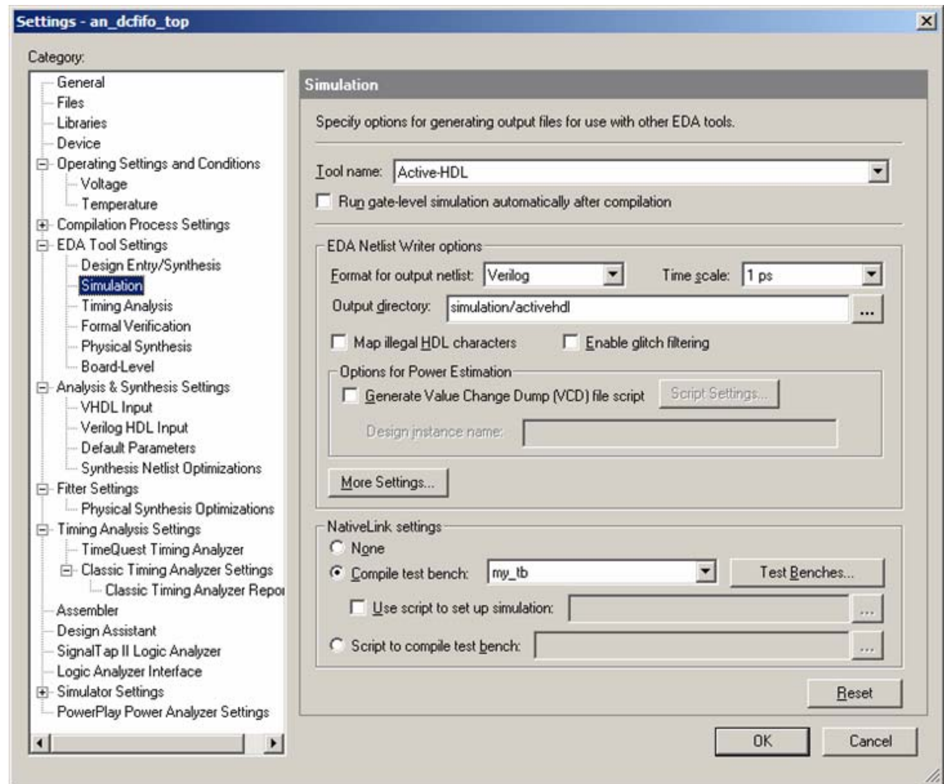
```
set_user_option -name EDA_TOOL_PATH_ACTIVEHDL <path to executables> ↵
```

Performing an RTL Simulation Using NativeLink

To run an RTL functional simulation with the Active-HDL software in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears (Figure 5–3).

Figure 5–3. Simulation Page in the Settings Dialog Box



3. In the **Tool name** list, select **Active-HDL**.
4. If your design is written entirely in Verilog HDL or VHDL, the NativeLink feature automatically chooses the correct language and Altera simulation libraries. If your design is written with mixed languages, the NativeLink feature uses the default language specified in the **Format for output netlist** list. To change the default language when there is a mixed language design, under **EDA Netlist Writer options**, in the **Format for output netlist** list, select **VHDL** or **Verilog**. Table 5–7 shows the design languages for output netlists and simulation models.

Table 5–7. NativeLink Design Languages

Device File	Format for Output Netlist	Simulation Models Used
Verilog HDL	Any	Verilog HDL
VHDL	Any	VHDL
Mixed	Verilog HDL	Verilog HDL
Mixed	VHDL	VHDL

For mixed language simulation, choose the same language that was used to generate your megafunctions to ensure correct parameter passing between the megafunctions and the Altera libraries. For example, if your ALTSYNCRAM megafunction was generated in VHDL, choose VHDL as the format for the output netlist.

When creating mixed language designs, it is important to be aware of the following:

- Seamless passing of parameters when a VHDL entity is instantiated in Verilog HDL designs is not allowed.
- The use of Verilog User Defined Primitives (UDPs) to be instantiated in VHDL designs is not allowed.

5. If you have testbench files or macro scripts, enter the information under **NativeLink settings**.

For more information about setting up a testbench with NativeLink, refer to “Setting Up a Testbench” on page 5–49.

6. Click **OK**.
7. On the Processing menu, point to **Start** and click **Start Analysis and Elaboration** to perform an analysis and elaboration. This command collects all your file name information and builds your design hierarchy in preparation for simulation.
8. On the Tools menu, point to **Run EDA Simulation Tool** and click **EDA RTL Simulation** to automatically run the Active-HDL software, compile all necessary design files, and complete a simulation.
9. If you want to generate only the Tcl script without using the GUI after the NativeLink process, perform the following steps:
   a. On the **Simulation** page, click **More NativeLink Settings**. The **More NativeLink Settings** dialog box appears.
   b. Under **Existing option settings**, click **Generate third-party EDA tool command scripts without running the EDA tool**.
   c. Under **Setting**, click **On**.

   If you turn this option on and run NativeLink, the Tcl file for the simulation process is generated without showing the results in the GUI. You can then run the simulation by typing the following command:

```
do <design_name>.do ↵
```

Performing a Gate-Level Timing Simulation Using NativeLink

To run a gate-level timing simulation with the Active-HDL software in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears (Figure 5–3).
3. In the **Tool name** list, select **Active-HDL**.
4. Under **EDA Netlist Writer options**, in the **Format for output netlist** list, choose **VHDL** or **Verilog**. You can also modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
5. To run a gate-level timing simulation after each full compilation, turn on **Run Gate Level Simulation automatically after compilation**.
6. If you have testbench files or macro scripts, enter the information under **NativeLink settings**.
7. Click **OK**.
8. On the Processing menu, point to **Start** and click **Start EDA Netlist Writer** to generate a simulation netlist of your design.

   If you have run full compilation after you set the EDA Tool Settings, the Start EDA Netlist Writer is not required.

9. On the Tools menu, point to **Run EDA Simulation Tool** and click **EDA Gate Level Simulation** to automatically run Active-HDL, compile all necessary design files, and complete a simulation.

   If multi-corner Timing Analysis is performed, a dialog box appears. Select the timing corner and click **Run**.

   The Active-HDL Macro File (***.do**) is generated in the <*project_directory*>**\simulation\activehdl** directory while running NativeLink. You can perform a simulation with the **.do** file directly from Active-HDL when you rerun a simulation without using NativeLink. To perform the simulation directly without NativeLink, type the following command in the Active-HDL console: `do` <*generated_do_file*>`.do`.

10. If you want to run Active-HDL in command-line mode when running it automatically after full compilation, you can perform the following steps:

    a. On the Simulation page, click **More NativeLink Settings**. The **More NativeLink Settings** dialog box appears.

    b. Under **Existing option settings**, click **Launch third-party EDA tool in command-line mode**.

    c. Under Setting, click **On**.

    d. Click **OK**.

11. To generate only the Tcl script without using the GUI after the NativeLink process, perform the following steps:
    a. On the **Simulation** Page, click **More NativeLink Settings**. The **More NativeLink Settings** dialog box appears.
    b. Under **Existing option settings**, click **Generate third-party EDA tool command scripts without running the EDA tool.**
    c. Under **Setting**, click **On**.

    If you turn this option on and run NativeLink, the Tcl file for the simulation process is generated without showing the results in the GUI. You can then run the simulation by typing the following command:

    ```
    do <design_name>.do ↵
    ```

Setting Up a Testbench

You can use NativeLink to compile your design files and testbench files, and run an EDA simulation tool to automatically perform a simulation.

To set up NativeLink for simulation, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, click the "+" icon to expand **EDA Tool Settings** and select **Simulation**. The **Simulation** page appears.
3. Under **NativeLink settings**, select **None**, **Compile test bench**, or **Script to compile test bench** (see Table 5–8).

Table 5–8. NativeLink Settings

Settings	Description
None	Compile simulation models and design files.
Compile test bench	NativeLink compiles simulation models, design files, testbench files, and starts simulation.
Script to compile test bench	NativeLink compiles the simulation models and design files. The script you provide is sourced after design files compile. Use this option when you want to create your own script to compile your testbench and perform simulation.

4. If you select **Compile test bench**, select your testbench setup from the **Compile testbench** list. You can use different testbench setups to specify different test scenarios. If there are no testbench setups entered, create a testbench setup by performing the following steps:

   a. Click **Test Benches**. The **Test Benches** dialog box appears.

   b. Click **New**. The **New Test Bench Settings** dialog box appears.

   c. In the **Test Bench name** dialog box, type in the testbench setup name that identifies the different testbench setups.

   d. In the **Test level module** box, type in the top-level testbench entity name. For example, for a Quartus II generated VHDL testbench, type `<Vector Waveform File name>_vhd_vec_tst`.

   e. In the **Instance** box, type in the full instance path to the top level of your FPGA design. For example, for a Quartus II generated VHDL testbench, type in `i1`.

   f. Under **Simulation period**, select **Run simulation until all vector stimuli are used** or specify the end time of the simulation.

   g. Under **Test bench files**, browse and add all your testbench files in the **File name** box. Use the **Up** and **Down** button to reorder your files. The script used by NativeLink compiles the files in order from top to bottom.

You can also specify the library name and the HDL version to compile the testbench file. NativeLink compiles the testbench into a library name using the specified HDL version.

   h. Click **OK**.

   i. In the **Test Benches** dialog box, click **OK**.

Creating a Testbench

In the Quartus II software, you can create a Verilog HDL or VHDL testbench from a Vector Waveform File. The generated testbench includes the behavior of the input stimulus and applies it to your instantiated top-level FPGA design.

To create a testbench, perform the following steps:

1. On the File menu, click **Open**. The **Open** dialog box appears.
2. Click the **Files of type** arrow and select **Waveform/Vector Files**. Select your Vector Waveform File.
3. Click **Open**.
4. On the File menu, click **Export**. The **Export** dialog box appears.
5. Click the **Save as type** arrow and select **VHDL Test Bench File** (***.vht**) or **Verilog Test Bench File** (***.vt**).
6. You can turn on **Add self-checking code to file** to check your simulation results against your Vector Waveform File.
7. Click **Export**. Your VHDL or Verilog HDL testbench file is generated in your project directory.

Generate Simulation Script from EDA Netlist Writer

In the Quartus II software version 9.0 and later, you can generate the simulation script (including the **.do** file, Tcl script, and option file) when you run the EDA Netlist Writer. You can use the simulation script to run your simulation in the preferred simulator in stand-alone mode.

To generate a simulation script with the EDA Netlist Writer, perform the following steps:

1. On the **Simulation** page, click **More EDA Netlist Writer Settings**. The **More EDA Netlist Writer Settings** dialog box appears.
2. Under Existing option settings, click **Generate third-party EDA tool command script for RTL simulation** (if you want to generate an RTL simulation script) or click **Generate third-party EDA tool command script for Gate-Level simulation** (if you want to generate a Gate-Level simulation script).
3. Under Setting, click **On**.
4. Click **OK**.
5. Follow the steps in "Generate Post-Synthesis Simulation Netlist Files" on page 5–7.

In the command-line, to generate the simulation script with the EDA Netlist Writer, type the following command:

```
quartus_eda --simulation --tools=<Your decided tool> --format=<vhdl or verilog>
    --gen_script=<rtl or gate_level> <Project Name> -c <Revision name> ↵
```

Generating VCD Files for PowerPlay

To generate a VCD file for PowerPlay, you must first generate a VCD script in the Quartus II software and run the VCD script from the Active-HDL software to generate a VCD file. This VCD file can then be used by PowerPlay for power estimation. The following instructions show you how to generate a VCD file.

Perform the following steps to generate VCD Scripts in the Quartus II software:

1. In the Quartus II software, on the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulator Settings**.
3. On the **Simulator Settings** page, in the **Tool Name** list, choose the appropriate third-party simulation tool (that is, **Active-HDL**), and turn on the **Generate Value Change Dump File Script** option.
4. To generate the VCD Script file, perform a full compilation.

Perform the following steps to generate a VCD file in the Active-HDL software:

1. In the Active-HDL software, before simulating your design, source the **<*revision_name*>_dump_all_vcd_nodes.tcl** script. To source the TCL script, run the following command before running the **vsim** command:

   ```
   source <revision_name>_dump_all_vcd_nodes.tcl ↵
   ```

2. Continue to run the simulation until the simulation is completed. Exit the Active-HDL software. If you do not exit the software, the Active-HDL software may end the writing process of the VCD files improperly, resulting in a corrupted VCD file.

For more details about using the VCD file for power estimation, refer to the *PowerPlay Power Analysis* chapter in volume 3 of the *Quartus II Handbook*.

Scripting Support

You can run procedures and create settings described in this chapter in a Tcl script. You can also run some procedures at the command-line prompt.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*.

For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

For detailed information about scripting command options, refer to the **Qhelp** command line and Tcl API help browser.

To start the Qhelp help browser, type the following command:

```
quartus_sh -qhelp ↵
```

Generating a Post-Synthesis Simulation Netlist for Active-HDL

You can use the Quartus II software to generate a post-synthesis simulation netlist with Tcl commands or with a command at the command-line prompt. The following examples assume you are selecting Active-HDL (Verilog HDL output from the Quartus II software).

Tcl Commands

Use the following Tcl commands to set the output format to Verilog HDL, the simulation tool to Active-HDL for Verilog HDL, and to generate a functional netlist:

```
set_global_assignment-name EDA_SIMULATION_TOOL "Active-HDL(Verilog)" ↵
set_global_assignment-name EDA_GENERATE_FUNCTIONAL_NETLIST ON ↵
```

Command Prompt

Use the following command to generate a simulation output file for the Active-HDL software. Specify VHDL or Verilog HDL for the format:

```
quartus_eda <project name> --simulation=on --format=<format> \
   --tool=activehdl --functional ↵
```

Generating a Gate-Level Timing Simulation Netlist for Active-HDL

You can use the Quartus II software to generate a gate-level timing simulation netlist with Tcl commands or with a command at the command prompt.

Tcl Commands

Use one of the following Tcl commands:

```
set_global_assignment -name EDA_SIMULATION_TOOL "Active-HDL (Verilog)" ↵
set_global_assignment -name EDA_SIMULATION_TOOL "Active-HDL (VHDL)" ↵
```

Command Line

Generate a simulation output file for the Active-HDL software by specifying VHDL or Verilog HDL for the format by typing the following command at the command prompt:

```
quartus_eda <project name> --simulation=on --format=<format> \
    --tool=activehdl ↵
```

Conclusion

Using the Active-HDL simulation software within the Altera FPGA design flow allows you to easily and accurately perform RTL functional simulations, post-synthesis simulations, and gate-level timing simulations on your designs. Proper verification of designs at the functional, post-synthesis, and post place-and-route stages using the Active-HDL software helps ensure design functionality success and, ultimately, a quick time-to-market.

Document Revision History

Table 5–9 shows the revision history for this chapter.

Table 5–9. Document Revision History

Date / Revision	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Removed "Compile Libraries Using the Altera Simulation Library Compiler". ■ Added "Compile Libraries Using the EDA Simulation Library Compiler" on page 5–10. ■ Added "Generate Simulation Script from EDA Netlist Writer" on page 5–51. ■ Minor editorial updates.	Updated for the Quartus II software version 9.0 release.
November 2008 v.8.1.0	Added the following sections: ■ "Compile Libraries Using the Altera Simulation Library Compiler" on page 5–10 ■ Added steps to the procedure "Performing an RTL Simulation Using NativeLink" on page 5–45 for using the Altera Simulation Library Compilation ■ Added steps to the procedure "Performing a Gate-Level Timing Simulation Using NativeLink" on page 5–47 for using the Altera Simulation Library Compilation ■ Minor editorial updates ■ Updated entire chapter using 8½" × 11" chapter template	Updated for the Quartus II software version 8.1 release.
May 2008 v.8.0.0	Initial Release.	—

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

6. Simulating Altera IP in Third-Party Simulation Tools

QII53014-9.0.0

Introduction

The capacity and complexity of Altera® FPGAs continues to increase as the need for intellectual property (IP) becomes increasingly critical. Using IP megafunctions reduces the design and verification time, allowing you to focus on design customization. Altera and the Altera Megafunction Partners Program (AMPP℠) offer a broad portfolio of IP megafunctions optimized for Altera FPGAs. Through parameterization, these reusable blocks of IP can be customized to meet your design requirements.

Even when the IP source code is encrypted or otherwise restricted, Altera's Quartus® II software allows you to easily simulate designs that contain Altera IP. With the Quartus II software, you can custom configure IP designs, then generate a VHDL or Verilog HDL functional simulation model to use with your choice of simulation tools.

This chapter provides an overview of the process for instantiating the IP megafunctions in your design and simulating its functional simulation model in an Altera-supported, third-party simulation tool. In this chapter, IP megafunctions refer to Altera megafunctions, IP MegaCore® functions, and IP AMPP megafunctions.

All IP MegaCore functions come with IP functional simulation (IPFS) models to support functional simulation. Some Altera megafunctions and some AMPP megafunctions also require IPFS models for functional simulation.

An IPFS model is a cycle-accurate VHDL or Verilog HDL model produced by the Quartus II software. The model allows for fast functional simulation of IP using industry-standard VHDL and Verilog HDL simulators.

Use these models only for simulation. Do not use them for synthesis or any other purpose. Using these models for synthesis creates a nonfunctional design.

This chapter discusses the following topics:

- "IP Functional Simulation Flow"
- "Instantiate the IP in Your Design" on page 6–3
- "Perform Simulation" on page 6–3
- "Design Language Examples" on page 6–9

IP Functional Simulation Flow

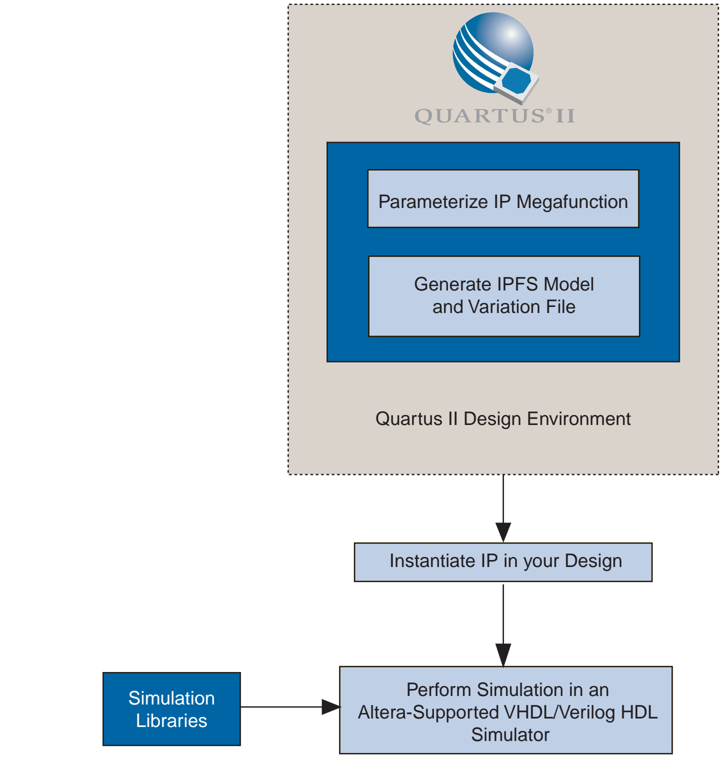
The IP megafunction's MegaWizard™ interface allows you to quickly and easily view documentation, specify parameters, generate an IPFS model, and output the files necessary to integrate a parameterized IP megafunction into your design. Within the Quartus II software, the MegaWizard Plug-In Manager can be used to select and parameterize your choice of IP megafunctions. The Quartus II software generates an

IP megafunction's variation file that is included in your Quartus II project. For IP megafunctions that require IPFS models, the Quartus II software can also generate a Verilog Output File (**.vo**) or VHDL Output File (**.vho**) that contains a Register Transfer Level (RTL) IPFS model after you have parameterized the megafunction. IPFS models are written to the Quartus II project directory.

Most Altera megafunctions and IP MegaCore functions support functional simulation in Verilog and VHDL for all Altera supported third-party simulators. Simulation libraries are required to simulate IP megafunctions. Refer to Table 6–2 on page 6–8 for a subset of simulation libraries supplied with the Quartus II software.

Figure 6–1 shows a typical simulation flow for Altera IP with third-party simulators.

Figure 6–1. IPFS Model Design Flow



Verilog HDL and VHDL IPFS Models

Some IP megafunctions require IPFS models to support functional simulation. These IPFS models are generated in RTL HDL. These RTL models in Verilog HDL or VHDL format differ from the low-level synthesized netlist in Verilog HDL or VHDL format generated by the Quartus II software for post-synthesis or post place-and-route simulations. The IPFS models generated by the Quartus II software are much faster than the low-level post-synthesis or post place-and-route netlists of your design because they are mapped to higher-level primitives such as adders, multipliers, and multiplexers. These IPFS models can be simulated together with the rest of your design in any Altera-supported simulator. Altera recommends that you generate IPFS models in the same hardware language as the IP megafunction's variation file hardware language.

You can use an IPFS model for simulation only. Do not use it for synthesis or any other purpose. Attempting to synthesize an IPFS model will result in a nonfunctional design.

Generating an IPFS model for Altera MegaCore functions does not require a license. However, generating an IPFS model for AMPP megafunctions may require a license. For more information about licensing requirements, contact the IP megafunction vendor.

For details about how to parameterize and generate an IP, refer to the applicable IP user guide.

Instantiate the IP in Your Design

For each IP megafunction in your design, you must instantiate the corresponding entity or module in your design. Each IP megafunction entity or module name is defined in its Quartus II generated megafunction variation file. After instantiating the IP megafunction in your design, you do not need to edit your design for synthesis or simulation.

To synthesize your design using the Quartus II software, add the Quartus II-generated Verilog HDL or VHDL variation file to your Quartus II project. When you create new variation files for a Quartus II project, they are added to the current open project when the megafunction is generated.

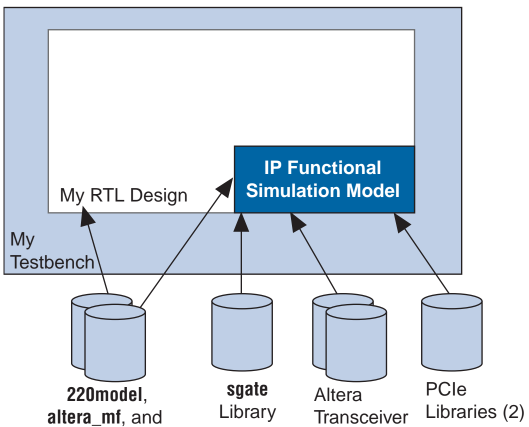
To synthesize your design using a third-party EDA tool, add the Quartus II-generated CMP file (<*megafunction variation*>**.cmp**) for your VHDL design or the Verilog HDL black box file (<*megafunction variation*>**_bb.v**) for your Verilog HDL design to your third-party synthesis project.

For more information about synthesis and compilation with the Quartus II software, refer to the applicable chapters in *Volume 1: Design Synthesis* of the *Quartus II Handbook*.

Perform Simulation

To perform simulation, in addition to adding your design files and testbench files, you also have to add the IP megafunction'is variation file or IPFS model to your simulation project. If the IP megafunction does not require an IPFS model for simulation, add the megafunction's variation file to your simulation project. If the IP megafunction you are simulating requires an IPFS model, add the IPFS model to your simulation project. Your simulation project also requireS Altera-supplied libraries for successful simulation. Figure 6–2 shows how the Altera libraries are used in IP functional simulation.

Figure 6–2. IPFS Library Usage



Notes to Figure 6–2:

(1) The IP that uses the transceiver requires the Altera transceiver libraries for simulation. Refer to Table 6–2 for all the Altera transceiver libraries.

(2) An IP that uses the PCI Express (PCIe) hard core in a Stratix IV device requires the PCIe libraries. Refer to Table 6–2 for all the PCIe transceiver libraries.

The Quartus II software contains all the libraries required for setting up and running a successful simulation of Altera IP. You can use the Quartus II NativeLink feature to set up your simulation if the IP megafunction you are using supports Quartus II NativeLink. Refer to the applicable IP megafunction user guide to determine if NativeLink is supported. Alternatively, you can simulate Altera IP with third-party simulators directly.

Simulating Altera IP Using the Quartus II NativeLink Feature

The Quartus II NativeLink feature eases the task of setting up and running a simulation. The NativeLink feature lets you launch the third-party simulator to perform simulation from within the Quartus II software. The NativeLink feature automates the compilation and simulation of testbenches.

The following list briefly describes the steps to simulate IP megafunctions with third-party simulators using the Quartus II NativeLink feature. Each of these steps is described in more detail in the sections that follow.

1. Select the Third-Party Simulation Tool.
2. Specify the Path for the Third-Party Simulator.
3. Specify the Testbench Settings.
4. Analyze and Elaborate the Quartus II Project.
5. Run RTL Functional Simulation.

Set up a Quartus II Project

To simulate IP megafunctions with the Quartus II NativeLink feature, you must open an existing project or create a new project in the Quartus II software. You can create and parameterize the IP you want to use in your design using the MegaWizard Plug-In Manager within the Quartus II software. Altera IP megafunction variation files are added to your Quartus II project when you create and parameterize the IP. You can also add any other required design files to your Quartus II project. If you are using the Quartus II NativeLink feature and your Quartus II project contains IP megafunctions that require IPFS models for simulation, you do not have to manually add the IPFS models to the Quartus II project for these IP megafunctions. When the Quartus II NativeLink feature launches the third-party simulator tool and starts the simulation, it automatically adds the IPFS model files required for simulation as long as they are present in the Quartus II project directory.

Select the Third-Party Simulation Tool

You can select the third-party simulation tool on the **Simulation** page in the **Settings** dialog box.

Table 6–1 lists the third-party simulators supported by the Quartus II NativeLink feature.

Table 6–1. Third-Party Simulator Support with the Quartus II NativeLink Feature

Third-Party Simulator	Can be Launched from Quartus II Software *(1)*	Testbench Support	Mixed Design (Verilog HDL and VHDL)
ModelSim® PE/SE	Yes	Yes	Yes
ModelSim-Altera Edition	Yes	Yes	No
Synopsys VCS	Yes	Yes	No
Synopsys VCS-MX	Yes	Yes	Yes
Cadence NC-Sim	Yes	Yes	Yes
Aldec Active-HDL	Yes	Yes	Yes

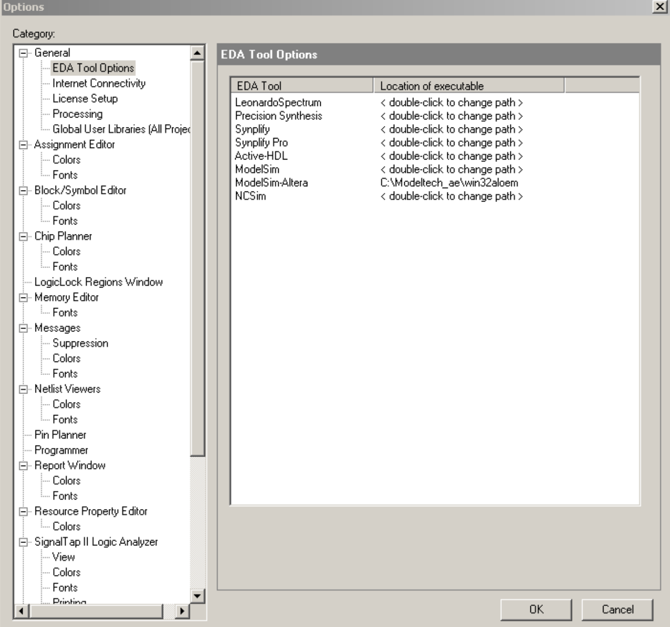
Note to Table 6–1:

(1) The Quartus II software must be running on the same platform as the third-party simulator to launch the simulator tool.

Specify the Path for the Third-Party Simulator

To launch the third-party simulation tool, the absolute path for the selected simulator must be provided on the **Options** page under the Tools menu. See Figure 6–3. Double-click the **Location of executable** field to change or specify the absolute path.

Figure 6–3. Specifying the Simulator Path



Specify the Testbench Settings

Specify the applicable testbench settings as follows:

1. Under **NativeLink settings** in the **Settings** dialog box (Figure 6–3), select the **Compile test bench** radio button and click **Test Benches** to display the **Test Benches** dialog box.
2. Click **New** to display the **New Test Bench Settings** dialog box.
3. In the **New Test Bench Settings** dialog box, set the appropriate fields with the names for the testbenches.

For specific instructions about specifying testbench settings for your MegaCore function, refer to your MegaCore function user guide.

4. After specifying the testbench files, close the **New Test Bench Settings**, **Test Benches**, and **Settings** dialog boxes.

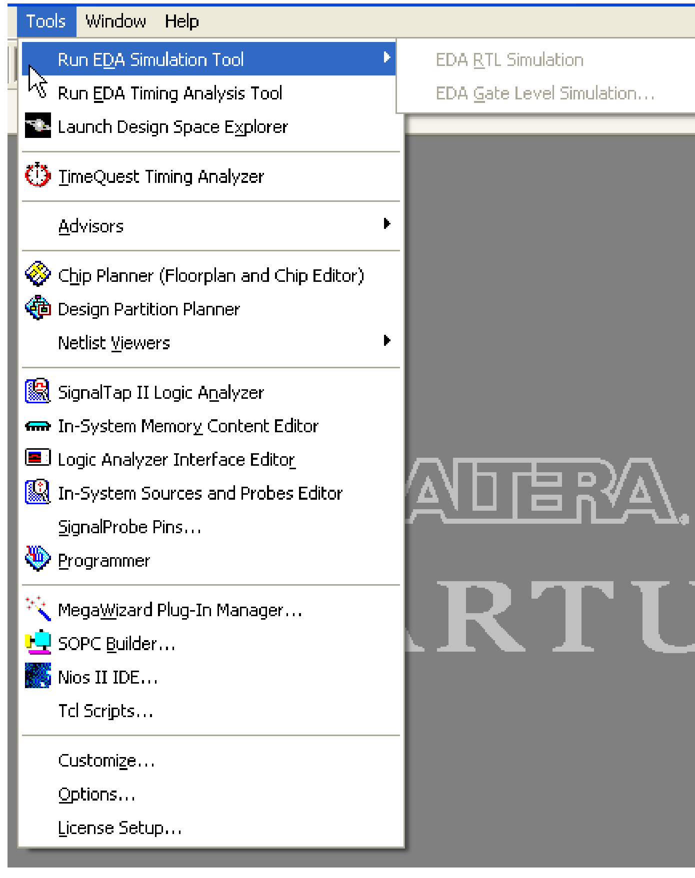
Analyze and Elaborate the Quartus II Project

Before starting the simulation using the NativeLink feature, make sure that each IP megafunction's variation files are included in your design project. On the Quartus II Processing menu, point to **Start**, then click **Start Analysis & Elaboration**.

Run RTL Functional Simulation

After the design is analyzed and elaborated, you can start the simulation by clicking **Run EDA Simulation Tool** from the Tools menu. See Figure 6–4. During RTL functional simulation, the IPFS models are compiled and used by the simulator.

Figure 6–4. Running Functional Simulation for IP using NativeLink



Simulating Altera IP Without the Quartus II NativeLink Feature

You can also simulate Altera IP directly with third-party simulators. If your design instantiates an IP megafunction, add its variation file to your simulation project. If the IP megafunction requires IPFS model files, **do not** add the megafunction's variation file to your simulation project. Rather, add its IPFS model files (either Verilog HDL or VHDL) to your simulation project. The IPFS model generated by the Quartus II software instantiates high-level primitives such as adders, multipliers, and multiplexers, as well as the library of parameterized modules (LPM) functions and Altera megafunctions.

To properly compile, load, and simulate the IP megafunctions, you must first compile the following libraries in your simulation tool:

- **sgate**—includes the definition of the high-level primitives (needed for IPFS models)
- **altera_mf**—includes the definition of Altera megafunctions
- **altera_primitives**—includes the definition of Altera primitives
- **220model**—includes the definition of LPM functions

- **Altera transceiver**—includes the definition of all Altera transceiver megafunctions. If you use IP with the transceiver block, you must compile these libraries, which are device dependent.
- **PCIe**—includes the definition of PCIe hard core megafunctions for Stratix IV. If you use IP with the PCIe hard core for Stratix IV, you must compile these libraries.

You can use these library files with any Altera-supported simulation tool. If you are using the ModelSim-Altera software, the libraries are precompiled and mapped.

To simulate a design containing a Nios® processor or Avalon® peripherals, refer to *AN 189: Simulating Nios Embedded Processor Designs*.

Table 6–2 lists the simulation library files, where <*path*> is the directory where the Quartus II software is installed.

Table 6–2. Simulation Library Files (Part 1 of 2)

Location	HDL Language	Description
<*path*>**/eda/sim_lib/sgate.v**	Verilog HDL	Libraries that contain simulation models for IP functional models
<*path*>**/eda/sim_lib/sgate.vhd**	VHDL	
<*path*>**/eda/sim_lib/sgate_pack.vhd**	VHDL	Libraries that contain VHDL component declarations for the **sgate.vhd** library
<*path*>**/eda/sim_lib/220model.v**	Verilog HDL	Libraries that contain simulation models for the Altera LPM version 2.2.0
<*path*>**/eda/sim_lib/220model.vhd**	VHDL

Design Language Examples

The following design language examples explain how to simulate IP megafunctions directly with third-party simulator tools. These design examples describe simulation with:

- ModelSim Verilog
- ModelSim VHDL
- NC-VHDL
- VCS

Verilog HDL Example: Simulating the IPFS Model in the ModelSim Software

The following example shows the process of simulating a Verilog HDL-based megafunction. The example assumes that the megafunction variation and the IPFS model are generated.

1. Create a ModelSim project by performing the following steps:
   a. In the ModelSim software, on the File menu, point to **New** and click **Project**. The **Create Project** dialog box appears.
   b. Specify the name of your simulation project.
   c. Specify the desired location for your simulation project.
   d. Specify the default library name and click **OK**.
   e. Add relevant files to your simulation project:
   - Your design files
   - The IPFS model generated by the Quartus II software (if you are using the ModelSim-Altera software, skip to step 5)
   - The **sgate.v**, **220model.v**, and **altera_mf.v** library files
   - The transceiver library files in Verilog HDL, if you use IP with transceivers. Transceiver libraries are family independent. Refer to Table 6–2 for more information.
   - The PCIe library files in Verilog HDL, if you use IP with the PCIe hard core for Stratix IV devices. Refer to Table 6–2 for more information.

2. Create the required simulation libraries by typing the following commands at the ModelSim prompt:

   ```
   vlib sgate ↵
   vlib lpm ↵
   vlib altera_mf ↵
   ```

3. Map to the required simulation libraries by typing the following commands at the ModelSim prompt:

   ```
   vmap sgate sgate ↵
   vmap lpm lpm ↵
   vmap altera_mf altera_mf ↵
   ```

4. Compile the HDL into libraries by typing the following commands at the ModelSim prompt:

   ```
   vlog -work altera_mf altera_mf.v ↵
   vlog -work sgate sgate.v ↵
   vlog -work lpm 220model.v ↵
   ```

5. Compile the IPFS model by typing the following command at the ModelSim prompt:

   ```
   vlog -work work <my_IP>.vo ↵
   ```

6. Compile your RTL by typing the following command at the ModelSim prompt:

   ```
   vlog -work work <my_design>.v ↵
   ```

7. Compile the testbench by typing the following command at the ModelSim prompt:

   ```
   vlog -work work <my_testbench>.v ↵
   ```

 © March 2009 Altera Corporation

8. Load the testbench by typing the following command at the ModelSim prompt:

```
vsim -L <altera_mf library_path> -L <lpm_library_path> \
-L <sgate_library_path> work.<my_testbench> ↵
```

VHDL Example: Simulating the IPFS Model in the ModelSim Software

The following example shows the process of performing a functional simulation of a VHDL-based, megafunction IPFS model. The example assumes that the megafunction's variation and the IPFS model are generated.

1. Create a ModelSim project by performing the following steps:
   a. In the ModelSim software, on the File menu, point to **New** and click **Project**. The **Create Project** dialog box appears.
   b. Specify the name for your simulation project.
   c. Specify the desired location for your simulation project.
   d. Specify the default library name and click **OK**.
   e. Add the relevant files to your simulation project:
   - Add your design files
   - Add the IPFS model generated by the Quartus II software (if you are using the ModelSim-Altera software, skip to step 5)
   - Add the **sgate.vhd**, **sgate_pack.vhd**, **220model.vhd**, **220pack.vhd**, **altera_mf.vhd**, and **altera_mf_components.vhd** library files
   - The transceiver library files in VHDL, if you use IP with transceivers. Transceiver libraries are family independent. Refer to Table 6–2 for more information.
   - The PCIe library files in VHDL, if you use IP with the PCIe hard core for Stratix IV. Refer to Table 6–2 for more information.
2. Create the required simulation libraries by typing the following commands at the ModelSim prompt:

```
vlib sgate ↵
vlib lpm ↵
vlib altera_mf ↵
```

3. Map to the required simulation libraries by typing the following commands at the ModelSim prompt:

```
vmap sgate sgate ↵
vmap lpm lpm ↵
vmap altera_mf altera_mf ↵
```

4. Compile the HDL into libraries by typing the following commands at the ModelSim prompt:

```
vcom -work altera_mf -93 -explicit altera_mf_components.vhd ↵
vcom -work altera_mf -93 -explicit altera_mf.vhd ↵
vcom -work lpm -93 -explicit 220pack.vhd ↵
vcom -work lpm -93 -explicit 220model.vhd ↵
vcom -work sgate -93 -explicit sgate_pack.vhd ↵
```

```
vcom -work sgate -93 -explicit sgate.vhd ↵
```

5. Compile the IPFS model by typing the following command at the ModelSim prompt:

```
vcom -work work -93 -explicit <output_netlist>.vho ↵
```

6. Compile the RTL by typing the following command at the ModelSim prompt:

```
vcom -work work -93 -explicit <RTL>.vhd ↵
```

7. Compile the testbench by typing the following command at the ModelSim prompt:

```
vcom -work work -93 -explicit <my_testbench>.vhd ↵
```

8. Load the testbench by typing the following command at the ModelSim prompt:

```
vsim work.my_testbench ↵
```

NC-VHDL Example: Simulating the IPFS Model in the NC-VHDL Software

The following example shows the process of performing a functional simulation of an NC-VHDL-based, megafunction IP functional-simulation model. The example assumes that the megafunction's variation and the IPFS model are generated.

1. Create a **cds.lib** file by typing the following entries:

```
DEFINE worklib ./worklib

DEFINE sgate ./sgate

DEFINE altera_mf ./altera_mf

DEFINE lpm ./lpm
```

2. Compile library files into appropriate libraries by typing the following commands at the command prompt:

```
ncvhdl -V93 -WORK lpm 220pack.vhd ↵
ncvhdl -V93 -WORK lpm 220model.vhd ↵
ncvhdl -V93 -WORK altera_mf altera_mf_components.vhd ↵
rncvhdl -V93 -WORK altera_mf altera_mf.vhd ↵
ncvhdl -V93 -WORK sgate sgate_pack.vhd ↵
ncvhdl -V93 -WORK sgate sgate.vhd ↵
```

3. Compile source code and testbench files by typing the following commands at the command prompt:

```
ncvhdl -V93 -WORK worklib <my_design>.vhd ↵
ncvhdl -V93 -WORK worklib <my_testbench>.vhd ↵
ncvhdl -V93 -WORK worklib <my_IPtoolbench_output_netlist>.vho ↵
```

4. Elaborate the design by typing the following command at the command prompt:

```
ncelab worklib.<my_testbench>:entity ↵
```

 © March 2009 Altera Corporation

Verilog HDL Example: Simulating Your IPFS Model in VCS

The following example illustrates the process of performing a functional simulation of a design that contains a Verilog HDL-based, megafunction IPFS model. This example assumes that the megafunction variation and the IPFS model are generated.

Single-Step Process

For the single-step process, type the following at the command prompt:

```
vcs <testbench>.v <RTL>.v <output_netlist>.v -v 220model.v \
altera_mf.v sgate.v -R ↵
```

Two-Step Process (Compilation and Simulation)

For compilation and simulation, perform the following steps:

1. Compile your design files by typing the following at the command prompt:

```
vcs <testbench>.v <RTL>.v <output_netlist>.v -v 220model.v \
altera_mf.v sgate.v -o simulation_out ↵
```

2. Load your simulation by typing the following at a command prompt:

```
source simulation_out ↵
```

For more information about simulating a design in VCS, refer to the *Synopsys VCS and VCS-MX Support* chapter in volume 3 of the *Quartus II Handbook*.

Conclusion

Altera Quartus II software provides full support for simulating IP megafunctions with third-party tools either directly or using its NativeLink feature. Using the Quartus II software, you can also generate IPFS models for supported megafunctions that enhance and simplify design verification. Using an IPFS model is transparent, requiring only the addition of different files in which to synthesize and simulate projects.

Section II. Timing Analysis

As designs become more complex, advanced timing analysis capability requirements grow. Static timing analysis is a method of analyzing, debugging, and validating the timing performance of a design. The Quartus® II software provides the features necessary to perform advanced timing analysis for today's system-on-a-programmable-chip (SOPC) designs.

Synopsys PrimeTime is an industry standard sign-off tool, used to perform static timing analysis on most ASIC designs. The Quartus II software provides a path to enable you to run PrimeTime on your Quartus II software designs, and export a netlist, timing constraints, and libraries to the PrimeTime environment.

This section explains the basic principles of static timing analysis, the advanced features supported by the Quartus II Timing Analyzer, and how you can run PrimeTime on your Quartus designs.

This section includes the following chapters:

- Chapter 7, The Quartus II TimeQuest Timing Analyzer
- Chapter 8, Best Practices for the Quartus II TimeQuest Timing Analyzer
- Chapter 9, Switching to the Quartus II TimeQuest Timing Analyzer
- Chapter 10, Quartus II Classic Timing Analyzer
- Chapter 11, Synopsys PrimeTime Support

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

7. The Quartus II TimeQuest Timing Analyzer

QII53018-9.0.0

Introduction

The Quartus® II TimeQuest Timing Analyzer is a powerful ASIC-style timing analysis tool that validates the timing performance of all logic in your design using an industry-standard constraint, analysis, and reporting methodology. Use the Quartus II TimeQuest Timing Analyzer's GUI or command-line interface to constrain, analyze, and report results for all timing paths in your design.

Before running the Quartus II TimeQuest Timing Analyzer, you must specify initial timing constraints that describe the clock characteristics, timing exceptions, and signal transition arrival and required times. You can specify timing constraints in the Synopsys Design Constraints (**.sdc**) file format using the GUI or command-line interface. The Quartus II Fitter optimizes the placement of logic to meet your constraints.

During timing analysis, the Quartus II TimeQuest Timing Analyzer analyzes the timing paths in the design, calculates the propagation delay along each path, checks for timing constraint violations, and reports timing results as slack in the **Report** pane and in the **Console** pane. If the Quartus II TimeQuest Timing Analyzer reports any timing violations, you can customize the reporting to view precise timing information about specific paths, and then constrain those paths to correct the violations. When your design is free of timing violations, you can be confident that the logic will operate as intended in the target device.

The Quartus II TimeQuest Timing Analyzer is a complete static timing analysis tool that you can use as a sign-off tool for Altera® FPGAs and HardCopy® ASICs.

This chapter contains the following sections:

Getting Started with the Quartus II TimeQuest Timing Analyzer

The Quartus II TimeQuest Timing Analyzer caters to the needs of the most basic to the most advanced designs for FPGAs.

This section provides a brief overview of the Quartus II TimeQuest Timing Analyzer, including the necessary steps to properly constrain a design, perform a full place-and-route, and perform reporting on the design.

Setting Up the Quartus II TimeQuest Timing Analyzer

The Quartus II software version 7.2 and later supports two native timing analysis tools: Quartus II TimeQuest Timing Analyzer and Quartus II Classic Timing Analyzer. When you specify the Quartus II TimeQuest Timing Analyzer as the default timing analysis tool, the Quartus II TimeQuest Timing Analyzer guides the Fitter and analyzes timing results after compilation.

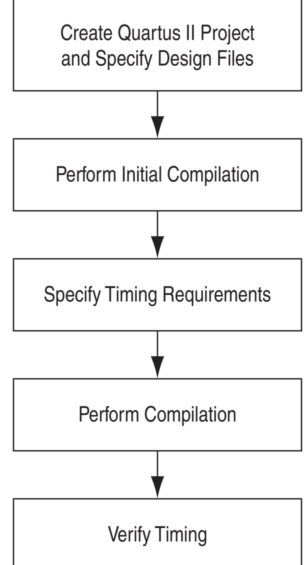
To specify the Quartus II TimeQuest Timing Analyzer as the default timing analyzer, on the Assignments menu, click **Settings**. In the **Settings** dialog box, in the **Category** list, select **Timing Analysis Settings** and turn on **Use TimeQuest Timing Analyzer during compilation**.

To add the TimeQuest icon to the Quartus II toolbar, on the Tools menu, click **Customize**. In the Customize dialog box, click the **Toolbars** tab, turn on **Processing**, and click **Close**.

Compilation Flow with the Quartus II TimeQuest Timing Analyzer Guidelines

When you enable the Quartus II TimeQuest Timing Analyzer as the default timing analyzer, everything from constraint validation to timing verification is performed by the Quartus II TimeQuest Timing Analyzer. Figure 7–1 shows the recommended design flow steps to maximize and leverage the benefits the Quartus II TimeQuest Timing Analyzer. Details about each step are provided after the figure.

Figure 7–1. Design Flow with the Quartus II TimeQuest Timing Analyzer



- **Create Quartus II Project and Specify Design Files**—Creates a project before you can compile design files. In this step you specify the target FPGA, any EDA tools used in the design cycle, and all design files.

  You can also modify existing design files for design optimization and add additional design files. For example, you can add HDL files or schematics to the project.

- **Perform Initial Compilation**—Creates an initial design database before you specify timing constraints for your design. Perform Analysis and Synthesis to create a post-map database, or perform a full compilation to create a post-fit database.

  Creating a post-map database for the initial compilation is faster than creating a post-fit database. A post-map database is sufficient for the initial database.

  Creating a post-fit database is recommended only if you previously created and specified an **.sdc** file for the project. A post-map database is sufficient for the initial compilation.

- **Specify Timing Requirements**—Timing requirements guide the Fitter as it places and routes your design.

  You must enter all timing constraints and exceptions in an **.sdc** file. This file must be included as part of the project. To add this file to your project, on the Project menu, click **Add/Remove Files in Project** and add the **.sdc** file in the **Files** dialog box.

- **Perform Compilation**—Synthesizes, places, and routes your design into the target FPGA.

  When compilation is complete, the TimeQuest Timing Analyzer generates summary clock setup and clock hold, recovery, and removal reports for all defined clocks in the design.

- **Verify Timing—**Verifies timing in your design with the Quartus II TimeQuest Timing Analyzer. Refer to "The Quartus II TimeQuest Timing Analyzer Flow Guidelines" on page 7–19.

Running the Quartus II TimeQuest Timing Analyzer

You can run the Quartus II TimeQuest Timing Analyzer in one of the following modes:

- Directly from the Quartus II software
- Stand-alone mode
- Command-line mode

This section describes each of the modes, and the behavior of the Quartus II TimeQuest Timing Analyzer.

Directly from the Quartus II Software

To run the Quartus II TimeQuest Timing Analyzer from the Quartus II software, on the Tools menu, click **TimeQuest Timing Analyzer**. The Quartus II TimeQuest Timing Analyzer is available after you have created a database for the current project. The database can be either a post-map or post-fit database; perform Analysis and Synthesis to create a post-map database, or a full compilation to create a post-fit database.

After a database is created, you can create a timing netlist based on that database. If you create a post-map database, you cannot create a post-fit timing netlist in the Quartus II TimeQuest Timing Analyzer.

When you launch the TimeQuest Timing Analyzer directly from the Quartus II software, the current project opens by default.

Stand-Alone Mode

To run the Quartus II TimeQuest Timing Analyzer in stand-alone mode, type the following command at the command prompt:

```
quartus_staw ↵
```

In stand-alone mode, you can perform static analysis on any project that contains either a post-map or post-fit database. To open a project, double-click **Open Project** in the **Tasks** pane.

Command-Line Mode

Use command-line mode for easy integration with scripted design flows. Using the command-line mode avoids interaction with the user interface provided by the Quartus II TimeQuest Timing Analyzer, but allows the automation of each step of the static timing analysis flow. Table 7–1 provides a summary of the options available in the command-line mode.

Table 7–1. Summary of Command Line Options

Command Line Option	Description
`-h | --help`	Provides help information on `quartus_sta`.
`-t <script file> |` `--script=<script file>`	Sources the <*script file*>.
`-s | --shell`	Enters shell mode.
`--tcl_eval <tcl command>`	Evaluates the Tcl command <*tcl command*>.

`--do_report_timing`	For all clocks in the design, run the following commands:
	`report_timing -npaths 1 -to_clock $clock`
	`report_timing -setup -npaths 1 -to_clock $clock`
	`report_timing -hold -npaths 1 -to_clock $clock`
	`report_timing -recovery -npaths 1 -to_clock $clock`
	`report_timing -removal -npaths 1 -to_clock $clock`

`--force_dat`	Forces the Delay Annotator to annotate the new delays from the recently compiled design to the compiler database.
`--lower_priority`	Lowers the computing priority of the `quartus_sta` process.
`--post_map`	Uses the post-map database results.
`--qsf2sdc`	Converts assignments from the Quartus II Settings File (**.qsf**) format to the Synopsys Design Constraints File format.
`--sdc=<SDC file>`	Specifies the **.sdc** file to read.
`--report_script=<script>`	Specifies a custom report script to be called.
`--speed=<value>`	Specifies the device speed grade to be used for timing analysis.
`--tq2hc`	Generate temporary files to convert the Quartus II TimeQuest Timing Analyzer **.sdc** file(s) to a PrimeTime **.sdc** file that can be used by the HardCopy Design Center (HCDC).
`--tq2pt`	Generates temporary files to convert the Quartus II TimeQuest Timing Analyzer **.sdc** file(s) to a PrimeTime **.sdc** file.
`-f <argument file>`	Specifies a file containing additional command-line arguments.
`-c <revision name> |` `--rev=<revision_name>`	Specifies which revision and its associated Quartus II Settings File (**.qsf**) to use.
`--multicorner`	Specifies that all slack summary reports be generated for both slow and fast corners.
`--multicorner[=on|off]`	Turns off the multicorner analysis by using the off value.
`--voltage=<value_in_mV>`	Specifies the device voltage (mV) to be used in timing analysis.
`--temperature=` `<value_in_C>`	Specifies the device temperature (C) to be used in timing analysis.
`--parallel` `[=<num_processors>]`	Specifies the number of computer processors to use on a multi-processor system.
`--64bit`	Enables 64-bit version of the executable.

To run the Quartus II TimeQuest Timing Analyzer in command-line mode, type the following command at the command prompt:

```
quartus_sta <options> ↵
```

Timing Analysis Overview

This section provides an overview of the Quartus II TimeQuest Timing Analyzer concepts. Understanding these concepts allows you to take advantage of the powerful timing analysis features available in the Quartus II TimeQuest Timing Analyzer.

The Quartus II TimeQuest Timing Analyzer follows the flow shown in Figure 7–2 when it analyzes your design. Table 7–2 lists the most commonly used commands for each step.

Figure 7–2. The Quartus II TimeQuest Timing Analyzer Flow

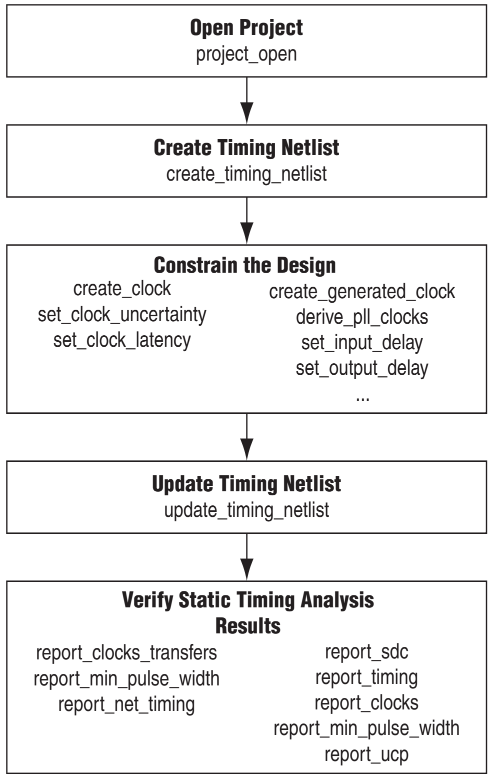


Table 7–2 describes Quartus II TimeQuest Timing Analyzer terminology.

Table 7–2. Quartus II TimeQuest Timing Analyzer Terms (Part 1 of 2)

Terminology	Definition
Nodes	Most basic timing netlist unit. Use to represent ports, pins, and registers.
Keepers	Ports or registers. *(1)*
Cells	Look-up table (LUT), registers, digital signal processing (DSP) blocks, TriMatrix memory, IOE, and so on. *(2)*
Pins	Inputs or outputs of cells.
Nets	Connections between pins.
Ports	Top-level module inputs or outputs; for example, device pins.

Table 7–2. Quartus II TimeQuest Timing Analyzer Terms (Part 2 of 2)

Terminology	Definition
Clocks	Abstract objects outside of the design.

Notes to Table 7–2:

(1) Pins can indirectly refer to keepers. For example, when the value in the `-from` field of a constraint is a clock pin to a dedicated memory. In this case, the clock pin refers to a collection of registers.

(2) For Stratix® devices and other early device families, the LUT and registers are contained in logic elements (LE) and act as cells for these device families.

The Quartus II TimeQuest Timing Analyzer requires a timing netlist before it can perform a timing analysis on any design. For example, for the design shown in Figure 7–3, the Quartus II TimeQuest Timing Analyzer generates a netlist equivalent to the one shown in Figure 7–4.

Figure 7–3. Sample Design

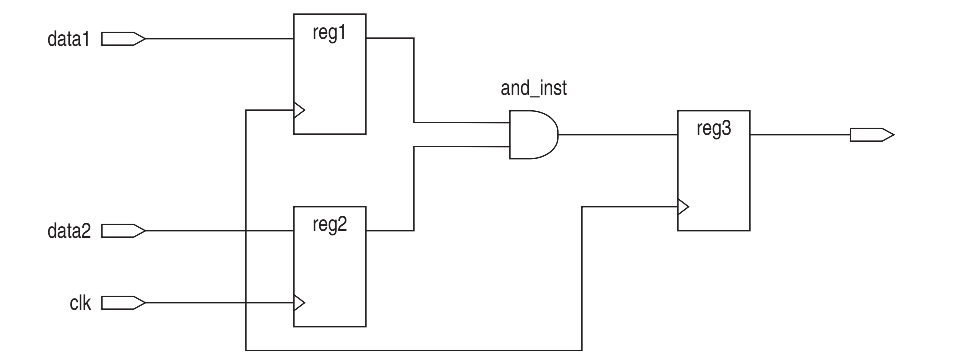

Figure 7–4. The Quartus II TimeQuest Timing Analyzer Timing Netlist

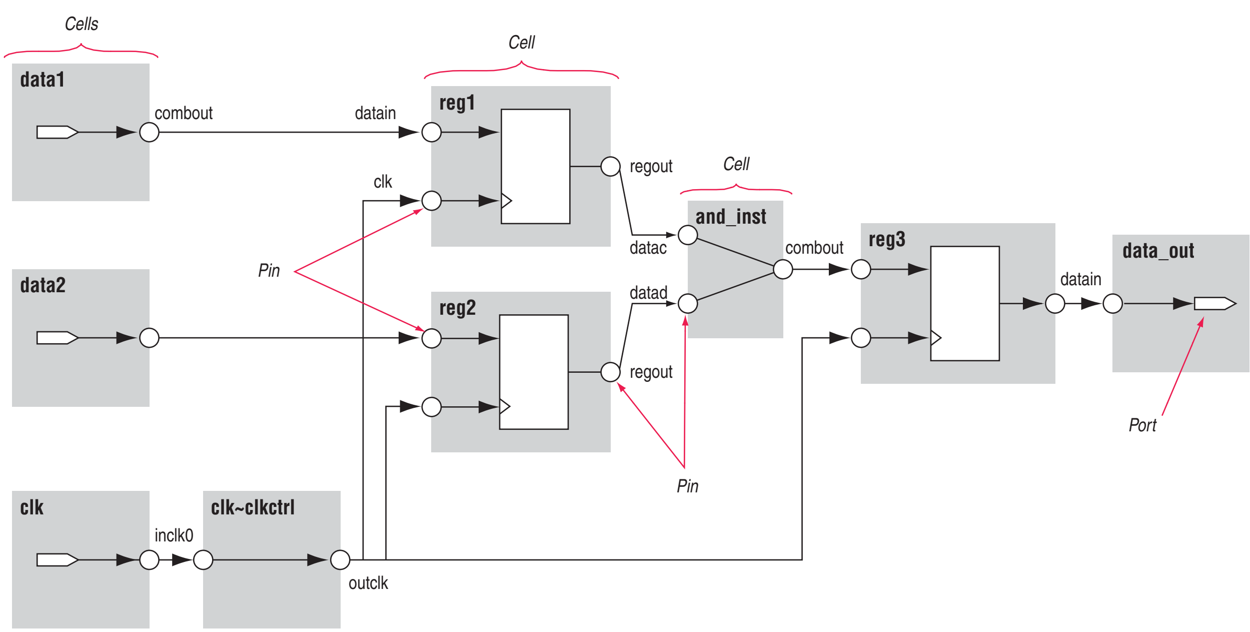

Figure 7–4 shows various cells, pins, nets, and ports. The following sample cell names are included:

- reg1
- reg2
- and_inst

The following sample pins names are included:

- data1|combout
- reg1|regout
- and_inst|combout

The following net names are included:

- data1~combout
- reg1
- and_inst

The following port names are included:

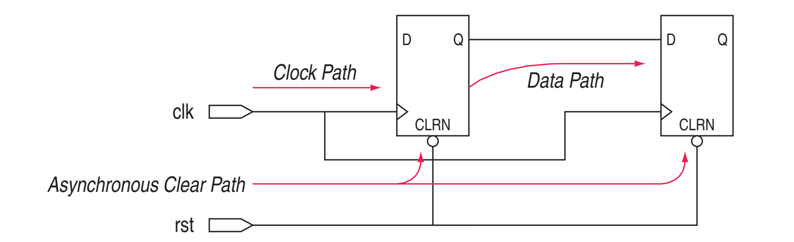
- data1, clk
- data_out

Paths connect two design nodes, such as the output of a register to the input of another register. Timing paths play a significant role in timing analysis. Understanding the types of timing paths is important to timing closure and optimization. The following list shows some of the commonly analyzed paths that are described in this section:

- **Edge paths**—the connections from ports-to-pins, from pins-to-pins, and from pins-to-ports.
- **Clock paths**—the edges from device ports or internally generated clock pins to the clock pin of a register.
- **Data paths**—the edges from a port or the data output pin of a sequential element to a port or the data input pin of another sequential element.
- **Asynchronous paths**—the edges from a port or sequential element to the asynchronous set or clear pin of a sequential element.

Figure 7–5 shows some of these commonly analyzed path types.

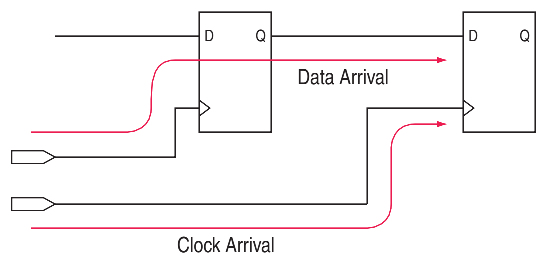
Figure 7–5. Path Types



After the Quartus II TimeQuest Timing Analyzer identifies the path type, it can report data and clock arrival times for valid register-to-register paths. The Quartus II TimeQuest Timing Analyzer calculates data arrival time by adding the delay from the clock source to the clock pin of the source register, the micro clock-to-out (μt_{CO}) of the source register, and the delay from the source register's Q pin to the destination register's D pin, where the μt_{CO} is the intrinsic clock-to-out for the internal registers in the FPGA.

The Quartus II TimeQuest Timing Analyzer calculates clock arrival time by adding the delay from the clock source to the destination register's clock pin. Figure 7–6 shows a data arrival path and a clock arrival path. The Quartus II TimeQuest Timing Analyzer calculates data required time by accounting for the clock arrival time and micro setup time (μt_{SU}) of the destination register, where the μt_{SU} is the intrinsic setup for the internal registers in the FPGA.

Figure 7–6. Data Arrival and Clock Arrival

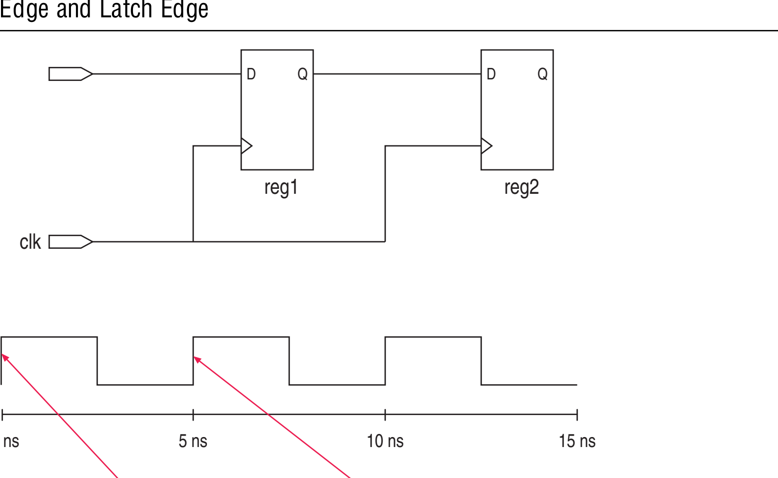


In addition to identifying various paths in a design, the Quartus II TimeQuest Timing Analyzer analyzes clock characteristics to compute the worst-case requirement between any two registers in a single register-to-register path. You should constrain all clocks in your design before performing this analysis.

The launch edge is an active clock edge that sends data out of a sequential element, acting as a source for the data transfer. A latch edge is the active clock edge that captures data at the data port of a sequential element, acting as a destination for the data transfer.

Figure 7–7 shows a single-cycle system that uses consecutive clock edges to transfer and capture data, a register-to-register path, and the corresponding launch and latch edges timing diagram. In this example, the launch edge sends the data out of register `reg1` at 0 ns, and register `reg2` latch edge captures the data at 5 ns.

Figure 7–7. Launch Edge and Latch Edge



The Quartus II TimeQuest Timing Analyzer validates clock setup and hold requirements relative to the launch and latch edges.

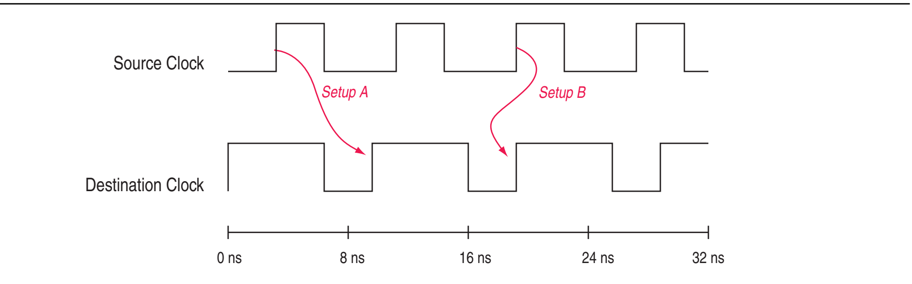
Clock Analysis

A comprehensive static timing analysis includes analysis of register-to-register, I/O, and asynchronous reset paths. The Quartus II TimeQuest Timing Analyzer uses data required times, data arrival times, and clock arrival times to verify circuit performance and detect possible timing violations. The Quartus II TimeQuest Timing Analyzer determines the timing relationships that must be met for the design to correctly function and checks arrival times against required times to verify timing.

Clock Setup Check

To perform a clock setup check, the Quartus II TimeQuest Timing Analyzer determines a setup relationship by analyzing each launch and latch edge for each register-to-register path. For each latch edge at the destination register, the Quartus II TimeQuest Timing Analyzer uses the closest previous clock edge at the source register as the launch edge. In Figure 7–8, two setup relationships are defined and are labeled setup A and setup B. For the latch edge at 10 ns, the closest clock that acts as a launch edge is at 3 ns and is labeled setup A. For the latch edge at 20 ns, the closest clock that acts as a launch edge is 19 ns and is labeled setup B.

Figure 7–8. Setup Check



The Quartus II TimeQuest Timing Analyzer reports the result of clock setup checks as slack values. Slack is the margin by which a timing requirement is met or not met. Positive slack indicates the margin by which a requirement is met; negative slack indicates the margin by which a requirement is not met. The Quartus II TimeQuest Timing Analyzer determines clock setup slack, as shown in Equation 7–1, for internal register-to-register paths.

Equation 7–1.

$$\text{Clock Setup Slack} = \text{Data Required Time} - \text{Data Arrival Time}$$
$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} + \text{Register-to-Register Delay}$$
$$\text{Data Required} = \text{Clock Arrival Time} - \mu t_{SU} - \text{Setup Uncertainty}$$
$$\text{Clock Arrival Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register}$$

If the data path is from an input port to a internal register, the Quartus II TimeQuest Timing Analyzer uses the equations shown in Equation 7–2 to calculate the setup slack time.

Equation 7–2.

$$\text{Clock Setup Slack Time} = \text{Data Required Time} - \text{Data Arrival Time}$$
$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay} + \text{Input Maximum Delay of Pin} + \text{Pin-to-Register Delay}$$
$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register} - \mu t_{SU}$$

If the data path is an internal register to an output port, the Quartus II TimeQuest Timing Analyzer uses the equations shown in Equation 7–3 to calculate the setup slack time.

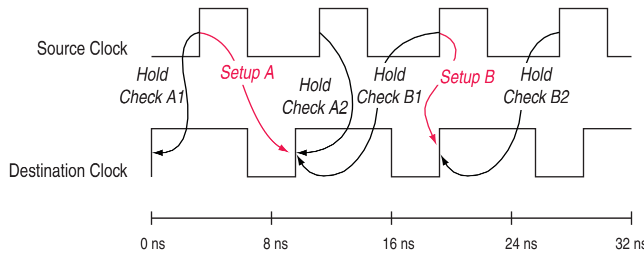
Equation 7–3.

$$\text{Clock Setup Slack Time} = \text{Data Required Time} - \text{Data Arrival Time}$$
$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} + \text{Register-to-Pin Delay}$$
$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay} - \text{Output Maximum Delay of Pin}$$

Clock Hold Check

To perform a clock hold check, the Quartus II TimeQuest Timing Analyzer determines a hold relationship for each possible setup relationship that exists for all source and destination register pairs. The Quartus II TimeQuest Timing Analyzer checks all adjacent clock edges from all setup relationships to determine the hold relationships. The Quartus II TimeQuest Timing Analyzer performs two hold checks for each setup relationship. The first hold check determines that the data launched by the current launch edge is not captured by the previous latch edge. The second hold check determines that the data launched by the next launch edge is not captured by the current latch edge. Figure 7–9 shows two setup relationships labeled setup A and setup B. The first hold check is labeled hold check A1 and hold check B1 for setup A and setup B, respectively. The second hold check is labeled hold check A2 and hold check B2 for setup A and setup B, respectively.

Figure 7–9. Hold Checks



From the possible hold relationships, the Quartus II TimeQuest Timing Analyzer selects the hold relationship that is the most restrictive. The hold relationship with the largest difference between the latch and launch edges (that is, latch – launch and not the absolute value of latch and launch) is selected because this determines the minimum allowable delay for the register-to-register path. For Figure 7–9, the hold relationship selected is hold check A2.

The Quartus II TimeQuest Timing Analyzer determines clock hold slack as shown in Equation 7–4.

Equation 7–4.

$$\text{Clock Hold Slack} = \text{Data Arrival Time} - \text{Data Required Time}$$

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} + \text{Register-to-Register Delay}$$

$$\text{Data Required Time} = \text{Clock Arrival Time} + \mu t_{H} + \text{Hold Uncertainty}$$

$$\text{Clock Arrival Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register}$$

If the data path is from an input port to an internal register, the Quartus II TimeQuest Timing Analyzer uses the equations shown in Equation 7–5 to calculate the hold slack time.

Equation 7–5.

$$\text{Clock Hold Slack Time} = \text{Data Arrival Time} - \text{Data Required Time}$$

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay} + \text{Input Minimum Delay of Pin} + \text{Pin-to-Register Delay}$$

$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register} + \mu t_{H}$$

If the data path is an internal register to an output port, the Quartus II TimeQuest Timing Analyzer uses the equations shown in Equation 7–6 to calculate the setup hold time.

Equation 7–6.

$$\text{Clock Hold Slack Time} = \text{Data Arrival Time} - \text{Data Required Time}$$

$$\text{Data Arrival Time} = \text{Latch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} + \text{Register-to-Pin Delay}$$

$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay} - \text{Output Minimum Delay of Pin}$$

Recovery and Removal

Recovery time is the minimum length of time the de-assertion of an asynchronous control signal; for example, `clear` and `preset`, must be stable before the next active clock edge. The recovery slack time calculation is similar to the clock setup slack time calculation, but it applies to asynchronous control signals. If the asynchronous control signal is registered, the Quartus II TimeQuest Timing Analyzer uses Equation 7–7 to calculate the recovery slack time.

Equation 7–7.

$$\text{Recovery Slack Time} = \text{Data Required Time} - \text{Data Arrival Time}$$
$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} + \text{Register-to-Register Delay}$$
$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register} - \mu t_{SU}$$

If the asynchronous control is not registered, the Quartus II TimeQuest Timing Analyzer uses the equations shown in Equation 7–8 to calculate the recovery slack time.

Equation 7–8.

$$\text{Recovery Slack Time} = \text{Data Required Time} - \text{Data Arrival Time}$$
$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay} + \text{Maximum Input Delay} + \text{Port-to-Register Delay}$$
$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register Delay} - \mu t_{SU}$$

If the asynchronous reset signal is from a port (device I/O), you must make an Input Maximum Delay assignment to the asynchronous reset port for the Quartus II TimeQuest Timing Analyzer to perform recovery analysis on that path.

Removal time is the minimum length of time the de-assertion of an asynchronous control signal must be stable after the active clock edge. The Quartus II TimeQuest Timing Analyzer removal time slack calculation is similar to the clock hold slack calculation, but it applies asynchronous control signals. If the asynchronous control is registered, the Quartus II TimeQuest Timing Analyzer uses the equations shown in Equation 7–9 to calculate the removal slack time.

Equation 7–9.

$$\text{Removal Slack Time} = \text{Data Arrival Time} - \text{Data Required Time}$$
$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} \text{ of Source Register} + \text{Register-to-Register Delay}$$
$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register} + \mu t_{H}$$

If the asynchronous control is not registered, the Quartus II TimeQuest Timing Analyzer uses the equations shown in Equation 7–10 to calculate the removal slack time.

Equation 7–10.

$$\text{Removal Slack Time} = \text{Data Arrival Time} - \text{Data Required Time}$$

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay} + \text{Input Minimum Delay of Pin} + \text{Minimum Pin-to-Register Delay}$$

$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register} + \mu t_H$$

If the asynchronous reset signal is from a device pin, you must specify the Input Minimum Delay constraint to the asynchronous reset pin for the Quartus II TimeQuest Timing Analyzer to perform a removal analysis on this path.

Multicycle Paths

Multicycle paths are data paths that require more than one clock cycle to latch data at the destination register. For example, a register may be required to capture data on every second or third rising clock edge. Figure 7–10 shows an example of a multicycle path between a multiplier's input registers and output register where the destination latches data on every other clock edge.

Figure 7–10. Example Diagram of a Multicycle Path

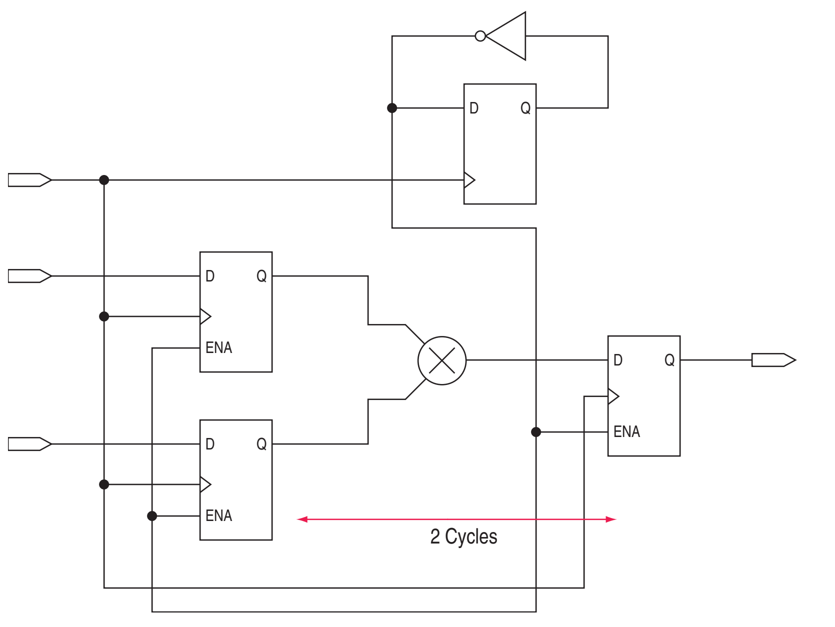


Figure 7–11 shows a register-to-register path where the source clock, `src_clk`, has a period of 10 ns and the destination clock, `dst_clk`, has a period of 5 ns.

Figure 7–11. Register-to-Register Path

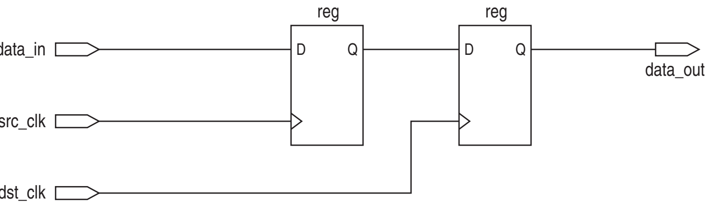

Figure 7–12 shows the respective timing diagrams for the source and destination clocks and the default setup and hold relationships. The default setup relationship is 5 ns; the default hold relationship is 0 ns.

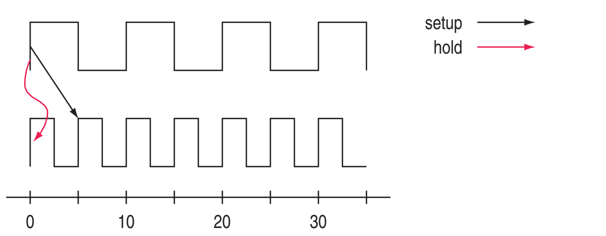
Figure 7–12. Default Setup and Hold Timing Diagram



The default setup and hold relationships can be modified with the `set_multicycle_path` command to accommodate the system requirements.

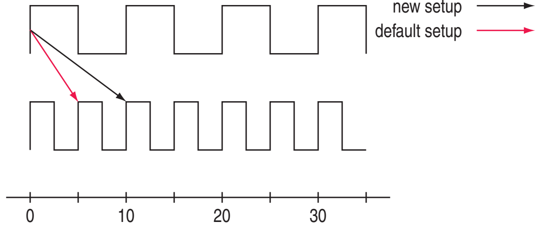
Table 7–3 shows the commands used to modify either the launch or latch edge times that the Quartus II TimeQuest Timing Analyzer Timing Analyzer uses to determine a setup relationship or hold relationship.

Table 7–3. Commands to Modify Edge Times

Command	Description of Modification
`set_multicycle_path -setup -end`	Latch edge time of the setup relationship
`set_multicycle_path -setup -start`	Launch edge time of the setup relationship
`set_multicycle_path -hold -end`	Latch edge time of the hold relationship
`set_multicycle_path -hold -start`	Launch edge time of the hold relationship

Figure 7–13 shows the timing diagram after a multicycle setup of two has been applied. The command moves the latch edge time to 10 ns from the default 5 ns.

Figure 7–13. Modified Setup Diagram



Metastability

Metastability problems can occur when a signal is transferred between circuitry in unrelated or asynchronous clock domains because the designer cannot guarantee that the signal will meet setup and hold time requirements. To minimize the failures due to metastability, circuit designers typically use a sequence of registers (synchronization register chain or synchronizer) in the destination clock domain to resynchronize the data signals to the new clock domain.

The Mean Time Before Failure (MTBF) is an estimate of the average time between instances of failure due to metastability.

The TimeQuest Timing Analyzer analyzes the robustness of the design for metastability and can calculate the MTBF for synchronization register chains in the design. The MTBF of the entire design is then estimated based on the synchronization chains it contains.

In addition to reporting synchronization register chains found in the design, the Quartus II software also protects these registers from optimizations that might negatively impact MTBF, such as register duplication and logic retiming. The Quartus II software can also optimize the MTBF of your design if the MTBF is too low.

Refer to "report_metastability" on page 7–57 for information about how to enable metastability analysis and report metastability in the TimeQuest Timing Analyzer.

For more information about metastability, its effects in FPGAs, and how MTBF is calculated, refer to the *Understanding Metastability in FPGAs* White Paper. For more information about metastability analysis, reporting, and optimization features in the Quartus II software, refer to the *Managing Metastability with the Quartus II Software* chapter in volume 1 of the *Quartus II Handbook*.

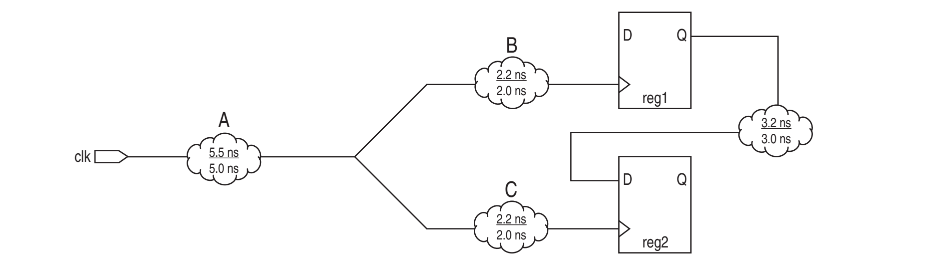
Common Clock Path Pessimism

Common clock path pessimism (CCPP) removal accounts for the minimum and maximum delay variation associated with common clock paths during a static timing analysis. CCPP removal accounts for this variation by adding the difference between the maximum and minimum delay value of the common clock path to the appropriate slack equation.

The minimum and maximum delay variation might arise when two different delay values are used for the same clock path. For example, in a simple setup analysis, the maximum clock path delay to the source register is used to determine the data arrival time. The minimum clock path delay to the destination register is used to determine the data required time. However, if the clock path to the source register and to the destination register share a common clock path, the analysis uses both the maximum delay and the minimum delay to model the common clock path. This results in an overly pessimistic analysis since two different delay values, the maximum and minimum delays, cannot be used to model the same clock path.

Figure 7–14 shows a typical register-to-register path with the maximum and minimum delay values shown.

Figure 7–14. Common Clock Path



Segment A is the common clock path between reg1 and reg2. The minimum delay is 5.0 ns; the maximum delay is 5.5 ns. The difference between the maximum and minimum delay value equals the CCPP removal value; in this case, CCPP equals 0.5 ns. The CCPP removal value is then added to the appropriate slack equation. Therefore, if the setup slack for the register-to-register in Figure 7–14 equals 0.7 ns *without* CCPP removal, the slack would be 1.2 ns *with* CCPP removal.

CCPP is also used when determining the minimum pulse width of a register. A clock signal must meet a register's minimum pulse width requirement to be recognized by the register. A minimum high time defines the minimum pulse width for a positive-edge triggered register. A minimum low time defines the minimum pulse width for a negative-edge triggered register.

Clock pulses that violate the minimum pulse width of a register prevent data from being latched at the data pin of the register. To calculate the slack of the minimum pulse width, the required minimum pulse width time is subtracted from the actual minimum pulse width time. The actual minimum pulse width time is determined by the clock requirement specified for the clock that feeds the clock port of the register. The required minimum pulse width time is determined by the maximum rise, minimum rise, maximum fall, and minimum fall times. Figure 7–15 shows a diagram of the required minimum pulse width time for both the high pulse and low pulse.

Figure 7–15. Required Minimum Pulse Width

With CCPP, the minimum pulse width slack can be increased by the smallest value of either the maximum rise time minus the minimum rise time, or the maximum fall time minus the minimum fall time. For Figure 7–15, the slack value can be increased by 0.2 ns, which is the smallest value between 0.3 ns (0.8 ns – 0.5 ns) and 0.2 ns (0.9 ns – 0.7 ns).

Refer to "report_min_pulse_width" on page 7–59 for more information about reporting CCPP in the TimeQuest Timing Analyzer.

You must use the **Enable common clock path pessimism removal** option to account for CCPP in the Fitter and timing analysis. This option defaults to ON for Stratix III, Cyclone III, and newer device families.

To access this option, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, next to **Timing Analysis Settings**, click the "+" icon to expand the menu. Click **TimeQuest Timing Analyzer**.

3. Turn on **Enable common clock path pessimism removal**.
4. Click **OK**.

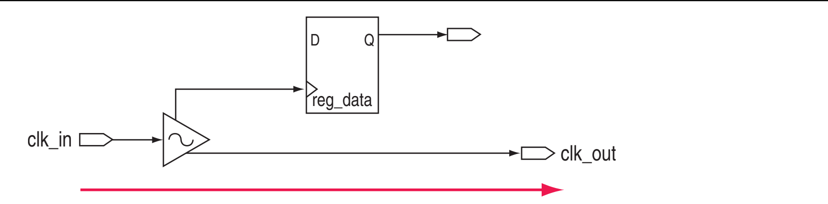
CCPP is supported for Stratix III, Cyclone III, and newer devices.

Clock-As-Data

The majority of FPGA designs contain simple connections between any two nodes known as either a data path or a clock path. A data path is a connection between the output of a synchronous element to the input of another synchronous element. A clock is a connection to the clock pin of a synchronous element. However, as FPGA designs become more complex, such as using source-synchronous interfaces, this simplified view is no longer sufficient.

The connection between port `clk_in` and port `clk_out` can be treated either as a clock path or a data path. The clock path is from the port `clk_in` to the register `reg_data` clock pin. The data path is from port `clk_in` to the port `clk_out`. In the design shown in Figure 7–16, the path from port `clk_in` to port `clk_out` is both a clock and a data path.

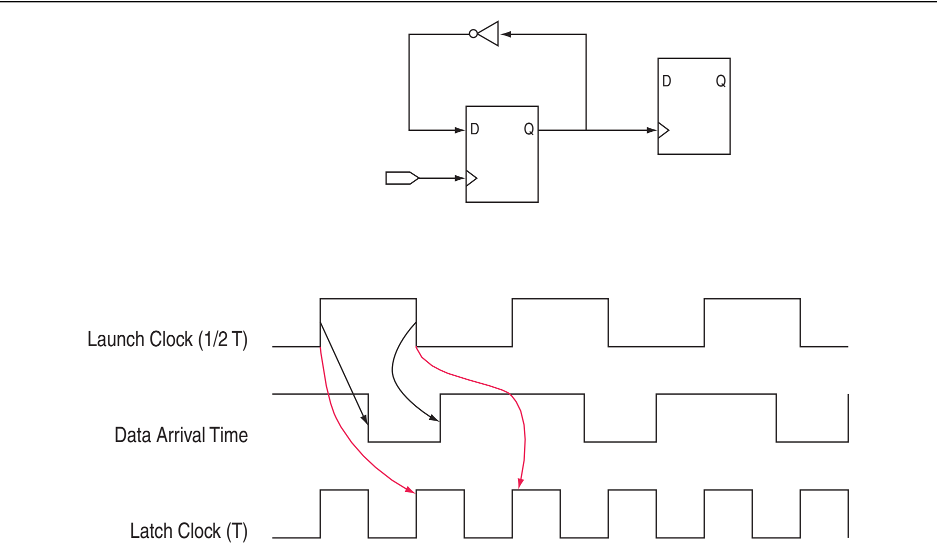
Figure 7–16. Simplified Source Synchronous Output



With clock-as-data analysis, the TimeQuest Timing Analyzer provides a more accurate analysis of the path based on the user constraints. For the clock path analysis, any phase shift associated with the PLL is taken into consideration. For the data path, any phase shift associated with the PLL is taken into consideration instead of being ignored.

The clock-as-data analysis also applies to internally generated clock dividers similar to Figure 7–17.

Figure 7–17. Clock Divider *(Note 1)*



Note to Figure 7–17:

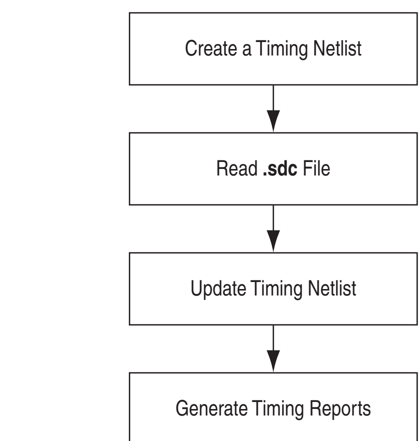
(1) In this figure, the inverter feedback path is analyzed during timing analysis. The output of the divider register is used to determine the launch time and the clock port of the register is used to determine the latch time.

A source-synchronous interface contains a clock signal that travels in parallel with data signals. The clock and data pair originates or terminates at the same device.

The Quartus II TimeQuest Timing Analyzer Flow Guidelines

Use the steps shown in Figure 7–18 to verify timing in the TimeQuest Timing Analyzer.

Figure 7–18. Timing Verification in the TimeQuest Timing Analyzer



The following sections describe each of the steps shown in Figure 7–18.

Create a Timing Netlist

After you perform a full compilation, you must create a timing netlist based on the fully annotated database from the post-fit results.

To create the timing netlist, double-click **Create Timing Netlist** in the **Tasks** pane, or type the following command in the **Console** pane:

```
create_timing_netlist ↵
```

Read the Synopsys Design Constraints File

After you create a timing netlist, you must read an **.sdc** file. This step reads all constraints and exceptions defined in the **.sdc** file.

You can read the **.sdc** file from either the **Task** pane or the **Console** pane.

To read the **.sdc** file from the **Tasks** pane, double-click the **Read SDC File** command.

The **Read SDC File** task reads the <*current revision*>**.sdc** file.

To read the **.sdc** file from the Console, type the following command in the Console:

```
read_sdc ↵
```

For more information about reading **.sdc** files in the TimeQuest Timing Analyzer, refer to "Synopsys Design Constraints File Precedence" on page 7–24.

Update Timing Netlist

You must update the timing netlist after you read an **.sdc** file. The TimeQuest Timing Analyzer applies all constraints to the netlist for verification and removes any invalid or false paths in the design from verification.

To update the timing netlist, double-click Update Timing Netlist in the **Tasks** pane, or type the following command in the Console pane:

```
update_timing_netlist ↵
```

Generate Timing Reports

You can generate timing reports for all critical paths in your design. The Tasks pane contains the commonly used reporting commands. Individual or custom reports can be generated for your design.

For more information about reporting, refer to the section "Timing Reports" on page 7–51.

For a full list of available report application program interfaces (APIs), refer to the *SDC & TimeQuest API Reference Manual*.

As you verify timing, you may encounter failures along critical paths. If this occurs, you can refine the existing constraints or create new ones to change the effects of existing constraints. If you modify, remove, or add constraints, you should perform a full compilation. This allows the Fitter to re-optimize the design based on the new constraints and brings you back to the Perform Compilation step in the process. This iterative process allows you to resolve your timing violations in the design.

For a sample Tcl script to automate the timing analysis flow, refer to the TimeQuest Quick Start Tutorial.

Collections

The Quartus II TimeQuest Timing Analyzer supports collection APIs that provide easy access to ports, pins, cells, or nodes in the design. Use collection APIs with any valid constraints or Tcl commands specified in the Quartus II TimeQuest Timing Analyzer.

Table 7–4 describes the collection commands supported by the Quartus II TimeQuest Timing Analyzer.

Table 7–4. Collection Commands

Command	Description
`all_clocks`	Returns a collection of all clocks in the design.
`all_inputs`	Returns a collection of all input ports in the design.
`all_outputs`	Returns a collection of all output ports in the design.
`all_registers`	Returns a collection of all registers in the design.
`get_cells`	Returns a collection of cells in the design. All cell names in the collection match the specified pattern. Wildcards can be used to select multiple cells at the same time.
`get_clocks`	Returns a collection of clocks in the design. When used as an argument to another command, such as the `-from` or `-to` of `set_multicycle_path`, each node in the clock represents all nodes clocked by the clocks in the collection. The default uses the specific node (even if it is a clock) as the target of a command.
`get_nets`	Returns a collection of nets in the design. All net names in the collection match the specified pattern. You can use wildcards to select multiple nets at the same time.
`get_pins`	Returns a collection of pins in the design. All pin names in the collection match the specified pattern. You can use wildcards to select multiple pins at the same time.
`get_ports`	Returns a collection of ports (design inputs and outputs) in the design.

Table 7–5 describes the SDC extension collection commands supported by the Quartus II TimeQuest Timing Analyzer.

Table 7–5. SDC Extension Collection Commands (Part 1 of 2)

Command	Description
`get_fanouts <filter>`	Returns a collection of fan-out nodes starting from <*filter*>.
`get_keepers <filter>`	Returns a collection of keeper nodes (non-combinational nodes) in the design.
`get_nodes <filter>`	Returns a collection of nodes in the design. The `get_nodes` collection cannot be used when specifying constraints or exceptions.
`get_partitions <filter>`	Returns a collection of partitions matching the <*filter*>.

Table 7–5. SDC Extension Collection Commands (Part 2 of 2)

Command	Description
`get_registers <filter>`	Returns a collection of registers in the design.
`get_fanins <filter>`	Returns a collection of fan-in nodes starting from <*filter*>.
`derive_pll_clocks`	Automatically creates generated clocks on the outputs of the PLL. The generated clock properties reflect the PLL properties that have been specified by the MegaWizard™ Plug-In Manager.
`get_assignment_groups <filter>`	Returns either a collection of keepers, ports, or registers that have been saved to the Quartus Settings File (**.qsf**) with the **Assignment (Time) Groups** option.
`remove_clock <clock list>`	Removes the list of clocks specified by <*clock list*>.
`set_scc_mode <size>`	Allows you to set the maximum Strongly Connected Components (SCC) loop size or force the Quartus II TimeQuest Timing Analyzer to always estimate delays through SCCs.
`set_time_format`	Sets time format, including time unit and decimal places.

For more information about collections, refer to the **.sdc** file and the *SDC and TimeQuest API Reference Manual*.

Application Examples

Example 7–1 shows various uses of the `create_clock` and `create_generated_clock` commands and specific design structures.

Example 7–1. create_clock and set_multicycle_path Commands and Specific Design Structures

```
# Create a simple 10 ns with clock with a 60 % duty cycle
create_clock -period 10 -waveform {0 6} -name clk [get_ports clk]
# The following multicycle applies to all paths ending at registers
# clocked by clk
set_multicycle_path -to [get_clocks clk] 2
```

SDC Constraint Files

The Quartus II TimeQuest Timing Analyzer stores all timing constraints in an **.sdc** file. You can create an **.sdc** file with different constraints for place-and-route and for timing analysis.

The **.sdc** file should contain only SDC and Tcl commands. Commands to manipulate the timing netlist or control the compilation flow should not be included in the **.sdc** file.

The Quartus II software does not automatically update **.sdc** files. You must explicitly write new or updated constraints in the TimeQuest Timing Analyzer GUI. Use the `write_sdc` command, or, in the Quartus II TimeQuest Timing Analyzer, on the Constraints menu, click **Write SDC File** to write your constraints to an **.sdc** file.

The constraints in the **.sdc** file are order-sensitive. A constraint must first be declared before any references are made to that constraint. For example, if a generated clock references a base clock with a name `clk`, the base clock constraint must be declared before the generated clock constraint.

Fitter and Timing Analysis with SDC Files

You can specify the same or different **.sdc** files for the Quartus II Fitter for place-and-route, and the Quartus II TimeQuest Timing Analyzer for static timing analysis. Using different **.sdc** files allows you to have one set of constraints for place-and-route and another set of constraints for final timing sign-off in the Quartus II TimeQuest Timing Analyzer.

Specifying SDC Files for Place-and-Route

To specify an **.sdc** file for the Fitter, you must add the **.sdc** file to your Quartus II project. To add the file to your project, use the following command in the Tcl console:

```
set_global_assignment -name SDC_FILE <SDC file name> ↵
```

Or, in the Quartus II software GUI, on the Project menu, click **Add/Remove Files in Project**.

The Fitter optimizes your design based on the requirements in the **.sdc** files in your project.

The results shown in the timing analysis report located in the Compilation Report are based on the **.sdc** files added to the project.

You must specify the Quartus II TimeQuest Timing Analyzer as the default timing analyzer to make the Fitter read the **.sdc** file.

Specifying SDC Files for Static Timing Analysis

After you create a timing netlist in the Quartus II TimeQuest Timing Analyzer, you must specify timing constraints and exceptions before you can perform a timing analysis. The timing requirements do not have to be identical to those provided to the Fitter. You can specify your timing requirements manually or you can read a previously created **.sdc** file.

To manually enter your timing requirements, you can use constraint entry dialog boxes or SDC commands. If you have an **.sdc** file that contains your timing requirements, use this file to apply your timing requirements. To specify the **.sdc** file for timing analysis in the Quartus II TimeQuest Timing Analyzer, use the following command:

```
read_sdc [<SDC file name>] ↵
```

If you use the TimeQuest GUI to apply the **.sdc** file for timing analysis, in the Quartus II TimeQuest Timing Analyzer, on the Constraints menu, click **Read SDC File**.

The `read_sdc` command has the `-hdl` option, allowing `read_sdc` to read SDC commands embedded in HDL that uses that `ALTERA_ATTRIBUTE` attribute.

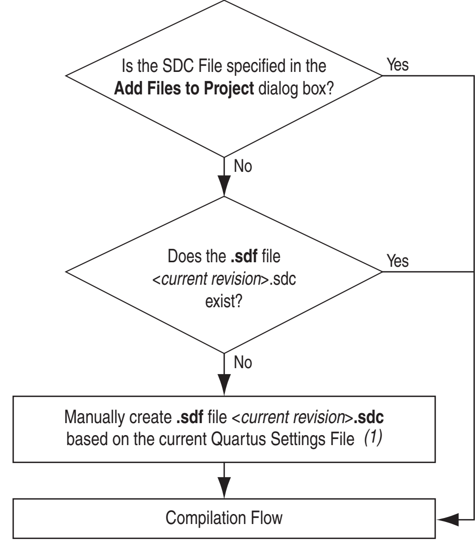
The `read_sdc` command without any options reads both your **.sdc** files and any HDL-embedded commands. By default, the **Read SDC File** command in the Tasks pane reads the **.sdc** files specified in the Quartus II Settings File (**.qsf**), which are the same **.sdc** files used by the Fitter.

Synopsys Design Constraints File Precedence

The Quartus II Fitter and the Quartus II TimeQuest Timing Analyzer reads the **.sdc** files from the files list in the **.qsf** file in the order they are listed, from top to bottom.

The Quartus II software searches for an **.sdc** file, as shown in Figure 7–19.

Figure 7–19. Synopsys Design Constraints File Order of Precedence



Note to Figure 7–19:

(1) This occurs only in the Quartus II TimeQuest Timing Analyzer and not during compilation in the Quartus II software. The Quartus II TimeQuest Timing Analyzer has the ability to automate the conversion of the QSF timing assignments to SDC if no **.sdc** file exists when the Quartus II TimeQuest Timing Analyzer is opened.

If you type the `read_sdc` command at the command line without any arguments, the precedence order shown in Figure 7–19 is followed.

Clock Specification

The specification of all clocks and any associated clock characteristics in your design is essential for accurate static timing analysis results. The Quartus II TimeQuest Timing Analyzer supports many SDC commands that accommodate various clocking schemes and any clock characteristics.

This section describes the **.sdc** file API available to create and specify clock characteristics.

Clocks

Use the `create_clock` command to create a clock at any register, port, or pin. You can create each clock with unique characteristics. Example 7–2 shows the `create_clock` command and options.

Example 7–2. create_clock Command

```
create_clock
-period <period value>
[-name <clock name>]
[-waveform <edge list>]
[-add]
<targets>
```

Table 7–6 describes the options for the `create_clock` command.

Table 7–6. create_clock Command Options

Option	Description
`-period <period value>`	Specifies the clock period. You can also specify the clock period in units of frequency, such as `-period <num>MHz`. (1)
`-name <clock name>`	Name of the specific clock; for example, `sysclock`. If you do not specify the clock name, the clock name is the same as the node to which it is assigned.
`-waveform <edge list>`	Specifies the clock's rising and falling edges. The edge list alternates between rising edge and falling edge. For example, a 10 ns period where the first rising edge occurs at 0 ns and the first falling edge occurs at 5 ns would be written as `-waveform {0 5}`. The difference must be within one period unit, and the rise edge must come before the fall edge. The default edge list is `{0 <period>/2}`, or a 50% duty cycle.
`-add`	Allows you to specify more than one clock to the same port or pin.
`<targets>`	Specifies the port(s) or pin(s) to which the assignment applies. If source objects are not specified, the clock is a virtual clock. Refer to "Virtual Clocks" on page 7–28 for more information.

Note to Table 7–6:

(1) The default time unit in the Quartus II TimeQuest Timing Analyzer is nanoseconds (ns).

Example 7–3 shows how to create a 10 ns clock with a 50% duty cycle, where the first rising edge occurs at 0 ns applied to port `clk`.

Example 7–3. 100MHz Clock Creation

```
create_clock -period 10 -waveform { 0 5 } clk
```

Example 7–4 shows how to create a 10 ns clock with a 50% duty cycle that is phase shifted by 90 degrees applied to port `clk_sys`.

Example 7–4. 100MHz Shifted by 90 Degrees Clock Creation

```
create_clock -period 10 -waveform { 2.5 7.5 } clk_sys
```

Clocks defined with the `create_clock` command have a default source latency value of zero. The Quartus II TimeQuest Timing Analyzer automatically computes the clock's network latency for non-virtual clocks.

Generated Clocks

The Quartus II TimeQuest Timing Analyzer considers clock dividers, ripple clocks, or circuits that modify or change the characteristics of the incoming or master clock as generated clocks. You should define the output of these circuits as generated clocks. This definition allows the Quartus II TimeQuest Timing Analyzer to analyze these clocks and account for any network latency associated with them.

Use the `create_generated_clock` command to create generated clocks. Example 7–5 shows the `create_generated_clock` command and the available options.

Example 7–5. create_generated_clock Command

```
create_generated_clock
[-name <clock name>]
-source <master pin>
[-edges <edge list>]
[-edge_shift <shift list>]
[-divide_by <factor>]
[-multiply_by <factor>]
[-duty_cycle <percent>]
[-add]
[-invert]
[-master_clock <clock>]
[-phase <phase>]
[-offset <offset>]
<targets>
```

Table 7–7 describes the options for the `create_generated_clock` command.

Table 7–7. create_generated_clock Command Options (Part 1 of 2)

Option	Description
`-name <clock name>`	Name of the generated clock; for example, `clk_x2`. If you do not specify the clock name, the clock name is the same as the first node to which it is assigned.
`-source <master pin>`	The <*master pin*> specifies the node in the design from which the clock settings derive.
`-edges <edge list>` | `-edge_shift <shift list>`	The `-edges` option specifies the new rising and falling edges with respect to the master clock's rising and falling edges. The master clock's rising and falling edges are numbered `1..`<*n*> starting with the first rising edge; for example, edge 1. The first falling edge after that is edge number 2, the next rising edge number 3, and so on. The <*edge list*> must be in ascending order. The same edge may be used for two entries to indicate a clock pulse independent of the original waveform's duty cycle. `-edge_shift` specifies the amount of shift for each edge in the <*edge list*>. The `-invert` option can be used to invert the clock after the `-edges` and `-edge_shifts` are applied. *(1)*
`-divide_by <factor>` | `-multiply_by <factor>`	The `-divide_by` and `-multiply_by` factors are based on the first rising edge of the clock, and extend or contract the waveform by the specified factors. For example, a `-divide_by 2` is equivalent to `-edges {1 3 5}`. For multiplied clocks, the duty cycle can also be specified. The Quartus II TimeQuest Timing Analyzer supports specifying multiply and divide factors at the same time.
`-duty_cycle <percent>`	Specifies the duty cycle of the generated clock. The duty cycle is applied last.
`-add`	Allows you to specify more than one clock to the same pin.

Table 7–7. create_generated_clock Command Options (Part 2 of 2)

Option	Description
-invert	Inversion is applied at the output of the clock after all other modifications are applied, except duty cycle.
-master_clock <*clock*>	-master_clock is used to specify the clock if multiple clocks exist at the master pin.
-phase <*phase*>	Specifies the phase of the generated clock.
-offset <*offset*>	Specifies the offset of the generated clock.
<*targets*>	Specifies the port(s) or pin(s) to which the assignment applies.

Note to Table 7–7:

(1) The Quartus II TimeQuest Timing Analyzer supports a maximum of three edges in the edge list.

Source latencies are based on clock network delays from the master clock (not necessarily the master pin). You can use the `set_clock_latency -source` command to override source latency.

Figure 7–20 shows how to create an inverted generated clock based on a 10 ns clock.

Figure 7–20. Generating an Inverted Clock

```
create_clock -period 10 [get_ports clk]
create_generated_clock -divide_by 1 -invert -source [get_registers clk] \
   [get_registers gen|clkreg]
```

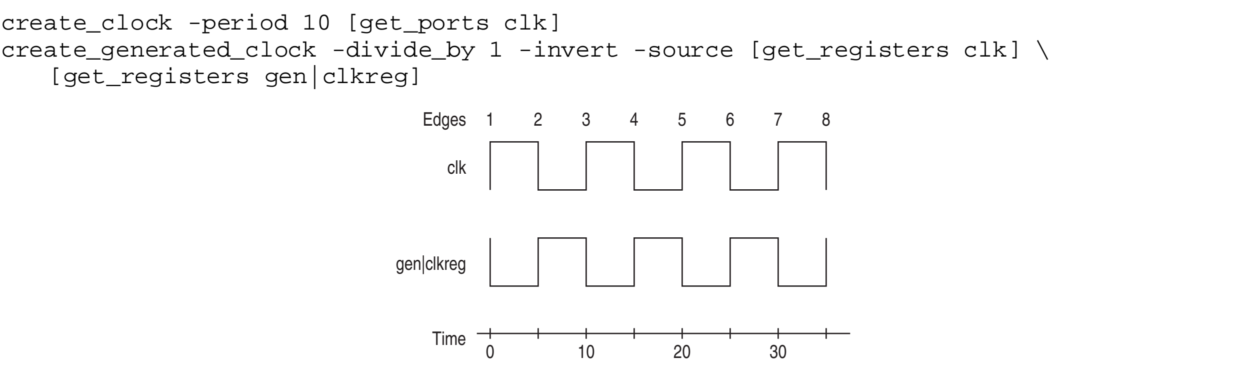


Figure 7–21 shows how to modify the generated clock using the -edges and -edge_shift options.

Figure 7–21. Edges and Edge Shifting a Generated Clock

```
create_clock -period 10 -waveform { 0 5} [get_ports clk]
# Creates a divide-by-t clock
create_generated_clock -source [get_ports clk] -edges {1 3 5 } [get_registers \
clkdivA|clkreg]
# Creates a divide-by-2 clock independent of the master clocks' duty cycle (now 50%)
create_generated_clock -source [get_ports clk] -edges {1 1 5} -edge_shift { 0 2.5 0 } \
[get_registers clkdivB|clkreg]
```

Figure 7–22 shows the effect of the -multiply_by option on the generated clock.

Figure 7–22. Multiplying a Generated Clock

```
create_clock -period 10 -waveform { 0 5 } [get_ports clk]
# Creates a multiply-by-2 clock
create_generated_clock -source [get_ports clk] -multiply_by 2 [get_registers \
clkmult|clkreg]
```

Virtual Clocks

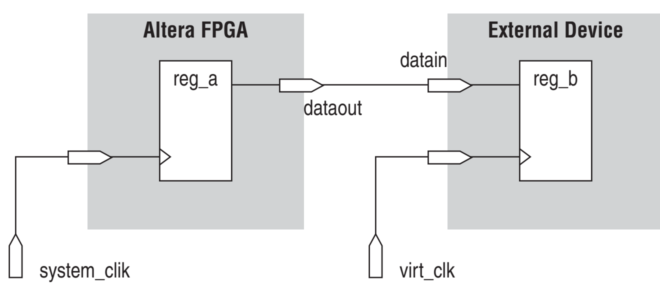
A virtual clock is a clock that does not have a real source in the design or that does not interact directly with the design. For example, if a clock feeds only an external device's clock port and not a clock port in the design, and the external device then feeds (or is fed by) a port in the design, it is considered a virtual clock.

Use the `create_clock` command to create virtual clocks, with no value specified for the `source` option.

You can use virtual clocks for `set_input_delay` and `set_output_delay` constraints.

Figure 7–23 shows an example where a virtual clock is required for the Quartus II TimeQuest Timing Analyzer to properly analyze the relationship between the external register and those in the design. Because the oscillator labeled `virt_clk` does not interact with the Altera device, but acts as the clock source for the external register, the clock `virt_clk` must be declared. Example 7–6 shows the command to create a 10 ns virtual clock named `virt_clk` with a 50% duty cycle where the first rising edge occurs at 0 ns. The virtual clock is then used as the clock source for an output delay constraint.

Figure 7–23. Virtual Clock Board Topology



After you create the virtual clock, you can perform register-to-register analysis between the register in the Altera device and the register in the external device.

Example 7–6. Virtual Clock Example 1

```
#create base clock for the design
create_clock -period 5 [get_ports system_clk]
#create the virtual clock for the external register
create_clock -period 10 -name virt_clk -waveform { 0 5 }
#set the output delay referencing the virtual clock
set_output_delay -clock virt_clk -max 1.5 [get_ports dataout]
```

Example 7–7 shows the command to create a 10 ns virtual clock with a 50% duty cycle that is phase shifted by 90°.

Example 7–7. Virtual Clock Example 2

```
create_clock -name virt_clk -period 10 -waveform { 2.5 7.5 }
```

Multi-Frequency Clocks

Certain designs have more than one clock source feeding a single clock port in the design. The additional clock may act as a low-power clock, with a lower frequency than the primary clock. To analyze this type of design, the `create_clock` command supports the `-add` option that allows you to add more than one clock to a clock node.

Example 7–8 shows the command to create a 10 ns clock applied to clock port `clk`, and then add an additional 15 ns clock to the same clock port. The Quartus II TimeQuest Timing Analyzer uses both clocks when it performs timing analysis.

Example 7–8. Multi-Frequency Example

```
create_clock -period 10 -name clock_primary -waveform { 0 5 } [get_ports
clk]
create_clock -period 15 -name clock_secondary -waveform { 0 7.5 }
[get_ports clk] -add
```

Automatic Clock Detection

To create clocks for all clock nodes in your design automatically, use the `derive_clocks` command. This command creates clocks on ports or registers to ensure every register in the design has a clock.

Example 7–9 shows the `derive_clocks` command and options.

Example 7–9. derive_clocks Command

```
derive_clocks
[-period <period value>]
[-waveform <edge list>]
```

Table 7–8 describes the options for the `derive_clocks` command.

Table 7–8. derive_clocks Command Options

Option	Description
`-period <period value>`	Creates the clock period. You can also specify the frequency as `-period <num>MHz`. (1)
`-waveform <edge list>`	Creates the clock's rising and falling edges. The edge list alternates between the rising edge and falling edge. For example, for a 10 ns period where the first rising edge occurs at 0 ns and the first falling edge occurs at 5 ns, the edge list is `waveform {0 5}`. The difference must be within one period unit, and the rising edge must come before the falling edge. The default edge list is `{0 period/2}`, or a 50% duty cycle.

Note to Table 7–8:

(1) This option uses the default time unit nanoseconds (ns).

The `derive_clocks` command does not create clocks for the output of the PLLs.

The `derive_clocks` command is equivalent to using `create_clock` for each register or port feeding the clock pin of a register.

Using the `derive_clocks` command for final timing sign-off is not recommended. You should create clocks for all clock sources using the `create_clock` and `create_generated_clock` commands.

Derive PLL Clocks

PLLs are used for clock management and synthesis in Altera devices. You can customize the clocks generated from the outputs of the PLL based on design requirements. Because a clock should be created for all clock nodes, all outputs of the PLL should have an associated clock.

 © March 2009 Altera Corporation

You can manually create a clock for each output of the PLL with the `create_generated_clock` command, or you can use the `derive_pll_clocks` command, which automatically searches the timing netlist and creates generated clocks for all PLL outputs according to the settings specified for each PLL output.

Use the `derive_pll_clocks` command to automatically create a clock for each output of the PLL. Example 7–10 shows the `derive_pll_clocks` command and options.

Example 7–10. derive_pll_clocks Command

```
derive_pll_clocks
[-create_base_clocks]
[-use_tan_name]
```

Table 7–9 describes the options for the `derive_pll_clocks` command.

Table 7–9. derive_pll_clocks Command Options

Option	Description
`-use_tan_name`	By default, the clock name is the output clock name. This option uses the net name similar to the names used by the Quartus II Classic Timing Analyzer.
`-create_base_clocks`	Creates the base clocks on input clock ports of the design that are feeding the PLL.

The `derive_pll_clocks` command calls the `create_generated_clock` command to create generated clocks on the outputs of the PLL. The source for the `create_generated_clock` command is the input clock pin of the PLL. Before or after the `derive_pll_clocks` command has been issued, you must manually create a base clock for the input clock port of the PLL. If a clock is not defined for the input clock node of the PLL, no clocks are reported for the PLL outputs. Instead, the Quartus II TimeQuest Timing Analyzer issues a warning message similar to Example 7–11 when the timing netlist is updated.

Example 7–11. Warning Message

```
Warning: The master clock for this clock assignment could not be
derived.
Clock: <name of PLL output clock pin name> was not created.
```

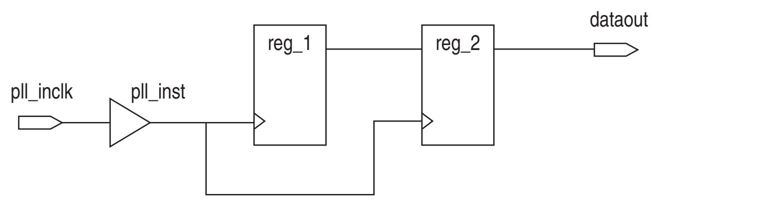
You can use the `-create_base_clocks` option to create the input clocks for the PLL inputs automatically.

You can include the `derive_pll_clocks` command in your **.sdc** file, which allows the `derive_pll_clocks` command to automatically detect any changes to the PLL. With the `derive_pll_clocks` command in your **.sdc** file, each time the file is read, the appropriate `create_generated_clocks` command for the PLL output clock pin is generated. If you use the `write_sdc-expand` command after the `derive_pll_clock` command, the new **.sdc** file contains the individual `create_generated_clock` commands for the PLL output clock pins and not the `derive_pll_clocks` command. Any changes to the properties of the PLL are not automatically reflected in the new **.sdc** file. You must manually update the `create_generated_clock` commands in the new **.sdc** file written by the `derive_pll_clocks` command to reflect the changes to the PLL.

The derive_pll_clocks constraint will also constrain any LVDS transmitters or LVDS receivers in the design by adding the appropriate multicycle constraints to account for any deserialization factors.

For example, Figure 7–24 shows a simple PLL design with a register-to-register path.

Figure 7–24. Simple PLL Design



Use the derive_pll_clocks command to automatically constrain the PLL. When this command is issued for the design shown in Figure 7–24, the messages shown in Example 7–12 are generated.

Example 7–12. derive_pll_clocks Generated Messages

```
Info:
Info: Deriving PLL Clocks:
Info: create_generated_clock -source
pll_inst|altpll_component|pll|inclk[0] -divide_by 2 -name
pll_inst|altpll_component|pll|clk[0]
pll_inst|altpll_component|pll|clk[0]
Info:
```

The node name pll_inst|altpll_component|pll|inclk[0] used for the source option refers to the input clock pin of the PLL. In addition, the name of the output clock of the PLL is the name of the PLL output clock node, pll_inst|altpll_component|pll|clk[0].

If the PLL is in clock switchover mode, multiple clocks are created for the output clock of the PLL; one for the primary input clock (for example, inclk[0]), and one for the secondary input clock (for example, inclk[1]). In this case, you should cut the primary and secondary output clocks using the set_clock_groups command with the -exclusive option.

Before you can generate any reports for this design, you must create a base clock for the PLL input clock port. Use a the following command or one similar:

```
create_clock -period 5 [get_ports pll_inclk]
```

You do not have to generate the base clock on the input clock pin of the PLL: pll_inst|altpll_component|pll|inclk[0]. The clock created on the PLL input clock port propagates to all fan-outs of the clock port, including the PLL input clock pin.

Default Clock Constraints

To provide a complete clock analysis, the Quartus II TimeQuest Timing Analyzer, by default, automatically creates clocks for all detected clock nodes in your design that have not be constrained, if there are no base clock constraints in the design. The Quartus II TimeQuest Timing Analyzer creates a base clock with a 1 GHz requirement to unconstrained clock nodes, using the following command:

```
derive_clocks -period 1 ↵
```

Individual clock constraints (for example, `create_clock` and `create_generated_clock`) should be made for all clocks in the design. This results in a thorough and realistic analysis of the design's timing requirements. Avoid using `derive_clocks` for final timing sign-off.

The default clock constraint is only applied when the Quartus II TimeQuest Timing Analyzer detects that all synchronous elements have no clocks associated with them. For example, if a design contains two clocks and only one clock has constraints, the default clock constraint is not applied. However, if both clocks have not been constrained, the default clock constraint is applied.

Clock Groups

Many clocks can exist in a design; however, not all of the clocks interact with one another and certain clock interactions are not possible.

Use the `set_clock_groups` command to specify clocks that are exclusive or asynchronous. Example 7–13 shows the `set_clock_groups` command and options.

Example 7–13. set_clock_groups Command

```
set_clock_groups
[-asynchronous | -exclusive]
-group <clock name>
[-group <clock name>]
[-group <clock name>] ...
```

Table 7–10 describes the options for the `set_clock_groups` command.

Table 7–10. set_clock_groups Command Options

Option	Description
`-asynchronous`	Asynchronous clocks—when the two clocks have no phase relationship and are active at the same time.
`-exclusive`	Exclusive clocks—when only one of the two clocks is active at any given time. An example of an exclusive clock group is when two clocks feed a 2-to-1 MUX.
`-group <clock name>`	Specifies valid destination clock names that are mutually exclusive. <*clock name*> is used to specify the clock names.

The exclusive option is used to declare when two clocks are mutually exclusive to each other and cannot coexist in the design at the same time. This can happen when multiple clocks are created on the same node or for multiplexed clocks. For example, a port can be clocked by either a 25-MHz or a 50-MHz clock. To constrain this port, two clocks should be created on the port with the `create_clock` command, then use `set_clock_groups -exclusive` to declare that they cannot coexist in the design at the same time.

This eliminates any clock transfers that may be derived between the 25-MHz clock and the 50-MHz clock. Example 7–14 shows the constraints for this.

Example 7–14. Exclusive Option

```
create_clock -period 40 -name clk_A [get_ports {port_A}]
create_clock -add -period 20 -name clk_B [get_ports {port_A}]
set_clock_groups -exclusive -group {clk_A} -group {clk_B}
```

A group is defined with the `-group` option. The TimeQuest Timing Analyzer cuts the timing paths between clocks each of the separate `-groups` groups.

The asynchronous option is used to group related and unrelated clocks. With the asynchronous option, clocks that are contained in groups are considered asynchronous to each other. Any clocks within each group are considered synchronous to each other.

For example, suppose you have three clocks: `clk_A`, `clk_B`, and `clk_C`. The clocks `clk_A` and `clk_B` are related to each other, but clock `clk_C` operates completely asynchronous with `clk_A` or `clk_B`. Example 7–15 makes `clk_A` and `clk_B` related in the same group and unrelated with the second group which contains `clk_C`.

Example 7–15. Asynchronous Option Example 1

```
set_clock_groups -asynchronous -group {clk_A clk_B} -group {clk_C}
```

Example 7–16 shows an alternative method of specifying the same constraint as Example 7–15.

Example 7–16. Asynchronous Option Example 2

```
set_clock_groups -asynchronous -group {clk_C}
```

This makes `clk_C` unrelated with every other clock in the design because `clk_C` is the only group in the constraint.

The TimeQuest Timing Analyzer assumes all clocks are related by default, unless constrained otherwise.

Example 7–17 shows a `set_clock_groups` command and the equivalent `set_false_path` commands.

Example 7–17. set_clock_groups

```
# Clocks A and C are never active when clocks B and D are active
set_clock_groups -exclusive -group {A C} -group {B D}

# Equivalent specification using false paths
set_false_path -from [get_clocks A] -to [get_clocks B]
set_false_path -from [get_clocks A] -to [get_clocks D]
set_false_path -from [get_clocks C] -to [get_clocks B]
set_false_path -from [get_clocks C] -to [get_clocks D]
set_false_path -from [get_clocks B] -to [get_clocks A]
set_false_path -from [get_clocks B] -to [get_clocks C]
set_false_path -from [get_clocks D] -to [get_clocks A]
set_false_path -from [get_clocks D] -to [get_clocks C]
```

Clock Effect Characteristics

The `create_clock` and `create_generated_clock` commands create ideal clocks that do not account for any board effects. This section describes how to account for clock effect characteristics with clock latency and clock uncertainty.

Clock Latency

There are two forms of clock latency: source and network. Source latency is the propagation delay from the origin of the clock to the clock definition point (for example, a clock port). Network latency is the propagation delay from a clock definition point to a register's clock pin. The total latency (or clock propagation delay) at a register's clock pin is the sum of the source and network latencies in the clock path.

The `set_clock_latency` command supports only source latency. The `-source` option must be specified when using the command.

Use the `set_clock_latency` command to specify source latency to any clock ports in the design. Example 7–18 shows the `set_clock_latency` command and options.

Example 7–18. set_clock_latency Command

```
set_clock_latency
-source
[-clock <clock_list>]
[-rise | -fall]
[-late | -early]
<delay>
<targets>
```

Table 7–11 describes the options for the `set_clock_latency` command.

Table 7–11. set_clock_latency Command Options (Part 1 of 2)

Option	Description
`-source`	Specifies a source latency.
`-clock <clock list>`	Specifies the clock to use if the target has more than one clock assigned to it.
`-rise | -fall`	Specifies the rising or falling delays.
`-late | -early`	Specifies the earliest or the latest arrival times to the clock.

Table 7–11. set_clock_latency Command Options (Part 2 of 2)

Option	Description
<delay>	Specifies the delay value.
<targets>	Specifies the clocks or clock sources if a clock is clocked by more than one clock.

The Quartus II TimeQuest Timing Analyzer automatically computes network latencies; therefore, the `set_clock_latency` command specifies only source latencies.

Clock Uncertainty

The `set_clock_uncertainty` command specifies clock uncertainty or skew for clocks or clock-to-clock transfers. Specify the uncertainty separately for setup and hold. Specify separate rising and falling clock transitions. The Quartus II TimeQuest Timing Analyzer subtracts setup uncertainty from the data required time for each applicable path and adds the hold uncertainty to the data required time for each applicable path.

Use the `set_clock_uncertainty` command to specify any clock uncertainty to the clock port. Example 7–19 shows the `set_clock_uncertainty` command and options.

Example 7–19. set_clock_uncertainty Command and Options

```
set_clock_uncertainty
[-rise_from <rise from clock> | -fall_from <fall from clock> |
   -from <from clock>]
[-rise_to <rise to clock> | -fall_to <fall to clock> | -to <to clock>]
[-setup | -hold]
<value>
-add
```

Table 7–12 describes the options for the `set_clock_uncertainty` command.

Table 7–12. set_clock_uncertainty Command Options

Option	Description
-from *<from clock>*	Specifies the `from` clock.
-rise_from *<rise from clock>*	Specifies the `rise-from` clock.
-fall_from *<fall from clock>*	Specifies the `fall-from` clock.
-to *<to clock>*	Specifies the `to` clock.
-rise_to *<rise to clock>*	Specifies the `rise-to` clock.
-fall_to *<fall to clock>*	Specifies the `fall-to` clock.
-setup | -hold	Specifies setup or hold.
<value>	Uncertainty value.
-add	Specifies that the uncertainty *<value>* should be added to the uncertainty value derived by the `derive_clock_uncertainty` command.

Derive Clock Uncertainty

Use the `derive_clock_uncertainty` command to automatically apply inter-clock, intra-clock, and I/O interface uncertainties. Both setup and hold uncertainties are calculated for each clock-to-clock transfer. Example 7–20 shows the `derive_clock_uncertainty` command and options.

Example 7–20. derive_clock_uncertainty Command

```
derive_clock_uncertainty
[-overwrite]
[-add]
```

Table 7–13 describes the options for the `derive_clock_uncertainty` command.

Table 7–13. derive_clock_uncertainty Command Options

Option	Description
`-overwrite`	Overwrites previously performed clock uncertainty assignments.
`-add`	Adds derived uncertainty results to any user-defined clock uncertainty assignments.

The Quartus II TimeQuest Timing Analyzer automatically applies clock uncertainties to clock-to-clock transfers in the design.

Any clock uncertainty constraints that have been applied to source and destination clock pairs with the `set_clock_uncertainty` command have a higher precedence than the clock uncertainties derived from the `derive_clock_uncertainty` command for the same source and destination clock pairs. For example, if `set_clock_uncertainty` is applied between `clka` and `clkb`, the `derive_clock_uncertainty` values for the clock transfer is ignored by default. The `set_clock_uncertainty` constraint has priority over the `derive_clock_uncertainty` constraint.

The clock uncertainty value that would have been used; however, is still reported for informational purposes. You can use the `-overwrite` command to overwrite previous clock uncertainty assignments, or remove them manually with the `remove_clock_uncertainty` command. You can also use the `-add` option to add clock uncertainty determined by the `derive_clock_uncertainty` command to any previously defined clock uncertainty value.

The following list shows the types of clock-to-clock transfers in which clock certainties can arise. They are modeled by the `derive_clock_uncertainty` command automatically.

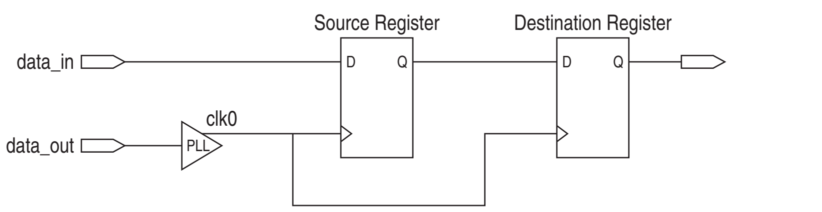
- Inter-clock
- Intra-clock
- I/O Interface

Altera recommends using the `derive_clock_uncertainty` command.

Intra-Clock Transfers

Intra-clock transfers occur when the register-to-register transfer happens in the core of the FPGA and source and destination clocks come from the same PLL output pin or clock port. An example of an intra-clock transfer is shown in Figure 7–25.

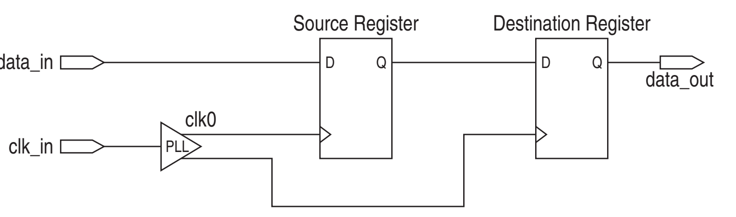
Figure 7–25. Intra-Clock Transfer



Inter-Clock Transfers

Inter-clock transfers occur when a register-to-register transfer happens in the core of the FPGA and source and destination clocks come from a different PLL output pin or clock port. An example of an inter-clock transfer is shown in Figure 7–26.

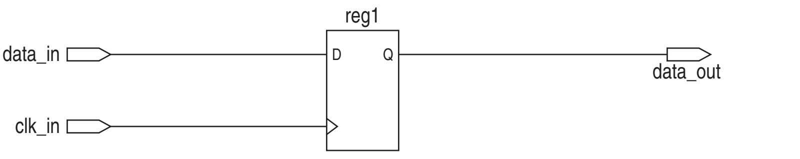
Figure 7–26. Inter-Clock Transfer



I/O Interface Clock Transfers

I/O interface clock transfers occur when data transfers from an I/O port to the core of the FPGA (input) or from the core of the FPGA to the I/O port (output). An example of an I/O interface clock transfer is shown in Figure 7–27.

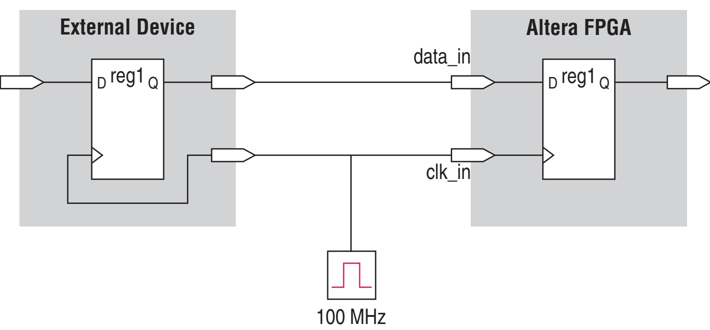
Figure 7–27. I/O Interface-Clock Transfer



For I/O interface uncertainty, you must create a virtual clock and constrain the input and output ports with the `set_input_delay` and `set_output_delay` commands that reference the virtual clock. The virtual clock is required to prevent the `derive_clock_uncertainty` command from applying clock uncertainties for either intra- or inter-clock transfers on an I/O interface clock transfer when the `set_input_delay` or `set_output_delay` commands reference a clock port or PLL output. If a virtual clock is not referenced in the `set_input_delay` or `set_output_delay` commands, the `derive_clock_uncertainty` command calculates intra- or inter-clock uncertainty value for the I/O interface.

Create the virtual clock with the same properties as the original clock that is driving the I/O port. For example, Figure 7–28 shows a typical input I/O interface with the clock specifications.

Figure 7–28. I/O Interface Specifications



Example 7–21 shows the SDC commands to constrain the I/O interface shown in Figure 7–28.

Example 7–21. SDC Commands to Constrain the I/O Interface

```
# Create the base clock for the clock port
create_clock -period 10 -name clk_in [get_ports clk_in]
# Create a virtual clock with the same properties of the base clock
# driving the source register
create_clock -period 10 -name virt_clk_in
# Create the input delay referencing the virtual clock and not the base
# clock
# DO NOT use set_input_delay -clock clk_in <delay_value>
# [get_ports data_in]
set_input_delay -clock virt_clk_in <delay value> [get_ports data_in]
```

I/O Specifications

The Quartus II TimeQuest Timing Analyzer supports Synopsys Design Constraints that constrain the ports in your design. These constraints allow the Quartus II TimeQuest Timing Analyzer to perform a system static timing analysis that includes not only the FPGA internal timing, but also any external device timing and board timing parameters.

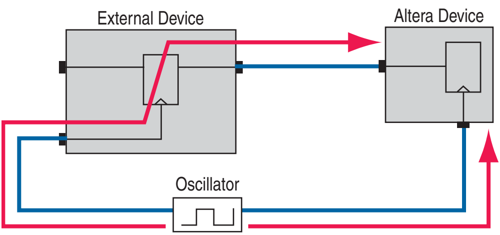
Input and Output Delay

Use input and output delay constraints to specify any external device or board timing parameters. When you apply these constraints, the Quartus II TimeQuest Timing Analyzer performs static timing analysis on the entire system.

Set Input Delay

The `set_input_delay` constraint specifies the data arrival time at a port (a device I/O) with respect to a given clock. Figure 7–29 shows an input delay path.

Figure 7–29. Set Input Delay



Use the set_input_delay command to specify input delay constraints to ports in the design. Example 7–22 shows the set_input_delay command and options.

Example 7–22. set_input_delay Command

```
set_input_delay
-clock <clock name>
[-clock_fall]
[-rise | -fall]
[-max | -min]
[-add_delay]
[-reference_pin <target>]
[-source_latency_included]
<delay value>
<targets>
```

Table 7–14 describes the options for the set_input_delay command.

Table 7–14. set_input_delay Command Options

Option	Description
-clock <*clock name*>	Specifies the source clock.
-clock_fall	Specifies the arrival time with respect to the falling edge of the clock.
-rise | -fall	Specifies either the rise or fall delay at the port.
-max | -min	Specifies the minimum or maximum data arrival time.
-add_delay	Adds another delay, but does not replace the existing delays assigned to the port.
-reference_pin <*target*>	Specifies a pin or port in the design from which to determine source and network latencies. This is useful to specify input delays relative to an output port fed by a clock.
-source_latency_ included	Specifies that the input delay value includes the source latency delay value; therefore, any source clock latency assigned to the clock is ignored.
<*delay value*>	Specifies the delay value.
<*targets*>	Specifies the destination ports or pins.

A warning message appears if you specify only a -max or -min value for the input delay value. The input minimum delay default value is equal to the input maximum delay; the input maximum delay default value is equal to the input minimum delay, if only one is specified. Similarly, a warning message appears if you specify only a -rise or -fall value for the delay value, and the delay defaults in the same manner as the input minimum and input maximum delays.

The maximum value is used for setup checks; the minimum value is used for hold checks.

By default, a set of input delays (min/max, rise/fall) is allowed for only one `-clock`, `-clock_fall`, `-reference_pin` combination. Specifying an input delay on the same port for a different clock, `-clock_fall` or `-reference_pin` removes any previously set input delays, unless you specify the `-add_delay` option. When you specify the `-add_delay` option, the worst-case values are used.

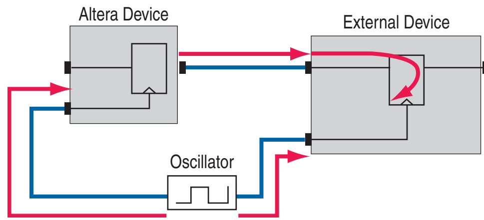
The `-rise` and `-fall` options are mutually exclusive, as are the `-min` and `-max` options.

Set Output Delay

The `set_output_delay` command specifies the data required time at a port (the device pin) with respect to a given clock.

Use the `set_output_delay` command to specify output delay constraints to ports in the design. Figure 7–30 shows an output delay path.

Figure 7–30. Output Delay



Example 7–23 shows the `set_output_delay` command and options.

Example 7–23. set_output_delay Command

```
set_output_delay
-clock <clock name>
[-clock_fall]
[-rise | -fall]
[-max | -min]
[-add_delay]
[-reference_pin <target>]
<delay value>
<targets>
```

Table 7–15 describes the options for the `set_output_delay` command.

Table 7–15. set_output_delay Command Options (Part 1 of 2)

Option	Description
`-clock <clock name>`	Specifies the source clock.
`-clock_fall`	Specifies the required time with respect to the falling edge of the clock.
`-rise | -fall`	Specifies either the rise or fall delay at the port.
`-max | -min`	Specifies the minimum or maximum data arrival time.
`-add_delay`	Adds another delay, but does not replace the existing delays assigned to the port.

Table 7–15. set_output_delay Command Options (Part 2 of 2)

Option	Description
`-reference_pin <target>`	Specifies a pin or port in the design from which to determine source and network latencies. Use this option to specify input delays relative to an output port fed by a clock.
`-source_latency_included`	Specifies that the input delay value includes the source latency delay value; therefore, any source clock latency assigned to the clock will subsequently be ignored.
`<delay value>`	Specifies the delay value.
`<targets>`	Specifies the destination ports or pins.

A warning message appears if you specify only a `-max` or `-min` value for the output delay value. The output minimum delay default value is the output maximum delay; the output maximum delay default value is the output minimum delay, if only one is specified.

The maximum value is used for setup checks; the minimum value is used for hold checks.

By default, a set of output delays (min/max, rise/fall) is allowed for only one clock, `-clock_fall`, port combination. Specifying an output delay on the same port for a different clock or `-clock_fall` removes any previously set output delays, unless you specify the `-add_delay` option. When you specify the `-add_delay` option, the worst-case values are used.

The `-rise` and `-fall` options are mutually exclusive, as are the `-min` and `-max` options.

Delay and Skew Specifications

The TimeQuest Timing Analyzer supports the ability to specify and report maximum, minimum, and skew delays between a source and destination points.

set_net_delay

Use the `set_net_delay` command in conjunction with the `report_net_delay` command to report the net delays and perform minimum or maximum analysis across nets. Example 7–24 shows the `set_net_delay` command and options.

The `set_net_delay` and `report_net_delay` commands can be used when verifying timing-critical delays for high-speed interfaces. For example, the command can be used to report the delay across a high-speed data bus for each bit.

Example 7–24. set_net_delay Command

```
set_net_delay
    -from <names>
    [-max]
    [-to <names>]
    [-min]
    <delay>
```

Table 7–16 describes the options for the `set_net_delay` command.

Table 7–16. set_net_delay Command Options

Option	Description
`-from <names>`	Valid source pins or ports (string patterns are matched using Tcl string matching).
`-max`	Specifies maximum delay.
`-min`	Specifies minimum delay.
`-to <names>`	Valid destination pins or ports (string patterns are matched using Tcl string matching). If `-to` is left unspecified, the missing value or values are substituted by an "*" character.
`<delay>`	Required delay.

When the `-min` option is specified, the slack is calculated with the minimum edge delay. When the `-max` option is specified, the slack is calculated with the maximum edge delay. When the `-skew` option is specified, the slack is calculated across all the valid edges that satisfy the `-from` and `-to` filters.

set_max_skew

Use the `set_max_skew` command to specify the maximum path-based skew requirements for registers and ports in the design. Example 7–25 shows the `set_max_delay` command and options.

Example 7–25. set_max_skew

```
set_max_skew
[-exclude <Tcl list>]
[-from <names>]
[-include <Tcl list>]
[-to <names>]
<skew>
```

Table 7–17 describes the options for the `set_max_skew` command.

Table 7–17. set_max_skew Command Options

Option	Description
`-exclude <list>`	A list of parameters to exclude during skew analysis. This list can include 1 or more of the following: `utsu`, `uth`, `utco`, `from_clock`, `to_clock`, `clock_uncertainty`, `input_delay`, `output_delay`.
`-from <names>`	Valid sources (string patterns are matched using Tcl string matching)
`-include <list>`	Tcl list of parameters to include during skew analysis. This list can include 0 or more of the following: `utsu`, `uth`, `utco`, `from_clock`, `to_clock`, `clock_uncertainty`, `input_delay`, `output_delay`.
`-to <names>`	Valid destinations (string patterns are matched using Tcl string matching)
`<skew>`	Required maximum skew

By default, the `set_max_skew` command excludes `set_input_delay`, `set_output_delay`, `utsu` and `uth`.

When this constraint is used, the results of max skew analysis are reported with the command `report_max_skew`.

For more information about the `report_max_skew` command, refer to "report_max_skew" on page 7–69.

Timing Exceptions

Timing exceptions modify the default analysis performed by the Quartus II TimeQuest Timing Analyzer. This section describes the following available timing exceptions:

- "False Path" on page 7–44
- "Minimum Delay" on page 7–45
- "Maximum Delay" on page 7–46
- "Multicycle Path" on page 7–47

Precedence

If a conflict of node names occurs between timing exceptions, the following order of precedence applies:

1. False path
2. Minimum delays and maximum delays
3. Multicycle path

The false path timing exception has the highest precedence. Within each category, assignments to individual nodes have precedence over assignments to clocks. Finally, the remaining precedence for additional conflicts is order-dependent, such that the last assignments overwrite (or partially overwrite) earlier assignments.

False Path

False paths are paths that can be ignored during timing analysis.

Use the `set_false_path` command to specify false paths in the design. Example 7–26 shows the `set_false_path` command and options.

Example 7–26. set_false_path Command

```
set_false_path
[-fall_from <clocks> | -rise_from <clocks> | -from <names>]
[-fall_to <clocks> | -rise_to <clocks> | -to <names>]
[-hold]
[-setup]
[-through <names>]
<delay>
```

Table 7–18 describes the options for the `set_false_path` command.

Table 7–18. set_false_path Command Options

Option	Description
`-fall_from <clocks>`	The <*names*> is a collection or list of objects in the design. Specifies false path begins at the fall from <*clocks*>.
`-fall_to <clocks>`	The <names> is a collection or list of objects in the design. Specifies false path ends at the fall to <*clocks*>.
`-from <names>`	The <*names*> is a collection or list of objects in the design. Specifies false path begins at the <*names*>.
`-hold`	Specifies the false path is valid during the hold analysis only.
`-rise_from <clocks>`	The <*names*> is a collection or list of objects in the design. Specifies false path begins at the rise from <*clocks*>.
`-rise_to <clocks>`	The <*names*> is a collection or list of objects in the design. Specifies false path ends at the rise to <*clocks*>.
`-setup`	Specifies the false path is valid during the setup analysis only.
`-through <names>`	The <*names*> is a collection or list of objects in the design. Specifies false path passes through <*names*>.
`-to <names>`	The <*names*> is a collection or list of objects in the design. Specifies false path ends at <*names*>.
`<delay>`	Specifies the delay value.

When the objects are timing nodes, the false path only applies to the path between the two nodes. When an object is a clock, the false path applies to all paths where the source node (`-from`) or destination node (`-to`) is clocked by the clock.

Minimum Delay

Use the `set_min_delay` command to specify an absolute minimum delay for a given path. Example 7–27 shows the `set_min_delay` command and options.

Example 7–27. set_min_delay Command

```
set_min_delay
[-fall_from <clocks> | -rise_from <clocks> | -from <names>]
[-fall_to <clocks> | -rise_to <clocks> | -to <names>]
[-through <names>]
<delay>
```

Table 7–19 describes the options for the `set_min_delay` command.

Table 7–19. set_min_delay Command Options (Part 1 of 2)

Option	Description
`-fall_from <clocks>`	The <*names*> is a collection or list of objects in the design. Specifies the minimum delay begins at the falling edge of <*clocks*>.
`-fall_to <clocks>`	The <*names*> is a collection or list of objects in the design. Specifies the minimum delay ends at the falling of <*clocks*>.
`-from <names>`	The <*names*> is a collection or list of objects in the design. The <*names*> acts as the start point of the path.

Table 7–19. set_min_delay Command Options (Part 2 of 2)

Option	Description
`-rise_from <clocks>`	The <*names*> is a collection or list of objects in the design. Specifies the minimum delay at the rising edge of <*clocks*>.
`rise_to <clocks>`	The <*names*> is a collection or list of objects in the design. Specifies the minimum delay at the rising edge of <*clocks*>.
`-through <names>`	The <*names*> is a collection or list of objects in the design. The <*names*> acts as the through point of the path.
`-to <names>`	The <*names*> is a collection or list of objects in the design. The <*names*> acts as the end point of the path.
`<delay>`	Specifies the delay value.

If the source or destination node is clocked, the clock paths are taken into account, allowing more or less delay on the data path. If the source or destination node has an input or output delay, that delay is also included in the minimum delay check.

When the objects are timing nodes, the minimum delay applies only to the path between the two nodes. When an object is a clock, the minimum delay applies to all paths where the source node (`-from`) or destination node (`-to`) is clocked by the clock.

You can apply the `set_min_delay` command exception to an output port that does not use a `set_output_delay` constraint. In this case, the setup summary and hold summary report the slack for these paths. Because there is no clock associated with the output port, no clock is reported for these paths and the Clock column is empty. In this case, you cannot report timing for these paths.

To report timing using clock filters for output paths with the `set_min_delay` command, you can use the `set_output_delay` command for the output port with a value of 0. You can use an existing clock from the design or a virtual clock as the clock reference in the `set_output_delay` command.

Maximum Delay

Use the `set_max_delay` command to specify an absolute maximum delay for a given path. Example 7–28 shows the `set_max_delay` command and options.

Example 7–28. set_max_delay Command

```
set_max_delay
[-fall_from <clocks> | -rise_from <clocks> | -from <names>]
[-fall_to <clocks> | -rise_to <clocks> | -to <names>]
[-through <names>]
<delay>
```

Table 7–20 describes the options for the `set_max_delay` command.

Table 7–20. set_max_delay Command Options

Option	Description
`-fall_from <clocks>`	The <*names*> is a collection or list of objects in the design. Specifies the maximum delay begins at the falling edge of <*clocks*>.
`-fall_to <clocks>`	The <*names*> is a collection or list of objects in the design. Specifies the maximum delay ends at the falling of <*clocks*>.
`-from <names>`	The <*names*> is a collection or list of objects in the design. The <*names*> acts as the start point of the path.
`-rise_from <clocks>`	The <*names*> is a collection or list of objects in the design. Specifies the maximum delay at the rising edge of <*clocks*>.
`rise_to <clocks>`	The <*names*> is a collection or list of objects in the design. Specifies the maximum delay at the rising edge of <*clocks*>.
`-through <names>`	The <*names*> is a collection or list of objects in the design. The <*names*> acts as the through point of the path.
`-to <names>`	The <*names*> is a collection or list of objects in the design. The <*names*> acts as the end point of the path.
`<delay>`	Specifies the delay value.

If the source or destination node is clocked, the clock paths are taken into account, allowing more or less delay on the data path. If the source or destination node has an input or output delay, that delay is also included in the maximum delay check.

When the objects are timing nodes, the maximum delay only applies to the path between the two nodes. When an object is a clock, the maximum delay applies to all paths where the source node (`-from`) or destination node (`-to`) is clocked by the clock.

You can apply the `set_max_delay` command exception to an output port that does not use a `set_output_delay` constraint. In this case, the setup summary and hold summary report the slack for these paths. Because there is no clock associated with the output port, no clock is reported for these paths and the Clock column is empty. In this case, you cannot report timing for these paths.

To report timing using clock filters for output paths with the `set_max_delay` command, you can use the `set_output_delay` command for the output port with a value of 0. You can use an existing clock from the design or a virtual clock as the clock reference in the `set_output_delay` command.

Multicycle Path

By default, the Quartus II TimeQuest Timing Analyzer uses a single-cycle analysis. When analyzing a path, the setup launch and latch edge times are determined by finding the closest two active edges in the respective waveforms. For a hold analysis, the timing analyzer analyzes the path against two timing conditions for every possible setup relationship, not just the worst-case setup relationship. Therefore, the hold launch and latch times may be completely unrelated to the setup launch and latch edges.

A multicycle constraint relaxes setup or hold relationships by the specified number of clock cycles based on the source (`-start`) or destination (`-end`) clock. An end multicycle constraint of 2 extends the worst-case setup latch edge by one destination clock period.

Hold multicycle constraints are based on the default hold position (the default value is 0). An end hold multicycle constraint of 1 effectively subtracts one destination clock period from the default hold latch edge.

Use the `set_multicycle_path` command to specify the multicycle constraints in the design. Example 7–29 shows the `set_multicycle_path` command and options.

Example 7–29. set_multicycle_path Command

```
set_multicycle_path
[-end]
[-fall_from <clocks> | -rise_from <clocks> | -from <names>]
[-fall_to <clocks> | -rise_to <clocks> | -to <names>]
[-hold]
[-setup]
[-start]
[-through <names>]
<path multiplier>
```

Table 7–21 describes the options for the `set_multicycle_path` command.

Table 7–21. set_multicycle_path Command Options

Option	Description
`fall_from <clocks>`	The <*names*> is a collection or list of objects in the design. Specifies the multicycle begins at the falling edge of <*clocks*>.
`fall_to <clocks>`	The <*names*> is a collection or list of objects in the design. Specifies the multicycle ends at the falling of <*clocks*>.
`-from <names>`	The <*names*> is a collection or list of objects in the design. The <*names*> acts as the start point of the path.
`-hold	-setup`	Specifies the type of multicycle to be applied.
`-rise_from <clocks>`	The <*names*> is a collection or list of objects in the design. Specifies the multicycle at the rising edge of <*clocks*>.
`-rise_to <clocks>`	The <*names*> is a collection or list of objects in the design. Specifies the multicycle ends at the rising edge of <*clocks*>.
`-start	-end`	Specifies whether the start or end clock acts as the source or destination for the multicycle.
`-through <names>`	The <*names*> is a collection or list of objects in the design. Specifies multicycle passes through <*names*>.
`-to <names>`	The <*names*> is a collection or list of objects in the design. The <*names*> acts as the end point of the path.
`<path multiplier>`	Specifies the multicycle multiplier value.

When the objects are timing nodes, the multicycle constraint only applies to the path between the two nodes. When an object is a clock, the multicycle constraint applies to all paths where the source node (`-from`) or destination node (`-to`) is clocked by the clock.

Annotated Delay

Use the `set_annotated_delay` command to annotate the cell delay between two or more pins/nodes on a cell, or the interconnect delay between two or more pins on the same net, in the current design. The annotated delay can be specified for specific transition edges: rise-rise, fall-rise, rise-fall, and fall-fall, and can also set different minimum and maximum values.

If no transition is specified, the given delay is assigned to all four values. Options `-max` and `-min` allow users to specify maximum or minimum delay.

Example 7–30 shows the `set_annotated` command and options.

Example 7–30. set_annotated_delay Command

```
set_annotated_delay
    [-cell|-net]
    [-from <names>]
    [-max|-min]
    [-operating_conditions <operating_conditions>]
    [-rr|-fr|-rf|-ff]
    [-to <names>]
    <delay>
```

Table 7–22 describes the options for the `set_annotated_delay` command.

Table 7–22. set_annotated_delay Command Options

Options	Description
`-cell`	Specifies that cell delay must be set.
`-ff`	Specifies that FF delay must be set.
`-fr`	Specifies that FR delay must be set.
`-from <names>`	Valid source pins or ports (string patterns are matched using Tcl string matching). If `-from` value is left unspecified, the "`*`" character is used.
`-max`	Specifies that only the maximum delay should be set.
`-min`	Specifies that only the minimum delay should be set.
`-net`	Specifies that net delay must be set.
`-operating_conditions <operating_conditions>`	Specifies the operating conditions Tcl object. Refer to Table 7–51 on page 7–75 for the operating conditions Tcl object.
`-rf`	Specifies that RF delay must be set.
`-rr`	Specifies that RR delay must be set.
`-to <names>`	Valid destination pins or ports (string patterns are matched using Tcl string matching). If `-to` value is left unspecified, the "`*`" character is used.
`<delay>`	The delay value in default time units.

With the `-operation_conditions` option, different operating conditions can be specified in a single **.sdc** file, removing the requirement of having multiple **.sdc** files that specify different operating conditions.

The delay annotation is deferred until the next time `update_timing_netlist` is called. To remove annotated delays, use the `remove_annotated_delay` command.

Application Examples

This section describes specific examples for the `set_multicycle_path` command.

Figure 7–31 shows a register-to-register path where the source clock, `src_clk`, has a period of 10 ns and the destination clock, `dst_clk`, has a period of 5 ns.

Figure 7–31. Register-to-Register Path

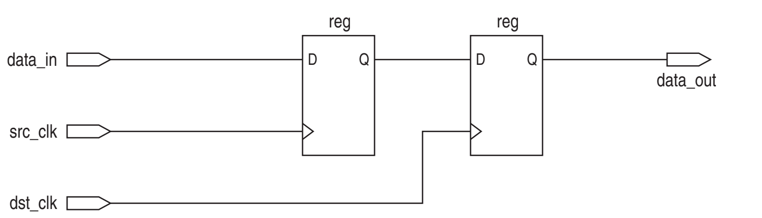


Figure 7–32 shows the respective timing diagrams for the source and destination clocks and the default setup and hold relationships. The default setup relationship is 5 ns; the default hold relationship is 0 ns.

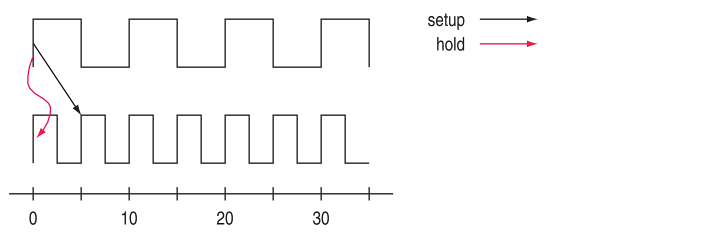
Figure 7–32. Default Setup and Hold Timing Diagram



The default setup and hold relationships can be modified with the `set_multicycle_path` command to accommodate system requirements.

Table 7–23 shows the commands used to modify either the launch or latch edge times that the TimeQuest Timing Analyzer uses to determine a setup relationship or hold relationship.

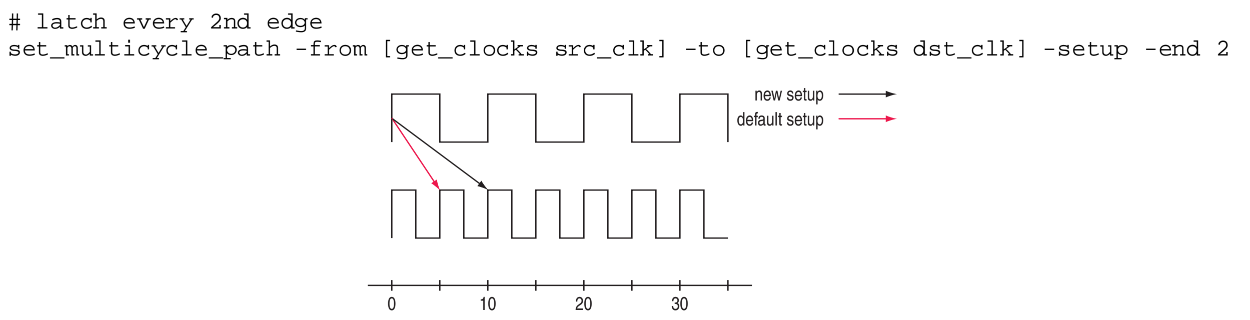
Table 7–23. Commands to Modify Edge Times

Command	Description of Modification
`set_multicycle_path -setup -end`	Latch edge time of the setup relationship
`set_multicycle_path -setup -start`	Launch edge time of the setup relationship
`set_multicycle_path -hold -end`	Latch edge time of the hold relationship
`set_multicycle_path -hold -start`	Launch edge time of the hold relationship

Figure 7–33 shows the command used to modify the setup latch edge and the resulting timing diagram. The command moves the latch edge time to 10 ns from the default 5 ns.

Figure 7–33. Modified Setup Diagram

```
# latch every 2nd edge
set_multicycle_path -from [get_clocks src_clk] -to [get_clocks dst_clk] -setup -end 2
```



Constraint and Exception Removal

When using the Quartus II TimeQuest Timing Analyzer interactively, it is usually necessary to remove a constraint or exception. In cases where constraints and exceptions either become outdated or have been erroneously entered, the Quartus II TimeQuest Timing Analyzer provides a convenient way to remove them.

Table 7–24 lists commands that allow you to remove constraints and exceptions from a design.

Table 7–24. Constraint and Exception Removal

Command	Description
`remove_clock [-all] [<clock list>]`	Removes any clocks specified by <*clock list*> that have been previously created. The `-all` option removes all declared clocks.
`remove_clock_groups -all`	Removes all clock groups previously created. Specific clock groups cannot be removed.
`remove_clock_latency -source <targets>`	Removes the clock latency constraint from the clock specified by <*targets*>.
`remove_clock_uncertainty -from <from clock> -to <to clock>`	Removes the clock uncertainty constraint from <*from clock*> to <*to clock*>.
`remove_input_delay <targets>`	Removes the input delay constraint from <*targets*>.
`remove_output_delay <targets>`	Removes the output delay constraint from <*targets*>.
`remove_annotated_delay -all`	Removes any annotated delay specified with the `set_annotated_delay` command.
`reset_design`	Removes all constraints and exceptions in the design.

Timing Reports

The Quartus II TimeQuest Timing Analyzer provides real-time static timing analysis result reports. Reports are generated only when requested. You can customize which report to display specific timing information, excluding those fields not required.

This section describes various report generation commands supported by the Quartus II TimeQuest Timing Analyzer.

report_timing

Use the `report_timing` command to generate a setup, hold, recovery, or removal report. Example 7–31 shows the `report_timing` command and options.

Example 7–31. report_timing Command

```
report_timing
[-append]
[-detail <summary|path_only|path_and_clock|full_path>]
[-fall_to_clock <names>|-rise_to_clock <names>]
[-to <names>|-to_clock <names>]
[-false_path]
[-file <name>]
[-from <names>]

Table 7–25 describes the options for the `report_timing` command.

Table 7–25. report_timing Command Options (Part 1 of 2)

Option	Description
`-append`	If output is sent to a file, this option appends the result to that file. Otherwise, the file is overwritten.
`-detail <summary|path_only|path_and_clock|full_path>`	Specifies whether or not the clock path detail is reported: `Path Only`: Clock network delay is lumped together `Summary`: Lists each individual path `Path and Clock`: Clock network delay is shown in detail `Full Path`: More clock network details, in particular for generated clocks
`-fall_from_clock <names>`	Specifies the falling edge of the <*names*> from the source register to be analyzed. The options `from_clock`, `fall_from_clock`, and `rise_from_clock` are mutually exclusive.
`-fall_to_clock <names>`	Specifies the falling edge of the <*names*> to the destination register to be analyzed; the options `to_clock`, `fall_to_clock`, and `rise_to_clock` are mutually exclusive.
`-false_path`	Reports only paths that are cut by a false path assignment.
`-file <names>`	Sends the results to an ASCII or HTML file. The extension specified in the file name determines the file type either ***.rpt**, ***.txt**, or ***.html**.
`-hold`	Specifies a clock hold analysis.
`-less_than_slack <slack limit>`	Limits the paths to be reported to the <*slack limit*> value.
`-npaths <number>`	Specifies the number of paths to report.
`-nworst <number>`	Restricts the number of paths per endpoint.
`-panel_name <names>`	Specifies the name of the panel in the **Reports** pane.

Table 7–25. report_timing Command Options (Part 2 of 2)

Option	Description
`-panel_name <names>`	Sends the results to the panel and specifies the name of the new panel.
`-pairs_only`	When set, paths with the same start and end points are considered equivalent; only the worst-case path for each unique combination is displayed.
`-recovery`	Specifies a recovery analysis.
`-removal`	Specifies a removal analysis.
`-rise_from_clock <names>`	Specifies the rising edge of the <*names*> from the source register to be analyzed; the options `from_clock`, `fall_from_clock`, and `rise_from_clock` are mutually exclusive.
`-rise_to_clock <names>`	Specifies the rising edge of the <*names*> to the destination register to be analyzed; the options `to_clock`, `fall_to_clock`, and `rise_to_clock` are mutually exclusive.
`-setup`	Specifies a clock setup analysis.
`-show_routing`	Displays detailed routing in the path.
`-stdout`	Indicates the report will be sent to `stdout`.
`-through <names>`	Specifies the through node for analysis.
`-to <names>`	Specifies the to node for analysis.
`-to_clock <names>`	Specifies the destination clock for analysis.

Example 7–32 shows a sample report that results from typing the following command:

```
report_timing -from_clock clk_async -to_clock clk_async -setup -npaths 1 ↵
```

```

The report_timing command generates a report of the specified analysis type—either setup, hold, recovery, or removal. Each of the column descriptions are described in the Table 7–26.

All columns appear only when a report panel is created. If the report_timing output is directed to a file or the console, only the Total, Incr, RF, Type, and Node columns appear.

Table 7–26. Timing Report Data

Column Name	Description
Total	Shows the accumulated time delay.
Incr	Shows the increment in delay.
RF	Shows the input and output transition of the element; this can be one of the following: R, F, RR, RF, FR, FF.
Type	Shows the node type; refer to Table 7–27 of a description of the various node types.
Fanout	Shows the number of fan-outs of the element.
Location	Shows the location of the element in the FPGA.
Element	Shows the name of the element.

Table 7–27 provides a description of the possible node type in the report_timing reports.

Table 7–27. Type Description (Part 1 of 2)

Type Name	Description
CELL	Indicates the element is either a register or a combinational element in the FPGA; t.he CELL can be a register in the ALM, memory blocks, DSP blocks, or I/O block
COMP	Indicates the PLL clock network compensation delay.

Table 7–27. Type Description (Part 2 of 2)

Type Name	Description
IC	Indicates the element is an interconnect delay.
utco	Indicates the element's micro clock-to-out time.
utsu	Indicates the element's micro setup time.
uth	Indicates the element's micro hold time.
iext	Indicates the element's external input delay time.
oext	Indicates the element's external output delay time.
LOOP	Indicates a lumped delay bypassing combinational loops.
RE	Indicates a specified routing delay.

report_exceptions

Use the `report_exceptions` command to generate a report that details the slack of all paths that have the timing exceptions `set_false_path`, `set_multicycle`, `set_min_delay`, or `set_max_delay` applied to them.

The `report_exceptions` command can be used to determine if all exceptions have been applied to the applicable paths in the design.

Example 7–33 shows the `report_exceptions` command and options.

Example 7–33. report_exceptions Command

```
report_exceptions
[-append]
[-detail <summary|path_summary|path_only|path_and_clock|full_path>]
[-fall_from_clock <names>]
[-fall_to_clock <names>]
[-file <name>]
[-from <names>]
[-from_clock <names>]
[-hold]
[-less_than_slack <slack limit>]
[-npaths <number>]
[-nworst <number>]
[-pairs_only]
[-panel_name <name>]
[-recovery]
[-removal]
[-rise_from_clock <names>]
[-rise_to_clock <names>]
[-setup]
[-stdout]
[-through <names>]
[-to <names>]
[-to_clock <names>]
```

Table 7–28 describes the options for the `report_exceptions` command.

Table 7–28. report_exceptions Command Options

Option	Description
`-append`	If output is sent to a file, this option appends the result to that file. Otherwise, the file is overwritten.
`-detail <summary|path_only|path_and_clock|full_path>`	Specifies whether or not the clock path detail is reported: `Path Only`: Clock network delay is lumped together `Summary`: Lists each individual path `Path and Clock`: Clock network delay is shown in detail `Full Path`: More clock network details, in particular for generated clocks
`-fall_from_clock <names>`	Specifies the falling edge of the <*names*> from the source register to be analyzed. The options `from_clock`, `fall_from_clock`, and `rise_from_clock` are mutually exclusive.
`-fall_to_clock <names>`	Specifies the falling edge of the <*names*> to the destination register to be analyzed; the options `to_clock`, `fall_to_clock`, and `rise_to_clock` are mutually exclusive.
`-false_path`	Reports only paths that are cut by a false path assignment.
`-file <names>`	Sends the results to an ASCII or HTML file. The extension specified in the file name determines the file type either ***.rpt**, ***.txt**, or ***.html**.
`-hold`	Specifies a clock hold analysis.
`-less_than_slack <slack limit>`	Limits the paths to be reported to the <*slack limit*> value.
`-npaths <number>`	Specifies the number of paths to report.
`-nworst <number>`	Restricts the number of paths per endpoint.
`-panel_name <names>`	Specifies the name of the panel in the **Reports** pane.
`-panel_name <names>`	Sends the results to the panel and specifies the name of the new panel.
`-pairs_only`	When set, paths with the same start and end points are considered equivalent; only the worst-case path for each unique combination is displayed.
`-recovery`	Specifies a recovery analysis.
`-removal`	Specifies a removal analysis.
`-rise_from_clock <names>`	Specifies the rising edge of the <*names*> from the source register to be analyzed; the options `from_clock`, `fall_from_clock`, and `rise_from_clock` are mutually exclusive.
`-rise_to_clock <names>`	Specifies the rising edge of the <*names*> to the destination register to be analyzed; the options `to_clock`, `fall_to_clock`, and `rise_to_clock` are mutually exclusive.
`-setup`	Specifies a clock setup analysis.
`-show_routing`	Displays detailed routing in the path.
`-stdout`	Indicates the report will be sent to `stdout`.
`-through <names>`	Specifies the through node for analysis.
`-to <names>`	Specifies the to node for analysis.
`-to_clock <names>`	Specifies the destination clock for analysis.

report_metastability

Use the `report_metastability` command to generate a report that lists the synchronization register chains for asynchronous transfers in your design, and details the MTBF for synchronization register chains.

To enable metastability analysis, you must set the **Synchronizer Identification** option to identify the synchronization register chains in the design. You can use automatic identification to generate a list of possible synchronizers in the metastability report, but MTBF is not reported for automatically-identified synchronizers.

The TimeQuest Timing Analyzer can analyze metastability MTBF only if a synchronization chain meets its timing requirements. Therefore, it is important for your design to be correctly constrained to get an accurate MTBF report. In addition, automatic synchronizer identification uses timing constraints to automatically detect the signal transfers between circuitry in unrelated or asynchronous clock domains, so clock domains must be related correctly with the timing constraints.

For details about metastability analysis and reporting, refer to the *Managing Metastability with the Quartus II Software* chapter in volume 1 of the *Quartus II Handbook*. This chapter describes how to use the **Synchronizer Identification** option, explains how TimeQuest timing constraints affect synchronizer chain identification and the reported MTBF, and provides details about the information reported with the `report_metastability` command.

Example 7–34. report_metastability command

```
report_metastabiity
[-append]
[-file <name>]
[-panel_name <name>]
[-stdout]
```

Table 7–29 describes the options for the `report_metastability` command.

Table 7–29. report_metastability Command Options

Option	Description
`-append`	If output is sent to a file, this option appends the result to that file. Otherwise, the file is overwritten.
`-file <name>`	Sends the results to an ASCII or HTML file. The extension specified in the file name determines the file type—either ***.txt** or ***.html**.
`-panel_name <name>`	Sends the results to the panel and specifies the name of the new panel.
`-stdout`	Indicates the report will be sent to the standard output, via messages. This option is required only if you have selected another output format, such as a file, and would also like to receive messages.

report_clock_transfers

Use the `report_clock_transfers` command to generate a report that details all clock-to-clock transfers in the design. A clock-to-clock transfer is reported if a path exists between two registers that are clocked by two different clocks. Information such as the number of destinations and sources is also reported.

Use the `report_clock_transfers` command to generate a setup, hold, recovery, or removal report.

Example 7–35 shows the `report_clock_transfers` command and options.

Example 7–35. report_clock_transfers Command

```
report_clock_transfers
[-append]
[-file <name>]
[-hold]
[-setup]
[-stdout]
[-recovery]
[-removal]
[-panel_name <name>]
```

Table 7–30 describes the options for the `report_clock_transfers` command.

Table 7–30. report_clock_transfers Command Options

Option	Description
`-append`	If output is sent to a file, this option appends the result to that file. Otherwise, the file is overwritten.
`-file <name>`	Sends the results to an ASCII or HTML file. The extension specified in the file name determines the file type either ***.txt** or ***.html**.
`-hold`	Creates a clock transfer summary for hold analysis.
`-setup`	Creates a clock transfer summary for setup analysis.
`-stdout`	Indicates the report will be sent to `stdout`.
`-recovery`	Creates a clock transfer summary for recovery analysis.
`-removal`	Creates a clock transfer summary for removal analysis.
`-panel_name <name>`	Sends the results to the panel and specifies the name of the new panel.

report_clocks

Use the `report_clocks` command to generate a report that details all clocks in the design. The report contains information such as type, period, waveform (rise and fall), and targets for all clocks in the design.

Example 7–36 shows the `report_clocks` command and options.

Example 7–36. report_clocks Command

```
report_clocks
[-append]
[-desc]
[-file <name>]
[-stdout]
[-panel_name <name>]
```

Table 7–31 describes the options for the `report_clocks` command.

Table 7–31. report_clocks Command Options

Option	Description
`-append`	If output is sent to a file, this option appends the result to that file. Otherwise, the file is overwritten.
`-file <name>`	Sends the results to an ASCII or HTML file. The extension specified in the file name determines the file type—either ***.txt** or ***.html**.
`-desc`	Specifies the clock names to sort in descending order. The default is ascending order.
`-stdout`	Indicates the report will be sent to `stdout`.
`-panel_name <name>`	Sends the results to the panel and specifies the name of the new panel.

report_min_pulse_width

The `report_min_pulse_width` command checks that a clock high or low pulse is sustained long enough to be recognized as an actual change in the clock signal. A failed minimum pulse width check indicates that the register may not recognize the clock transition. Use the `report_min_pulse_width` command to generate a report that details the minimum pulse width for all clocks in the design. The report contains information for high and low pulses for all clocks in the design.

The `report_min_pulse_width` command also reports minimum period checks for RAM and DSP, as well as I/O edge rate limits for input and output clock ports. For output ports, the port must either have a clock (or generated clock) assigned to it or used as the `-reference_pin` for input/output delays.

The `report_min_pulse_width` command checks the I/O edge rate limits, but does not always perform the check for output clock ports. For the `report_min_pulse_width` command to check the I/O edge rate limits for output clock ports, the output clock port must fall into one of the following categories:

- Have a clock or generated clock constraint assigned to it

or

- Use a `-reference_pin` for an input or output delay constraint

Each register in the design is reported twice per clock that clocks the register: once for the high pulse and once for the low pulse. Example 7–37 shows the `report_min_pulse_width` command and options.

Example 7–37. report_min_pulse_width Command

```
report_min_pulse_width
[-append]
[-file <name>]
[-nworst <number>]
[-stdout]
[<targets>]
[-panel_name <name>]
```

Table 7–32 describes the options for the `report_min_pulse_width` command.

Table 7–32. report_min_pulse_width Command Options

Option	Description
`-append`	If output is sent to a file, this option appends the result to that file. Otherwise, the file is overwritten.
`-file <name>`	Sends the results to an ASCII or HTML file. The extension specified in the file name determines the file type—either ***.txt** or ***.html**.
`-nworst <number>`	Specifies the number of pulse width checks to report. The default is 1.
`-stdout`	Redirects the output to `stdout` via messages; only required if another output format, such as a file, has been selected and is also to receive messages.
`<targets>`	Specifies registers.
`-panel_name <name>`	Sends the results to the panel and specifies the name of the new panel.

report_net_timing

Use the `report_net_timing` command to generate a report that details the delay and fan-out information about a net in the design. A net corresponds to a cell's output pin.

Example 7–38 shows the `report_net_timing` command and options.

Example 7–38. report_net_timing Command

```
report_net_timing
[-append]
[-file <name>]
[-nworst_delay <number>]
[-nworst_fanout <number>]
[-stdout]
[-panel_name <name>]
```

Table 7–33 describes the options for the `report_net_timing` command.

Table 7–33. report_net_timing Command Options

Option	Description
`-append`	If output is sent to a file, this option appends the result to that file. Otherwise, the file is overwritten.
`-file <name>`	Sends the results to an ASCII or HTML file. The extension specified in the file name determines the file type—either ***.txt** or ***.html**.
`-nworst_delay <number>`	Specifies that <*number*> worst net delays be reported.
`-nworst_fanout <number>`	Specifies that <*number*> worst net fan-outs be reported.
`-stdout`	Indicates the report will be sent to `stdout`.
`-panel_name <name>`	Sends the results to the panel and specifies the name of the new panel.

 © March 2009 Altera Corporation

report_sdc

Use the `report_sdc` command to generate a report of all the Synopsys design constraints in the project.

Example 7–39 shows the `report_sdc` command and options.

Example 7–39. report_sdc Command

```
report_sdc
[-ignored]
[-append]
[-file]
[-stdout]
[-panel_name <name>]
```

Table 7–34 describes the options for the `report_sdc` command.

Table 7–34. report_sdc Command Options

Option	Description
`-ignored`	Reports assignments that were ignored.
`-append`	If output is sent to a file, this option appends the result to that file. Otherwise, the file is overwritten.
`-file`	Sends the results to an ASCII or HTML file. The extension specified in the file name determines the file type—either ***.txt** or ***.html**.
`-stdout`	Indicates that the report will be sent to `stdout`.
`-panel_name <name>`	Sends the results to the panel and specifies the name of the new panel.

report_ucp

Use the `report_ucp` command to generate a report of all unconstrained paths in the design.

Example 7–40 shows the `report_ucp` command and options.

Example 7–40. report_ucp Command

```
report_ucp
[-append]
[-file <name>]
[-hold]
[-setup]
[-stdout]
[-summary]
[-panel_name <name>]
```

Table 7–35 describes the options for the `report_ucp` command.

Table 7–35. Option Descriptions for report_ucp (Part 1 of 2)

Option	Description
`-append`	If output is sent to a file, this option appends the result to that file. Otherwise, the file is overwritten.
`-file <name>`	Sends the results to an ASCII or HTML file. The extension specified in the file name determines the file type—either ***.txt** or ***.html**.

Table 7–35. Option Descriptions for report_ucp (Part 2 of 2)

Option	Description
`-hold`	Reports all unconstrained hold paths.
`-setup`	Reports all unconstrained setup paths.
`-stdout`	Indicates the report be sent to `stdout`.
`-summary`	Generates only the summary panel.
`-panel_name <name>`	Sends the results to the panel and specifies the name of the new panel.

Table 7–36 summarizes all reporting commands available in the Quartus II TimeQuest Timing Analyzer.

Table 7–36. Reports from the Tasks Pane and Tcl Commands

Task Pane Report	Tcl Command	Description
Report Setup Summary	`create_timing_summary -setup`	Generates a clock setup summary for all defined clocks.
Report Hold Summary	`create_timing_summary -hold`	Generates a clock hold summary for all defined clocks.
Report Recovery Summary	`create_timing_summary -recovery`	Generates a clock recovery summary for all defined clocks.
Report Removal Summary	`create_timing_summary -removal`	Generates a clock removal summary for all defined clocks.
Report Clocks	`report_clocks`	Generates a clock summary for all defined clocks.
Report Clock Transfers	`report_clock_transfers`	Generates a clock transfer summary for all clock-to-clock transfers in the design.
Report SDC	`report_sdc`	Generates a summary of all **.sdc** file commands read.
Report Unconstrained Paths	`report_ucp`	Generates a summary of all unconstrained paths in the design.
Report Timing	`report_timing`	Generates a detailed summary for specific paths in the design.
Report Net Timing	`report_net_timing`	Generates a detailed summary for specific nets in the design.
Report Minimum Pulse Width	`report_min_pulse_width`	Generates a detailed summary for specific registers in the design.
Create Slack Histogram	`create_slack_histogram`	Generates a detailed histogram for a specific clock in the design.

report_bottleneck

Use the `report_bottleneck` command to report a rating per node based on the number of failing paths through each node for the worst 1,000 setup paths. Example 7–41 shows the `report_bottleneck` command and options.

Example 7–41. report_bottleneck Command

```
report_bottleneck
[-cmetric <cmetric_name>]
[-details]
[-metric <default|tns|num_paths|num_fpaths|num_fanins|num_fanouts>]
[-panel <panel_name>]
[-stdout]
[<paths>]
```

By default, the report_bottleneck command reports a rating for the worst 1,000 setup paths.

In addition to the default metric, there are a few additional "standard" metrics to choose from, such as:

- -metric num_fanouts
- -metric tns

You can also create a custom metric to evaluate the nodes based on the combination of the number of fanouts, fanins, failing paths, total paths, and other keepers. The paths to be analyzed can be specified by passing the result of any get_timing_paths call as the last argument to report_bottleneck.

Table 7–37 describes the options for the report_bottleneck command.

Table 7–37. report_bottleneck Command

Option	Description
-cmetric <*cmetric_name*>	Custom metric function to evaluate individual nodes.
-details	Show the detailed information (number of failing edges, number of fan-ins, and so forth).
-metric <*default*|*tns*|*num_paths*|*num_fpaths*|*num_fanins*|*num_fanouts*>	Indicate the metric to use to rate individual nodes.
-panel <*panel_name*>	Sends the results to the panel and specifies the name of the new panel.
-stdout	Indicates the report will be sent to stdout.
<*paths*>	Paths to be analyzed.

Example 7–42 shows how to create a custom metric with the report_bottleneck command.

Example 7–42. report_bottleneck Custom Metric

```
#set the number of paths to be reported
set paths [ get_timing_paths -npaths 1000 -setup ]

#create the custom metric
proc report_bottleneck_custom_metric {arg} {
   # Description: use the number of fanins as the custom metric.
   upvar $arg metric
   set rating $metric(num_fanins)
   return $rating
}
#reporting the results of the custom metric
report_bottleneck -cmetric report_bottleneck_custom_metric -panel
"Timing Analysis Bottleneck Report - Custom" $paths
```

report_datasheet

Use the `report_datasheet` command to generate a datasheet report which summarizes the timing characteristics of the entire design. It reports setup (`tsu`), hold (`th`), clock-to-output (`tco`), minimum clock-to-output (`mintco`), propagation delay (`tpd`), and minimum propagation delay (`mintpd`) times. Example 7–43 shows the `report_datasheet` command and options.

Example 7–43. report_datasheet Command

```
report_datasheet
[-append]
[-file <name>]
[-stdout]
[panel_name <name>]
```

Table 7–38 describes the options for the `report_datasheet` command.

Table 7–38. report_datasheet Command Options

Option	Description
`-append`	If output is sent to a file, this option appends the result to that file. Otherwise, the file is overwritten.
`-file <name>`	Sends the results to an ASCII or HTML file. The extension specified in the file name determines the file type—either ***.txt** or ***.html**.
`-stdout`	Indicates the report will be sent to `stdout`.
`-panel_name <name>`	Sends the results to the panel and specifies the name of the new panel.

The delays are reported with respect to a base clock or port for which they are relevant. If there is a case where there are multiple paths for a clock, the maximum delay of the longest path is taken for the t_{SU}, t_H, t_{CO}, and t_{PD}, and the minimum delay of the shortest path is taken for $mint_{CO}$ and $mint_{PD}$.

report_rskm

Use the `report_rskm` command to generate a report that details the receiver skew margin for LVDS receivers.

Example 7–44 shows the `report_rskm` command and options.

Example 7–44. report_rskm Command

```
report_rskm
[-append]
[-file <name>]
[-panel_name <name>]
[-stdout]
```

Table 7–39 describes the options for the `report_rskm` command.

Table 7–39. report_rskm Command Options

Type Name	Description
`-append`	If output is sent to a file, this option appends the result to that file. Otherwise, the file is overwritten.
`-file <name>`	Sends the results to an ASCII or HTML file. The extension specified in the file name determines the file type—either ***.txt** or ***.html**.
`-panel_name <name>`	Sends the results to the panel and specifies the name of the new panel.
`-stdout`	Indicates the report will be sent to `stdout`.

The receiver input skew margin (RSKM) is the time margin available before the LVDS receiver megafunction fails to operate. RSKM is defined as the total time margin that remains after subtracting the sampling window (SW) size and the receiver channel-to-channel skew (RCCS) from the time unit interval (TUI), as expressed in the formula shown in Equation 7–11:

Equation 7–11.

$$RSKM = \frac{(TUI - SW - RCCS)}{2}$$

The time unit interval is the LVDS clock period ($1/f_{MAX}$). The sampling window is the period of time that the input data must be stable to ensure that the data is successfully sampled by the LVDS receiver megafunction. The sampling window size varies by device speed grade; RCCS reflects channel-to-channel skew seen by the LVDS receiver. This RCCS includes transmitter channel-to-channel skew (TCCS) of the upstream transmitter and maximum channel-to-channel skew between the transmitter and receiver. RCCS is equal to the difference between the maximum input delay and minimum input delay. If no input delay is set, RCCS defaults to zero.

report_tccs

Use the `report_tccs` command to generate a report that details the channel-to-channel skew margin for LVDS transmitters.

Example 7–45 shows the `report_tccs` command and options.

Example 7–45. report_tccs Command

```
report_tccs
[-append]
[-file <name>]
[-panel_name <name>]
[-quiet]
[-stdout]
```

Table 7–40 describes the options for the `report_tccs` command.

Table 7–40. report_tccs Command Options

Type Name	Description
`-append`	Specifies that the current report be appended to the file specified by the `-file` option.
`-file <name>`	Indicates that the current report is written to the file <*name*>.
`-panel_name <name>`	Sends the results to the panel and specifies the name of the new panel.
`-quiet`	Specifies that nothing is printed if there are no LVDS receivers in the design.
`-stdout`	Indicates the report will be sent to `stdout`.

The TCCS is the timing difference between the fastest and slowest output transitions, including t_{CO} variations and clock skew.

report_partitions

Use the `report_partitions` command to generate a timing report listing the worst-case setup checks for each partition in the design.

Example 7–46 shows the `report_partitions` command and options.

Example 7–46. report_partitions Command

```
report_partitions
[-nworst <number>]
[-panel_name <name>]
[-stdout]
```

Table 7–41 describes the options for the `report_partitions` command.

Table 7–41. report_partitions Command Options

Type Name	Description
`-nworst`	Specifies the maximum number of paths to report for each endpoint.
`-panel_name`	Sends the results to the panel and specifies the name of the new panel.
`-stdout`	Indicates the report will be sent to `stdout`.

report_path

Use the `report_path` command to generate a report that details the longest delay paths between any two arbitrary keeper nodes.

Example 7–47 shows the `report_path` command and options.

Example 7–47. report_path Command

```
report_path
[-append]
[-file <name>]
[-from <names>]
[-min_path]
[-npaths <number>]
[-nworst <number>]
[-panel_name <name>]
[-stdout]
[-summary]
[-through <names>]
[-to <names>]
```

Table 7–42 describes the options for the `report_path` command.

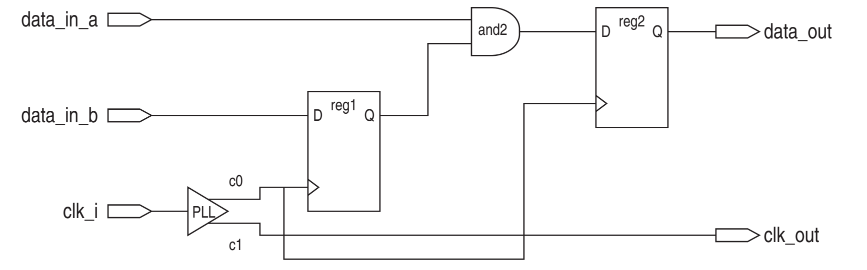
Table 7–42. report_path Command Options

Type Name	Description
`-append`	Specifies that the current report be appended to the file specified by the `-file` option.
`-file <name>`	Indicates that the current report is written to the file <*name*>.
`-from <names>`	The <*names*> is a collection or list of objects in the design. The <*names*> acts as the start point of the path.
`-min_path`	Displays the minimum delay paths.
`-npaths <number>`	Specifies the number of paths to report.
`-nworst <number>`	Specifies the maximum number of paths to report for each endpoint.
`-panel_name <name>`	Sends the results to the panel and specifies the name of the new panel.
`-stdout`	Indicates the report will be sent to `stdout`.
`-summary`	Creates a single table with a summary of each path found.
`-through <names>`	The <*names*> is a collection or list of objects in the design. Specifies false path passes through <*names*>.
`-to <names>`	The <*names*> is a collection or list of objects in the design. The <*names*> acts as the end point of the path.

The delay path reported cannot pass through a keeper node; for example, a register or port. Instead, the delay path must be from the output pin of a keeper node to the input pin of a keeper node.

Figure 7–34 shows a simple design with a register-to-register path.

Figure 7–34. Simple Register-to-Register Path



Example 7–48 shows the report generated from the following command:

```
report_path -from [get_pins {reg1|regout}] -to [get_pins \
{reg2|datain}] -npaths 1 -panel_name "Report Path" -stdout
```

Example 7–48. report_path from Keeper Output Pin to Keeper Input Pin

```
 Info: ===================================================================
Info: From Node : reg1|regout
Info: To Node : reg2|datain
Info:
Info: Path:
Info:
Info: Total (ns) Incr (ns) Type Element
Info: ========== ========= == ==== ====================
Info: 0.000 0.000 reg1|regout
Info: 0.206 0.206 RR IC and2|datae
Info: 0.360 0.154 RR CELL and2|combout
Info: 0.360 0.000 RR IC reg2|datain
Info:
Info: Total Path Delay : 0.360
Info: ===================================================================
```

Example 7–49 shows the report generated from the following command:

```
report_path -from [get_ports data_in_a] -to [get_pins {reg2|regout}] \
-npaths 1
```

Example 7–49. report_path from Keeper-to-Keeper Output Pin

```
Info: Report Path: No paths were found
0 0.000
```

No paths were reported in Example 7–49 because the destination passes through an input pin of a keeper node.

report_net_delay

Use the `report_net_delay` to generate a slack report for paths constrained with the `set_net_delay` command. The `report_net_delay` command reports the results of all `set_net_delay` commands in a single report. The report contains each `set_net_delay` command with the worst case slack result followed by the results of each edge matching the criteria set by that `set_net_delay` command. These results are ordered based on the slack value. Example 7–50 shows the `report_net_delay` command and options.

Example 7–50. report_net_delay Command

```
report_net_delay
    [-append]
    [-file <name>]
    [-nworst <number>]
    [-panel_name <name>]
    [-stdout]
```

Table 7–43 describes the options for the `report_net_delay` command.

Table 7–43. report_net_delay Command Options

Options	Description
`-append`	If output is sent to a file, this option appends the result to that file. Otherwise, the file is overwritten.
`-file <name>`	Sends the results to an ASCII or HTML file. The extension specified in the file name determines the file type—either ***.txt** or ***.html**.
`-nworst <number>`	Specifies the maximum number of paths to report for each analysis. If unspecified, there is no limit.
`-panel_name <name>`	Sends the results to the panel and specifies the name of the new panel.
`-stdout`	Send output to `stdout`, via messages. You only have to use this option if you have selected another output format, such as a file, and would also like to receive messages.

report_max_skew

Use the `report_max_skew` to generate a slack report for paths constrained with the `set_max_skew` command. The `report_max_skew` command reports the results of all `set_max_skew` commands in a single report. The report contains each `set_max_skew` command with the worst case slack result followed by the results of each edge matching the criteria set by that `set_max_skew` command. These results are ordered based on the slack value. Example 7–51 shows the `report_max_skew` command and options.

Example 7–51. report_max_skew Command

```
report_max_skew
[-detail <summary|path_only|path_and_clock|full_path>]
[-file <name>]
[-less_than_slack <slack limit>]
[-npaths <number>]
[-panel_name <name>]
[-show_routing]
[-stdout]
```

Table 7–44 describes the options for the report_max_skew command.

Table 7–44. report_max_skew Command Options

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td>[-detail <<i>summary|path_only|path_and_clock|full_path</i>>]</td><td>Specifies whether or not the clock path detail is reported:
Path Only: Clock network delay is lumped together
Summary: Lists each individual path
Path and Clock: Clock network delay is shown in detail
Full Path: More clock network details, in particular for generated clocks</td></tr>
<tr><td>[-file <<i>name</i>>]</td><td>Sends the results to an ASCII or HTML file. The extension specified in the file name determines the file type—either *.txt or *.html.</td></tr>
<tr><td>[-less_than_slack <<i>slack limit</i>>]</td><td>Limits the paths reported to the <<i>slack limit</i>> value.</td></tr>
<tr><td>[-npaths <<i>number</i>>]</td><td>Specifies the number of paths to report.</td></tr>
<tr><td>[-panel_name <<i>name</i>>]</td><td>Sends the results to the panel and specifies the name of the new panel.</td></tr>
<tr><td>[-show_routing]</td><td>Displays detailed routing in the path.</td></tr>
<tr><td>[-stdout]</td><td>Indicates the report will be sent to stdout.</td></tr>
</table>

No results are displayed if the -from/-from_clock and -to/-to_clock are applied to less than two paths.

check_timing

Use the check_timing command to generate a report on any potential problem with the design or applied constraints. Not all check_timing results are serious issues. The results should be examined to see if the results are desired. Example 7–52 shows the check_timing command and options.

Example 7–52. check_timing Command

```
check_timing
[-append]
[-file <name>]
[-include <check_list>]
[-stdout]
[-panel_name <name>]
```

Table 7–45 describes the options for the check_timing command.

Table 7–45. check_timing Command Options

Option	Description
-append	Specifies that the current report be appended to the file specified by the -file option.
-file <*name*>	Indicates that the current report is written to the file <*name*>.
-include	Indicates that a check is to be performed with the <*check_list*>. Refer to Table 7–46 for a list of checks.
-stdout	Indicates the report will be sent to stdout.
-panel_name <*name*>	Sends the results to the panel and specifies the name of the new panel.

Table 7–46 describes the possible checks.

Table 7–46. Possible Checks (Part 1 of 2)

Option	Description
no_clock	Checks that registers have at least one clock at their clock pin and ensures that ports determined to be clocks have a clock assigned to them.
multiple_clock	Checks that registers have at most one clock at their clock pin. When multiple clocks reach a register's clock pin, both clocks are used for analysis.
generated_clock	Checks that generated clocks are valid. Generated clocks must have a source that is clocked by a valid clock. They must also not depend on each other in a loop (clk1 cannot have clk2 as a source if clk2 already uses clk1 as a source).
no_input_delay	Checks that every input port that is not determined to be a clock has an input delay set on it.
no_output_delay	Checks that every output port has an output delay set on it.
partial_input_delay	Checks that input delays are complete. Makes sure that input delays have a rise-min, fall-min, rise-max, and fall-max portion set.
partial_output_delay	Checks that output delays are complete. Makes sure that output delays have a rise-min, fall-min, rise-max, and fall-max portion set.
reference_pin	Checks if reference pins specified in set_input_delay and set_output_delay using the reference_pin option are valid. A reference_pin is valid if the clock option specified in the same set_input_delay/set_output_delay command matches the clock that is in the direct fan-in of the reference_pin. Being in the direct fan-in of the reference_pin means that there must be no keepers between the clock and reference_pin.
latency_override	Ensures that the clock latency constraint applied on a port or pin overrides the more generic clock latency set on a clock. Clock latency set to a clock applies to all keepers clocked by the clock. Clock latency set to a pin or a port applies to registers in the fan-out of the port or pin.
loops	Checks that there are no strongly connected components in the design. These loops prevent a design from being properly analyzed. Indicates that loops exist but were marked so that they would not be traversed.
latches	Checks whether there are latches in the design. The Quartus II TimeQuest Timing Analyzer warns the user that the latches exist and cannot be properly analyzed.
pos_neg_clock_domain	Checks whether any register is clocked by both the rising and falling edges of the same clock. if this scenario is necessary, such as in a clock multiplexer, create two separate clocks that have similar settings and are assigned to the same node.

Table 7–46. Possible Checks (Part 2 of 2)

Option	Description
pll_cross_check	Checks the clocks that are assigned to a PLL against the PLL setting defined in the user's design files. Inconsistent setting or an unmatched number of clocks associated with the PLL are reported to the user.
no_uncertainty	Checks that each clock-to-clock transfer has a clock uncertainty assignment set between the two clocks.
virtual_clock	Checks that each virtual clock is referenced.
partial_multicycle	Checks that each setup multicycle assignment has a corresponding hold multicycle assignment, and each hold multicycle assignment has a corresponding setup multicyle assignment.
multicycle_consistency	Checks that all of the multicycle cases in which a setup multicycle does not equal one greater than the hold multicycle. Hold multicycle assignments are usually one cycle fewer than setup multicycle assignments.
partial_min_max_delay	Verifies that each minimum delay assignment has a corresponding maximum delay assignment, and that each maximum delay assignment has a corresponding minimum delay assignment.
clock_assignments_ on_output_ports	Checks that reports all of the clock assignments that have been applied to output ports.
generated_io_delay	Checks that all of the I/O delays with no reference pin, generated -clock, or no -source_atencey_included.

Example 7–53 shows how the check_timing command can be used.

Example 7–53. The check_timing Command

```
# Constrain design
create_clock -name clk -period 4.000 -waveform { 0.000 2.000 } \
[get_ports clk]
set_input_delay -clock clk2 1.5 [get_ports in*]
set_output_delay -clock clk 1.6 [get_ports out*]
set_false_path -from [get_keepers in] -through [get_nets r1] -to \
[get_keepers out]

# Check if there were any problems for combinational loops, latches, or
# misssing or incomplete input delays
check_timing -include {loops latches no_input_delay
partial_input_delay}
```

report_clock_fmax_summary

Use the report_clock_fmax_summary to report potential f_{MAX} for every clock in the design, regardless of the user-specified clock periods. f_{MAX} is only computed for paths where the source and destination registers or ports are driven by the same clock. Paths of different clocks, including generated clocks, are ignored. For paths between a clock and its inversion, f_{MAX} is computed as if the rising and falling edges are scaled along with f_{MAX}, such that the duty cycle (in terms of a percentage) is maintained.

Example 7–54 shows the `report_clock_fmax_summary` command and options.

Example 7–54. report_clock_fmax_summary Command

```
report_clock_fmax_summary
[-append]
[-file <name>]
[-panel_name <name>]
[-stdout]
```

Table 7–47 describes the options for the `report_clock_fmax_summary` command.

Table 7–47. report_clock_fmax_summary Command Options

Option	Description
`-append`	Specifies that the current report be appended to the file specified by the `-file` option.
`-file <name>`	Indicates that the current report is written to the file *<name>*.
`-stdout`	Indicates the report will be sent to `stdout`.
`-panel_name <name>`	Sends the results to the panel and specifies the name of the new panel.

The f_{MAX} Summary report contains four columns: f_{MAX}, Restricted f_{MAX}, Clock Name, and Note. The description of each column is given in Table 7–48.

Table 7–48. f_{MAX} Summary Report Column

Column Name	Description
f_{MAX}	Shows the fastest possible frequency at which the internal register-to-register can run. This is not the fastest the clock port can be driven.
Restricted f_{MAX}	Shows fastest possible frequency at which the clock port can run. This number may be lower than the f_{MAX} column for various reasons, including hold timing requirements, I/O edge rate limits for clocks (which also depends on I/O standards), minimum pulse width checks for registers, and minimum period checks for RAM and DSP registers.
Clock Name	Shows the clock name.
Note	Shows any notes related to the clock.

create_timing_summary

Reports the worst-case clock setup and clock hold slacks and endpoint total negative slack (TNS) per clock domain. Total negative slack is the sum of all slacks less than zero for each destination register or port in the clock domain.

Example 7–55 shows the `create_timing_summary` command and options.

Example 7–55. create_timing_summary Command

```
create_timing_summary
[-append]
[-file <name>]
[-hold]
[-panel_name <name>]
[-recovery]
[-removal]
[-setup]
[-stdout]
```

Table 7–49 describes the options for the `create_timing_summary` command.

Table 7–49. create_timing_summary Command Options

Option	Description
`-append`	Specifies that the current report be appended to the file specified by the `-file` option.
`-file <name>`	Indicates that the current report is written to the file *<name>*.
`-hold`	Generates a clock hold check summary report.
`-panel_name <name>`	Sends the results to the panel and specifies the name of the new panel.
`-recovery`	Generates a recovery check summary report.
`-removal`	Generates a removal check summary report.
`-setup`	Generates a clock setup check summary report.
`-stdout`	Indicates the report will be sent to `stdout`.

Timing Analysis Features

The TimeQuest Timing Analyzer supports many features that enhances and provides a through analysis of your designs. This section covers the many features available in the TimeQuest Timing Analyzer.

Multi-Corner Analysis

Multi-corner analysis allows a design to be verified under a variety of operating conditions (voltage, process, and temperature) while performing a static timing analysis on the design.

Use the `set_operating_conditions` command to change the operating conditions or speed grade of the device used for static timing analysis.

Example 7–56 shows the `set_operating_conditions` command and options.

Example 7–56. set_operating_conditions Command

```
set_operating_conditions
[-model <fast|slow>]
[-speed <speed grade>]
[-temperature <value in °C>]
[-voltage <value in mV>]
[<operating condition Tcl object>]
```

Table 7–50 describes the options for the `set_operating_conditions` command.

Table 7–50. set_operating_conditions Command Options

Option	Description
`-model <fast|slow>`	Specifies the timing model.
`-speed <speed grade>`	Specifies the device speed grade.
`-temperature <value in °C>`	Specifies the operating temperature.
`-voltage <value in mV>`	Specifies the operating voltage.
`<operating condition Tcl object>`	Specifies the operating condition Tcl object that specifies the operating conditions.

If an operating condition Tcl object *is* used, the model, speed, temperature, and voltage options are not required. If an operating condition Tcl object *is not* used, the model must be specified, and the -speed, -temperature, and -voltage options are optional, using the appropriate defaults for the device where applicable.

Table 7–51 shows a few of the available operating conditions that can be set for each device family.

Table 7–51. Device Family Operating Conditions

Device Family	Available Conditions				Operating Condition Tcl Objects
	Speed Grade	Model	Voltage (mV)	Temp (°C)	
Stratix III	4	Slow Slow Fast	1100 1100 1100	85 0 0	`4_slow_1100mv_85c` `4_slow_1100mv_0c` `MIN_fast_1100mv_0c`
Cyclone® III	7	Slow Slow Fast	1200 1200 1200	85 0 0	`7_slow_1200mv_85c` `7_slow_1200mv_0c` `MIN_fast_1200mv_0c`
Stratix II	4	Slow Fast	—	—	`4_slow` `MIN_fast`
Cyclone II	6	Slow Fast	—	—	`6_slow` `MIN_fast`

Use the `get_available_operating_conditions-all` command to obtain a list of available operating conditions for the target device.

Table 7–52 shows the operating conditions of each model for device families that support only two operating conditions, that is, fast and slow.

Table 7–52. Operating Conditions for Fast and Slow Models

Model	Speed Grade	Voltage	Temperature
Slow	Slowest speed grade in device density	V_{cc} minimum supply *(1)*	Maximum T_J *(1)*
Fast	Fastest speed grade in device density	V_{cc} maximum supply *(1)*	Minimum T_J *(1)*

Note to Table 7–52:

(1) Refer to the DC & Switching Characteristics chapter of the applicable device Handbook for V_{CC} and T_J.

A static timing analysis should be performed under all available operating conditions. This ensures that no violations will occur under various conditions during the device operation.

Example 7–57 shows how to set the operating conditions for a Stratix III design to the slow model, 1100 mV, and 85° C.

Example 7–57. Setting Operating Conditions with Individual Values

```
set_operating_conditions -model slow -temperature 85 -voltage 1100
```

Alternatively, you can set the operating conditions in Example 7–57 with the Tcl object as shown in Example 7–58.

Example 7–58. Setting Operating Conditions with a Tcl Object

```
set_operating_conditions 4_slow_1100mv_85c
```

Advanced I/O Timing and Board Trace Model Assignments

The Quartus II TimeQuest Timing Analyzer is able to use Advanced I/O Timing and Board Trace Model assignments to model I/O buffer delays in your design.

To turn the Advanced I/O feature on or off, in the **Settings** dialog box, under the **TimeQuest Timing Analyzer** option, choose **on** or **off**.

If you turn the **Advanced I/O Timing** on or off or change Board Trace Model assignments and do not recompile before you analyze timing, you must use the `-force_dat` command when you create the timing netlist. Type the following command in the Tcl console of the Quartus II TimeQuest Timing Analyzer:

```
create_timing_netlist -force_dat ↵
```

If you turn the **Advanced I/O Timing** or change Board Trace Model assignments on or off and recompile before you analyze timing, you do not have to use the `-force_dat` command when you create the timing netlist. You can create the timing netlist with the `create_timing_netlist` command, or with the **Create Timing Netlist** task in the **Tasks** pane.

For more information about the Advanced I/O Timing feature, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

Wildcard Assignments and Collections

To simplify the task of applying constraints to many nodes in a design, the Quartus II TimeQuest Timing Analyzer accepts the "*" and "?" wildcard characters. Use these wildcard characters to reduce the number of individual constraints you must specify in your design.

The "*" wildcard character matches any string. For example, given an assignment made to a node specified as `reg*`, the Quartus II TimeQuest Timing Analyzer searches for and applies the assignment to all design nodes that match the prefix `reg` with none, one, or several characters following, such as `reg1`, `reg[2]`, `regbank`, and `reg12bank`.

The "?" wildcard character matches any single character. For example, given an assignment made to a node specified as `reg?`, the Quartus II TimeQuest Timing Analyzer searches and applies the assignment to all design nodes that match the prefix `reg` and any single character following; for example, `reg1`, `rega`, and `reg4`.

Both the collection commands `get_cells` and `get_pins` have three options that allow you to refine searches that include the wildcard character. To refine your search results, select the default behavior, the `-hierarchical` option, or the `-compatibility` option.

The pipe character is used to separate one hierarchy level from the next in the Quartus II TimeQuest Timing Analyzer. For example, <*absolute full cell name*>|<*pin suffix*> represents a hierarchical pin name with the "|" separating the hierarchy from the pin name.

When you use the collection commands `get_cells` and `get_pins` without an option, the default search behavior is performed on a per-hierarchical level of the pin name; that is, the search is performed level by level. A full hierarchical name may contain multiple hierarchical levels where a "|" is used to separate the hierarchical levels, and each wildcard character represents only one hierarchical level. For example,"*" represents the first hierarchical level and "*|*" represents the first and second hierarchical levels.

When you use the collection commands `get_cells` and `get_pins` with the `-hierarchical` option, a recursive match is performed on the relative hierarchical path name of the form <*short cell name*>|<*pin name*>. The search is performed on the node name; for example, the last hierarchy of the name and not the hierarchy path. Unlike the default behavior, this option does not limit the search to each hierarchy level represented by the pipe character.

The pipe character cannot be used in the search with the `get_cells -hierarchical` option. However, the pipe character can be used with the `get_pins` collection search.

When you use the collection commands `get_cells` and `get_pins` with the `-compatibility` option, the search performed is similar to that of the Quartus II Classic Timing Analyzer. This option searches the entire hierarchical path and pipe characters are not treated as special characters.

Assuming the following cells exist in a design:

```
foo
foo|bar
```

and the following pin names:

```
foo|dataa
foo|datab
foo|bar|datac
foo|bar|datad
```

Table 7–53 shows the results of using these search strings.

Table 7–53. Sample Search Strings and Search Results (Part 1 of 2)

Search String	Search Result
`get_pins *|dataa`	`foo|dataa`
`get_pins *|datac`	<*empty*>
`get_pins *|*|datac`	`foo|bar|datac`
`get_pins foo*|*`	`foo|dataa, foo|datab`
`get_pins -hierarchical *|*|datac`	<*empty*> *(1)*
`get_pins -hierarchical foo|*`	`foo|dataa, foo|datab`
`get_pins -hierarchical *|datac`	`foo|bar|datac`
`get_pins -hierarchical foo|*|datac`	<*empty*> *(1)*

Table 7–53. Sample Search Strings and Search Results (Part 2 of 2)

Search String	Search Result
`get_pins -compatibility *|datac`	`foo|bar|datac`
`get_pins -compatibility *|*|datac`	`foo|bar|datac`

Note to Table 7–53:

(1) Due to the additional `*|*|` in the search string, the search result is <*empty*>.

Resetting a Design

Use the `reset_design` command to remove all timing constraints and exceptions from the design under analysis. The command removes all clocks, generated clocks, derived clocks, input delays, output delays, clock latency, clock uncertainty, clock groups, false paths, multicycle paths, min delays, and max delays.

This command provides a convenient way to return to the initial state of analysis without the need to delete and re-create a new timing netlist.

Cross-Probing

The cross-probing feature allows you to locate paths and elements from the TimeQuest Timing Analyzer to various tools available in the Quartus II software (and vice versa).

From the TimeQuest GUI, you can right-click any path in the **View** pane and select either **Locate Path** or **Locate**.

The source is the element in the **From Node** column and the destination is the element in the **To Node** column.

The **Locate Path** option allows you to located the data arrival path, default, of the currently selected row. To locate the data required time path select a row in the data required path panel.

The **Locate Required Path** command is available only when there is a path to show; unless the user reports the clock path as well, there is probably only a single node in the required path. In this case, the command is not available.

The **Locate** option allows you to locate the highlighted element.

The **Locate Path** and **Locate** commands can cross-probe to either the Chip Planner, Technology Map Viewer, or Resource Property Editor. Additionally, the **Locate Path** option can cross-probe to Critical Path Settings.

From the **Critical Path Settings** dialog box in the Chip Planner, you can cross-probe to the TimeQuest Timing Analyzer to report critical paths in the design.

locate

Use the `locate` command in the **Console** pane to cross-probe to the Chip Editor, Critical Path Settings, Resource Property Editor, and the Technology Map Viewer.

Example 7–59 shows the `locate` command and options.

Example 7–59. locate Command

```
locate
[-chip]
[-color <black|blue|brown|green|grey|light_grey|orange|purple|red|white>]
[-cps]
[-label <label>]
[-rpe]
[-tmv]
<items>
```

Table 7–54 describes the options for the `locate` command.

Table 7–54. locate Options

Option	Description
`-chip`	Locates the object in the Chip Planner.
`-color <black|blue|brown|green|grey|light_grey|orange|purple|red|white>`	Identifies the objects you are locating.
`-cps`	Locates the object in the Critical Path Settings dialog of the Chip Planner.
`-label <label>`	Specifies a label used to identify the objects you are locating.
`-rpe`	Locates in the Resource Property Editor.
`-tmv`	Locates the object in the Technology Map Viewer.
`<items>`	Items to locate. Any collection or object (such as paths, points, nodes, nets, keepers, registers, etc.) may be located by passing a reference to the corresponding collection or object.

Example 7–60 shows how to cross-probe ten paths from TimeQuest Timing Analyzer to the Chip Editor and locate all data ports in the Technology Map Viewer.

Example 7–60. Cross-probing from TimeQuest

```
# Locate all of the nodes in the longest ten paths
# into the Chip Editor
locate [get_path -npaths 10] -chip

# locate all ports that begin with data to the Tech Map Viewer

locate [get_ports data*] -tmv
```

The TimeQuest Timing Analyzer GUI

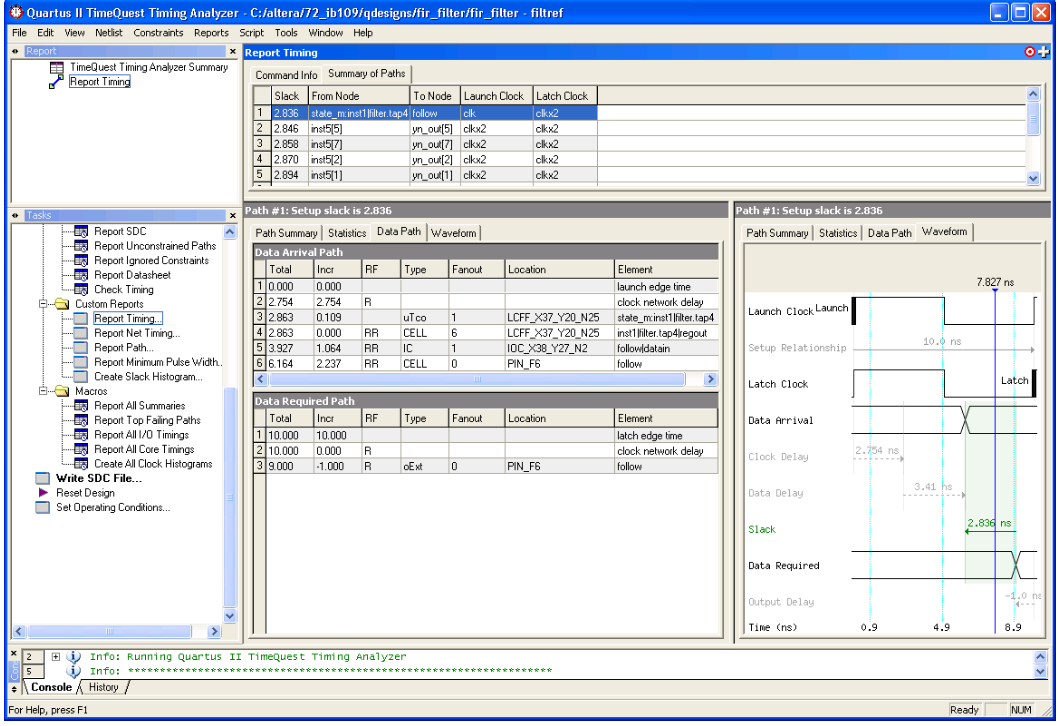
The Quartus II TimeQuest Timing Analyzer provides an intuitive and easy-to-use GUI that allows you to efficiently constrain and analyze your designs. The GUI consists of the following panes:

- "The Quartus II Software Interface and Options" described on page 7–80
- "View Pane" described on page 7–81
- "Tasks Pane" described on page 7–83

- "Console Pane" described on page 7–85
- "Report Pane" described on page 7–85
- "Constraints" described on page 7–85
- "Name Finder" described on page 7–87
- "Target Pane" described on page 7–88
- "SDC Editor" described on page 7–89

Each pane provides features that enhance productivity (Figure 7–35).

Figure 7–35. The TimeQuest GUI



The Quartus II Software Interface and Options

The Quartus II software allows you to configure various options for the Quartus II TimeQuest Timing Analyzer report generation that are generated in the Compilation Report for the design.

The TimeQuest Timing Analyzer settings, in the **Settings** dialog box, allow you to configure the options shown in Table 7–55.

Table 7–55. The Quartus II TimeQuest Timing Analyzer Settings (Part 1 of 2)

Options	Description
.sdc files to include in the project	Adds and removes **.sdc** files associated with the project.
Enable Advanced I/O Timing	Generates advanced I/O timing results from board trace models specified for each pin.
Enable multicorner timing analysis during compilation	Generates multiple reports for all available operating conditions of the target device.

Table 7–55. The Quartus II TimeQuest Timing Analyzer Settings (Part 2 of 2)

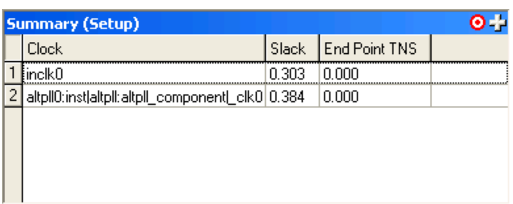
Options	Description
Report worst-case paths during compilation	Generates worst-case path reports per clock domain.
Tcl Script File for customizing report during compilation	Specifies any custom scripts to be sourced for any custom report generation.

The options shown in Table 7–55 control only the reports generated in the Compilation Report, and do not control the reports generated in the Quartus II TimeQuest Timing Analyzer.

View Pane

The **View** pane is the main viewing area for the timing analysis results. Use the **View** pane to view summary reports, custom reports, or histograms. Figure 7–36 shows the **View** pane after you select the **Summary (Setup)** report from the Report pane.

Figure 7–36. Summary (Setup) Report

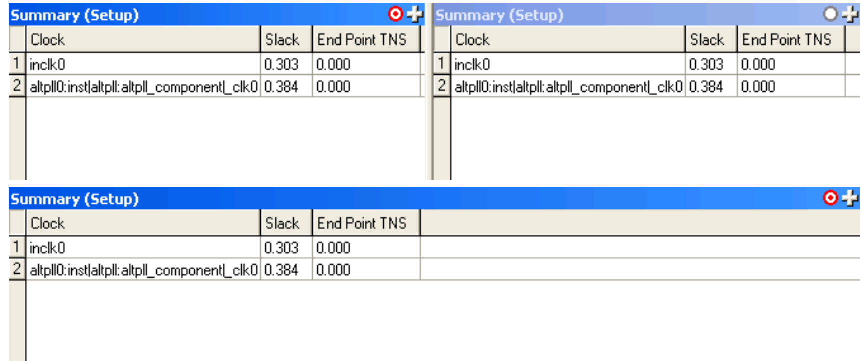


View Pane: Splitting

For analyzing the timing results properly, comparing multiple reports is extremely important. To facilitate multiple report viewing, the **View** pane supports window splitting. Window splitting divides the **View** pane into multiple windows, allowing you to view different reports side-by-side.

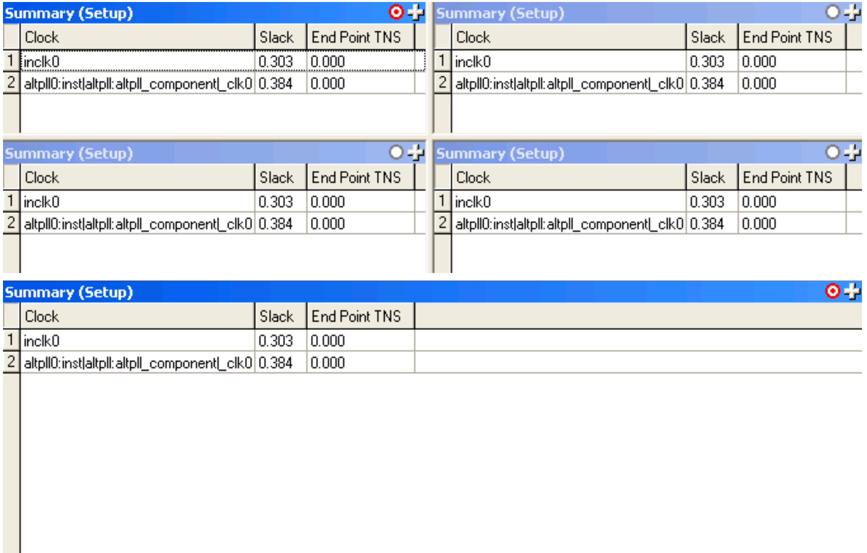
You can split the **View** pane into multiple windows using the split icon located in the upper right corner of the **View** pane. Drag the icon in different directions to generate additional window views in the **View** pane. For example, if you drag the split icon to the left, the **View** pane creates a new window to the right of the current window (Figure 7–37).

Figure 7–37. Splitting the View Pane to the Left (Before and After Split Left)



If you drag the split icon diagonally, the **View** pane creates three new windows in the **View** pane (Figure 7–38).

Figure 7–38. Splitting the View Pane Diagonally (Before and After Diagonal Split)

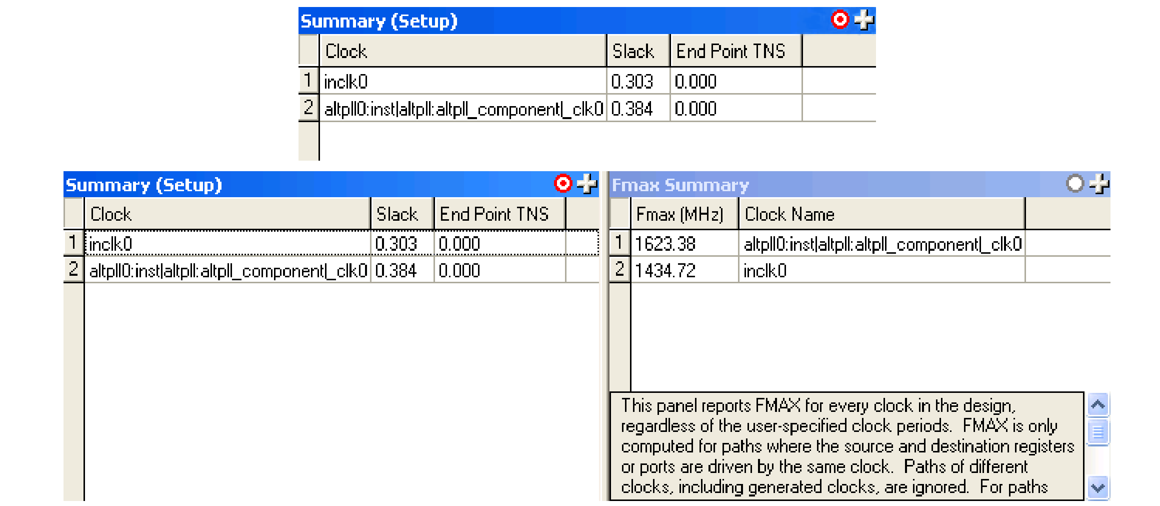


Drag the split icon downward to create a new window directly below the current window.

View Pane: Removing Split Windows

You can remove windows that you create in the View pane using the split icon by dragging the border of the window over the window you wish to remove (Figure 7–39).

Figure 7–39. Removing a Split Window (Before and After Split is Removed)



Tasks Pane

Use the **Tasks** pane to access common commands such as netlist setup and report generation.

The following common commands are located in the **Tasks** pane: Open Project, Set Operating Conditions, and Reset Design. The other commands, including timing netlist setup and report generation, are contained in the following folders:

- Netlist Setup
- Reports

Each command in the **Tasks** pane has an equivalent Tcl command that is displayed in the **Console** pane when the command runs.

Opening a Project and Writing a Synopsys Design Constraints File

To open a project in the Quartus II TimeQuest Timing Analyzer, double-click the **Open Project** task. If you launch the Quartus II TimeQuest Timing Analyzer from the Quartus II software GUI, the project opens automatically.

You can add or remove constraints from the timing netlist after the Quartus II TimeQuest Timing Analyzer reads the initial **.sdc** file. After the file is read, the initial **.sdc** file becomes outdated compared to the constraints in the Quartus II TimeQuest Timing Analyzer. Use the **Write SDC File** command to generate an **.sdc** file that is up-to-date and reflects the current state of constraints in the Quartus II TimeQuest Timing Analyzer.

Netlist Setup Folder

The Netlist Setup folder contains tasks that are used to set up the timing netlist for timing analysis. The three tasks located in this folder are Create Timing Netlist, Read SDC File, and Update Timing Netlist.

Use the Create Timing Netlist task to create a netlist that the Quartus II TimeQuest Timing Analyzer uses to perform static timing analysis. This netlist is used only for timing analysis by the Quartus II TimeQuest Timing Analyzer.

You must always create a timing netlist before you perform an analysis with the Quartus II TimeQuest Timing Analyzer.

Use the Read SDC File command to apply constraints to the timing netlist. By default, the Read SDC File command reads the <*current revision*>**.sdc** file.

Use the `read_sdc` command to read an **.sdc** file that is not associated with the current revision of the design.

Use the Update Timing Netlist command to update the timing netlist after you enter constraints or read an **.sdc** file. You should use this command if any constraints are added or removed from the design.

Reports Folder

The Reports folder contains commands to generate timing summary reports of the static timing analysis results. The twelve commands located in this folder are summarized in Table 7–56.

Table 7–56. Reports Folder Commands

Report Task	Description
Report Fmax Summary	Generates a f_{MAX} summary report for all clocks in the design.
Report Setup Summary	Generates a clock setup summary report for all clocks in the design.
Report Hold Summary	Generates a clock hold summary report for all clocks in the design.
Report Recovery Summary	Generates a recovery summary report for all clocks in the design.
Report Removal Summary	Generates a removal summary report for all clocks in the design.
Report Clocks	Generates a summary report of all created clocks in the design.
Report Clock Transfers	Generates a summary report of all clock transfers detected in the design.
Report Minimum Pulse Width	Generates a summary report of all minimum pulse widths in the design.
Report SDC	Generates a summary report of the constraints read from the **.sdc** file.
Report Unconstrained Paths	Generates a summary report of all unconstrained paths in the design.
Report Ignored Constraints	Generates a summary report of all ignored SDC constraints for the design.
Report Datasheet	Generates a datasheet report for the design.

Macros Folder

The Macros folder contains commands that perform custom tasks available in the Quartus II TimeQuest Timing Analyzer utility package. These commands are: Report All Summaries, Report Top Failing Paths, and Create All Clock Histograms.

Table 7–57 describes the commands available in the Macros folder.

Table 7–57. Macros Folder Commands

Macro Task	Description
Report All Summaries	This command runs the Report Setup Summary, Report Hold Summary, Report Recovery Summary, Report Removal Summary, and Minimum Pulse Width commands to generate all summary reports.
Report Top Failing Paths	This command generates a report containing a list of top failing paths.
Create All Clock Histograms	This command runs the Create Slack Histogram command to generate a clock histogram for all clocks in the design.
Report All I/O Timings	This command generates a report of all timing paths that start or end at a device port.
Report All Core Timings	This command generates a report of all timing paths that start and end at the device register.

Console Pane

The **Console** pane is both a message center for the Quartus II TimeQuest Timing Analyzer and an interactive Tcl console. The **Console** pane has two tabs: the **Console** tab and the **History** tab. The **Console** tab shows all messages, such as info and warning messages. Also, the Console tab allows you to enter and run Synopsys design constraints and Tcl commands. The Console tab shows the Tcl equivalent of all commands that you run in the **Tasks** pane. The History tab records all the Synopsys design constraints and Tcl commands that are run.

To run the commands located in the History tab after the timing netlist has been updated, right-click the command and click **Rerun**.

You can copy Tcl commands from the Console and History tabs to easily generate Tcl scripts to perform timing analysis.

Report Pane

Use the **Report** pane to access all reports generated from the **Tasks** pane, and by any custom report commands. When you select a report in the **Report** pane, the report is shown in the active window in the **View** pane.

If a report is out-of-date with respect to the current constraints, a "?" icon is shown next to the report.

Constraints

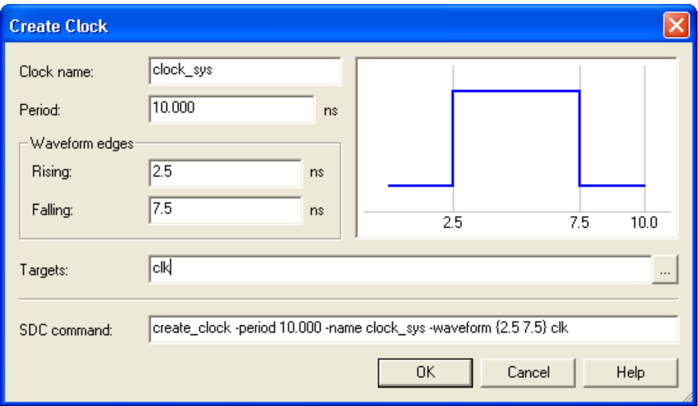
Use the Constraints menu to access commonly used constraints, exceptions, and commands. You can access this menu from the toolbar, click **Edit** and then click **Constraint menu**.

The following commands are available on the Constraints menu:

- **Create Clock**
- **Create Generated Clock**
- **Set Clock Latency**
- **Set Clock Uncertainty**
- **Set Clock Groups**
- **Remove Clock**

For example, use the **Create Clock** dialog box to create clocks in your design. Figure 7–40 shows the **Create Clock** dialog box.

Figure 7–40. Create Clock Dialog Box



The following commands specify timing exceptions and are available on the Constraints menu:

- **Set False Path**
- **Set Multicycle Path**
- **Set Maximum Delay**
- **Set Minimum Delay**

All the dialog boxes used to specify timing constraints or exceptions from commands have an SDC command field. This field contains the SDC command that is run when you click OK.

All commands and constraints created in the Quartus II TimeQuest Timing Analyzer user interface are echoed in the **Console** pane.

The constraints specified with Constraints menu commands are not saved to the current **.sdc** file automatically. You must run the **Write SDC File** command to save your constraints.

The following commands are available on the Constraints menu in the Quartus II TimeQuest Timing Analyzer:

- **Generate SDC File from QSF**
- **Read SDC File**
- **Write SDC File**

The **Generate SDC File from QSF** command runs a Tcl script that converts the Quartus II Classic Timing Analyzer constraints in a QSF file to an **.sdc** file for the Quartus II TimeQuest Timing Analyzer. The file *<current revision>***.sdc** is created by this command.

For information about the **Generate SDC File from QSF** command, refer to the *Switching to the Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

The Generate SDC File from QSF command attempts to convert all timing constraints and exceptions in the QSF file to their equivalent **.sdc** file constraints. However, not all QSF file constraints are convertible to **.sdc** file constraints. Review the **.sdc** file after it is created to ensure that all constraints have been successfully converted.

The **Read SDC File** command reads the <*current revision*>**.sdc** file.

When you select the **Write SDC File** command, an up-to-date **.sdc** file that reflects the current state of constraints in the Quartus II TimeQuest Timing Analyzer is generated.

Name Finder

Use the **Name Finder** dialog box to select the target for any constraints or exceptions in the Quartus II TimeQuest Timing Analyzer GUI. The **Name Finder** dialog box allows you to specify collections, filters, and filter options. The Collections field in the **Name Finder** dialog box allows you to specify the type of name to select. To select the type, in the **Collection** list, select the desired collection API from the following list:

- `get_cells`
- `get_clocks`
- `get_keepers`
- `get_nets`
- `get_nodes`
- `get_pins`
- `get_ports`
- `get_registers`

For more information about the various collection APIs, refer to “Collections” on page 7–21.

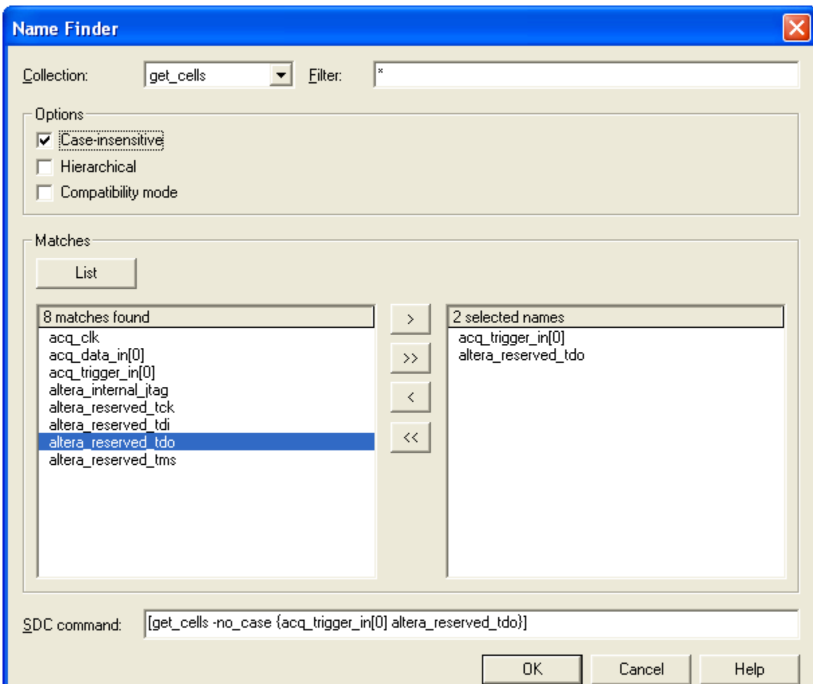
The Filter field allows you to filter names based on your own criteria, including wildcard characters. You can further refine your results using the following filter options:

- Case-insensitive
- Hierarchical
- Compatibility mode

For more information about the filter options, refer to “Wildcard Assignments and Collections” on page 7–76.

The Name Finder dialog box also provides an SDC command field that displays the currently selected name search command. You can copy the value from this field and use it for other constraint target fields. The **Name Finder** dialog box is shown in Figure 7–41.

Figure 7–41. Name Finder Dialog Box



Target Pane

When using the TimeQuest GUI, you can split the **View** pane into multiple windows. The splitting feature allows you to display multiple reports in the **View** pane. After splitting the **View** pane, the last active window is updated with any new reports. You can change this behavior by changing the state of each split window. To change the window state, click the target circle in the upper right corner (Figure 7–42). Table 7–58 describes the state of each window.

Figure 7–42. Target Pane

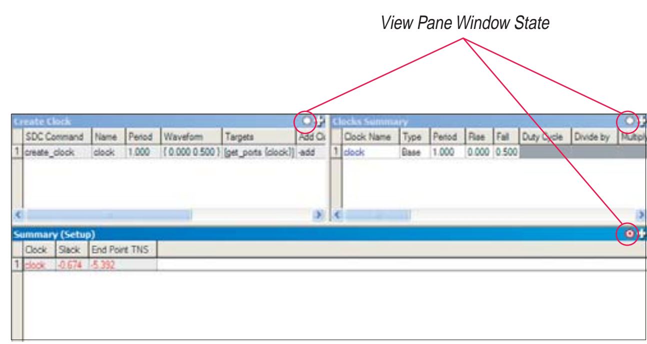


Table 7–58. View Pane Window State

State	Description
Partially Filled Red Circle	Indicates that the active window displays any new reports.
Fully Filled Red Circle	Indicates that the window, independent of it being the active window, displays any new reports.
Empty Circle	Indicates that the window does not display any new reports.

Clicking on the circle in the upper right corner of an active window changes the state of the window.

SDC Editor

The TimeQuest Timing Analyzer GUI also provides an SDC editor. The SDC editor provides an easy and convenient way to write, edit, and view **.sdc** files. The SDC editor is context sensitive. After an SDC constraint or exception has been entered, a tooltip appears that shows the options and format for the constraint or exception.

The SDC editor also provides helpful tools, including SDC templates and SDC templates for common design structures. To find these templates, when the SDC editor is active, look on the **Edit** menu.

On the menu bar, the Constraints menu opens the **Constraints** dialog box. After you have finished entering all required parameters, the **.sdc** file is inserted at the current cursor position.

Conclusion

The Quartus II TimeQuest Timing Analyzer addresses the requirements of complex designs, resulting in increased productivity and efficiency through its intuitive user interface, support of industry-standard constraints format, and scripting capabilities. The Quartus II TimeQuest Timing Analyzer is a next-generation timing analysis tool that supports the industry-standard SDC format and allows designers to create, manage, and analyze complex timing constraints and to perform advanced timing verification.

Document Revision History

Table 7–59 shows the revision history for this chapter.

Table 7–59. Document Revision History (Part 1 of 2)

Date and Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Updated Table 7–1 ■ Updated "Metastability" on page 7–15 ■ Updated "Delay and Skew Specifications" on page 7–42 ■ Added "set_max_skew" on page 7–43 ■ Added "report_exceptions" on page 7–55 ■ Updated "report_metastability" on page 7–57 ■ Added "report_partitions" on page 7–66 ■ Added "report_max_skew" on page 7–69 ■ Updated "Multi-Corner Analysis" on page 7–74 ■ Added Table 7–52 ■ Removed report_path section ■ Minor editorial updates	Updated for the Quartus II software version 9.0 release.

Table 7–59. Document Revision History (Part 2 of 2)

Date and Version	Changes Made	Summary of Changes

November 2008 v8.1.0	Updated for the Quartus II software version 8.1, including:
	■ Added the following sections:
	  ■ "set_net_delay" on page 7–42
	  ■ "Annotated Delay" on page 7–49
	  ■ "report_net_delay" on page 7–66
	■ Updated the descriptions of the `-append` and `-file` <*name*> options in tables throughout the chapter
	■ Updated entire chapter using 8½" × 11" chapter template
	■ Minor editorial updates
		Medium update for the Quartus II software version 8.1 release.

May 2008 v8.0.0	Updated for the Quartus II software version 8.0, including: ■ Changed the heading "Specify Design Timing Requirements" to "The Quartus II TimeQuest Timing Analyzer Flow Guidelines" on page 7–26 ■ In "SDC Constraint Files" on page 7–29, added information about order-sensitivity ■ Added a new section on "Metastability" on page 7–19 ■ Added a new section on "Common Clock Path Pessimism" on page 7–22 ■ Removed information about Asynchronous clocks from "Clock Groups" on page 7–43 ■ Updated information in Example 7–28 ■ Added three entries to Table 7–22 ■ Added information to Table 7–24 ■ Added information about the RSKM to "report_rskm" on page 7–80, including a formulaic equation (Equation 12) ■ Added the section "Clock Groups" on page 7–43 ■ Added Table 7–44 to "report_clock_fmax_summary" on page 7–86 ■ Added qualifier to introduction of Table 7–46 ■ Added Speed Grade information to Table 7–46 ■ Removed [-dtw] and added [-add] to information about the derive_clock_uncertainty command ("Derive Clock Uncertainty" on page 7–47) ■ Added the section "report_metastability" on page 7–68 ■ Added a new information about RSKM to "report_rskm" on page 7–80 ■ Added the section "Cross-Probing" on page 7–93 ■ Minor editorial updates ■ Added hyperlinks to referenced documents throughout chapter	Significant update for the Quartus II software version 8.0 release.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

8. Best Practices for the Quartus II TimeQuest Timing Analyzer

QII53024-9.0.0

Introduction

Timing constraints and exceptions are vital to all designs that target FPGAs. Timing constraints and exceptions allow designers to specify requirements and verify timing of their systems or FPGAs. This chapter provides the steps necessary to fully constrain an FPGA design with the Quartus® II TimeQuest Timing Analyzer.

This chapter assumes that you are familiar with the Quartus II TimeQuest Timing Analyzer.

This chapter is divided into three major sections. The ordering of the sections also shows the recommended flow to apply timing constraints and exceptions in the Quartus II TimeQuest Timing Analyzer.

This chapter contains the following sections:

1. "Clock Requirements"
2. "I/O Requirements" on page 8–4
3. "Exceptions" on page 8–5

For more information about constraints and exceptions supported by the Quartus II TimeQuest Timing Analyzer, refer to the *Quartus II TimeQuest Timing Analyzer* chapter of volume 3 in the *Quartus II Handbook* or the *SDC and TimeQuest API Reference Manual*.

Clock Requirements

Clocks play a major role in timing constraints. The Quartus II TimeQuest Timing Analyzer supports three different types of clocks:

- Base clocks
- Derived clocks
- Virtual clocks

Clocks are used to specify register-to-register requirements for synchronous transfers and guide the Fitter optimization algorithms to achieve the best possible placement and routes for the design.

Clocks should be the first constraints specified in any design's SDC files. This is important because the Quartus II TimeQuest Timing Analyzer reads SDC constraints and exceptions from the top of the file to the bottom of the file. Also, many constraints reference clocks and, therefore, the clocks must be defined first.

Base Clocks

Base clocks are the primary input clocks generated into the FPGA. These clocks are usually generated from off-chip oscillators or forwarded from an external device. Base clocks are not clocks derived within the FPGA, such as PLLs. Base clocks should be defined first, because derived clocks and other constraints can reference them.

Use the SDC command `create_clock` to constrain all primary input clocks. The target for `create_clock` should use the collection `get_ports`. For example, specifying a 100-MHz requirement on an input clock port `clk_sys` is shown in Example 8–1.

Example 8–1. create_clock Command

```
create_clock -period 10 [get_ports clk_sys]
```

With the `-add` option, you can apply multiple clocks on the same clock node. For example, if two oscillators can drive the same clock port on the FPGA, the following SDC commands can be used:

```
create_clock -period 10 [get_ports clk_sys] ↵
create_clock -period 5 [get_ports clk_sys] -add ↵
```

Derived Clocks

Derived clocks are clocks generated internally in the FPGA. These clocks modify or synthesize a source clock signal. For example, derived clocks can be PLLs or register clock dividers. Derived clocks should be constrained after all base clocks have been constrained. This ensures that all properties of the base clock are properly accounted for in the derived clock.

Use the SDC command `create_generated_clock` to constrain all generated clocks in the design. The source of the `create_generated_clock` should be a node in the design and not a previously constrained clock.

TimeQuest supports the command `derive_pll_clocks` to automatically constrain all PLL outputs used in the FPGA. This removes the requirement to manually constrain each PLL output clock.

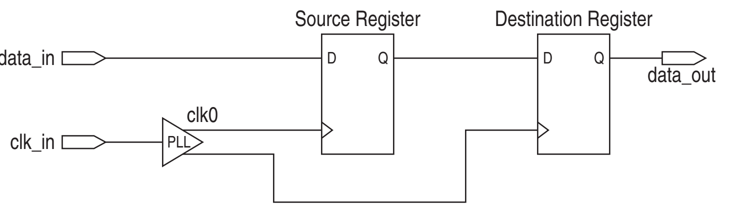
Virtual Clocks

A virtual clock is a clock that does not have a real source in the design or that does not interact directly with the design. Virtual clocks are created with the `create_clock` command, but no targets are specified. For example, to create a 10 ns virtual clock us the following command:

```
create_clock -period 10 -name my_virt_clk ↵
```

Figure 8–1 and Example 8–2 show when a virtual clock should be used. If an FPGA interfaces with an external device and both the FPGA and external device have different clock sources, the clock source for the external device must be modeled with a virtual clock.

Figure 8–1. Inter-Clock Transfer



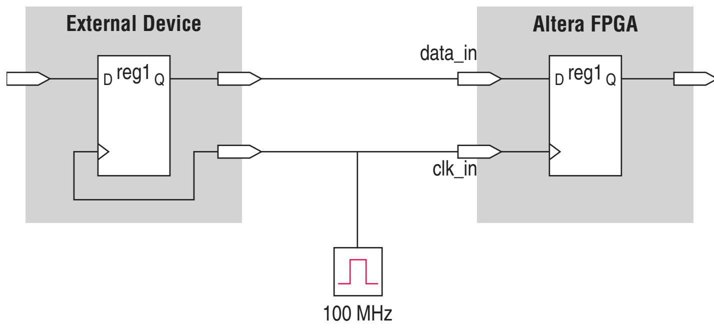
Example 8–2. Virtual Clock Example 1

```
#create base clock for the design
create_clock -period 5 [get_ports system_clk]
#create the virtual clock for the external register
create_clock -period 10 -name virt_clk -waveform { 0 5 }
#set the output delay referencing the virtual clock
set_output_delay -clock virt_clk -max 1.5 [get_ports dataout]
```

Altera recommends that you use virtual clocks when modeling external delays using the `set_input_delay` and `set_output_delay` constraints. This is important when using the command `derive_clock_uncertainty` for the design. The virtual clock prevents the `derive_clock_uncertainty` command from applying clock uncertainties for either intra- or inter-clock transfers on an I/O interface clock transfer.

For each clock in the design that feeds an input or output port, an equivalent virtual clock should be created. Figure 8–2 and Example 8–3 show an example of this.

Figure 8–2. I/O Interface Specifications



Example 8–3. SDC Commands to Constrain the I/O Interface

```
# Create the base clock for the clock port
create_clock -period 10 -name clk_in [get_ports clk_in]
# Create a virtual clock with the same properties of the base clock
# driving the source register
create_clock -period 10 -name virt_clk_in
# Create the input delay referencing the virtual clock and not the base
# clock
# DO NOT use set_input_delay -clock clk_in <delay_value>
# [get_ports data_in]
set_input_delay -clock virt_clk_in <delay value> [get_ports data_in]
```

I/O Requirements

To fully analyze a design, all timing requirements must be specified. This includes specifying internal timing requirements as well as external timing requirements. With external timing requirements specified, the I/O interface or periphery of the FPGA can be verified against any system specification. The Quartus II TimeQuest Timing Analyzer supports two types of external delay modeling: input and output.

I/O requirements should be specified after all clocks in the design have been constrained. Also, when specifying I/O requirements, a virtual clock should be referenced in the constraints.

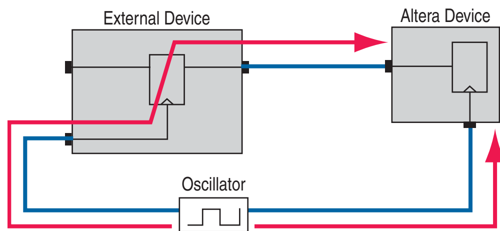
Either the input or output requirements can be specified after the clock constraints.

Input Requirements

The input requirements allow all external delays feeding into the FPGA to be specified. The requirements need to be specified for all input ports in the design.

Use the SDC command `set_input_delay` to specify external input delay requirements. The `set_input_delay` should reference a virtual clock for the `-clock` option. The virtual clock defines the launching clock for the input port. The latching clock inside the chip that captures the input data is automatically determined because all clocks in the chip have been defined. Figure 8–3 shows an example of an input delay referencing a virtual clock.

Figure 8–3. Set Input Delay

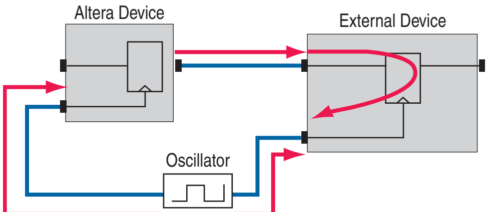


Output Requirements

The output requirements allow all external delays from the FPGA to be specified. The requirements must be specified for all output ports in the design.

Use the SDC command `set_output_delay` to specify external output delay requirements. The `set_output_delay` should reference a virtual clock for the `-clock` option. The virtual clock defines the latching clock for the output port. The launching clock inside the chip that launches the output data is automatically determined because all clocks in the chip have been defined. Figure 8–4 shows an example of an output delay referencing a virtual clock.

Figure 8–4. Output Delay



Exceptions

Timing exceptions in the Quartus II TimeQuest Timing Analyzer provide a way to modify the default timing analysis behavior to match the analysis required by your design. The Quartus II TimeQuest Timing Analyzer supports these three major categories of exceptions:

- False paths
- Minimum and maximum delays
- Multicycles

Because timing exceptions modify the default analysis, they should be specified after the clocks and input and output delay constraints.

False Paths

By specifying a false path in your design, you are removing the specified path from analysis. This path can be point-to-point or clock-to-clock. An example is a static configuration register that is written once during power up initialization, but will never change state again. These signals often cross clock domains, but because some data may transfer across those clock domains, you may not want to cut the clock transfers, but instead, selectively cut the path from the static configuration register to all endpoints.

Example 8–4 shows how to cut the path from all registers beginning with **A** to all registers beginning with **B**.

Example 8–4. False Path

```
set_false_path -from [get_pins A*] -to [get_pins B*]
```

The Quartus II TimeQuest Timing Analyzer assumes all clocks are related until you specify otherwise. Setting clock groups is an efficient way of cutting false clock-to-clock timing relationships in the design. It requires fewer line entries to cut the paths between clocks, compared to writing multiple `set_false_path` exceptions between every clock transfer to be cut. Use the `set_clock_groups` command to collect groups of signals related to each other, and use `-asynchronous` to specify that each group of clocks is asynchronous with each other. In the case of multiple clocks applied to the same port for multi-mode operation, use `set_clock_groups` with `-exclusive` to declare these clocks are placed into separate groups and mutually exclusive to each other. In other words, the clocks cannot physically exist in the design at the same time.

Minimum and Maximum Delays

Asynchronous signals that do not have a specific clock relationship in the design, but need a bounded maximum and minimum path delay, can be accomplished with the use of the `set_max_delay` and `set_min_delay` constraints. Typically, this timing exception is used for paths that go from port to port through the FPGA without a register stage in the path. When using this timing exception to constrain the path delay, specify both the maximum and minimum delay of the path. Do not constrain only the maximum the minimum value. The `set_max_delay` and `set_min_delay` commands modify the setup and hold relationship equal to the constraint's value.

Alternatively, you can use the `set_net_delay` constraint to specify the maximum, minimum, or skew for any edge in your design. This constraint is used in situations where no clock relationships are defined or required.

For more information about the `set_net_delay` constraint, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Multicycles

Multicycle paths are often difficult to identify in a design. This requires intimate knowledge of the design functionality to know if a signal is updated or sampled on the default clock edge relationships derived by the TimeQuest Timing Analyzer. Thorough coverage of multicycle paths in the design can greatly increase performance of the Fitter and provide better quality of results in compiles because it relaxes some invalid setup and hold edge relationships.

An example of a potential multicycle path would be long combinational paths where the latching register does not require data stability on every clock edge, but only on every second clock edge. This is dependent on the endpoint register's usage of that signal. In this case, a `set_multicycle_path -setup` 2 states that data is stable at the endpoint every two clock cycles of the endpoint latch clock.

When specifying a multicycle path, both the setup and hold multicycle relationships should be defined. For the preceding example, though it can take two clock cycles to set data at the endpoint, the minimum hold time relationship must be defined with a multicycle as well. Typically, the `set_multicycle_path -hold` value is (N – 1), where N is equal to the `set_multicycle_path -setup` value, for a register-to-register path within the same clock domain. However, if data is crossing across different clock domains, the phase and period of the launch and latch clock may change the proper `-setup` and `-hold` values to something different than `-setup` N and `-hold` (N – 1). Use these with caution and examine the timing paths carefully in the TimeQuest Timing Analyzer before and after applying the multicycle to determine if the launch and latch clock edges are in the proper relationship.

For more information about multicycles in the TimeQuest Timing Analyzer, refer to *AN 481: Applying Multicycle Exceptions in the TimeQuest Timing Analyzer*.

Conclusion

Specifying all timing constraints and exceptions for your design is one of the most important aspects of design implementation in the Quartus II software. Constraints and exceptions allow the Quartus II Fitter to focus on the critical paths in the design and reduce the amount of time spent on non-critical parts of the design. Also, constraints and exceptions provide an easy method to verify the design's timing requirements. Following the guidelines and flow in this chapter provides you with an easy path to a successful design implementation in the Quartus II software.

9. Switching to the Quartus II TimeQuest Timing Analyzer

QII53019-9.0.0

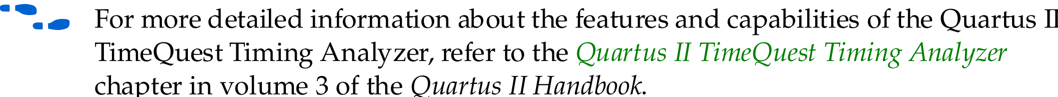
Introduction

The Quartus II TimeQuest Timing Analyzer provides more powerful timing analysis features than the Quartus II Classic Timing Analyzer. This chapter describes the benefits of switching to the Quartus II TimeQuest Timing Analyzer, the differences between the Quartus II TimeQuest and Quartus II Classic Timing Analyzers, and the process you should follow to switch a design from using the Quartus II Classic Timing Analyzer to the Quartus II TimeQuest Timing Analyzer.

Benefits of Switching to the Quartus II TimeQuest Timing Analyzer

Increasing design complexity requires a timing analysis tool with greater capabilities and flexibility. The Quartus II TimeQuest Timing Analyzer offers the following benefits:

- Industry-standard Synopsys Design Constraint (SDC) support increases productivity.
- Simple, flexible reporting uses industry-standard terminology and makes timing sign-off faster.



For more detailed information about the features and capabilities of the Quartus II TimeQuest Timing Analyzer, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

These features ease constraint and analysis of modern, complex designs. SDC constraints support complex clocking schemes, high-speed interfaces, and more logic. An example includes designs that have multiplexed clocks, regardless of whether they are switched on or off chip. Designs with source-synchronous interfaces, such as DDR memory interfaces, are much simpler to constrain and analyze with the Quartus II TimeQuest Timing Analyzer.

There are three main differences between the Quartus II Classic and Quartus II TimeQuest Timing Analyzers. Unlike the Quartus II Classic Timing Analyzer, the Quartus II TimeQuest Timing Analyzer has the following three benefits:

- All clocks are related by default. (Refer to "Related and Unrelated Clocks" on page 9–11.)
- The default hold multicycle value is zero. (Refer to "Hold Multicycle" on page 9–20.)
- You must constrain all ports and ripple clocks. (Refer to "Automatic Clock Detection" on page 9–16.)

Chapter Contents

"Switching to the Quartus II TimeQuest Timing Analyzer" describes the four-step process you should follow to switch a design to the Quartus II TimeQuest Timing Analyzer.

"Differences Between Quartus II TimeQuest and Quartus II Classic Timing Analyzers" on page 9–4 covers terminology, constraints, clocks, hold multicycle, and other differences.

"Timing Assignment Conversion" on page 9–26 is a comprehensive guide to converting Quartus II Classic QSF timing assignments to Quartus II TimeQuest SDC constraints.

"Conversion Utility" on page 9–44 describes a utility that helps you convert Classic QSF timing assignments to the Quartus II TimeQuest SDC constraints.

"Notes" on page 9–54 includes notes about support for specific features in the current version of the Quartus II TimeQuest Timing Analyzer.

Switching to the Quartus II TimeQuest Timing Analyzer

You should use the following process to switch a design from the Quartus II Classic Timing Analyzer to the Quartus II TimeQuest Timing Analyzer. The process is composed of the following steps, which are described in detail in the next sections:

1. Compile your design and perform timing analysis with the Quartus II Classic Timing Analyzer (page 9–2).
2. Create a Synopsys Design Constraints (**.sdc**) file that contains timing constraints (page 9–2).
3. Perform timing analysis with the Quartus II TimeQuest Timing Analyzer and examine the reports (page 9–3).
4. Set the default timing analyzer to TimeQuest (page 9–4).

Compile Your Design

To begin, compile your design with the Quartus® II software. You should run the Quartus II Classic Timing Analyzer during compilation because it is easier to convert your assignments to SDC constraints when you create an **.sdc** file. To run the Quartus II Classic Timing Analyzer in the Quartus II GUI, on the Processing menu, click **Start**, then click **Start Timing Analyzer**. To run the Quartus II Classic Timing Analyzer if you are a command-line user, type `quartus_tan` <*project*> ↵ at a system command prompt.

Create an .sdc File

The Quartus II TimeQuest Timing Analyzer supports SDC format constraints. If you are familiar with SDC terminology, you can create an **.sdc** file with any text editor and skip to "Perform Timing Analysis with the Quartus II TimeQuest Timing Analyzer" on page 9–3. Name the **.sdc** file <*revision*>**.sdc** (<*revision*> is the current revision of your project) and save it in your project directory.

Refer to the *SDC and TimeQuest Tcl API Reference Manual* for a TimeQuest SDC command reference.

Alternately, you can use a Quartus II TimeQuest conversion utility to help you convert the timing assignments in an existing Quartus II Settings File (**.qsf**) to corresponding SDC constraints.

Conversion Utility

To run the Quartus II TimeQuest conversion utility, click **Generate SDC file from QSF** on the Constraints menu. You can also run the conversion utility by typing either of the following commands at a system command prompt:

- `quartus_tan --qsf2sdc` <*project name*> ↵

or

- `quartus_sta --qsf2sdc` <*project name*> ↵

The **.sdc** file created by the conversion utility is named <*revision*>**.sdc**.

For information about how to run the Quartus II TimeQuest Timing Analyzer, refer to "Run the Quartus II TimeQuest Timing Analyzer".

If you use the conversion utility, you must review the **.sdc** file to ensure it is correct and complete, and make changes if necessary. Refer to "Constraint File Priority" on page 9–8 for the recommended way to make changes.

The conversion utility cannot convert some types of Quartus II Classic Timing Analyzer assignments for the following reasons:

- No corresponding SDC constraint exists
- Multiple SDC constraints are valid, so correct conversion requires knowledge of the intended function of your design

You must manually convert any such assignments based on the guidelines in "Timing Assignment Conversion" on page 9–26.

Perform Timing Analysis with the Quartus II TimeQuest Timing Analyzer

When your **.sdc** file is complete, use the reporting capabilities in the Quartus II TimeQuest Timing Analyzer. If you use the Quartus II TimeQuest GUI, double-click any of the reports listed in the Tasks pane. You can also type commands in the Quartus II TimeQuest Tcl shell to generate reports.

You should also review "Notes" on page 9–54 to ensure the Quartus II TimeQuest Timing Analyzer supports all stages of your design flow.

For complete information about how to use the Quartus II TimeQuest Timing Analyzer, and descriptions of commands and reports, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*, and the *SDC and TimeQuest Tcl API Reference Manual*.

Run the Quartus II TimeQuest Timing Analyzer

If you are using the Quartus II software, to open the Quartus II TimeQuest GUI, on the Tools menu, click **TimeQuest Timing Analyzer**. The Quartus II TimeQuest GUI automatically opens the project you have open in the Quartus II GUI.

If you use the system command prompt to open the Quartus II TimeQuest Timing Analyzer, type `quartus_staw` ↵ to open the Quartus II TimeQuest GUI, or type `quartus_sta -s` ↵ to start the Quartus II TimeQuest Timing Analyzer in Tcl shell mode. Use the **project_open** command to open your project, or, on the File menu, click **Open Project**.

Set the Default Timing Analyzer

To use the Quartus II TimeQuest Timing Analyzer as the default timing analyzer for your project, turn on **Use TimeQuest Timing Analyzer during compilation**. In the Quartus II GUI, on the Assignments menu, click **Settings**, then select the **Timing Analysis Settings** category, and turn on **Use TimeQuest Timing Analyzer during compilation**. You can make the same setting in your project's **.qsf** file with the following Tcl command:

```
set_global_assignment -name USE_TIMEQUEST_TIMING_ANALYZER ON
```

This setting directs the Quartus II software to use the Quartus II TimeQuest Timing Analyzer instead of the Quartus II Classic Timing Analyzer.

The setting to make the Quartus II TimeQuest Timing Analyzer the default timing analyzer is specific to each project, so you can decide on a per-project basis whether to use the Quartus II TimeQuest Timing Analyzer or the Quartus II Classic Timing Analyzer.

If you want to use the Quartus II Classic Timing Analyzer instead of the Quartus II TimeQuest Timing Analyzer, ensure **Use Classic Timing Analyzer during compilation** is selected. You can delete the *<revision>***.sdc** file, because the Quartus II Classic Timing Analyzer does not use it.

In the Quartus II software, a timing analyzer performs two functions:

- Processing timing constraints and exceptions that affect how your design is placed and routed
- Reporting after place and route is complete so you know whether the design meets timing requirements

Although you can use one timing analyzer to process timing constraints during place and route and the other for reporting, you should use the same timing analyzer for both. The Quartus II Classic Timing Analyzer uses assignments in the **.qsf** file, and the Quartus II TimeQuest Timing Analyzer uses constraints in the **.sdc** file. Any differences between the timing assignments in the two files may cause inconsistent results.

Differences Between Quartus II TimeQuest and Quartus II Classic Timing Analyzers

The Quartus II TimeQuest Timing Analyzer is different from the Quartus II Classic Timing Analyzer in the following ways:

- "Terminology" on page 9–5
- "Constraints" on page 9–6
- "Clocks" on page 9–11
- "Hold Multicycle" on page 9–20
- "Fitter Behavior" on page 9–22
- "Reporting" on page 9–22
- "Scripting API" on page 9–25

Terminology

This section introduces the industry-standard SDC terminology that the Quartus II TimeQuest Timing Analyzer uses.

For more detailed information about this terminology, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Netlist

The Quartus II TimeQuest Timing Analyzer uses SDC naming conventions for netlists. Netlists consist of cells, pins, nets, ports, and clocks.

- Cells are instances of fundamental hardware elements in Altera® FPGAs (such as logic elements, look-up tables, and registers).
- Pins are inputs and outputs of cells.
- Nets are connections between output pins and input pins.
- Ports are top-level module inputs and outputs (device inputs and outputs).
- Clocks are abstract objects outside the netlist.

The terminology of pins and ports is opposite to that of the Quartus II Classic Timing Analyzer. In the Quartus II Classic Timing Analyzer, ports are inputs and outputs of cells, and pins are top-level module inputs and outputs (device inputs and outputs).

Figure 9–1 shows a simple design, and Figure 9–2 shows the Quartus II TimeQuest netlist representation of the design. Netlist elements in Figure 9–2 are labeled to illustrate the SDC terminology.

Figure 9–1. Sample Design

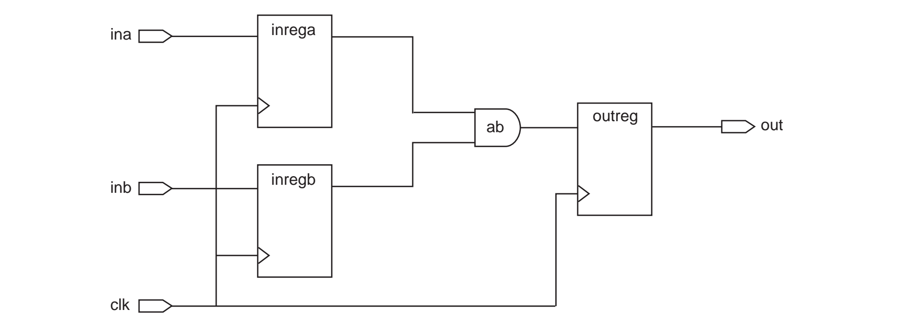


Figure 9–2. Quartus II TimeQuest Timing Analyzer Netlist

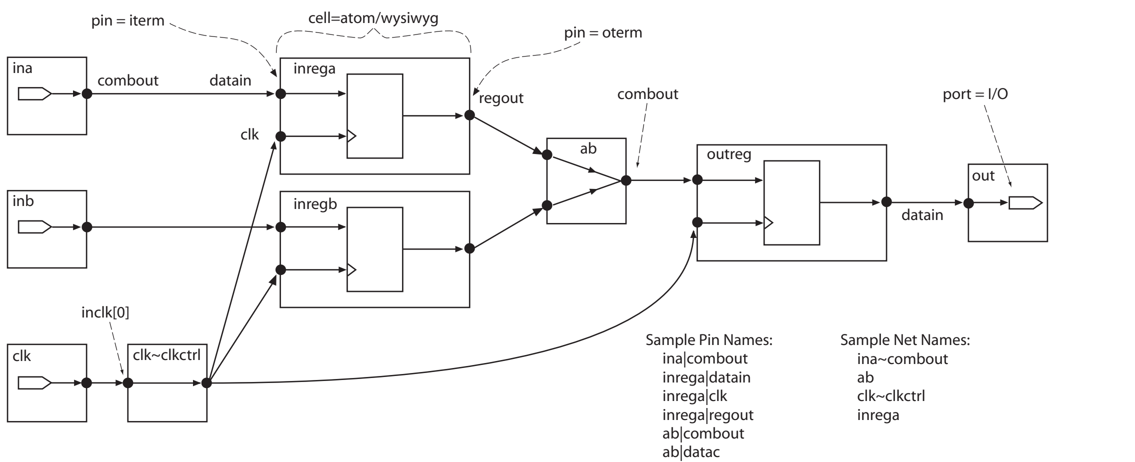


Collections

In addition to standard SDC collections, the Quartus II TimeQuest Timing Analyzer supports the following Altera-specific collection types:

- **Keepers**—Non-combinational nodes in a netlist
- **Nodes**—Nodes can be combinational, registers, latches, or ports (device inputs and outputs)
- **Registers**—Registers or latches in the netlist

You can use the **get_keepers**, **get_nodes**, or **get_registers** commands to access these collections.

Constraints

The Quartus II Classic and Quartus II TimeQuest Timing Analyzers store constraints in different files, support different methods for constraint entry, and prioritize constraints differently. The following sections detail these differences.

Constraint Files

The Quartus II TimeQuest Timing Analyzer stores all SDC timing constraints in **.sdc** files. The Quartus II Classic Timing Analyzer stores all timing assignments in your project's **.qsf** file. The **.qsf** file contains all your project's assignments and settings except for the Quartus II TimeQuest Timing Analyzer constraints. The Quartus II TimeQuest Timing Analyzer ignores the timing assignments in your **.qsf** file except when the conversion utility converts Quartus II Quartus II Classic QSF timing assignments to Quartus II TimeQuest SDC constraints. There is no automatic process that keeps timing constraints synchronized between your **.qsf** and **.sdc** files. If you want to keep the constraints synchronized, you must convert them manually.

Constraint Entry

In the Quartus II Classic Timing Analyzer, you enter timing assignments with the **Settings** dialog box, the Assignment Editor, or with commands in Tcl scripts. The Quartus II TimeQuest Timing Analyzer does not use the Assignment Editor for its constraints, and you cannot use the Assignment Editor to enter SDC constraints. You must use one of the following methods to enter Quartus II TimeQuest constraints:

- Enter constraints at the Tcl prompt in the Quartus II TimeQuest Timing Analyzer
- Enter constraints in an **.sdc** file with a text editor or SDC editor
- Use the constraint entry commands on the Constraints menu in the Quartus II TimeQuest Timing Analyzer GUI

You can enter timing assignments for the Quartus II Classic Timing Analyzer even if no timing netlist exists for your design. The Quartus II TimeQuest Timing Analyzer requires that a netlist exist for interactive constraint entry. Each Quartus II TimeQuest Timing Analyzer constraint is a Tcl command evaluated in real-time, if entered directly in the Tcl console. As part of this evaluation, the Quartus II TimeQuest Timing Analyzer validates all names. To do this, SDC commands can only be evaluated after a netlist is created. An **.sdc** file can be created at any time using the Quartus II TimeQuest Timing Analyzer or any other text editor, but a netlist is required before an **.sdc** file can be sourced. You must create a timing netlist in the Quartus II TimeQuest Timing Analyzer before you can enter constraints with either of the following interactive methods:

- At the Tcl console of the Quartus II TimeQuest Timing Analyzer
- With commands on the Constraints menu in the Quartus II TimeQuest Timing Analyzer GUI

If you enter constraints with a text editor separate from the Quartus II TimeQuest Timing Analyzer, no timing netlist is required.

To create a timing netlist in the Quartus II TimeQuest Timing Analyzer, use the **create_timing_netlist** command, or double-click **Create Timing Netlist** in the Tasks pane of the Quartus II TimeQuest GUI.

If you have never compiled your design, and you want to use the Quartus II TimeQuest Timing Analyzer to enter constraints interactively, you must synthesize your design before you create a timing netlist. To synthesize your design, type the following command at a system command prompt:

```
quartus_map <project name> ↵
```

If you use the Quartus II GUI, ensure that your project is open, then click **Start** on the Processing menu, and click **Start Analysis and Synthesis**.

To create the netlist, open the Quartus II TimeQuest Timing Analyzer. Then, on the Netlist menu, click **Create Timing Netlist...**, select **Post-map**, and click **OK**. Alternately, at the TCL console, type the following command:

```
create_timing_netlist -post_map ↵
```

Time Units

Enter time values are in default time units of nanoseconds (ns) with up to three decimal places. Note that the Quartus II TimeQuest Timing Analyzer does not display the default time unit when it displays time values.

You can specify a different default time unit with the **set_time_format -unit** <*default time unit*> command, or specify another unit when you enter a time value, for example, `300ps`.

Specifying time units with the value is not part of the standard SDC format. This is a Quartus II TimeQuest Timing Analyzer extension.

You can specify clock constraints with period or frequency in the Quartus II TimeQuest Timing Analyzer. For example, you can use either of the following constraints:

- `create_clock -period 10.000`
  (assuming default units and decimal places)
- `create_clock -period "100 MHz"`
- `create_clock -period "10 ns"`

MegaCore Functions

If you change any MegaCore function settings and regenerate the core after you convert your timing assignments to SDC constraints, you must manually update the SDC constraints or reconvert your assignments. You must update or reconvert, because changes to MegaCore function settings can affect timing assignments embedded in the hardware description language files of the core. The timing assignments are not converted automatically when the core settings change.

You should make a backup copy of your **.sdc** file before reconverting assignments. If you made changes to the **.sdc** file, you can manually copy the updated MegaCore timing constraints to your **.sdc** file.

Bus Name Format

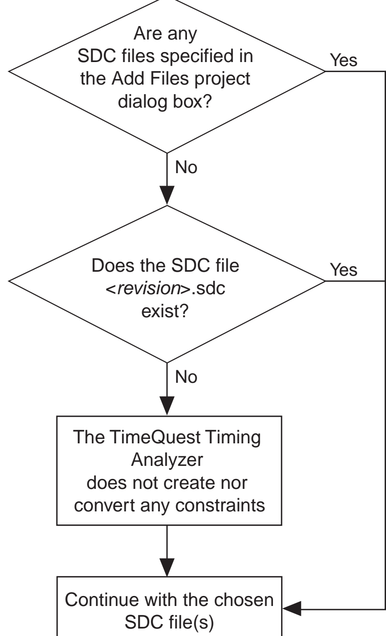
In the Quartus II Classic Timing Analyzer, you can make a timing assignment to all bits in a bus with the bus name (or the bus name followed by an asterisk enclosed in square brackets) as the target. For example, to make an assignment to all bits of a bus called address, use `address` or `address[*]` as the target of the assignment.

In the Quartus II TimeQuest Timing Analyzer, you must use the bus name followed by square brackets enclosing an asterisk, like this: `address[*]`.

Constraint File Priority

The Quartus II TimeQuest Timing Analyzer searches for **.sdc** files with a specific priority, as shown in Figure 9–3.

Figure 9–3. .sdc File Search Order



If you specify constraints in multiple **.sdc** files, or if you use a single **.sdc** file with a name other than <*revision*>**.sdc**, you must add the files to your project so the Quartus II TimeQuest Timing Analyzer can find them. If you use the Quartus II software, click **Add/Remove Files in Project** on the Project menu, and add the appropriate **.sdc** files. You can also add **.sdc** files to your project with the following Tcl command in your **.qsf** file, repeated once for each **.sdc** file:

```
set_global_assignment -name SDC_FILE <SDC file name>
```

The Quartus II TimeQuest Timing Analyzer reads constraint files from the files list in the order they are listed, first to last.

☞ If you use an **.sdc** file created by the conversion utility, you should place it before all other **.sdc** files in the list of files. When conflicting constraints apply to the same node, the last constraint has the highest priority. Therefore, **.sdc** files with your additions or changes should be listed after the **.sdc** file created by the conversion utility, so your constraints have higher priority.

Beginning with version 6.1, the Quartus II TimeQuest Timing Analyzer does not run the conversion utility automatically when it cannot find an **.sdc** file according to the priority shown in Figure 9–3. It may prompt you to run the conversion utility from the Constraints menu in the Quartus II TimeQuest GUI.

☞ You must review the **.sdc** file as you would when manually running the conversion utility. Refer to "Reviewing Conversion Results" on page 9–51 for information about how to review the converted constraints.

If no **.sdc** file exists when you run the Quartus II Fitter, and you have turned on **Use TimeQuest Timing Analyzer during compilation**, the Fitter does not create an **.sdc** file automatically, but it attempts to meet a default 1 GHz constraint on all clocks in your design.

Constraint Priority

The Quartus II Classic Timing Analyzer prioritizes assignments based on the specificity of the nodes to which they are assigned. The more specific an assignment is, the higher its priority. The Quartus II TimeQuest Timing Analyzer simplifies these precedence rules. When overlaps occur in the nodes to which the constraints apply, constraints at the bottom of the file take priority over constraints at the top of the file.

As an example, in the Quartus II Classic Timing Analyzer, point-to-point multicycle assignments have higher priority than single point multicycle assignments. The two assignments in Example 9–1 result in a multicycle assignment of 2 between `A_reg` and all nodes beginning with B, including `B_reg`. The single point assignment does not apply to paths from `A_reg` to `B_reg`, because the specific point-to-point assignment takes priority over the general single point assignment.

Example 9–1. Quartus II Classic Timing Analyzer Multicycle Assignments

```
set_instance_assignment -name MULTICYCLE -from A_reg -to B* 2
set_instance_assignment -name MULTICYCLE -to B_reg 3
```

Example 9–2 shows SDC versions of the preceding Quartus II Classic Timing Analyzer timing assignments. However, the Quartus II TimeQuest Timing Analyzer evaluates the constraints from top to bottom (regardless of point-to-point or single point), so the path from `A_reg` to `B_reg` receives a multicycle exception of 3 because it is second in order.

Example 9–2. Quartus II TimeQuest Timing Analyzer Multicycle Exceptions

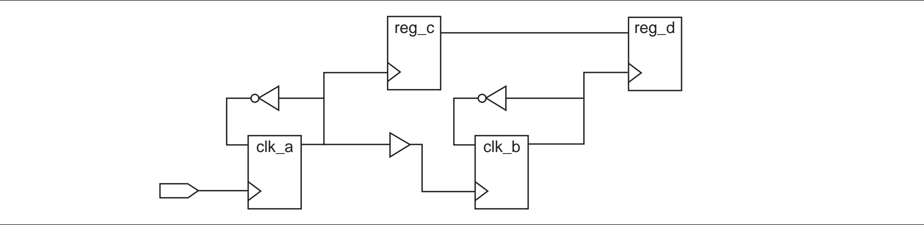
```
set_multicycle_path -from [get_keepers A_reg] -to [get_keepers B*] 2
set_multicycle_path -to [get_keepers B_reg] 3
```

Ambiguous Constraints

Because of new capabilities in the Quartus II TimeQuest Timing Analyzer, some Quartus II Classic assignments can be ambiguous after conversion by the conversion utility. These assignments require manual updating based on your knowledge of your design.

Figure 9–4 shows a ripple clock circuit. The explanation that follows shows an ambiguous constraint for that circuit, and how to edit the constraint to remove the ambiguity in the Quartus II TimeQuest Timing Analyzer.

Figure 9–4. Ripple Clock Circuit



In the Quartus II Classic Timing Analyzer, the following QSF multicycle assignment from `clk_a` to `clk_b` with a value of 2 applies to paths transferring data from the `clk_a` domain to the `clk_b` domain:

```
set_instance_assignment -name MULTICYCLE -from clk_a -to clk_b 2
```

In Figure 9–4, this assignment applies to the path from `reg_c` to `reg_d`. In the Quartus II TimeQuest Timing Analyzer, the use of the clock node names in the following equivalent multicycle exception is ambiguous:

```
set_multicycle_path -setup -from clk_a -to clk_b 2
```

The exception could apply to the path between `clk_a` and `clk_b`, or it could apply to paths from one ripple clock domain to the other ripple clock domain (`reg_c` to `reg_d`).

The Quartus II TimeQuest exceptions shown in Example 9–3 are not ambiguous because they use collections to explicitly specify the targets of the exception.

Example 9–3. Unambiguous Quartus II TimeQuest Timing Analyzer Exceptions

```
# Applies to path from reg_c to reg_d
set_multicycle_path -setup -from [get_clocks clk_a] \
   -to [get_clocks clk_b] 2
# Applies to path from clk_a to clk_b
set_multicycle_path -setup -from [get_registers clk_a] \
   -to [get_registers clk_b] 2
```

Clocks

The Quartus II Classic and Quartus II TimeQuest Timing Analyzers detect, analyze, and report clocks differently. The following sections describe these differences.

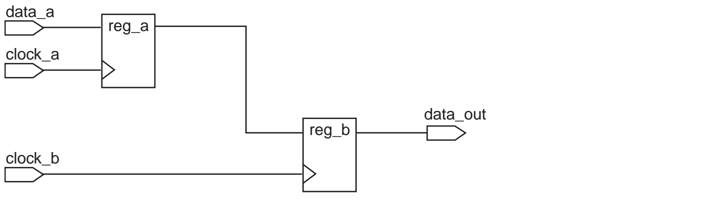
Related and Unrelated Clocks

In the Quartus II TimeQuest Timing Analyzer, all clocks are related by default, and you must add assignments to indicate unrelated clocks. However, in the Quartus II Classic Timing Analyzer, all base clocks are unrelated by default. All derived clocks of a base clock are related to each other, but are unrelated to other base clocks and their derived clocks.

You can change the default behavior of the Quartus II Classic Timing Analyzer to treat all clocks as related clocks. On the Assignments menu, click **Timing Analysis Settings**. Click **More Settings** and then select **Cut paths between unrelated clock domains**. Ensure that the setting is off.

Figure 9–5 on page 9–12 shows a simple circuit with a path between two clock domains. The Quartus II TimeQuest Timing Analyzer analyzes the path from `reg_a` to `reg_b` because all clocks are related by default. The Quartus II Classic Timing Analyzer does not analyze the path from `reg_a` to `reg_b` by default.

Figure 9–5. Cross Clock Domain Path



To make clocks unrelated in the Quartus II TimeQuest Timing Analyzer, use the **set_clock_groups** command with the `-exclusive` option. For example, the following command makes `clock_a` and `clock_b` unrelated, so the Quartus II TimeQuest Timing Analyzer does not analyze paths between the two clock domains.

```
set_clock_groups -exclusive -group {clock_a} -group {clock_b}
```

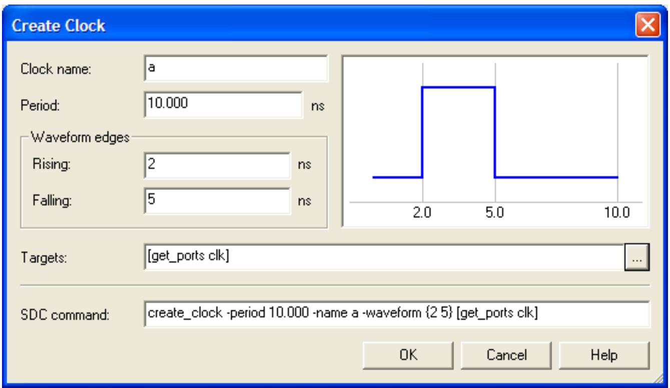
Clock Offset

In the Quartus II TimeQuest Timing Analyzer, clocks can have non-zero values for the rising edge of the waveform, a feature that the Quartus II Classic Timing Analyzer does not support. To specify an offset for your clock, use the waveform option for the **create_clock** command to specify the rising and falling edge times, as shown in this example:

```
-waveform {<rising edge time> <falling edge time>}
```

Figure 9–6 shows a clock constraint with an offset in the Quartus II TimeQuest Timing Analyzer GUI.

Figure 9–6. Create Clock Screen



Clock offset affects setup and hold relationships. Launch and latch edges are evaluated after offsets are applied. Depending on the offset, the setup relationship can be the offset value, or the difference between the period and offset. You should not use clock offset to emulate latency. You should use the clock latency constraint instead. Refer to “Offset and Latency Example” on page 9–13 for an example that illustrates the different effects of offset and latency.

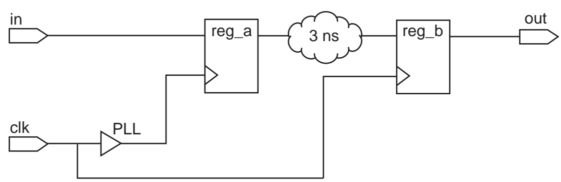
Clock Latency

The Quartus II TimeQuest Timing Analyzer does not ignore early clock latency and late clock latency differences when the clock source is the same, as the Quartus II Classic Timing Analyzer does. When you specify latencies, you should take common clock path pessimism into account and use uncertainty to control pessimism differences for clock-to-clock data transfers. Unlike clock offset, clock latency affects skew, and launch and latch edges are evaluated before latencies are applied, so the setup relationship is always equal to the period.

Offset and Latency Example

Figure 9–7 shows a simple register-to-register circuit used to illustrate the different effects of offset and latency. The examples show why you should not use clock offset to emulate clock latency. You should always turn on the **Enable Clock Latency** option in the Quartus II Classic Timing Analyzer. This option is in the **More Settings** box of the **Timing Settings** dialog box.

Figure 9–7. Simple Circuit for Offset and Latency Examples

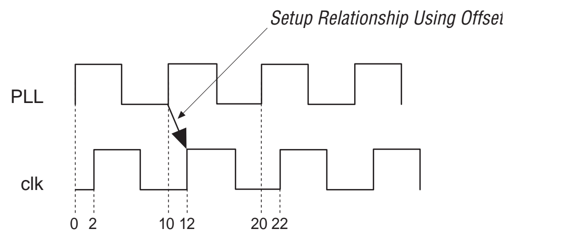


The period for `clk` is 10 ns, and the period for the PLL output is 10 ns. The PLL compensation value is –2 ns. The network delay from the PLL to `reg_a` equals the network delay from `clk` to `reg_b`. Finally, the delay from `reg_a` to `reg_b` is 3 ns.

Clock Offset Scenario

Treat the PLL compensation value of –2 ns as a clock offset of –2 ns with a clock skew of 0 ns. Launch and latch edges are evaluated after offsets are applied, so the setup relationship is 2 ns (Figure 9–8).

Figure 9–8. Setup Relationship Using Offset



Equation 9–1 shows how to calculate the slack value for the path from `reg_a` to `reg_b`.

Equation 9–1.

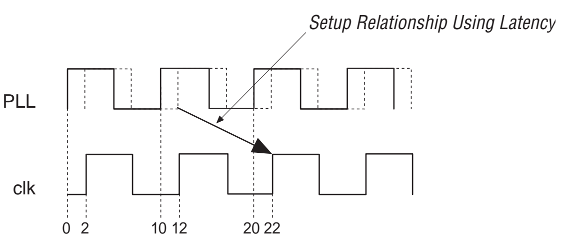
$$\text{slack} = \text{clock arrival} - \text{data arrival}$$
$$\text{slack} = \text{setup relationship} + \text{clock skew} - \text{reg_to_reg delay}$$
$$\text{slack} = 2\text{ns} + 0\text{ns} - 3\text{ns}$$
$$\text{slack} = -1\text{ns}$$

The negative slack requires a multicycle assignment with a value of 2 and a hold multicycle assignment with a value of 1 to correct. With these assignments from `reg_a` to `reg_b`, the setup relationship is then 12 ns, resulting in a slack of 9 ns.

Clock Latency Scenario

Treat the PLL compensation value of –2 ns as latency with a clock skew of 2 ns. Because launch and latch edges are evaluated before latencies are applied, the setup relationship is 10 ns (the period of `clk` and the PLL) (Figure 9–9).

Figure 9–9. Setup Relationship Using Latency



Equation 9–2 shows how to calculate the slack value for the path from `reg_a` to `reg_b`.

Equation 9–2.

$$\text{slack} = \text{clock arrival} - \text{data arrival}$$
$$\text{slack} = \text{setup relationship} + \text{clock skew} - \text{reg_to_reg delay}$$
$$\text{slack} = 10\text{ns} + 2\text{ns} - 3\text{ns}$$
$$\text{slack} = 9\text{ns}$$

The slack of 9 ns is identical to the slack computed in the previous example, but because this example uses latency instead of offset, no multicycle assignment is required.

Clock Uncertainty

The Quartus II Classic Timing Analyzer ignores **Clock Setup Uncertainty** and **Clock Hold Uncertainty** assignments when you specify a setup or hold relationship between two clocks. However, the Quartus II TimeQuest Timing Analyzer does not ignore clock uncertainty when you specify a setup or hold relationship between two clocks. Figure 9–10 and Figure 9–11 illustrate the different behavior between the Quartus II TimeQuest and Quartus II Classic Timing Analyzers.

In both figures, the constraints are identical. There is a 20-ns period for `clk_a` and `clk_b`. There is a setup relationship (a **set_max_delay** exception in the Quartus II TimeQuest Timing Analyzer) of 7 ns from `clk_a` to `clk_b`, and a clock setup uncertainty constraint of 1 ns from `clk_a` to `clk_b`. The actual setup relationship in the Quartus II TimeQuest Timing Analyzer is 1 ns less than in the Quartus II Classic Timing Analyzer because of the way they analyze clock uncertainty.

Figure 9–10. Quartus II Classic Timing Analyzer Behavior

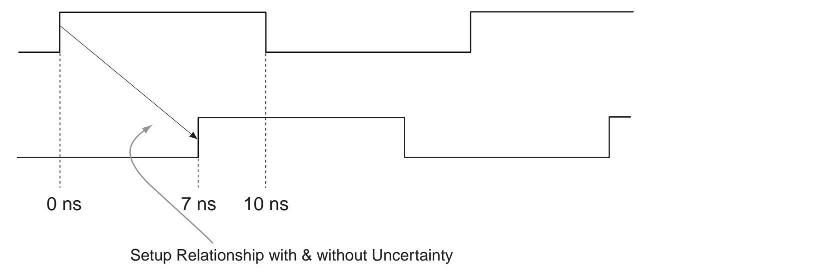


Figure 9–11. Quartus II TimeQuest Timing Analyzer Behavior

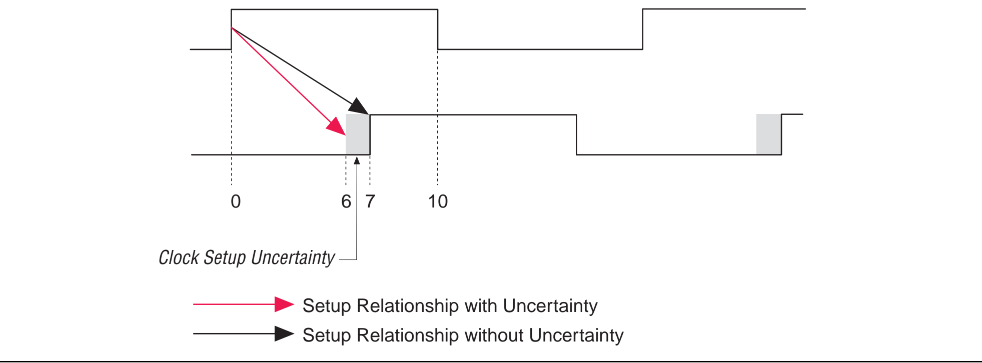


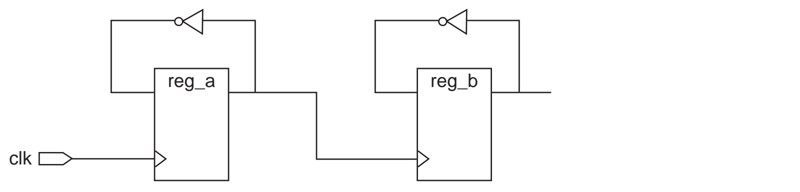
Derived and Generated Clocks

Generated clocks in the Quartus II TimeQuest Timing Analyzer are different than derived clocks in the Quartus II Classic Timing Analyzer. In the Quartus II Classic Timing Analyzer, the source of a derived clock must be a base clock. However, in the Quartus II TimeQuest Timing Analyzer, the source of a generated clock can be any other clock in the design (including virtual clocks), or any node to which a clock propagates through the clock network. Because generated clocks are related through the clock network, you can specify generated clocks for isolated modules, such as IP, without knowing the details of the clocks outside of the module.

In the Quartus II TimeQuest Timing Analyzer, you can specify generated clocks relative to specific edges and edge shifts of a master clock, a feature that the Quartus II Classic Timing Analyzer does not support.

Figure 9–12 shows a simple ripple clock that you should constrain with generated clocks in the Quartus II TimeQuest Timing Analyzer.

Figure 9–12. Generated Clocks Circuit



The Quartus II TimeQuest Timing Analyzer constraints shown in Example 9–4 constrain the clocks in the circuit above. Note that the source of each generated clock can be the input pin of the register itself, not the name of another clock.

Example 9–4. Generated Clock Constraints

```
create_clock -period 10 -name clk clk
create_generated_clock -divide_by 2 -source reg_a|CLK -name reg_a reg_a
create_generated_clock -divide_by 2 -source reg_b|CLK -name reg_b reg_b
```

Automatic Clock Detection

The Quartus II Classic and Quartus II TimeQuest Timing Analyzers identify clock sources of registers that do not have a defined clock source. The Quartus II Classic Timing Analyzer traces back along the clock network, through registers and logic, until it reaches a top-level port in your design. The Quartus II TimeQuest Timing Analyzer also traces back along the clock network, but it stops at registers.

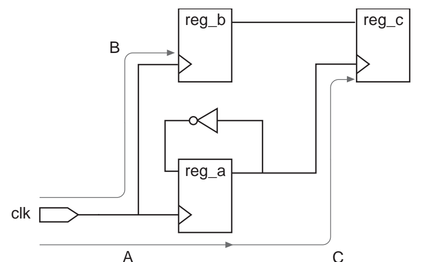
You can use two SDC commands in the Quartus II TimeQuest Timing Analyzer to automatically detect and create clocks for unconstrained clock sources:

- **derive_clocks**—creates clocks on sources of clock pins that do not already have at least one clock sourcing the clock pin
- **derive_pll_clocks**—identifies PLLs and creates generated clocks on the clock output pins

derive_clocks Command

Figure 9–13 shows a simple circuit with a divide-by-2 register and indicates the clock network delays as A, B, and C. The following explanation describes how the Quartus II Classic and Quartus II TimeQuest Timing Analyzers detect the clocks in Figure 9–13.

Figure 9–13. Circuit for derive_clocks Example



The Quartus II Classic Timing Analyzer detects that `clk` is the clock source for registers `reg_a`, `reg_b`, and `reg_c`. It detects that `clk` is the clock source for `reg_c` because it traces back along the clock network for `reg_c` through `reg_a`, until it finds the `clk` port. The Quartus II Classic Timing Analyzer computes the clock arrival time for `reg_c` as $A + C$.

The **derive_clocks** command in the Quartus II TimeQuest Timing Analyzer creates two base clocks, one on the `clk` port and one on `reg_a`, because the command does not trace through registers on the clock network. The clock arrival time for `reg_c` is C because the clock starts at `reg_a`.

To make the Quartus II TimeQuest Timing Analyzer compute the same clock arrival time ($A + C$) as the Quartus II Classic Timing Analyzer for `reg_c`, make the following modifications to the clock constraints created by the **derive_clocks** command:

- Change the base clock named `reg_a` to a generated clock
- Make the source the clock pin of `reg_a` (`reg_a|clk`) or the port `clk`
- Add a `-divide_by 2` option

These modifications cause the clock arrival times to `reg_c` to match between the Quartus II Classic Timing Analyzer and the Quartus II TimeQuest Timing Analyzer. However, the clock for `reg_c` is shown as `reg_a` instead of `clk`, and the launch and latch edges may change for some paths due to the divide-by-2.

You can use the **derive_clocks** command at the beginning of your design cycle when you do not know all of the clock constraints for your design, but you should not use it during timing sign-off. Instead, you should constrain each clock in your design with the **create_clock** or **create_generated_clocks** commands.

The **derive_clocks** command detects clocks in your design using the following rules:

1. An input clock port is detected as a clock only if there are no other clocks feeding the destination registers.
   a. Input clock ports are not detected automatically if they feed only other base clocks.
   b. If other clocks feed the port's register destinations, the port is assumed to be an enable or data port for a gated clock.
   c. When no clocks are defined, and multiple clocks feed a destination register, the auto-detected clock is selected arbitrarily.
2. All ripple clocks (registers in a clock path) are detected as clocks automatically using the same rules for input clock ports. If both an input port and a register feed register clock pins, the input port is selected as the clock.

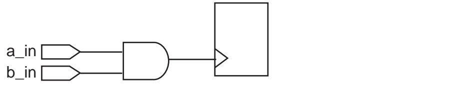
The following examples show how the **derive_clocks** command detects clocks in the simple circuit shown in Figure 9–14.

Figure 9–14. Simple Circuit 1

- If you do not make any clock settings, and then you run **derive_clocks**, it detects `a_in` as a clock according to rule 1, because there are no other clocks feeding the register.
- If you create a clock with `b` as its target, and then you run **derive_clocks**, it does not detect `a_in` as a clock according to rule 1a, because `a_in` feeds only another clock.

The following examples show how the **derive_clocks** command detects clocks in the simple circuit shown in Figure 9–15.

Figure 9–15. Simple Circuit 2



- If you do not make any clock settings and then you run **derive_clocks**, it selects a clock arbitrarily, according to rule 1c.
- If you create a clock with `a_in` as its target and then you run **derive_clocks**, it does not detect `b_in` as a clock according to rule 1b, because another clock (`a_in`) feeds the register.

derive_pll_clocks Command

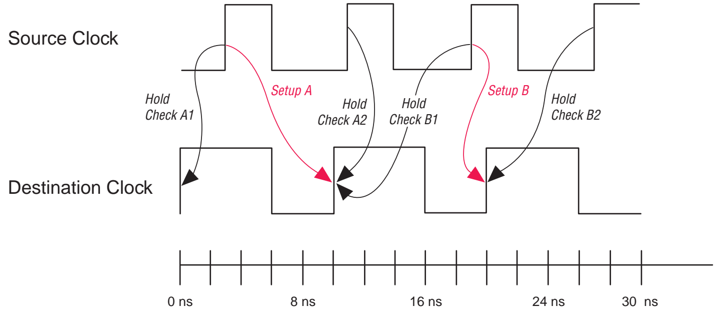
The **derive_pll_clocks** command names the generated clocks according to the names of the PLL output pins by default, and you cannot change these generated clock names. If you want to use your own clock names, you must use the **create_generated_clock** command for each PLL output clock and specify the names with the `-name` option.

If you use the PLL clock-switchover feature, the **derive_pll_clocks** command creates additional generated clocks on each output clock pin of the PLL based on the secondary clock input to the PLL. This may require **set_clock_groups** or **set_false_path** commands to cut the primary and secondary clock outputs. For information about how to make clocks unrelated, refer to “Related and Unrelated Clocks” on page 9–11.

Hold Relationship

The Quartus II TimeQuest and Quartus II Classic Timing Analyzers choose the worst-case hold relationship differently. Refer to Figure 9–16 for sample waveforms to illustrate the different effects.

Figure 9–16. Worst-Case Hold



The Quartus II Classic Timing Analyzer first identifies the worst-case setup relationship. The worst-case setup relationship is **Setup B**. Then the Quartus II Classic Timing Analyzer chooses the worst-case hold relationship (Hold Check B1 or Hold Check B2) for that specific setup relationship, Setup B. The Quartus II Classic Timing Analyzer chooses Hold Check B2 for the worst-case hold relationship.

However, the Quartus II TimeQuest Timing Analyzer calculates worst-case hold relationships for all possible setup relationships and chooses the absolute worst-case hold relationship. The Quartus II TimeQuest Timing Analyzer checks two hold relationships for every setup relationship:

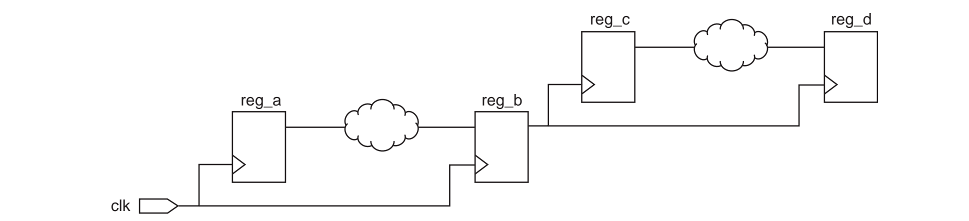
- Data launched by the current launch edge not captured by the previous latch edge (Hold Check A1 and Hold Check B1)
- Data launched by the next launch edge not captured by the current latch edge (Hold Check A2 and Hold Check B2)

The Quartus II TimeQuest Timing Analyzer chooses Hold Check A2 as the absolute worst-case hold relationship.

Clock Objects

The Quartus II Classic Timing Analyzer treats nodes with clock settings assigned to them as special objects in the timing netlist. Any node in the timing netlist with a clock setting is treated as a clock object, regardless of its actual type, such as a register. When a register has a clock setting assigned to it, the Quartus II Classic Timing Analyzer does not analyze register-to-register paths beginning or ending at that register. Figure 9–17 shows a circuit that illustrates this situation.

Figure 9–17. Clock Objects



With no clock assignments on any of the registers, the Quartus II Classic Timing Analyzer analyzes timing on the path from `reg_a` to `reg_b`, and from `reg_c` to `reg_d`. If you make a clock setting assignment to `reg_b`, `reg_b` is no longer considered a register node in the netlist, and the path from `reg_a` to `reg_b` is no longer analyzed.

In the Quartus II TimeQuest Timing Analyzer, clocks are abstract objects that are associated with nodes in the timing netlist. The Quartus II TimeQuest Timing Analyzer analyzes the path from `reg_a` to `reg_b` even if there is a clock assigned to `reg_b`.

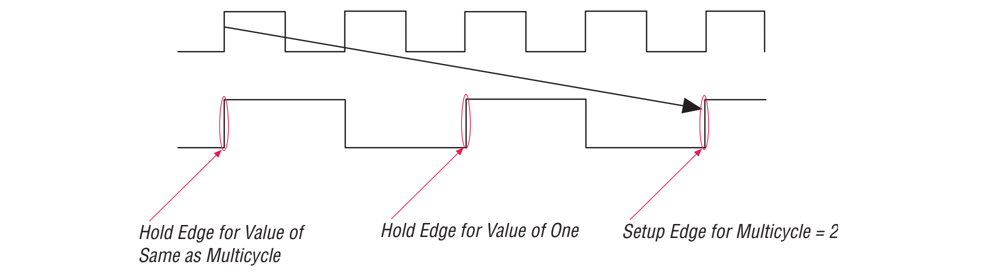
Hold Multicycle

The hold multicycle value numbering scheme is different in the Quartus II Classic and Quartus II TimeQuest Timing Analyzers. Also, you can choose between two values for the default hold multicycle value in the Quartus II Classic Timing Analyzer but you cannot change the default value in the Quartus II TimeQuest Timing Analyzer. The hold multicycle value specifies which clock edge is used for hold analysis when you change the latch edge with a multicycle assignment.

In the Quartus II Classic Timing Analyzer, the hold multicycle value is based on 1, and is the number of clock cycles away from the setup edge. In the Quartus II TimeQuest Timing Analyzer, the hold multicycle value is based on zero, and is the number of clock cycles away from the default hold edge. In the Quartus II TimeQuest Timing Analyzer, the default hold edge is one edge before or after the setup edges. Subtract 1 from any hold multicycle value in the Quartus II Classic Timing Analyzer to compute the equivalent value for the Quartus II TimeQuest Timing Analyzer.

In the Quartus II Classic Timing Analyzer, you can set the default value of the hold multicycle assignment to **One** or **Same as Multicycle**. The default value applies to any multicycle assignment in your design that does not also have a multicycle hold assignment. Figure 9–18 illustrates the difference between **One** and **Same as Multicycle** for a multicycle assignment of 2 using the Quartus II Classic Timing Analyzer.

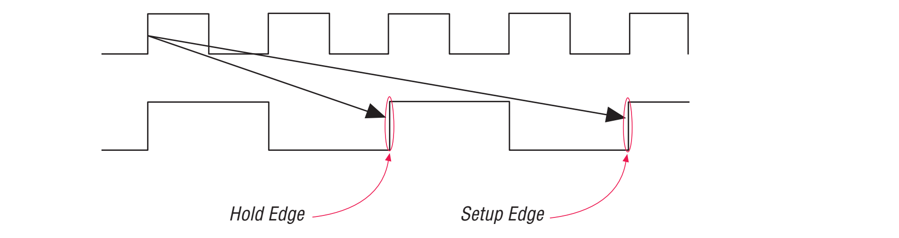
Figure 9–18. Difference Between One and Same As Multicycle



If the default value is **One**, the Quartus II Classic Timing Analyzer uses the clock edge one before the setup edge for hold analysis. If the default value is **Same as Multicycle**, the Quartus II Classic Timing Analyzer uses the clock edge that is <*value of multicycle assignment*> edges back from the setup edge.

Figure 9–19 shows simple waveforms for a cross-clock domain transfer with the indicated setup and hold edges.

Figure 9–19. First Relationship Example



In the Quartus II TimeQuest Timing Analyzer, only a multicycle exception of 2 is required to constrain the design for the indicated setup and hold relationships.

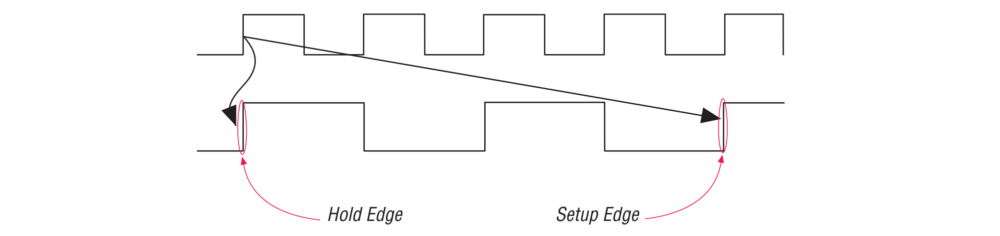
In the Quartus II Classic Timing Analyzer, if the **Default Hold Multicycle** value is **One**, only a multicycle assignment of 2 is required to constrain the design.

In the Quartus II Classic Timing Analyzer, if the **Default Hold Multicycle** value is **Same as Multicycle**, you must make two assignments to constrain the design:

- A multicycle assignment of 2
- A hold multicycle assignment of 1 to override the default value

Figure 9–20 shows simple waveforms for a different cross-clock domain transfer with indicated setup and hold edges. The following explanation shows what exceptions to apply to achieve the desired setup and hold relationships.

Figure 9–20. Second Relationship Example



In the Quartus II TimeQuest Timing Analyzer, you must use the following two exceptions:

- A multicycle exception of 2
- A hold multicycle exception of 1, because the hold edge is one edge behind the default hold edge, which is one edge after the setup edge.

In the Quartus II Classic Timing Analyzer, if the **Default Hold Multicycle** value is **One**, you must make two assignments to constrain the design:

- A multicycle assignment of 2
- A hold multicycle assignment of 2 to override the default value

In the Quartus II Classic Timing Analyzer, if the **Default Hold Multicycle** value is **Same as Multicycle**, only a multicycle assignment of 2 is required to constrain the design.

You should always add a hold multicycle assignment for every multicycle assignment to ensure the correct exceptions are applied regardless of the timing analyzer you use, or, for the Quartus II Classic Timing Analyzer, the **Default Hold Multicycle** setting.

Fitter Behavior

The behavior for one value of the **Optimize hold time** Fitter assignment differs between the Quartus II TimeQuest Timing Analyzer and the Quartus II Classic Timing Analyzer. When you set the Quartus II TimeQuest Timing Analyzer as the default timing analyzer, the **I/O Paths and Minimum TPD Paths** value directs the Fitter to optimize all hold time paths, which has the same affect as the **All Paths** value.

Fitter Performance

If you use the Quartus II TimeQuest Timing Analyzer as your default timing analyzer, the Fitter memory use and compilation time may increase. However, the timing analysis time may decrease.

Reporting

The Quartus II TimeQuest Timing Analyzer provides a more flexible and powerful interface for reporting timing analysis results than the Quartus II Classic Timing Analyzer. Although the interface and constraints are more flexible and powerful, both analyzers use the same device timing models, except for device families that support rise/fall analysis. The Quartus II Classic Timing Analyzer does not support rise/fall analysis, but the Quartus II TimeQuest Timing Analyzer does. Therefore, you may see slightly different delays on identical paths in device families that support rise/fall analysis if you analyze timing in both analyzers.

This means that both analyzers report identical delays along identically constrained paths in your design. The Quartus II TimeQuest Timing Analyzer allows you to constrain some paths that you could not constrain with the Quartus II Classic Timing Analyzer. Differently constrained paths result in different reported values, but for identical paths in your design that are constrained the same way, the delays are exactly the same. Both timing analyzers use the same timing models.

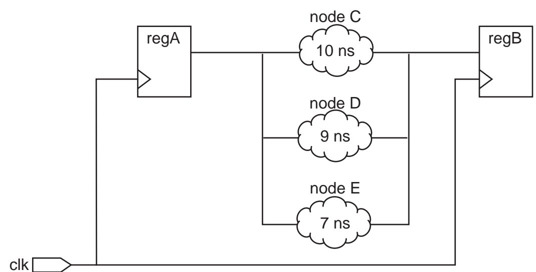
For information about reporting with the Quartus II TimeQuest Timing Analyzer, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Paths and Pairs

In reporting, the most significant difference between the two analyzers is that the Quartus II TimeQuest Timing Analyzer reports paths, while the Quartus II Classic Timing Analyzer reports pairs. Path reporting means that the analyzer separately reports every path between two registers. Pair reporting means that the analyzer reports only the worst-case path between two registers. One benefit of path reporting over pair reporting is that you can more easily identify common points in failing paths that may be good targets for optimization.

If your design does not meet timing constraints, this reporting difference can give the impression that there are many more timing failures when you use the Quartus II TimeQuest Timing Analyzer. Figure 9–21 shows a sample circuit followed by a description of the differences between path and pair reporting.

Figure 9–21. Failing Paths



There is an 8-ns period constraint on `clk`, resulting in two paths that fail timing: `regA` → `C` → `regB` and `regA` → `D` → `regB`. The Quartus II Classic Timing Analyzer reports only worst-case path `regA` → `C`→ `regB`. The Quartus II TimeQuest Timing Analyzer reports both failing paths `regA` → `C` → `regB` and `regA` → `D` → `regB`. It also reports path `regA` → `E` → `regB` with positive slack.

Default Reports

The Quartus II TimeQuest Timing Analyzer generates only a small number of reports by default, as compared to the Quartus II Classic Timing Analyzer, which generates every report by default. With the Quartus II TimeQuest Timing Analyzer, you generate desired reports on demand.

To learn how to create custom reports, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the Quartus II Handbook.

Netlist Names

The Quartus II Classic Timing Analyzer uses register names in reporting, but the Quartus II TimeQuest Timing Analyzer uses register pin names (with the exception of port names of the top-level module). Buried nodes or register names are used when necessary.

Example 9–5 shows how register names are used in Quartus II Classic Timing Analyzer reports.

Example 9–5. Netlist Names in the Quartus II Classic Timing Analyzer

```
Info: + Shortest register to register delay is 0.538 ns
    Info: 1: + IC(0.000 ns) + CELL(0.000 ns) = 0.000 ns; Loc. =
LCFF_X1_Y5_N1;
Fanout = 1; REG Node = 'inst'
    Info: 2: + IC(0.305 ns) + CELL(0.149 ns) = 0.454 ns; Loc. =
LCCOMB_X1_Y5_N20; Fanout = 1; COMB Node = 'inst3~feeder'
    Info: 3: + IC(0.000 ns) + CELL(0.084 ns) = 0.538 ns; Loc. =
LCFF_X1_Y5_N21; Fanout = 1; REG Node = 'inst3'
    Info: Total cell delay = 0.233 ns ( 43.31 % )
    Info: Total interconnect delay = 0.305 ns ( 56.69 % )
```

Example 9–6 shows the same information as presented in a Quartus II TimeQuest Timing Analyzer report. In this example, register pin names are used in place of register names.

Example 9–6. Netlist Names in the Quartus II TimeQuest Timing Analyzer

```

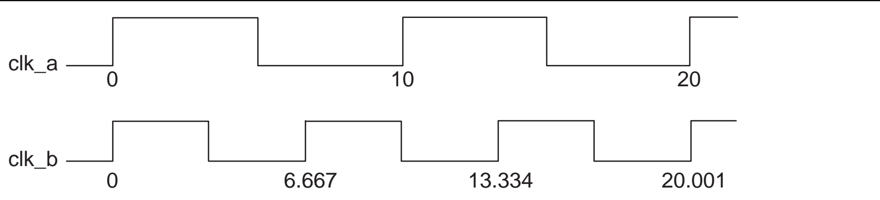
```

Non-Integer Clock Periods

In some cases when related clock periods are not integer multiples of each other, a lack of precision in clock period definition in the Quartus II TimeQuest Timing Analyzer can result in reported setup or hold relationships of a few picoseconds. In addition, launch and latch times for the relationships can be very large. If you experience this, use the **set_max_delay** and **set_min_delay** exceptions to specify the correct relationships. The Quartus II Classic Timing Analyzer can maintain additional information about clock frequency that mitigates the lack of precision in clock period definition.

When the clock period cannot be expressed as an integer in terms of picoseconds, you have the problem detailed in Figure 9–22. This figure shows two clocks: `clk_a` has a 10 ns period, and `clk_b` has a 6.667 ns period.

Figure 9–22. Very Small Setup Relationship



There is a 1 ps setup relationship at 20 ns because you cannot specify the 6.667 ns period beyond picosecond precision. You should apply the maximum and minimum delay exceptions shown in Example 9–7 between the two clocks to specify the correct relationships.

Example 9–7. Minimum and Maximum Delay Exceptions

```
set_max_delay -from [get_clocks clk_a] -to [get_clocks clk_b] 3.333
set_min_delay -from [get_clocks clk_a] -to [get_clocks clk_b] 0
```

Other Features

The Quartus II TimeQuest Timing Analyzer reports time values without units. By default, the units are nanoseconds, and three decimal places are displayed. You can change the default time unit and decimal places with the **set_time_format** command.

When you use the Quartus II TimeQuest Timing Analyzer in a Tcl shell, output is ASCII-formatted, and columns are aligned for easy reading on 80-column consoles. Example 9–8 shows sample output from a **report_timing** command from the Quartus II TimeQuest Timing Analyzer.

Example 9–8. ASCII-Formatted Quartus II TimeQuest Timing Analyzer Report

Scripting API

In versions of the Quartus II software earlier than 6.0, the **::quartus::project** Tcl package contained the following SDC-like commands for making timing assignments:

- **create_base_clock**
- **create_relative_clock**
- **get_clocks**
- **set_clock_latency**
- **set_clock_uncertainty**
- **set_input_delay**
- **set_multicycle_assignment**

- **set_output_delay**
- **set_timing_cut_assignment**

These commands are not SDC-compliant. Beginning with version 6.0, these commands are in a new package called **::quartus::timing_assignment**. To ensure backward compatibility with existing Tcl scripts, the **::quartus::timing_assignment** package is loaded by default in the following executables:

- **quartus**
- **quartus_sh**
- **quartus_cdb**
- **quartus_sim**
- **quartus_stp**
- **quartus_tan**

The **::quartus::timing_assignment** package is not loaded by default in the **quartus_sta** executable. The **::quartus::sdc** Tcl package includes SDC-compliant versions of the commands listed above. That package is available only in the **quartus_sta** executable, and it is loaded by default.

Timing Assignment Conversion

This section describes Quartus II Classic QSF timing assignments and their equivalent Quartus II TimeQuest constraints. You can convert many Quartus II Classic timing assignments to SDC constraints. Some Quartus II Classic timing assignments can be converted to two different SDC constraints, and you must understand the intended functionality of the design to make an appropriate conversion. You cannot convert some Quartus II Classic timing assignments because there is no equivalent SDC constraint.

This section includes the following topics, arranged alphabetically:

- "Clock Enable Multicycle" on page 9–30
- "Clock Latency" on page 9–27
- "Clock Uncertainty" on page 9–28
- "Cut Timing Path" on page 9–41
- "Default Required f_{MAX} Assignment" on page 9–29
- "Hold Relationship" on page 9–27
- "Input and Output Delay" on page 9–31
- "Inverted Clock" on page 9–28
- "Maximum Clock Arrival Skew" on page 9–42
- "Maximum Data Arrival Skew" on page 9–42
- "Maximum Delay" on page 9–41
- "Minimum Delay" on page 9–42
- "Minimum t_{CO} Requirement" on page 9–38

- "Minimum t_{PD} Requirement" on page 9–41
- "Multicycle" on page 9–30
- "Not a Clock" on page 9–28
- "Setup Relationship" on page 9–27
- "t_{CO} Requirement" on page 9–36
- "t_{H} Requirement" on page 9–34
- "t_{PD} Requirement" on page 9–40
- "t_{SU} Requirement" on page 9–32
- "Virtual Clock Reference" on page 9–29

Setup Relationship

The **Setup Relationship** assignment overrides the setup relationship between two clocks. By default, the Quartus II Classic Timing Analyzer automatically calculates the setup relationship based on your clock settings. The QSF variable for the **Setup Relationship** assignment is SETUP_RELATIONSHIP. In the Quartus II TimeQuest Timing Analyzer, use the **set_max_delay** command to specify the maximum setup relationship for a path.

The setup relationship value is the time between latch and launch edges before the Quartus II TimeQuest Timing Analyzer accounts for clock latency, source μt_{CO}, or destination μt_{SU}.

Hold Relationship

The **Hold Relationship** assignment overrides the hold relationship between two clocks. By default, the Quartus II Classic Timing Analyzer automatically calculates the hold relationship based on your clock settings. The QSF variable for the **Hold Relationship** assignment is HOLD_RELATIONSHIP. In the Quartus II TimeQuest Timing Analyzer, use the **set_min_delay** command to specify the minimum hold relationship for a path.

Clock Latency

Table 9–1 shows the equivalent SDC constraints for each of these Quartus II Classic assignments.

Table 9–1. Quartus II Classic and SDC Equivalent Constraints

Quartus II Classic Timing Assignment		
Assignment Name	**QSF Variable**	**SDC Constraint**
Early Clock Latency	EARLY_CLOCK_LATENCY	set_clock_latency -source -late
Late Clock Latency	LATE_CLOCK_LATENCY	set_clock_latency -source -early

For more information about clock latency support in the Quartus II TimeQuest Timing Analyzer, refer to "Clock Latency" on page 9–13.

Clock Uncertainty

This section describes the conversion for the following Quartus II Classic Timing Analyzer assignments:

- Clock Setup Uncertainty
- Clock Hold Uncertainty

Table 9–2 shows the equivalent SDC constraints for each of these Quartus II Classic Timing Analyzer assignments.

Table 9–2. Quartus II Classic and SDC Equivalent Constraints

Quartus II Classic Timing Analyzer Timing Assignment		SDC Constraint
Assignment Name	**QSF Variable**	
Clock Setup Uncertainty	CLOCK_SETUP_UNCERTAINTY	set_clock_uncertainty -setup
Clock Hold Uncertainty	CLOCK_HOLD_UNCERTAINTY	set_clock_uncertainty -hold

Inverted Clock

The Quartus II Classic Timing Analyzer detects inverted clocks automatically when the clock inversion occurs at the input of the LCELL that contains the register specified in the assignment. You must make an **Inverted Clock** assignment in all other situations for Quartus II Classic Timing Analyzer analysis. The QSF variable for the **Inverted Clock** assignment is INVERTED_CLOCK. The Quartus II TimeQuest Timing Analyzer detects inverted clocks automatically, regardless of the type of inversion circuit, in designs that target device families that support unateness: Stratix® II, Cyclone® II, and HardCopy® II. For designs that target any other device family, you must create a generated clock with the `-invert` option on the output of the cell that inverts the clock.

For more information about unateness, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Not a Clock

The **Not a Clock** assignment directs the Quartus II Classic Timing Analyzer that the specified node is not a clock source when it would normally be detected as a clock because of a global f_{MAX} requirement. The QSF variable for the **Not a Clock** assignment is NOT_A_CLOCK. This assignment is not supported in the Quartus II TimeQuest Timing Analyzer and there is no equivalent constraint. Appropriate clock constraints are created in the Quartus II TimeQuest Timing Analyzer only.

Default Required f_{MAX} Assignment

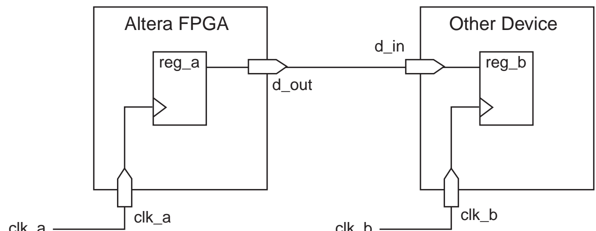
The **Default Required** $\mathbf{f_{MAX}}$ assignment allows you to specify an f_{MAX} requirement for the Quartus II Classic Timing Analyzer for all unconstrained clocks in your design. The QSF variable for the **Default Required** $\mathbf{f_{MAX}}$ assignment is FMAX_REQUIREMENT. You can use the **derive_clocks** command to create clocks on sources of clock pins in your design that do not already have clocks assigned to them. You should constrain each individual clock in your design with the **create_clock** or **created_generated_clock** command, not the **derive_clocks** command. Refer to "Automatic Clock Detection" on page 9–16 to learn why you should constrain individual clocks in your design.

Virtual Clock Reference

The **Virtual Clock Reference** assignment allows you to define timing characteristics of a reference clock outside the FPGA. The QSF variable for the **Virtual Clock Reference** assignment is VIRTUAL_CLOCK_REFERENCE. The Quartus II TimeQuest Timing Analyzer supports virtual clocks by default, while the Quartus II Classic Timing Analyzer requires the **Virtual Clock Reference** assignment to indicate that a clock setting is for a virtual clock. To create a virtual clock in the Quartus II TimeQuest Timing Analyzer, use the **create_clock** or **create_generated_clock** commands with the `-name` option and no targets.

Figure 9–23 shows a simple circuit that requires a virtual clock, and the following example shows how to constrain the circuit. The circuit shows data transfer between an Altera FPGA and another device, and the clocks for the two devices are not related. You can constrain the path with an output delay assignment, but that assignment requires a virtual clock that defines the clock characteristics of the destination device.

Figure 9–23. Virtual Clock Sample Circuit



Assume the circuit has the following assignments in the Quartus II Classic Timing Analyzer:

- Clock period of 10 ns on `system_clk` (clock for the Altera FPGA)
- Clock period of 8 ns on `virt_clk` (clock for the other device)
- Virtual Clock Reference setting for `virt_clk` is on (indicates that `virt_clk` is a virtual clock)
- Output Maximum Delay of 5 ns on `dataout` with respect to `virt_clk` (constrains the path between the two devices)

The SDC commands shown in Example 9–9 constrain the circuit the same way.

Example 9–9. SDC Constraints

```
# Clock for the Altera FPGA
create_clock -period 10 -name system_clk [get_ports system_clk]
# Virtual clock for the other device, with no targets
create_clock -period 8 -name virt_clk
# Constrains the path between the two devices
set_output_delay -clock virt_clk 5 [get_ports dataout]
```

Clock Settings

The Quartus II Classic Timing Analyzer includes a variety of assignments to describe clock settings. These include duty cycle, f_{MAX}, offset, and others. In the Quartus II TimeQuest Timing Analyzer, use the **create_clock** and **create_generated_clock** commands to constrain clocks.

Multicycle

Table 9–3 shows the equivalent SDC exceptions for each of these Quartus II Classic Timing Analyzer timing assignments.

Table 9–3. Quartus II Classic and SDC Equivalent Exceptions

Quartus II Classic Timing Assignment		SDC Exception
Assignment Name	**QSF Variable**	
Multicycle *(1)*	MULTICYCLE	set_multicycle_path -setup -end
Source Multicycle *(2)*	SRC_MULTICYCLE	set_multicycle_path -setup -start
Multicycle Hold *(3)*	HOLD_MULTICYCLE	set_multicycle_path -hold -end
Source Multicycle Hold	SRC_HOLD_MULTICYCLE	set_multicycle_path -hold -start

Notes to Table 9–3:

(1) A multicycle assignment is also known as a “destination multicycle setup” assignment.

(2) A source multicycle assignment is also known as a “source multicycle setup” assignment.

(3) A multicycle hold is also known as a “destination multicycle hold “assignment.

The default value and numbering scheme for the hold multicycle value is different in the Quartus II Classic and Quartus II TimeQuest Timing Analyzers. Refer to “Hold Multicycle” on page 9–20 for more information about the difference between the default value and numbering scheme for the hold multicycle value in the Quartus II Classic and Quartus II TimeQuest Timing Analyzers.

For more information about how to convert the hold multicycle value, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Clock Enable Multicycle

The Quartus II Classic Timing Analyzer supports the following clock enable multicycle assignments. Corresponding types of multicycle assignments are applied to all registers enabled by the targets of the specified clock.

- Clock Enable Multicycle
- Clock Enable Source Multicycle

- Clock Enable Multicycle Hold
- Clock Enable Source Multicycle Hold

The Quartus II TimeQuest Timing Analyzer supports clock-enabled multicycle constraints with the **get_fanouts** command. Use the **get_fanouts** command to create a collection of nodes that have a common source signal, such as a clock enable.

I/O Constraints

FPGA I/O timing assignments have typically been made with FPGA-centric t_{SU} and t_{CO} requirements for the Quartus II Classic Timing Analyzer. However, the Quartus II Classic Timing Analyzer also supports input and output delay assignments to accommodate industry-standard, system-centric timing constraints. Where possible, you should use system-centric constraints to constrain your designs for the Quartus II TimeQuest Timing Analyzer. Table 9–4 includes Quartus II Classic I/O assignments, the equivalent FPGA-centric SDC constraints, and recommended system-centric SDC constraints.

For setup checks (t_{SU} and t_{CO}), <*latch – launch*> equals the clock period for same-clock transfers. For hold checks (t_H and Minimum t_{CO}), <*latch – launch*> equals 0 for same-clock transfers. Conversions from Quartus II Classic assignments to `set_input_delay` and `set_output_delay` constraints work well only when the source and destination registers' clocks are the same (same clock and polarity). If the source and destination registers' clocks are different, the conversion may not be straightforward and you should take extra care when converting to `set_input_delay` and `set_output_delay` constraints.

Table 9–4. Quartus II Classic and Quartus II TimeQuest Timing Analyzers Equivalent I/O Constraints

Classic	FPGA-centric SDC	System-centric SDC
t_{SU} Requirement	set_max_delay <*t_{SU} requirement*>	set_input_delay -max <*latch – launch – t_{SU} requirement*>
t_H Requirement	set_min_delay – <*t_H requirement*> *(1)*	set_input_delay -min <*latch – launch + t_H requirement*>
t_{CO} Requirement	set_max_delay <*t_{CO} requirement*>	set_output_delay -max <*latch – launch – t_{CO} requirement*>
Minimum t_{CO} Requirement	set_min_delay <*minimum t_{CO} requirement*>	set_output_delay -min <*latch – launch – minimum t_{CO} requirement*>
t_{PD} Requirement	set_max_delay <*t_{PD} requirement*>	*(2)*
Minimum t_{PD} Requirement	set_min_delay <*minimum t_{PD} requirement*>	*(2)*

Notes to Table 9–4:

(1) Refer to "t_H Requirement" on page 9–34 for an explanation about why this exception uses the negative t_H requirement.

(2) The input and output delays can be used for t_{PD} paths, such that they will be analyzed as a system f_{MAX} path. This is a feature unique to the Quartus II TimeQuest Timing Analyzer.

Input and Output Delay

Table 9–5 shows the equivalent SDC exceptions for each of these Quartus II Classic Timing Analyzer timing assignments.

Table 9–5. Quartus II Classic and SDC Equivalent Exceptions

Quartus II Classic Timing Assignment		SDC Exception
Assignment Name	**QSF Variable**	
Input Maximum Delay	INPUT_MAX_DELAY	set_input_delay -max
Input Minimum Delay	INPUT_MIN_DELAY	set_input_delay -min
Output Maximum Delay	OUTPUT_MAX_DELAY	set_output_delay -max
Output Minimum Delay	OUTPUT_MIN_DELAY	set_output_delay -min

In some circumstances, you may receive the following warning message when you update the SDC netlist:

```
Warning: For set_input_delay/set_output_delay, port "<port>" does not
have delay for flag (<rise|fall>, <min|max>)
```

This warning occurs whenever port constraints have maximum or minimum delay assignments, but not both. In the Quartus II Classic Timing Analyzer, device inputs can have **Input Maximum Delay** assignments, **Input Minimum Delay** assignments, or both, and device outputs can have **Output Maximum Delay** assignments, **Output Minimum Delay** assignments, or both.

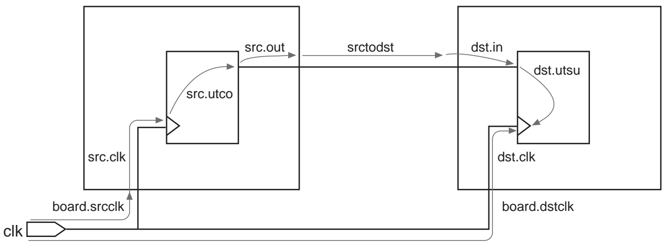
To avoid receiving the warning, your **.sdc** file must specify both the `-max` and `-min` options for each port, or specify neither. If a device I/O in your design includes both the maximum and minimum delay assignments in the Quartus II Classic Timing Analyzer, the conversion utility converts both, and no warning appears about that device I/O. If a device I/O has only maximum or minimum delay assignments in the Quartus II Classic Timing Analyzer, you have the following options:

- Add the missing minimum or maximum delay assignment to the device I/O before performing the conversion.
- Modify the SDC constraint after the conversion to add appropriate `-max` or `-min` values.
- Modify the SDC constraint to remove the `-max` or `-min` option so the value is used for both by default.

t_{SU} Requirement

The **t_{SU} Requirement** assignment specifies the maximum acceptable clock setup time for the input (data) pin. The QSF variable for the **t_{SU} Requirement** assignment is TSU_REQUIREMENT. You can convert the **t_{SU} Requirement** assignment to the **set_max_delay** command or the **set_input_delay** command with the `-max` option. The delay value for the **set_input_delay** command is <*latch – launch – t_{SU} requirement*>. Refer to the labeled paths in Figure 9–24 to understand the names in Equation 9–3 and Equation 9–4.

Figure 9–24. Path Names



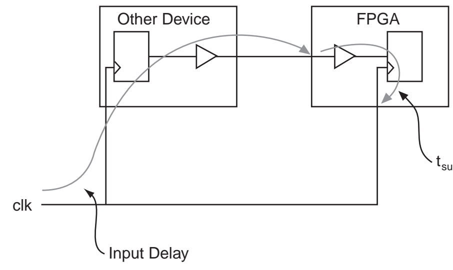
Equation 9–3 shows the derivation of this conversion.

Equation 9–3.

$$\text{required} - \text{arrival} > 0$$
$$\text{required} = \text{latch} + \text{board.dstclk} + \text{dst.clk} - \text{dst.utsu}$$
$$\text{arrival} = \text{launch} + \text{board.srcclk} + \text{src.clk} + \text{src.utco} + \text{src.out} + \text{srctodst} + \text{dst.in}$$
$$\text{input_delay} = \text{board.srcclk} + \text{src.clk} + \text{src.utcu} + \text{src.out} + \text{srctodst} - \text{board.dstclk}$$
$$\text{required} = \text{latch} + \text{dst.clk} - \text{dst.utsu}$$
$$\text{arrival} = \text{launch} + \text{input_delay} + \text{dst.in}$$
$$(\text{latch} + \text{dst.clk} - \text{dst.utsu}) - (\text{launch} + \text{input_delay} + \text{dst.in}) > 0$$
$$t_{su}\,\text{requirement} - \text{actual}\ t_{su} > 0$$
$$\text{actual}\ t_{su} = \text{dst.in} + \text{dst.utsu} - \text{dst.clk}$$
$$t_{su}\,\text{requirement} - (\text{dst.in} + \text{dst.utsu} - \text{dst.clk}) > 0$$
$$t_{su}\,\text{requirement} = \text{latch} - \text{launch} - \text{input_delay}$$
$$\text{input_delay} = \text{latch} - \text{launch} - t_{su}\,\text{requirement}$$

The delay value is the difference between the period of the clock source of the register and the t_{SU} **Requirement** value, as shown in Figure 9–25.

Figure 9–25. t_{SU} Requirement



The delay value for the **set_max_delay** command is the t_{SU} **Requirement** value. Equation 9–4 shows the derivation of this conversion.

Equation 9–4.

$$\text{required} - \text{arrival} > 0$$
$$\text{required} = \text{latch} + \text{board.dstclk} + \text{dst.clk} - \text{dst.utsu}$$
$$\text{arrival} = \text{launch} + \text{board.srcclk} + \text{src.clk} + \text{src.utco} + \text{src.out} + \text{srctodst} + \text{dst.in}$$
$$\text{max_delay} = \text{latch} + \text{board.dstclk} + - \text{launch} - \text{board.srcclk} - \text{src.clk} - \text{src.out} - \text{srctodst}$$
$$\text{required} = \text{max_delay} + \text{dst.clk} - \text{dst.utsu}$$
$$\text{arrival} = \text{dst.in}$$
$$(\text{max_delay} + \text{dst.clk} - \text{dst.utsu}) - (\text{dst.in}) > 0$$
$$t_{su}\ \text{requirement} - t_{su} > 0$$
$$\text{actual}\ t_{su} = \text{dst.in} + \text{dst.utsu} - \text{dst.clk}$$
$$t_{su}\ \text{requirement} - (\text{dst.in} + \text{dst.utsu} - \text{dst.clk}) > 0$$
$$\text{set_max_delay} = t_{su}\ \text{requirement}$$

Table 9–6 shows the different ways you can make t_{SU} assignments in the Quartus II Classic Timing Analyzer, and the corresponding options for the **set_max_delay** exception.

Table 9–6. t_{SU} Requirement and set_max_delay Equivalence

t_{SU} Requirement Options	set_max_delay Options
-to <*pin*>	-from [get_ports <*pin*>] -to [get_registers *]
-to <*clock*>	-from [get_ports *] -to [get_clocks <*clock*>]
-to <*register*>	-from [get_ports *] -to [get_registers <*register*>]
-from <*pin*> -to <*register*>	-from [get_ports <*pin*>] -to [get_registers <*register*>]
-from <*clock*> -to <*pin*>	-from [get_ports <*pin*>] -to [get_clocks <*clock*>] *(1)*

Notes to Table 9–6:

(1) If the pin in this assignment feeds registers clocked by the same clock, it is equivalent to the first option, `-to` <*pin*>. If the pin feeds registers clocked by different clocks, use **set_input_delay** to constrain the paths properly.

To convert a global t_{SU} assignment to an equivalent SDC exception, use the command shown in Example 9–10.

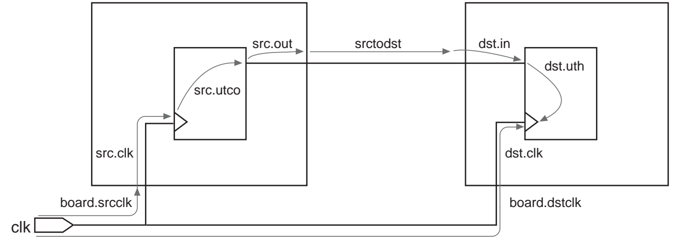
Example 9–10. Converting a Global t_{SU} Assignment to an Equivalent SDC Exception

```
set_max_delay -from [all_inputs] -to [all_registers] <tSU value>
```

t_H Requirement

The **t_H Requirement** specifies the maximum acceptable clock hold time for the input (data) pin. The QSF variable for the **t_H Requirement** assignment is TH_REQUIREMENT. You can convert the **t_H Requirement** assignment to the **set_min_delay** command, or the **set_input_delay** command with the `-min` option. The delay value for the **set_input_delay** command is <*latch – launch + t_H requirement*>. Refer to the labeled paths in Figure 9–26 to understand the names in Equation 9–5 and Equation 9–6.

Figure 9–26. Path Names



Equation 9–5 shows the derivation of this calculation.

Equation 9–5.

$$\text{arrival} - \text{required} > 0$$
$$\text{arrival} = \text{launch} + \text{board.srcclk} + \text{src.clk} + \text{src.utco} + \text{src.out} + \text{srctodst} + \text{dst.in}$$
$$\text{required} = \text{latch} + \text{board.dstclk} + \text{dst.clk} + \text{dst.uth}$$
$$\text{input_delay} = \text{board.srcclk} + \text{src.clk} + \text{srcutcu} + \text{src.out} + \text{srctodst} - \text{board.dstclk}$$
$$\text{arrival} = \text{launch} + \text{input_delay} + \text{dst.in}$$
$$\text{required} = \text{latch} + \text{dst.clk} + \text{dst.uth}$$
$$(\text{launch} + \text{input_delay} + \text{dst.in}) - (\text{latch} + \text{dst.clk} + \text{dst.uth}) > 0$$
$$t_H \text{ requirement} - \text{actual } t_H > 0$$
$$\text{actual } t_H = \text{dst.clk} + \text{dst.uth} - \text{dst.in}$$
$$t_H \text{ requirement} - (\text{dst.clk} + \text{dst.uth} - \text{dst.in}) > 0$$
$$t_H \text{ requirement} = \text{launch} - \text{latch} + \text{input_delay}$$
$$\text{input_delay} = \text{latch} - \text{launch} + t_H \text{ requirement}$$

The delay value for the **set_min_delay** command is the $\mathbf{t_H}$ **Requirement** value. Equation 9–6 shows the derivation of this conversion.

Equation 9–6.

$$\text{arrival} - \text{required} > 0$$
$$\text{arrival} = \text{dst.in}$$
$$\text{required} = \text{min_delay} + \text{dst.clk} + \text{dst.uth}$$
$$\text{dst.in} - (\text{min_delay} + \text{dst.clk} + \text{dst.uth})$$
$$t_H \text{ requirement} - \text{actual } t_H > 0$$
$$\text{actual } t_H = \text{dst.clk} + \text{dst.uth} - \text{dst.in}$$
$$t_H \text{ requirement} - (\text{dst.clk} + \text{dst.uth} - \text{dst.in}) > 0$$
$$\text{set_min_delay} = -t_H \text{ requirement}$$

Table 9–7 shows the different ways you can make t_H assignments in the Quartus II Classic Timing Analyzer, and the corresponding options for the **set_min_delay** command.

Table 9–7. t_H Requirement and set_min_delay Equivalence

t_H Requirement Options	set_min_delay Options
-to <*pin*>	-from [get_ports <*pin*>] -to [get_registers *]
-to <*clock*>	-from [get_ports *] -to [get_clocks <*clock*>]
-to <*register*>	-from [get_ports *] -to [get_registers <*register*>]
-from <*pin*> -to <*register*>	-from [get_ports <*pin*>] -to [get_registers <*register*>]
-from <*clock*> -to <*pin*>	-from [get_ports <*pin*>] -to [get_clocks <*clock*>] *(1)*

Note to Table 9–7:

(1) If the pin in this assignment feeds registers clocked by the same clock, it is equivalent to the first option, `-to` <*pin*>. If the pin feeds registers clocked by different clocks, use **set_input_delay** to constrain the paths properly. Refer to "Input and Output Delay" on page 9–31 for additional information.

To convert a global t_H assignment to an equivalent SDC exception, use the command shown in Example 9–11.

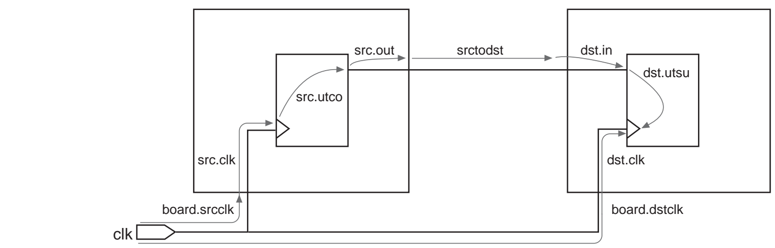
Example 9–11. Converting a Global t_H Assignment to an Equivalent SDC Exception

```
set_min_delay -from [all_inputs] -to [all registers] <negative tH value>
```

t_{CO} Requirement

The **t_{CO} Requirement** assignment specifies the maximum acceptable clock to output delay to the output pin. The QSF variable for the **t_{CO} Requirement** assignment is TCO_REQUIREMENT. You can convert the **t_{CO} Requirement** assignment to the **set_max_delay** command or the **set_output_delay** with the `-max` option. The delay value for the **set_output_delay** command is <*latch – launch + tCO requirement*>. Refer to the labeled paths in Figure 9–27 to understand the names in Equation 9–7 and Equation 9–8.

Figure 9–27. Path Names



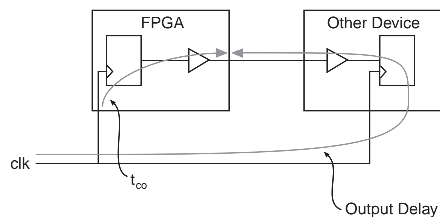
Equation 9–7 shows the derivation of this conversion.

Equation 9–7.

$$\text{required} - \text{arrival} > 0$$
$$\text{required} = \text{latch} - \text{output_delay}$$
$$\text{arrival} = \text{launch} + \text{src.clk} + \text{src.utco} + \text{src.out}$$
$$\text{output_delay} = \text{srctodst} + \text{dst.in} + \text{dst.utsu} - \text{dst.clk} - \text{board.dstc.k} + \text{board.srcclk}$$
$$(\text{latch} - \text{output_delay}) - (\text{launch} + \text{src.clk} + \text{src.utco} + \text{src.out}) > 0$$
$$t_{CO}\ \text{requirement} - \text{actual}\ t_{CO} > 0$$
$$\text{actual}\ t_{CO} = \text{launch} + \text{src.clk} + \text{src.utco} + \text{src.out}$$
$$t_{CO}\ \text{requirement} - (\text{src.clk} + \text{src.utco} + \text{src.out}) > 0$$
$$t_{CO}\ \text{requirement} = \text{latch} - \text{launch} - \text{output_delay}$$
$$\text{output_delay} = \text{latch} - \text{launch} - t_{CO}\ \text{requirement}$$

The delay value is the difference between the period of the clock source of the register and the t_{CO} **Requirement** value, as illustrated in Figure 9–28.

Figure 9–28. t_{CO} Requirement



The delay value for the **set_max_delay** command is the t_{CO} **Requirement** value. Equation 9–8 shows the derivation of this conversion.

Equation 9–8.

$$\text{required} - \text{arrival} > 0$$
$$\text{required} = \text{set_max_delay}$$
$$\text{arrival} = \text{src.clk} + \text{src.utco} + \text{src.out}$$
$$\text{set_max_delay} - (\text{src.clk} + \text{src.utco} + \text{src.out}) > 0$$
$$t_{CO}\ \text{requirement} - \text{actual}\ t_{CO} > 0$$
$$\text{actual}\ t_{CO} = \text{src.clk} + \text{src.utco} + \text{src.out}$$
$$t_{CO}\ \text{requirement} - (\text{src.clk} + \text{src.utco} + \text{src.out}) > 0$$
$$\text{set_max_delay} = t_{CO}\ \text{requirement}$$

Table 9–8 shows the different ways you can make t_{CO} assignments in the Quartus II Classic Timing Analyzer, and the corresponding options for the **set_max_delay** exception.

Table 9–8. t_{CO} Requirement and set_max_delay Equivalence

t_{CO} Requirement Options	set_max_delay Options
-to <*pin*>	-from [get_registers *] -to [get_ports <*pin*>]
-to <*clock*>	-from [get_clocks <*clock*>] -to [get_ports *]
-to <*register*>	-from [get_registers <*register*>] -to [get_ports *]
-from <*register*> -to <*pin*>	-from [get_registers <*register*>] -to [get_ports <*pin*>]
-from <*clock*> -to <*pin*>	-from [get_clocks <*clock*>] -to [get_ports <*pin*>] *(1)*

Note to Table 9–8:

(1) If the pin in this assignment feeds registers clocked by the same clock, it is equivalent to the first option, `-to` <*pin*>. If the pin feeds registers clocked by different clocks, you should use **set_output_delay** to constrain the paths properly.

To convert a global t_{CO} assignment to an equivalent SDC exception, use the command in Example 9–12.

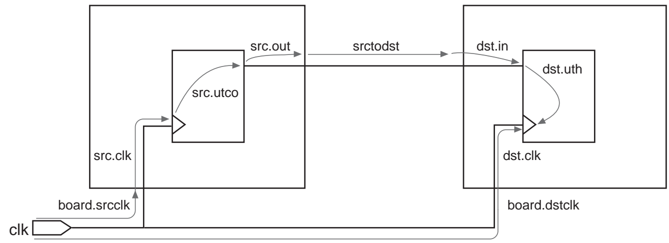
Example 9–12. Converting a Global t_{CO} Assignment to an Equivalent SDC Exception

```
set_max_delay -from [all registers] -to [all_outputs] <tCO value>
```

Minimum t_{CO} Requirement

The **Minimum t_{CO} Requirement** assignment specifies the minimum acceptable clock to output delay to the output pin. The QSF variable for the **Minimum t_{CO} Requirement** assignment is MIN_TCO_REQUIREMENT. You can convert the **Minimum t_{CO} Requirement** assignment to the **set_min_delay** command or the **set_output_delay** command with the `-min` option. The delay value for the **set_output_delay** command is <*latch – launch + minimum t_{CO} requirement*>. Refer to the labeled paths in Figure 9–29 to understand the names in Equation 9–9 and Equation 9–10.

Figure 9–29. Path Names



Equation 9–9 shows the derivation of this conversion.

Equation 9–9.

$$arrival + required > 0$$
$$arrival = launch + src.clk + src.utco + src.out$$
$$required = latch - output_delay$$
$$output_delay = srctodst + dst.in - dst.uth - dst.clk - board.dstclk + board.srcclk$$
$$(launch + src.clk + src.utco + src.out) - (latch - output_delay) > 0$$
$$minimum\ t_{co} - minimum\ t_{co} requirement > 0$$
$$minimum\ t_{co} = launch + src.clk + src.utco + src.out$$
$$(launch + src.clk + src.utco + src.out) - minimum\ t_{co}\ requirement > 0$$
$$minimum\ t_{co}\ requirement = latch - launch - output_delay$$
$$output_delay = latch - launch - minimum\ t_{co}\ requirement$$

The delay value for the **set_min_delay** command is the **Minimum t_{CO} Requirement**. Equation 9–10 shows the derivation of this conversion.

Equation 9–10.

$$arrival - required > 0$$
$$arrival = src.clk + src.utco + src.out$$
$$required = min_delay$$
$$(src.clk + src.utco + src.out) - (set_min_delay) > 0$$
$$minimum\ t_{co} - minimum\ t_{co}\ requirement > 0$$
$$minimum\ t_{co} = src.clk + src.utco + src.out$$
$$(src.clk + src.utco + src.out) - minimum\ t_{co} requirement > 0$$
$$set_min_delay = minimum\ t_{co}\ requirement$$

Table 9–9 shows the different ways you can make minimum t_{CO} assignments in the Quartus II Classic Timing Analyzer, and the corresponding options for the **set_min_delay** exception.

Table 9–9. Minimum t_{CO} Requirement and set_min_delay Equivalence

Minimum t_{co} Requirement Options	set_min_delay Options
-to <*pin*>	-from [get_registers *] -to [get_ports <*pin*>]
-to <*clock*>	-from [get_clocks <*clock*>] -to [get_ports *]
-to <*register*>	-from [get_registers <*register*>] -to [get_ports *]
-from <*register*> -to <*pin*>	-from [get_registers <*register*>] -to [get_ports <*pin*>]
-from <*clock*> -to <*pin*>	-from [get_clocks <*clock*>] -to [get_ports <*pin*>] *(1)*

Note to Table 9–9:

(1) If the pin in this assignment feeds registers clocked by the same clock, it is equivalent to the first option, `-to <pin>`. If the pin feeds registers clocked by different clocks, use **set_output_delay** to constrain the paths properly.

To convert a global **Minimum t_{CO} Requirement** to an equivalent SDC exception, use the command shown in Example 9–13.

Example 9–13. Converting a Global Minimum t_{CO} Requirement to an Equivalent SDC Exception

```
set_min_delay -from [all_registers] -to [all_outputs] <minimum tCO value>
```

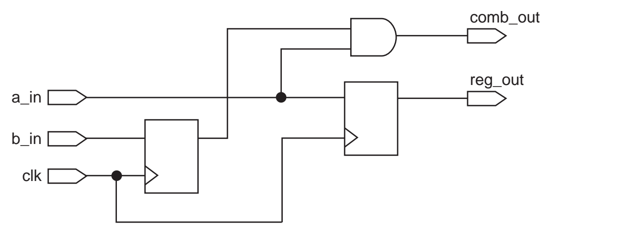
t_{PD} Requirement

The **t_{PD} Requirement** assignment specifies the maximum acceptable input to non-registered output delay, that is, the time required for a signal from an input pin to propagate through combinational logic and appear at an output pin. The QSF variable for the **t_{PD} Requirement** assignment is TPD_REQUIREMENT. You can use the **set_max_delay** command in the Quartus II TimeQuest Timing Analyzer as an equivalent constraint as long as you account for input and output delays. The **t_{PD} Requirement** assignment does not take into account input and output delays, but the **set_max_delay** exception does, so you must modify the **set_max_delay** value to take into account input and output delays.

Combinational Path Delay Scenario

Figure 9–30 shows a simple circuit followed by an example of a **t_{PD} Requirement** to **set_max_delay** conversion.

Figure 9–30. t_{PD} Example



Assume the circuit has the following assignments in the Quartus II Classic Timing Analyzer:

- Clock period of 10 ns
- **t_{PD} Requirement** from `a_in` to `comb_out` of 10 ns
- **Input Max Delay** on `a_in` relative to `clk` of 2 ns
- **Output Max Delay** on `comb_out` relative to `clk` of 2 ns

The path from `a_in` to `comb_out` is not affected by the input and output delays. The slack is equal to the <*t_{PD} Requirement from* `a_in` *to* `comb_out`> – <*path delay from* `a_in` *to* `comb_out`>.

Assume the circuit has the SDC constraints shown in Example 9–14 in the Quartus II TimeQuest Timing Analyzer.

Example 9–14. SDC Constraints

```
create_clock -period 10 -name clk [get_ports clk]
set_max_delay -from a_in -to comb_out 10
set_input_delay -clk clk 2 [get_ports a_in]
set_output_delay -clk clk 2 [get_ports comb_out]
```

The path from `a_in` to `comb_out` is affected by the input and output delays. The slack is equal to:

```
<set_max_delay value from a_in to comb_out>    <input delay>    <output delay>    <path delay from a_in to comb_out>
```

To convert a global **t_{PD} Requirement** assignment to an equivalent SDC exception, use the command shown in Example 9–15. You should add the input and output delays to the value of your converted **t_{PD} Requirement** (**set_max_delay** exception value) to achieve an equivalent SDC exception.

Example 9–15. Converting a Global t_{PD} Requirement Assignment to an Equivalent SDC Exception

```
set_max_delay -from [all_inputs] -to [all_outputs] <value>
```

Minimum t_{PD} Requirement

The **Minimum t_{PD} Requirement** assignment specifies the minimum acceptable input to non-registered output delay, that is, the minimum time required for a signal from an input pin to propagate through combinational logic and appear at an output pin. The QSF variable for the **Minimum t_{PD} Requirement** assignment is MIN_TPD_REQUIREMENT. You can use the **set_min_delay** command in the Quartus II TimeQuest Timing Analyzer as an equivalent constraint as long as you account for input and output delays. The **Minimum t_{PD} Requirement** assignment does not take into account input and output delays, but the **set_min_delay** exception does.

Refer to "Combinational Path Delay Scenario" on page 9–40 to see how input and output delays affect minimum and maximum delay exceptions.

To convert a global **Minimum t_{PD} Requirement** assignment to an equivalent SDC exception, use the command shown in Example 9–16.

Example 9–16. Converting a Global Minimum t_{PD} Requirement Assignment to an Equivalent SDC Exception

```
set_min_delay -from [all_inputs] -to [all_outputs] <value>
```

Cut Timing Path

The **Cut Timing Path** assignment in the Quartus II Classic Timing Analyzer is equivalent to the **set_false_path** command in the Quartus II TimeQuest Timing Analyzer. The QSF variable for the **Cut Timing Path** assignment is CUT.

Maximum Delay

The **Maximum Delay** assignment specifies the maximum required delay for the following types of paths:

- Pins to registers
- Registers to registers
- Registers to pins

The QSF variable for the **Maximum Delay** assignment is MAX_DELAY. This overwrites the requirement computed from the clock setup relationship and clock skew. There is no equivalent constraint in the Quartus II TimeQuest Timing Analyzer.

The **Maximum Delay** assignment for the Quartus II Classic Timing Analyzer is not related to the **set_max_delay** exception in the Quartus II TimeQuest Timing Analyzer.

Minimum Delay

The **Minimum Delay** assignment specifies the minimum required delay for the following types of paths:

- Pins to registers
- Registers to registers
- Registers to pins

The QSF variable for the **Minimum Delay** assignment is MIN_DELAY. This overwrites the requirement computed from the clock hold relationship and clock skew. There is no equivalent constraint in the Quartus II TimeQuest Timing Analyzer.

The **Minimum Delay** assignment for the Quartus II Classic Timing Analyzer is not related to the **set_min_delay** exception in the Quartus II TimeQuest Timing Analyzer.

Maximum Clock Arrival Skew

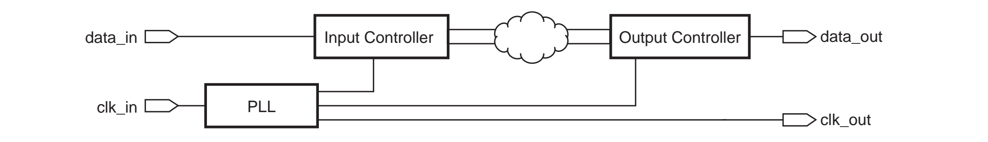
The **Maximum Clock Arrival Skew** assignment specifies the maximum clock skew between a set of registers. The QSF variable for the **Maximum Clock Arrival Skew** assignment is MAX_CLOCK_ARRIVAL_SKEW. In the Quartus II Classic Timing Analyzer, this assignment is specified between a clock node name and a set of registers. **Maximum Clock Arrival Skew** is not supported in the Quartus II TimeQuest Timing Analyzer.

Maximum Data Arrival Skew

The **Maximum Data Arrival Skew** assignment specifies the maximum data arrival skew between a set of registers, pins, or both. The QSF variable for the **Maximum Data Arrival Skew** assignment is MAX_DATA_ARRIVAL_SKEW. In this case, the data arrival delay represents the t_{CO} from the clock to the given register, pin, or both. This assignment is specified between a clock node and a set of registers, pins, or both.

The Quartus II TimeQuest Timing Analyzer does not support a constraint to specify maximum data arrival skew, but you can specify setup and hold times relative to a clock port to constrain an interface like this. Figure 9–31 shows a simplified source-synchronous interface used in the following example.

Figure 9–31. Source-Synchronous Interface Diagram

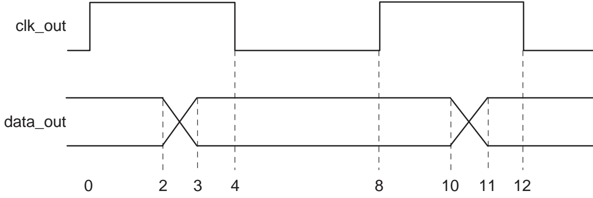


Constraining Skew on an Output Bus

This example constrains the interface so that all bits of the `data_out` bus go off-chip between 2 and 3 ns after the `clk_out` signal. Assume that `clock_in` and `clock_out` have a period of 8 ns.

The following equations and example show how to create timing requirements that satisfy the timing relationships shown in Figure 9–32.

Figure 9–32. Source-Synchronous Timing Diagram



Equation 9–11 shows how to compute the value for the **set_output_delay** `-min` command that creates the 2 ns hold requirement on the destination. For hold requirement calculations in which source and destination clocks are the same, *<latch>* – *<launch>* = 0.

Equation 9–11.

$$\text{latch} - \text{launch} = 0\text{ns}$$
$$\text{output delay} = \text{latch} - \text{launch} - 2\text{ns}$$
$$\text{output delay} = -2\text{ns}$$

Equation 9–12 shows how to compute the value for the **set_output_delay** command that creates the 3 ns setup requirement on the destination. For setup requirement calculations in which source and destination clocks are the same, *<latch>* – *<launch>* = clock period.

Equation 9–12.

$$\text{latch} - \text{launch} = 8\text{ns}$$
$$\text{output delay} = \text{latch} - \text{launch} - 3\text{ns}$$
$$\text{output delay} = 5\text{ns}$$

Refer to "I/O Constraints" on page 9–31 for an explanation of the above equations.

Example 9–17 shows the three constraints together.

Example 9–17. Constraining a DDR Interface

```
set period 8.000
create_clock -period $period \
             -name clock_in \
             clock_in
derive_pll_clocks
set_output_delay -add_delay \
    -clock ddr_pll_1_inst|altpll_component|pll|CLK[0] \
    -reference_pin clk_out \
    -min -2.000 \
    [get_ports data_out*]
set_output_delay -add_delay \
    -clock ddr_pll_1_inst|altpll_component|pll|CLK[0] \
    -reference_pin clk_out \
    -max [expr $period - 3.000] \
    [get_ports data_out*]
```

Conversion Utility

The Quartus II TimeQuest Timing Analyzer includes a conversion utility to help you convert Quartus II Classic timing assignments in a **.qsf** file to SDC constraints in an **.sdc** file. The utility can use information from your project report database (in the **\db** folder), if it exists, so you should compile your design before the conversion.

The conversion utility ignores all disabled QSF assignments. Disabled assignments show **No** in the **Enabled?** column of the Assignment Editor, and include the `-disable` option in the **.qsf** file.

Refer to "Conversion Utility" on page 9–3 to learn how to run the conversion utility.

Unsupported Global Assignments

The conversion utility checks whether any of the global timing assignments in Table 9–10 exist in your project. Any global assignments not supported by the conversion utility are ignored during the conversion. Refer to the indicated page for information about each assignment, and how to manually convert these global assignments to SDC commands.

Table 9–10. Global Timing Assignments

Assignment Name	QSF Variable	More Information
t_{SU} Requirement	TSU_REQUIREMENT	page 9–32
t_{H} Requirement	TH_REQUIREMENT	page 9–34
t_{CO} Requirement	TCO_REQUIREMENT	page 9–36
Minimum t_{CO} Requirement	MIN_TCO_REQUIREMENT	page 9–38
t_{PD} Requirement	TPD_REQUIREMENT	page 9–40
Minimum t_{PD} Requirement	MIN_TPD_REQUIREMENT	page 9–41

Recommended Global Assignments

When any unsupported assignments have been identified, the conversion utility checks the global assignments in Table 9–11 to ensure they match the specified values.

Table 9–11. Recommended Global Assignments

Quartus II Classic Assignment Name	QSF Variable	Value
Cut off clear and preset signal paths	CUT_OFF_CLEAR_AND_PRESET_PATHS	ON
Cut off feedback from I/O pins	CUT_OFF_IO_PIN_FEEDBACK	ON
Cut off read during write signal paths	CUT_OFF_READ_DURING_WRITE_PATHS	ON
Analyze latches as synchronous elements	ANALYZE_LATCHES_AS_SYNCHRONOUS_ELEMENTS	ON
Enable Clock Latency	ENABLE_CLOCK_LATENCY	ON
Display Entity Name	PROJECT_SHOW_ENTITY_NAME	ON

The following assignments are checked to ensure the functionality of the Quartus II Classic Timing Analyzer with the specified values corresponds to the behavior of the Quartus II TimeQuest Timing Analyzer.

- **Cut off clear and preset signal paths**— The Quartus II TimeQuest Timing Analyzer does not support this functionality. You should use Recovery and Removal analysis instead to analyze register control paths. The Quartus II Classic Timing Analyzer does not support this option.
- **Cut off feedback from I/O pins**—The Quartus II TimeQuest Timing Analyzer does not match the functionality of the Quartus II Classic Timing Analyzer when this assignment is OFF.
- **Cut off read during write signal paths**—The Quartus II TimeQuest Timing Analyzer does not match the functionality of the Quartus II Classic Timing Analyzer when this assignment is OFF.
- **Analyze latches as synchronous elements**—The Quartus II TimeQuest Timing Analyzer analyzes latches as synchronous elements by default and does not match the functionality of the Quartus II Classic Timing Analyzer when this assignment is OFF. Beginning with version 5.1 of the Quartus II software, the Quartus II Classic Timing Analyzer analyzes latches as synchronous elements by default.
- **Enable Clock Latency**—The Quartus II TimeQuest Timing Analyzer includes clock latency in its calculations. The Quartus II TimeQuest Timing Analyzer does not match the functionality of the Quartus II Classic Timing Analyzer when this assignment is OFF. Latency on a clock can be viewed as a simple delay on the clock path, and affects clock skew. This is in contrast to an offset, which alters the setup and hold relationship between two clocks. Refer to "Offset and Latency Example" on page 9–13 for an example of the different effects of offset and latency. When you turn on **Enable Clock Latency** in the Quartus II Classic Timing Analyzer, it affects the following aspects of timing analysis:
  - **Early Clock Latency** and **Late Clock Latency** assignments are honored
  - The compensation delay of a PLL is analyzed as latency
  - For clock settings where you do not specify an offset, the automatically computed offset is treated as latency.

- **Display Entity Name**—Any entity-specific assignments are ignored in the Quartus II TimeQuest Timing Analyzer because they do not include the entity name when this option is ON.

If your design meets timing requirements in the Quartus II Classic Timing Analyzer without all of the settings recommended in Table 9–11 on page 9–45, you should perform one of the following actions:

- Change the settings and re-constrain and re-verify as necessary.
  or
- Add or modify SDC constraints as appropriate because analysis in the Quartus II TimeQuest Timing Analyzer may be different after conversion.

Clock Conversion

Next, the conversion utility adds the **derive_pll_clocks** command to the **.sdc** file. This command creates generated clocks on all PLL outputs in your design each time the **.sdc** file is read. The command does not add a clock on the FPGA port that drives the PLL input.

The conversion utility includes the **derive_pll_clocks -use_tan_name** command in the **.sdc** file it creates. The `-use_tan_name` option overrides the default clock naming behavior (the PLL pin name) so the clock name is the same as the net name in the Quartus II Classic Timing Analyzer.

Including the `-use_tan_name` option ensures that the conversion utility converts clock-to-clock exceptions properly. If you remove the `-use_tan_name` option, you must also edit references to the clock names in other SDC commands so they match the PLL pin names.

If your design includes a global f_{MAX} assignment, the assignment is converted to a **derive_clocks** command. The behavior of a global f_{MAX} assignment is different from the behavior of clocks created with the **derive_clocks** command, and you should use the **report_clocks** command when you review conversion results to evaluate the clock settings. Refer to "Automatic Clock Detection" on page 9–16 for an explanation of the differences. As soon as you know the appropriate clock settings, you should use the **create_clock** or **create_generated_clock** command instead of the **derive_clocks** command.

The conversion utility adds a **post_message** command before the **derive_clocks** command to remind you that the clocks are derived automatically. The Quartus II TimeQuest Timing Analyzer displays the reminder the first time it reads the **.sdc** file. Remove or comment out the **post_message** command to prevent the message from displaying.

Next, the conversion utility identifies and converts clock settings in the **.qsf** file. If a project database exists, the utility also identifies and converts any additional clocks in the report file that are not in the **.qsf**, such as PLL base clocks.

If you change the PLL input frequency, you must modify the SDC constraint manually.

The conversion utility ignores clock offsets on generated clocks. Refer to "Clock Offset" on page 9–12 for information about how to use offset values in the Quartus II TimeQuest Timing Analyzer.

Instance Assignment Conversion

Next, the conversion utility converts the instance assignments shown in Table 9–12. Refer to the indicated page for information about each assignment.

Table 9–12. Instance Timing Assignments

Assignment Name	QSF Variable	More Information
Late Clock Latency	LATE_CLOCK_LATENCY	page 9–27
Early Clock Latency	EARLY_CLOCK_LATENCY	
Clock Setup Uncertainty	CLOCK_SETUP_UNCERTAINTY	page 9–28
Clock Hold Uncertainty	CLOCK_HOLD_UNCERTAINTY	
Multicycle *(1)*	MULTICYCLE	page 9–30
Source Multicycle *(2)*	SRC_MULTICYCLE	
Multicycle Hold *(3)*	HOLD_MULTICYCLE	
Source Multicycle Hold	SRC_HOLD_MULTICYCLE	
Clock Enable Multicycle	CLOCK_ENABLE_MULTICYCLE	page 9–30
Clock Enable Source Multicycle	CLOCK_ENABLE_SOURCE_MULTICYCLE	
Clock Enable Multicycle Hold	CLOCK_ENABLE_MULTICYCLE_HOLD	
Clock Enable Source Multicycle Hold	CLOCK_ENABLE_SOURCE_MULTICYCLE_HOLD	
Cut Timing Path	CUT	page 9–41
Input Maximum Delay	INPUT_MAX_DELAY	page 9–31
Input Minimum Delay	INPUT_MIN_DELAY	
Output Maximum Delay	OUTPUT_MAX_DELAY	
Output Minimum Delay	OUTPUT_MIN_DELAY	

Notes to Table 9–12:

(1) A multicycle assignment can also be known as a "destination multicycle setup" assignment.

(2) A source multicycle assignment can also be known as a "source multicycle setup" assignment.

(3) A multicycle hold can also be known as a "destination multicycle hold" assignment.

Depending on input and output delay assignments, you may receive a warning message when the **.sdc** file is read. The message warns that the **set_input_delay** command, **set_output_delay** command, or both are missing the `-max` option, `-min` option, or both. Refer to "Input and Output Delay" on page 9–31 for an explanation of why the warning occurs and how to avoid it.

Beginning in version 7.1 of the Quartus II software, the conversion utility automatically adds multicycle hold exceptions for each multicycle setup assignment. The value of each multicycle hold exception depends on the **Default hold multicycle** assignment value in your project. If the value is **One**, the conversion utility uses a value of 0 (zero) for each multicycle hold exception it adds. If the value is **Same as multicycle**, the conversion utility uses a value one less than the corresponding multicycle setup assignment value for each multicycle hold exception it adds. Refer to "Hold Multicycle" on page 9–20 for more information on hold multicycle differences between the Quartus II Classic and Quartus II TimeQuest Timing Analyzers.

Next, the conversion utility converts the instance assignments shown in Table 9–13. Refer to the indicated page for information about each assignment. If the t_{PD} and minimum t_{PD} assignment targets also have input or output delays that apply to them, the t_{PD} and minimum t_{PD} conversion values may be incorrect. This is described in more detail on the indicated pages for the appropriate assignments.

Table 9–13. Instance Timing Assignments

Assignment Name	QSF Variable	More Information
t_{PD} Requirement *(1)*	TPD_REQUIREMENT	page 9–40
Minimum t_{PD} Requirement *(1)*	MIN_TPD_REQUIREMENT	page 9–41
Setup Relationship	SETUP_RELATIONSHIP	page 9–27
Hold Relationship	HOLD_RELATIONSHIP	page 9–27

Note to Table 9–13:

(1) Refer to "t_{PD} and Minimum t_{PD} Requirement Conversion" on page 9–56 for more information about how the conversion utility converts single-point t_{PD} and minimum t_{PD} assignments.

The conversion utility converts Quartus II Classic I/O timing assignments to FPGA-centric SDC constraints. Table 9–14 includes Quartus II Classic assignments, the equivalent FPGA-centric SDC constraints, and recommended system-centric SDC constraints.

Table 9–14. Quartus II Classic and Quartus II TimeQuest Equivalent Constraints

Quartus II Classic	FPGA-Centric SDC	System-Centric SDC	More Information
t_{SU} Requirement *(1)*	set_max_delay	set_input_delay -max	page 9–32
t_H Requirement *(1)*	set_min_delay	set_input_delay -min	page 9–34
t_{CO} Requirement *(2)*	set_max_delay	set_output_delay -max	page 9–36
Minimum t_{CO} Requirement *(2)*	set_min_delay	set_output_delay -min	page 9–38

Notes to Table 9–14:

(1) Refer to "t_{PD} and Minimum t_{PD} Requirement Conversion" on page 9–56 for more information about how the conversion utility converts this type of assignment.

(2) Refer to "t_{CO} Requirement Conversion" on page 9–49 for more information about how the conversion utility converts this type of assignment.

The conversion utility can convert Quartus II Classic I/O timing assignments only to the FPGA-centric constraints without additional information about your design. Making system-centric constraints requires information about the external circuitry interfacing with the FPGA such as external clocks, clock latency, board delay, and clocking exceptions. You cannot convert Quartus II Classic timing assignments to system-centric constraints without that information. If you use the conversion utility, you can modify the SDC constraints to change the FPGA-centric constraints to system-centric constraints as appropriate.

PLL Phase Shift Conversion

The conversion utility does not account for PLL phase shifts when it converts values of the following FPGA-centric I/O timing assignments:

- **t_{SU} Requirement**
- **t_H Requirement**

- t_{CO} **Requirement**
- **Minimum** t_{CO} **Requirement**

If any of your paths go through PLLs with a phase shift, you must correct the converted values for those paths according to the following formula:

Equation 9–13.

$$\textit{<correct value>} = \textit{<converted value>} - \frac{(\textit{<pll output period>} \times \textit{<phase shift>})}{360}$$

Example 9–18 shows the incorrect conversion result for a t_{CO} assignment and how to correct it. For the example, assume the PLL output frequency is 200 MHz (period is 5 ns), the phase shift is 90 degrees, the t_{CO} **Requirement** value is 1 ns, and it is made to `data[0]`. The **.qsf** file contains the following assignment:

Example 9–18. Assignment

```
set_instance_assignment -name TCO_REQUIREMENT -to data[0] 1.0
```

The conversion utility generates the SDC command shown in Example 9–19.

Example 9–19. SDC Command

```
set_max_delay -from [get_registers *] -to [get_ports data[0]] 1.0
```

To correct the value, use the formula and values above, as shown in the following example:

$$1.0 - \frac{(5 \times 90)}{360} = -0.25$$

Then, change the value so the SDC command looks like Example 9–20.

Example 9–20. SDC Command with Correct Values

```
set_max_delay -from [get_registers *] -to [get_ports data[0]] -0.25
```

t_{CO} Requirement Conversion

The conversion utility uses a special process to convert t_{CO} **Requirement** and **Minimum** t_{CO} **Requirement** assignments. In addition to the **set_max_delay** or **set_min_delay** commands, the conversion utility adds a **set_output_delay** constraint relative to a virtual clock named N/C (Not a Clock). It also creates the virtual clock named N/C with a period of 10 ns. Adding the virtual clock allows you to report timing on the output paths. Without the virtual clock N/C, the clock used for reporting would be blank. Example 9–21 shows how the conversion utility converts a t_{CO} **Requirement** assignment of 5.0 ns to `data[0]`.

Example 9–21. Converting a t_{CO} Requirement Assignment of 5.0 ns to data[0]

```
set_max_delay -from [get_registers *] -to [get_ports data[0]]
set_output_delay -clock "N/C" 0 [get_ports data[0]]
```

Entity-Specific Assignments

Next, the conversion utility converts the entity-specific assignments listed in Table 9–15 that exist in the **Timing Analyzer Settings** report panel. This usually occurs if you have any timing assignments in your Verilog HDL or VHDL source, which can include MegaCore function files. These entity-specific assignments cannot be automatically converted unless your project is compiled and a **\db** directory exists.

Table 9–15. Entity-Specific Timing Assignments

Quartus II Classic	QSF Variable	More Information
Multicycle	MULTICYCLE	page 9–30
Source Multicycle	SRC_MULTICYCLE	
Multicycle Hold	HOLD_MULTICYCLE	
Source Multicycle Hold	SRC_HOLD_MULTICYCLE	
Setup Relationship	SETUP_RELATIONSHIP	page 9–27
Hold Relationship	HOLD_RELATIONSHIP	page 9–27
Cut Timing Path	CUT	page 9–41

You must manually convert all other entity-specific timing assignments.

Paths Between Unrelated Clock Domains

Beginning in version 7.1 of the Quartus II software, the conversion utility can create exceptions that cut paths between unrelated clock domains, which matches the default behavior of the Quartus II Classic Timing Analyzer. When **Cut paths between unrelated clock domains** is on, the conversion utility creates clock groups with the **set_clock_groups** command and uses the `-exclusive` option to cut paths between the clock groups.

Unsupported Instance Assignments

Finally, the conversion utility checks for the unsupported instance assignments listed in Table 9–16 and warns you if any exist. Refer to the indicated page for information about each assignment.

You can manually convert some of the assignments to SDC constraints.

Table 9–16. Instance Timing Assignments

Assignment Name	QSF Variable	More Information
Inverted Clock	INVERTED_CLOCK	page 9–28
Maximum Clock Arrival Skew	MAX_CLOCK_ARRIVAL_SKEW	page 9–42
Maximum Data Arrival Skew	MAX_DATA_ARRIVAL_SKEW	page 9–42
Maximum Delay	MAX_DELAY	page 9–41
Minimum Delay	MIN_DELAY	page 9–42
Virtual Clock Reference	VIRTUAL_CLOCK_REFERENCE	page 9–29

Reviewing Conversion Results

You must review the messages that are generated during the conversion process, and review the **.sdc** file for correctness and completeness. Warning and critical warning messages identify significant differences between the Quartus II Classic Timing Analyzer and Quartus II TimeQuest Timing Analyzer behaviors. In some cases, warning messages indicate that the conversion utility ignored assignments because it could not determine the intended functionality of your design. You must add to or modify the SDC constraints as necessary based on your knowledge of the design.

The conversion utility creates an **.sdc** file with the same name as your current revision, <*revision*>**.sdc**, and it overwrites any existing <*revision*>**.sdc** file. If you use the conversion utility to create an **.sdc** file, you should make additions or corrections in a separate **.sdc** file, or a copy of the **.sdc** file created by the conversion utility. That way, you can re-run the conversion utility later without overwriting your additions and changes. If you have constraints in multiple **.sdc** files, refer to“Constraint File Priority” on page 9–8 to learn how to add constraints to your project.

Warning Messages

The conversion utility may generate any of the following warning messages. Refer to the information provided for each warning message to learn what to do in that instance.

Ignored QSF Variable <*assignment*>

The conversion utility ignored the specified assignment. Determine whether an equivalent constraint is necessary and manually add one if appropriate. Refer to “Timing Assignment Conversion” on page 9–26 for information about conversions for all QSF timing assignments.

Global <*name*> = <*value*>

The conversion utility ignored the global assignment <*name*>. Manually add an equivalent constraint if appropriate. Refer to “Unsupported Global Assignments” on page 9–44 for information about conversions for these assignments.

QSF: Expected <*name*> to be set to <*expected value*> but it is set to <*actual value*>

The behavior of the Quartus II TimeQuest Timing Analyzer is closest to the Quartus II Classic Timing Analyzer when the value for the specified assignment is the expected value. Because the actual assignment value is not the expected value in your project, the Quartus II TimeQuest Timing Analyzer analysis may be different from the Quartus II Classic Timing Analyzer analysis. Refer to “Recommended Global Assignments” on page 9–45 for an explanation about the indicated QSF variable names.

QSF: Found Global Fmax Requirement. Translation will be done using derive_clocks

Your design includes a global f_{MAX} requirement, and the requirement is converted to the **derive_clocks** command. Refer to “Default Required f_{MAX} Assignment” on page 9–29 for information about how to convert to an SDC constraint.

TAN Report Database not found. HDL based assignments will not be migrated

You did not analyze your design with the Quartus II Classic Timing Analyzer before running the conversion utility. As a result, the conversion utility did not convert any timing assignments in your HDL source code to SDC constraints. If you have timing assignments in your HDL source code, you must find and convert them manually, or analyze your design with the Quartus II Classic Timing Analyzer and rerun the conversion utility.

Ignored Entity Assignment (Entity <entity>): *<variable>* = *<value>* -from *<from>* -to *<to>*

The conversion utility ignored the specified entity assignment because the utility cannot automatically convert the assignment. Table 9–15 on page 9–50 lists the entity-specific assignments the script can convert automatically.

Refer to "Timing Assignment Conversion" on page 9–26 for information about how to convert the entity assignment manually.

Ignoring OFFSET_FROM_BASE_CLOCK assignment for clock *<clock>*

In some cases, this assignment is used to work around a limitation in how the Quartus II Classic Timing Analyzer handles some forms of clock inversion. The conversion script ignores the assignment because it cannot determine whether the assignment is used as a workaround. Review your clock setting and add the assignment in your **.sdc** file if appropriate. Refer to "Clock Offset" on page 9–12 for more information about converting clock offset.

Clock *<clock>* has no FMAX_REQUIREMENT - No clock was generated

The conversion utility did not convert the clock named <*clock*> because it has no f_{MAX} requirement. You should add a clock constraint with an appropriate period to your **.sdc** file.

No Clock Settings defined in QSF file

If your **.qsf** file has no clock settings, ignore this message. You must add clock constraints in your **.sdc** file manually.

Clocks

Ensure that the conversion utility converted all clock assignments correctly. Run **report_clocks**, or double-click **Report Clocks** in the Tasks pane in the Quartus II TimeQuest Timing Analyzer GUI. Make sure that the right number of clocks is reported. If any clock constraints are missing, you must add them manually with the appropriate SDC commands (**create_clock** or **create_generated_clock**). Confirm that each option for each clock is correct.

The Quartus II TimeQuest Timing Analyzer can create more clocks, such as:

- `derive_clocks` selecting ripple clocks
- `derive_pll_clocks`, adding
  - Extra clocks for PLL switchover
  - Extra clocks for LVDS pulse-generated clocks (`~load_reg`)

Clock Transfers

After you confirm that all clock assignments are correct, run **report_clock_transfers**, or double-click **Report Clock Transfers** in the Tasks pane in the Quartus II TimeQuest Timing Analyzer GUI. The command generates a summary table with the number of paths between each clock domain. If the number of cross-clock domain paths seems high, remember that all clock domains are related in the Quartus II TimeQuest Timing Analyzer. You must cut unrelated clock domains. Refer to "Related and Unrelated Clocks" on page 9–11 for information about how to cut unrelated clock domains.

Path Details

If you have unexpected differences between the Quartus II Classic and Quartus II TimeQuest Timing Analyzers on some paths, follow these steps to identify the cause of the difference.

1. List the path in the Quartus II Classic Timing Analyzer.
2. Report timing on the path in the Quartus II TimeQuest Timing Analyzer.
3. Compare slack values.
4. Compare source and destination clocks.
5. Compare the launch/latch times in the Quartus II TimeQuest Timing Analyzer to the setup/hold relationship in the Quartus II Classic Timing Analyzer. The times are absolute in the Quartus II TimeQuest Timing Analyzer and relative in the Quartus II Classic Timing Analyzer.
6. Compare clock latency values.

Unconstrained Paths

Next, run `report_ucp`, or double-click **Report Unconstrained Paths** in the Tasks pane in the Quartus II TimeQuest Timing Analyzer GUI. This command generates a series of reports that detail any unconstrained paths in your design. If your design was completely constrained in the Quartus II Classic Timing Analyzer but there are unconstrained paths in the Quartus II TimeQuest Timing Analyzer, some assignments may not have been converted properly. Also, some of the assignments could be ambiguous. The Quartus II TimeQuest Timing Analyzer analyzes more paths than the Quartus II Classic Timing Analyzer does, so any unconstrained paths might be paths you could not constrain in the Quartus II Classic Timing Analyzer.

Bus Names

If your design includes Quartus II Classic Timing Analyzer timing assignments to buses, and the bus names do not include square brackets enclosing an asterisk, such as: `address[*]`, you should review the SDC constraints to ensure the conversion is correct. Refer to "Bus Name Format" on page 9–8 for more information.

Other

Review the notes listed in "Conversion Utility" on page 9–56.

Re-Running the Conversion Utility

You can force the conversion utility to run even if it can find an **.sdc** file according to the priority described in "Constraint File Priority" on page 9–8. Any method described in "Conversion Utility" on page 9–3 forces the conversion utility to run even if it can find an **.sdc** file.

Notes

This section describes notes for the Quartus II TimeQuest Timing Analyzer.

Output Pin Load Assignments

The Quartus II TimeQuest Timing Analyzer takes **Output Pin Load** values into account when it analyzes your design. If you change **Output Pin Load** assignments and do not recompile before you analyze timing, you must use the `-force_dat` option when you create the timing netlist. Type the following command at the Tcl console of the Quartus II TimeQuest Timing Analyzer:

```
create_timing_netlist -force_dat ↵
```

If you change **Output Pin Load** assignments and recompile before you analyze timing, do not use the `-force_dat` option when you create the timing netlist. You can create the timing netlist with the **create_timing_netlist** command, or with the **Create Timing Netlist** task in the Tasks pane.

Also note that the SDC `set_output_load` command is not supported, so you must make all output load assignments in the Quartus II Settings File (**.qsf**).

Constraint Target Types

In version 6.0 of the Quartus II software, the Quartus II TimeQuest Timing Analyzer did not support constraints between clocks and non-clocks. Beginning with version 6.1, the Quartus II TimeQuest Timing Analyzer supports mixed exception types; you can apply an exception of any clock/node combination.

DDR Constraints with the DDR Timing Wizard

The DDR Timing Wizard (DTW) creates an **.sdc** file that contains constraints for a DDR interface. You can use that **.sdc** file with the Quartus II TimeQuest Timing Analyzer to analyze only the DDR interface part of a design.

You should use the **.sdc** file created by DTW for constraining a DDR interface in the Quartus II TimeQuest Timing Analyzer. Additionally, your **.qsf** file should not contain timing assignments for the DDR interface if you plan to use the conversion utility to create an **.sdc** file. You should run the conversion utility before you use DTW, and you should choose not to apply assignments to the **.qsf** file.

However, if you used DTW and chose to apply assignments to a **.qsf** file, before you used the conversion utility, you should remove the DTW-generated QSF timing assignments and re-run the conversion utility. The conversion utility creates some incompatible SDC constraints from the DTW QSF assignments.

HardCopy Stratix Device Handoff

If you target the HardCopy device family, you should not use the Quartus II TimeQuest Timing Analyzer. The Quartus II TimeQuest Timing Analyzer is not supported for the HardCopy Stratix design process. The Quartus II TimeQuest Timing Analyzer supports HardCopy II series devices.

Unsupported SDC Features

Some SDC commands and features are not supported by the current version of the Quartus II TimeQuest Timing Analyzer. The following commands are included:

- The **get_designs** command, because the Quartus II software supports a single design, so this command is not necessary
- True latch analysis with time-borrowing feature; it can, however, convert latches to negative-edge-triggered registers
- The case analysis feature
- Loads, clock transitions, input transitions, and other features

Constraint Passing

The Quartus II software can read constraints generated by other EDA software, and write constraints to be read by other EDA software.

Other synthesis software can generate constraints that target the **.qsf** file. If you change timing constraints in synthesis software after creating an **.sdc** file for the Quartus II TimeQuest Timing Analyzer, you must update the SDC constraints. You can use the conversion utility, or update the **.sdc** file manually.

Optimization

Gate-level re-timing is not supported if you turn on the Quartus II TimeQuest Timing Analyzer as your default timing analyzer.

If you use physical synthesis with the Quartus II TimeQuest Timing Analyzer, the design may have lower performance.

Clock Network Delay Reporting

In the Quartus II software version 6.0, the Quartus II TimeQuest Timing Analyzer reports delay on the clock network as a single number, rather than node-to-node segments, as the Quartus II Classic Timing Analyzer does. Beginning with version 6.0 SP1, the TimeQuest Timing Analyzer reports delay on the clock network by node-to-node segments.

PowerPlay Power Analysis

You must perform the following steps to generate an **Early Power Estimator** output file when you use the Quartus II TimeQuest Timing Analyzer and your design targets one of the following device families:

- Cyclone
- Stratix
- HardCopy Stratix

To generate an **Early Power Estimator** output file for designs targeting those families, you must perform the following steps.

1. Turn off the Quartus II TimeQuest Timing Analyzer. Refer to "Set the Default Timing Analyzer" on page 9–4 to learn how to turn off the Quartus II TimeQuest Timing Analyzer.
2. Manually convert your Quartus II TimeQuest Timing Analyzer timing constraints in the **.sdc** file to Quartus II Classic Timing Analyzer timing assignments. You can use the Assignment Editor to enter your Quartus II Classic Timing Analyzer timing assignments in your **.qsf** file.
3. Perform Quartus II Classic timing analysis.
4. Generate an **Early Power Estimator** output file.
5. Turn on the Quartus II TimeQuest Timing Analyzer.

Project Management

If you use the **project_open** Tcl command in the Quartus II TimeQuest Timing Analyzer to open a project compiled with an earlier version of the Quartus II software, the Quartus II TimeQuest Timing Analyzer overwrites the compilation results (**\db** folder) without warning. Opening a project any other way results in a warning, and you can choose not to open the project.

Conversion Utility

This section describes the notes for the QSF assignment to SDC constraint conversion utility.

t_{PD} and Minimum t_{PD} Requirement Conversion

The conversion utility treats the targets of single-point t_{PD} and minimum t_{PD} assignments as device outputs. It does not correctly convert targets of single-point t_{PD} and minimum t_{PD} assignments that are device inputs. The following QSF assignment applies to an a device input named `d_in`:

```
set_intance_assignment -name TPD_REQUIREMENT -to d_in "3 ns"
```

The conversion utility creates the following SDC command, regardless of whether `d_in` is a device input or device output:

```
set_max_delay "3 ns" -from [get_ports *] -to [get_ports d_in]
```

You must update any incorrect SDC constraints manually.

Document Revision History

Table 9–17. Document Revision History

Date and Version	Changes Made	Summary of Changes
March 2009 v9.0.0	This was chapter 8 in version 8.1.	Updated for the Quartus II 9.0 software release.
November 2008 v8.1.0	Changed to 8-1/2 x 11 page size. No change to content.	Updated for the Quartus II 8.1 software release.
May 2008 v8.0.0	■ Updated to Quartus II software version 8.0 and date. ■ Added hyperlinks to referenced Altera documentation throughout the chapter.	—

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

10. Quartus II Classic Timing Analyzer

QII53004-9.0.0

Introduction

Static timing analysis is a method for analyzing, debugging, and validating the timing performance of a design. The classic timing analyzer analyzes the delay of every design path and analyzes all timing requirements to ensure correct circuit operation. Static timing analysis, used in conjunction with functional simulation, allows you to verify overall design operation.

For information about switching to the Quartus® II TimeQuest Timing Analyzer, refer to the *Switching to the Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

As part of the compilation flow, the Quartus II software automatically performs a static timing analysis so that you do not need to launch a separate timing analysis tool. The Quartus II Classic Timing Analyzer checks every path in the design against your timing constraints for timing violations and reports results in the Timing Analysis reports, giving you immediate access to the data.

This chapter assumes you have some Tcl expertise; Tcl commands are used throughout this chapter to describe alternative methods for making timing analysis assignments. Refer to "Timing Analysis Using the Quartus II GUI" on page 10–34 for GUI-equivalent timing constraints.

This chapter details the following aspects of timing analysis:

- "Timing Analysis Tool Setup" on page 10–2
- "Static Timing Analysis Overview" on page 10–2
- "Clock Settings" on page 10–7
- "Clock Types" on page 10–8
- "Clock Uncertainty" on page 10–10
- "Clock Latency" on page 10–11
- "Timing Exceptions" on page 10–13
- "I/O Analysis" on page 10–21
- "Asynchronous Paths" on page 10–24

Timing Analysis Tool Setup

The Quartus II software version 6.0 and above supports two static timing analysis tools namely, the classic timing analyzer and the Quartus II TimeQuest Timing Analyzer. Use the **Timing Analysis** option under the Settings menu to set the Timing Analyzer that is used in the compilation process.

Arria® GX is not supported by the Quartus II Classic Timing Analyzer. To perform a static timing analysis for Arria GX, the Quartus II TimeQuest Timing Analyzer must be enabled.

The following steps set the classic timing analyzer as the default timing analysis tool in the Quartus II software.

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, click the "+" icon to expand **Timing Analysis Settings** and select the **Use Classic Timing Analyzer during compilation** radio button.

Refer to the *Quartus II TimeQuest Timing Analyzer* chapter of the *Quartus II Handbook* for more information about the Quartus II TimeQuest Timing Analyzer.

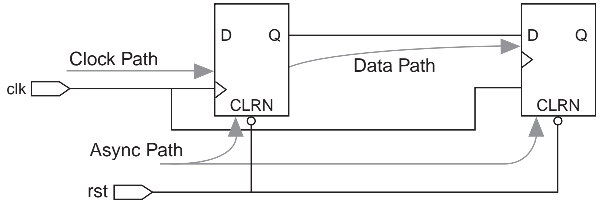
Static Timing Analysis Overview

This section provides information about static timing analysis concepts used throughout this chapter and used by the Quartus II Classic Timing Analyzer. A complete understanding of the concepts presented in this section allows you to take advantage of the powerful static timing analysis features available in the Quartus II software.

Various paths exist within any given design which connect design elements together, including the path from an output of a register to the input of another register. Timing paths play a significant role during a static timing analysis. Understanding the types of timing paths is important for timing closure and optimization. Some of the commonly analyzed paths are described in this section and are shown in Figure 10–1.

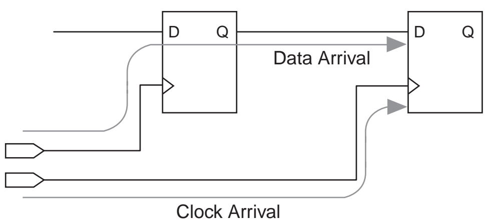
- *Clock paths*—Clock paths are the paths from device pins or internally generated clocks (nodes designated as a clock via a clock setting) to the clock ports of sequential elements such as registers.
- *Data paths*—Data paths are the paths from the data output port of a sequential element to the data input port of another sequential element.
- *Asynchronous paths*—Asynchronous paths are paths from a node to the asynchronous set or clear port of a sequential element.

Figure 10–1. Path Types



After the path types are identified, the classic timing analyzer computes data and clock arrival times for all valid register-to-register paths. Data arrival time is the delay from the source clock to the destination register. The Quartus II Classic Timing Analyzer calculates this delay by adding the clock path delay to the source register, the micro clock-to-out (t_{CO}) of the source register, and the data path delay from the source register to the destination register. Clock arrival time is the delay from the destination clock node to the destination register. Figure 10–2 shows a data arrival path and a clock arrival path.

Figure 10–2. Data Arrival and Clock Arrival

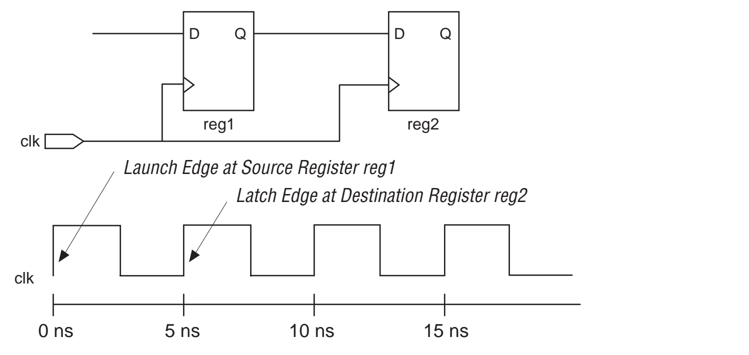


In addition to identifying various paths within a design, the Quartus II Classic Timing Analyzer analyzes clock characteristics to compute the worst-case requirement between any two registers in a single register-to-register path. You must use timing constraints to specify the characteristics of all clock signals in the design before this analysis occurs.

The active clock edge that sends data out of a sequential element, acting as a source for the data transfer, is the launch edge. The active clock edge that captures data at the data port of a sequential element, acting as a destination for the data transfer, is the latch edge.

Figure 10–3 shows a single-cycle system that uses consecutive clock edges to transmit and capture data, a register-to-register path, and the corresponding launch and latch edges timing diagram. In this example, the launch edge sends the data out of register `reg1` at 0 ns, and register `reg2` latch edge captures the data at 5 ns.

Figure 10–3. Launch Edge and Latch Edge



By analyzing specific paths relative to the launch and latch edges, the Quartus II Classic Timing Analyzer performs clock setup and clock hold checks, validating them against your timing assignments.

Clock Analysis

A comprehensive static timing analysis includes analysis of register-to-register, I/O, and asynchronous reset paths. Static Timing Analysis tools use data required times, data arrival times, and clock arrival times to verify circuit performance and detect possible timing violations. The Quartus II Classic Timing Analyzer determines the timing relationships that must be met for the design to correctly function, and checks arrival times against required times to verify timing.

Clock Setup Check

To determine if a design meets performance, the Quartus II Classic Timing Analyzer calculates clock timing, timing requirements, and timing exceptions to perform a clock setup check at each destination register based on the source and destination clocks and timing constraints, or exceptions that are applicable to those paths. A clock setup check ensures that data launched by a source register is latched correctly by the destination register. To perform a clock setup check, the Quartus II Classic Timing Analyzer determines the clock arrival time and data arrival time at the destination register by using the longest path for the data arrival time and the shortest path for the clock arrival time. The Quartus II Classic Timing Analyzer then checks that the difference is greater than or equal to the micro setup (t_{SU}) of the destination register as shown in Equation 10–1.

Equation 10–1.

$$\text{Clock Arrival Time} - \text{Data Arrival Time} \geq \text{micro } t_{SU}$$

By default, the Quartus II Classic Timing Analyzer assumes the launched and latched edges happen on consecutive active clock edges.

The results of clock setup checks are reported in terms of slack. Slack is the margin by which a timing requirement is met or not met. Positive slack indicates the margin by which a requirement is met, and negative slack indicates the margin by which a requirement is not met. The Quartus II Classic Timing Analyzer determines clock setup slack using Equation 10–2 through Equation 10–5.

Equation 10–2.

$$\text{Clock Setup Slack} = \text{Data Required Time} - \text{Data Arrival Time}$$

Equation 10–3.

$$\text{Data Required} = \text{Clock Arrival Time} - \text{micro } t_{SU} - \text{Setup Uncertainty}$$

Equation 10–4.

$$\text{Clock Arrival Time} = \text{Latch Edge} + \text{Shortest Clock Path to Destination Register}$$

Equation 10–5.

$$\begin{aligned}\text{Data Arrival Time} = {} & \text{Launch Edge} + \text{Longest Clock Path to Source Register} \\ & + \text{micro } t_{CO} + \text{Longest Data Delay}\end{aligned}$$

The Quartus II Classic Timing Analyzer reports clock setup slack using Equation 10–6 through Equation 10–9 (which are equivalent to Equation 10–2 through Equation 10–5).

Equation 10–6.

$$\text{Clock Setup Slack} = \text{Largest Register-to-Register Requirement} - \text{Longest Register-to-Register Delay}$$

Equation 10–7.

$$\begin{aligned}\text{Largest Register-to-Register Requirement} &= \text{Setup Relationship between Source and Destination} \\ &+ \text{largest clock skew} - \text{micro } t_{CO} \text{ of Source Register} - \text{micro } t_{SU} \text{ of Destination Register}\end{aligned}$$

Equation 10–8.

$$\begin{aligned}&\text{Setup Relationship between Source \& Destination Register} = \\ &\quad \text{Latch Edge} - \text{Launch Edge Setup Uncertainty}\end{aligned}$$

Equation 10–9.

$$\begin{aligned}\text{Largest Clock Skew} &= \text{Shortest Clock Path to Destination Register} \\ &- \text{Longest Clock Path to Source Register}\end{aligned}$$

Both sets of equations can be used to determine the slack value of any path.

Clock Hold Check

To prevent hold violations, the Quartus II Classic Timing Analyzer calculates clock timing, timing requirements, and timing exceptions to perform a clock hold check at each destination register. A clock hold check ensures data launched from the source register is not captured by an active clock edge earlier than the setup latch edge, and that the destination register does not capture data launched from the next active launch edge. To perform a clock hold check, the Quartus II Classic Timing Analyzer determines the clock arrival time and data arrival time at the destination register using the shortest path for the data arrival time and the longest path for the clock arrival time. The Quartus II Classic Timing Analyzer checks that the difference is greater than or equal to the micro hold time (t_H) of the destination register, as shown in Equation 10–10.

Equation 10–10.

$$\text{Data Arrival Time} - \text{Clock Arrival Time} \geq t_H$$

The Quartus II Classic Timing Analyzer determines clock hold slack using Equation 10–11 through Equation 10–14.

Equation 10–11.

$$\text{Clock Hold Slack} = \text{Data Arrival Time} - \text{Data Required Time}$$

Equation 10–12.

$$\text{Data Required Time} = \text{Clock Arrival Time} + \text{micro } t_H + \text{Hold Uncertainty}$$

Equation 10–13.

$$\text{Clock Arrival Time} = \text{Latch Edge} + \text{Longest Clock Path to Destination Register}$$

Equation 10–14.

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Shortest Clock Path to Source Register} + \text{micro } t_{CO} + \text{Shortest Data Delay}$$

The Quartus II Classic Timing Analyzer reports clock hold slack using Equation 10–15 through Equation 10–18.

Equation 10–15.

$$\text{Clock Hold Slack} = \text{Shortest Register-to-Register Delay} - \text{Smallest Register-to-Register Requirement}$$

Equation 10–16.

$$\text{Smallest Register-to-Register Requirement} = \text{Hold Relationship between Source \& Destination} + \text{Smallest Clock Skew} - \text{micro } t_{CO} \text{ of Source Register} + \text{micro } t_H \text{ of Destination Register}$$

Equation 10–17.

$$\text{Hold Relationship between Source and Destination Register} = \text{Latch} - \text{Launch} + \text{Hold Uncertainty}$$

Equation 10–18.

$$\text{Smallest Clock Skew} = \text{Longest Clock Path from Clock to Destination Register} - \text{Shortest Clock Path from Clock to Source Register}$$

These equations can be used to determine the slack value of any path.

Multicycle Paths

Multicycle paths are data paths that require more than one clock cycle to latch data at the destination register. For example, a register may be required to capture data on every second or third rising clock edge. Figure 10–4 shows an example of a multicycle path between a multiplier's input registers and output register where the destination latches data on every other clock edge.

Refer to "Multicycle" on page 10–13 for more information about multicycle exceptions.

Figure 10–4. Example Diagram of a Multicycle Path

Figure 10–5 shows the default clock setup analysis launch and latch edges where multicycle assignment is equal to 1.

Figure 10–5. Default Clock Setup Analysis

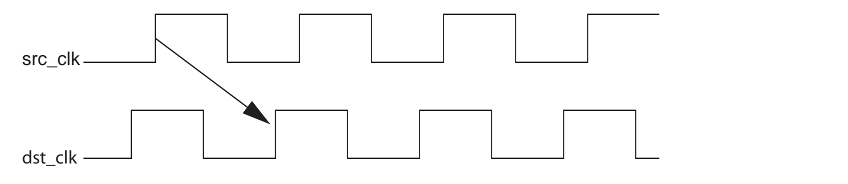

Figure 10–6 shows an analysis similar to Figure 10–5, but with a multicycle of 2.

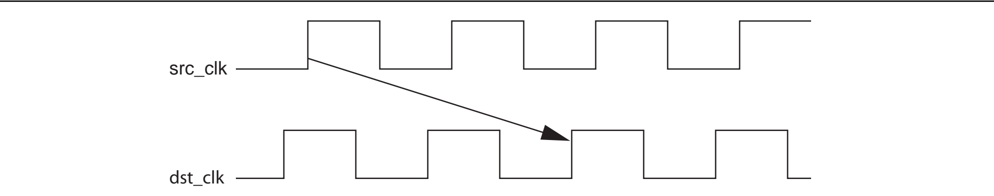
Figure 10–6. Multicycle = 2 Clock Setup Analysis



Clock Settings

You can use individual and default clock settings to define the clocks in your design. You can base these clock settings on other clock settings already defined in your design.

To ensure the Quartus II Fitter achieves the desired performance requirements and the Quartus II Classic Timing Analyzer performs a thorough static timing analysis, you must specify all timing assignments prior to compiling the design.

Individual Clock Settings

Individual clock settings allow you to specify clock properties including performance requirements, offsets, duty cycles, and other properties for individual clock signals in your design.

You can define individual clock settings using the `create_base_clock` Tcl command. The following example defines an individual clock setting named `sys_clk` with a requirement of 100 MHz (10 ns), and assigns it to clock node `clk`.

```
create_base_clock -fmax 100MHz -target clk sys_clk
```

Default Clock Settings

You can assign a project-wide clock requirement to constrain all detected clocks in a design that do not have individual clock settings.

The `set_global_assignment -name FMAX_REQUIREMENT` Tcl command specifies a global default requirement assignment. The following example defines a 100 MHz default clock requirement:

```
set_global_assignment -name FMAX_REQUIREMENT "100.0 MHz"
```

For best placement and routing results, apply individual clock settings to all clocks in your design. All clocks adopting the default f_{MAX} are by default unrelated.

Clock Types

This section describes the types of clocks recognized by the Timing Analyzer:

- Base clocks
- Derived clocks
- Undefined clocks
- PLL clocks

Base Clocks

A base clock is independent of other clocks in a design. For example, a base clock is typically a clock signal driven directly by a device pin. A base clock is defined by individual clock settings, or automatically detected using the default clock setting.

You can use the `create_base_clock` Tcl command to define a base clock setting and assign the clock setting to a clock node. The following Tcl command creates a clock setting called `sys_clk` with a requirement of 5 ns (200 MHz) and applies the clock setting to clock node `main_clk`:

```
create_base_clock -fmax 5ns -target main_clk sys_clk
```

Derived Clocks

A derived clock is based on a previously defined base clock. For a derived clock, you can specify the phase shift, offset, multiplication and division factors, and duty cycle relative to the base clock.

You can use the `create_relative_clock` Tcl command to define and assign a derived clock setting. The following example creates a derived clock setting named `system_clockx2` that is twice as fast as the base clock `system_clock` applied to clock node `clkx2`.

```
create_relative_clock -base_clock system_clock -duty_cycle 50 \
-multiply 2 -target clkx2 system_clockx2
```

Undefined Clocks

The Quartus II Classic Timing Analyzer detects undeclared clocks in your design and displays a warning similar to the following:

```
Warning: Found pins functioning as undefined clocks and/or memory
enables
    Info: Assuming node "clk_src" is an undefined clock
    Info: Assuming node "clk_dst" is an undefined clock
```

The Quartus II Classic Timing Analyzer reports actual data delay for undefined clocks, but because no clock requirements exist for undefined clocks, the Quartus II Classic Timing Analyzer does not report slack for any register-to-register paths driven by an undefined clock.

PLL Clocks

Phase-locked loops (PLLs) are used for clock synthesis in Altera® devices. This device feature is configured and connected to your design using the altpll megafunction included with the Quartus II software. Using the MegaWizard™ Plug-In Manager, you can customize the input clock frequency, multiplication factors, division factors, and other parameters of the altpll megafunction.

For more information about using the PLL feature in your design, refer to the *ALTPLL Megafunction User Guide* or the handbook for the targeted device family.

For PLLs, the Quartus II Classic Timing Analyzer automatically creates derived clock settings based on the parameterization of the PLL and automatically creates a base clock setting for the input clock pin. For example, if the input clock frequency to a PLL is 100 MHz and the multiplication and division ratio is 5:2, the clock period of the PLL clock is set to 4.0 ns and is automatically calculated by the Quartus II Classic Timing Analyzer.

For the Stratix® and Cyclone® device families, you can override the PLL input clock frequency by applying a clock setting to the input clock pin of the PLL. For example, if the PLL input clock period is set to 10 ns (100 MHz) with a multiplication and division ratio of 5:2, but a clock setting of 20 ns (50 MHz) is applied to the input clock pin of the PLL, the setup relationship is 8.0 ns (125 MHz) and not 4.0 ns (250 MHz). The Quartus II Classic Timing Analyzer issues a message similar to the following:

```
Warning: ClockLock PLL "mypll_test:inst|altpll:altpll_component|_clk1"
input frequency requirement of 200.0 MHz overrides default required fmax
of 100.0 MHz -- Slack information will be reported
```

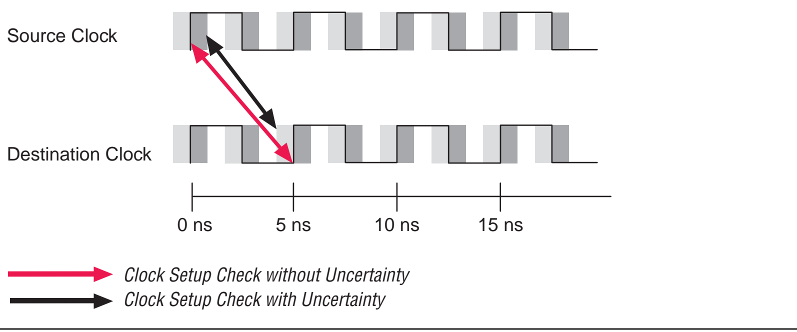
You cannot override the PLL output clock frequency with a clock setting in the Quartus II Classic Timing Analyzer.

Clock Uncertainty

You can use Clock Setup Uncertainty and Clock Hold Uncertainty assignments to model jitter, skew, or add a guard band associated with clock signals.

When a clock uncertainty assignment exists for a clock signal, the Timing Analyzer performs the most conservative setup and hold checks. For clock setup check, the setup uncertainty is subtracted from the data required time. Figure 10–7 shows an example of clock sources with a clock setup uncertainty applied.

Figure 10–7. Clock Setup Uncertainty

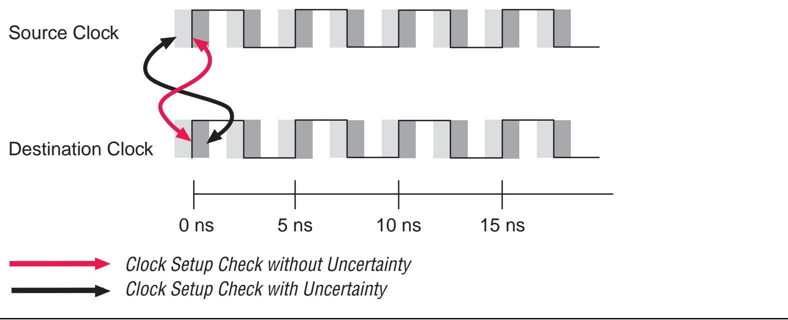


You can create clock uncertainty assignments using the Tcl command `set_clock_uncertainty`. The `set_clock_uncertainty` assignment used with the switch `-setup` specifies a clock setup uncertainty assignment. The following example creates a Clock Setup Uncertainty assignment with a value of 2 ns applied to clock signal `clk`:

```
set_clock_uncertainty -to clk -setup 2ns
```

For the clock hold check, the hold uncertainty is added to the data required time. Figure 10–8 shows an example of clock setup check with a clock setup uncertainty and clock hold uncertainty applied.

Figure 10–8. Clock Hold Uncertainty



You can use the `set_clock_uncertainty` Tcl command with the option `-hold` to specify a Clock Hold Uncertainty assignment. The following example creates a Clock Hold Uncertainty assignment with a value of 2 ns for clock signal `clk`.

```
set_clock_uncertainty -to clk -hold 2ns
```

You can also apply the clock uncertainty assignments between two clock sources. The following example creates a Clock Setup Uncertainty assignment for clock setup checks where `clk1` is the source clock and `clk2` is the destination clock:

```
set_clock_uncertainty -from clk1 -to clk2 -setup 2ns
```

Clock Latency

You can use clock latency assignments to model delays from the clock source. For example, you can use clock latency to model an external delay from an ideal clock source, such as an oscillator, to the clock pin or port of the device.

The Early Clock Latency assignment allows you to specify the shortest or earliest delay of the clock source. Conversely, the Late Clock Latency assignment allows you to specify the longest or latest delay of the clock source.

During setup analysis, the Quartus II Classic Timing Analyzer adds the Late Clock Latency assignment value to the source clock path delay and adds the Early Clock Latency assignment value to the destination clock path delay when determining clock skew for the path. During clock hold analysis, the Quartus II Classic Timing Analyzer adds the Early Clock Latency assignment value to the source clock path delay and adds the Late Clock Latency assignment value to the destination clock path delay when determining clock skew for the path.

The Early Clock Latency and Late Clock Latency assignments do not change the latch and launch edges defined by the clock setting and therefore does not change the setup or hold relationships between source and destination clocks. The clock latency assignments add only delay to the clock network and therefore only affects clock skew.

Figure 10–9 shows the clock edges used to calculate clock skew for a setup check when the Early Clock Latency and Late Clock Latency assignments are used.

Figure 10–9. Clock Setup Check Clock Skew

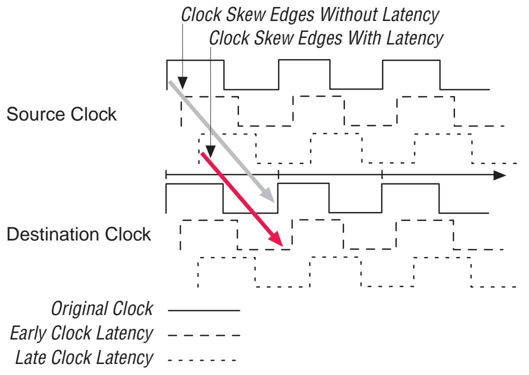


Figure 10–10 shows the clock edges used to calculate clock skew for a hold check when the Early Clock Latency and Late Clock Latency assignments are used.

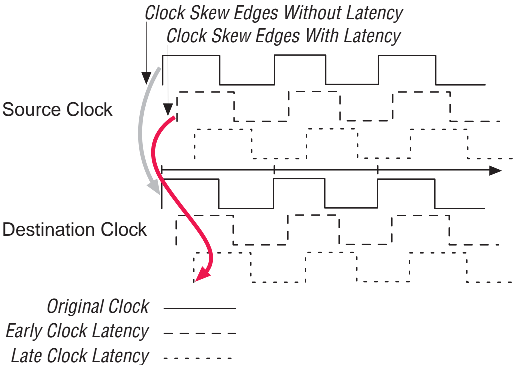
Figure 10–10. Clock Hold Check Clock Skew



The Quartus II Classic Timing Analyzer ignores clock latency if the clock signal at the source and destination registers are the same.

You can use the `set_clock_latency` Tcl command with the switches `-early` or `-late` to specify an Early Clock Latency assignment or Late Clock Latency assignment, respectively. Example 10–1 specifies that the clock signal at `clk2` arrives as early as 1.8 ns and as late as 2.0 ns.

Example 10–1. Specifying Early or Late Clock Latency at clk2

```
set_clock_latency -early -to clk2 1.8ns
set_clock_latency -late -to clk2 2ns
```

The early clock latency default value is the same as the late clock latency delay, and the late clock latency default value is the same as the early clock latency delay, if only one is specified.

The **Enable Clock Latency** option must be set to **ON** for the Quartus II Classic Timing Analyzer to analyze clock latency. When this option is set to **ON**, the Quartus II Classic Timing Analyzer reports clock latency as part of the clock skew calculation for either the source or destination clock path depending upon the analysis performed. To set the **Enable Clock Latency** option to **ON**, you can use the following Tcl command:

```
set_global_assignment -name ENABLE_CLOCK_LATENCY ON
```

When the **Enable Clock Latency** option is enabled, the Quartus II Classic Timing Analyzer automatically calculates latencies for derived clocks instead of automatically calculating offsets; for example, PLL compensation delays. These clock path delays are accounted for as clock skew instead of part of the setup or hold relationship as done with offsets.

For more information about clock latency, refer to *AN 411: Understanding PLL Timing for Stratix II Devices*.

Timing Exceptions

Timing exceptions allow you to modify the default behavior of the Quartus II Classic Timing Analyzer. This section describes the following timing exceptions:

- Multicycle
- Setup relationship and hold relationship
- Maximum delay and minimum delay
- False paths

Not all timing exceptions presented in this chapter are applicable to the HardCopy® II devices. If you are designing for the HardCopy II device family, refer to the *Timing Constraints for HardCopy II Devices* chapter in the *HardCopy II Handbook*.

Multicycle

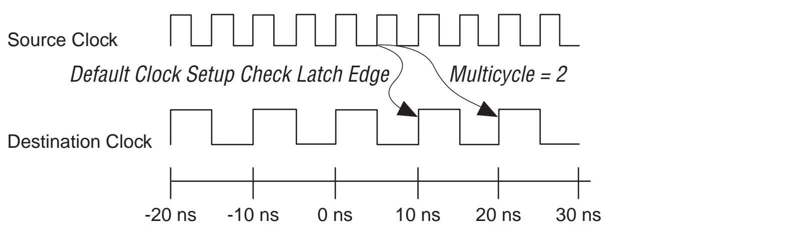
By default, the Quartus II Classic Timing Analyzer performs a single-cycle analysis for all valid register-to-register paths in the design. Multicycle assignments specify the number of clock periods before a source register launches the data or a destination register latches the data. Multicycle assignments adjust the latch or launch edges, which relaxes the required clock setup check or clock hold check between the source and destination register pairs. You can specify multicycles separately for setup and hold, and multicycles can be based on the source clock or destination clock. Apply Multicycle exception to time groups, clock nodes, or common clock enables.

Destination Multicycle Setup Exception

A destination multicycle setup, referred to as a Multicycle exception, specifies the minimum number of clock cycles required before a register should latch a value. A Multicycle exception changes the latch edge by relaxing the required setup relationship. Figure 10–11 shows a timing diagram for a multicycle path that exists in a design with related clocks, and with the latch edge label for a clock setup check.

By default, the Multicycle exception value is 1.

Figure 10–11. Multicycle Setup



You can apply Multicycle exception between any two registers or between any two clock domains. Use the Tcl command `set_multicycle_assignment`, and the switch `-setup` and `-end`. For example, to apply a Multicycle exception of 2 between all registers clocked by source clock `clk_src`, and all registers clocked by destination clock `clk_dst`, enter the following Tcl command:

```
set_multicycle_assignment -setup -end -from clk_src -to clk_dst 2
```

To apply a Multicycle exception of 2 between the source register `reg1` and the destination register `reg2`, enter the following Tcl command:

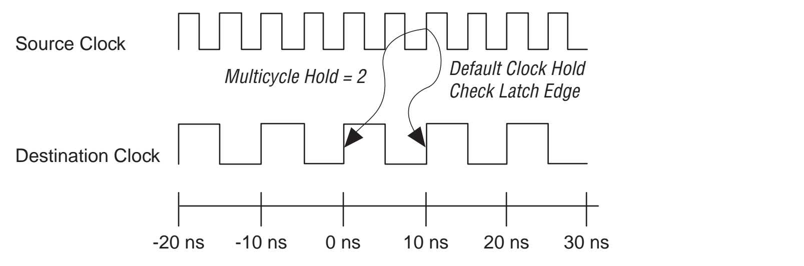
```
set_multicycle_assignment -setup -end -from reg1 -to reg2 2
```

Destination Multicycle Hold Exception

A destination multicycle hold, referred to as a Multicycle Hold exception, modifies the latch edge used for a clock hold check for the register-to-register path based on the destination clock. A Multicycle Hold exception changes the latch edge by relaxing the required hold relationship. Figure 10–12 shows a timing diagram labeling the latching edge for a clock setup check.

If no Multicycle Hold value is specified, the Multicycle Hold value defaults to the value of the multicycle exception.

Figure 10–12. Multicycle Hold



You can create Multicycle Hold exceptions with the Tcl command `set_multicycle_assingment` and the switch `-hold` and `-end`. The following example specifies a Multicycle Hold exception of 3 from register `reg1` to register `reg2`:

```
set_multicycle_assignment -hold -end -from reg1 -to reg2 3
```

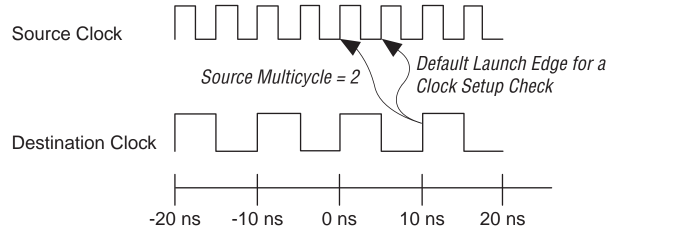
By default, the hold multicycle is set to equal that of the setup multicycle value along the same path. For example, if a setup multicycle of 2 has been applied to a register-to-register path without a separate hold multicycle, the hold multicycle value would be set to 2. The default hold multicycle value can also be changed to a value of 1. This forces all paths with a setup multicycle assignment to have a default hold multicycle of 1. To change the default hold multicycle value, in the **Settings** dialog box, click the **More Timing Settings** option.

If your design requires a hold multicycle value not equal to the setup multicycle or 1, you must explicitly apply a hold multicycle assignment to the path.

Source Multicycle Setup Exception

A source multicycle setup, referred to as Source Multicycle Setup exception, is used to extend the required delay by adjusting the source clock's launch edge rather than the destination clock's latch edge; for example, multicycle setup. Source Multicycle exceptions are useful when the source and destination registers are clocked by related clocks at different frequencies. Figure 10–13 shows an example of a Source Multicycle exception with the launch edge labeled for a clock setup check.

Figure 10–13. Source Multicycle



You can create Source Multicycle Setup exceptions with the Tcl command `set_multicycle_assignment` and the switches `-setup` and `-start`. The following example specifies a Source Multicycle exception of 3 from register `reg1` to register `reg2`:

```
set_multicycle_assignment -setup -start -from reg1 -to reg2 3
```

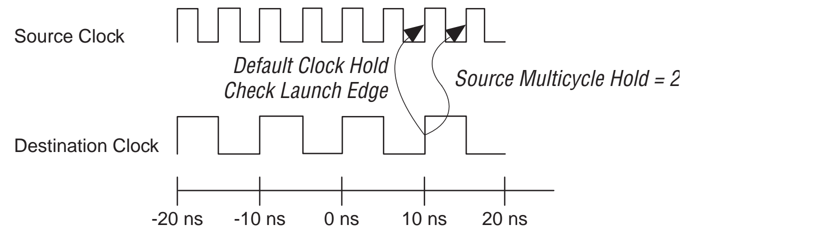
By default, the hold multicycle is set to equal that of the setup multicycle value along the same path. For example, if a setup multicycle of 2 has been applied to a register-to-register path without a separate hold multicycle, the hold multicycle value would be set to 2. The default hold multicycle value can also be changed to a value of 1. This forces all paths with a setup multicycle assignment to have a default hold multicycle of 1. To change the default hold multicycle value, in the **Settings** dialog box, click the **More Timing Settings** option.

If your design requires a hold multicycle value not equal to the setup multicycle or 1, you must explicitly apply a hold multicycle assignment to the path.

Source Multicycle Hold Exception

The Source Multicycle Hold exception modifies the latch edge used for a clock hold check for the register-to-register path based on the source clock. Source Multicycle Hold exceptions increase the required hold delay by adding source clock cycles. Figure 10–14 shows an example of a source multicycle hold with launch edge labeled for a clock hold check.

Figure 10–14. Source Multicycle Hold



You can create Source Multicycle Hold exceptions with the Tcl command `set_multicycle_assingment` and the switch `-setup` and `-start`. The following example specifies a Source Multicycle Hold exception of 3 from register `reg1` to register `reg2`:

```
set_multicycle_assignment -hold -start -from reg1 -to reg2 3
```

Default Hold Multicycle

The Quartus II Classic Timing Analyzer sets the hold multicycle value to equal the multicycle value when a multicycle exception has been entered without a corresponding hold multicycle. You can change the behavior with the `DEFAULT_HOLD_MULTICYCLE` assignment. The value of the assignment can either be "`ONE`" or "`SAME AS MULTICYCLE`".

The assignment has the following syntax:

```
set_global_assignment -name DEFAULT_HOLD_MULTICYCLE "<value>"
```

Clock Enable Multicycle

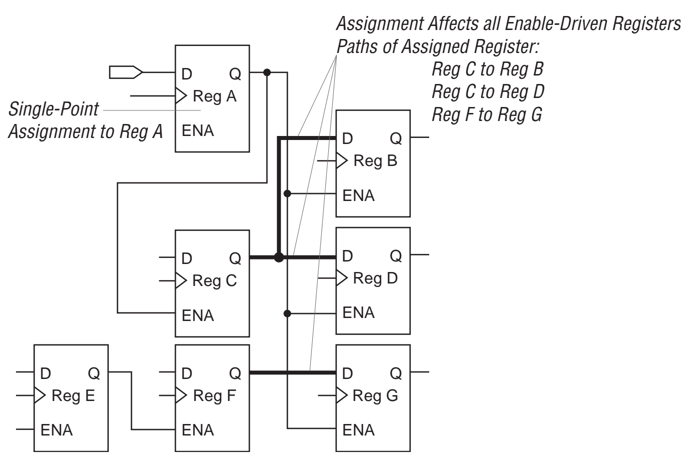
For all enable-driven registers, the setup relationship or hold relationship can be modified with the Clock Enable Multicycle, Clock Enable Multicycle Hold, Clock Enable Source Multicycle, or Clock Enable Multicycle Source Hold.

The **Clock Enable Multicycle** modifies the latching edge when a clock setup check is performed for all registers driven by the specified clock enables, and the **Clock Enable Multicycle Hold** modifies the latching edge when a clock hold check is performed for all registers driven by the specified clock enable. The **Clock Enable Source Multicycle** modifies the launching edge when a clock setup check is performed for all enabled driven registers, and the **Clock Enable Source Multicycle Hold** modifies the launching edge when a clock hold check is performed for all enabled driven registers.

Clock enable-based multicycle exceptions apply only to registers using dedicated clock enable circuitry. If the enable is synthesized into a logic cell; for example, due to signal prioritization, the multicycle does not apply.

The Clock Enable Multicycle, Clock Enable Multicycle Hold, Clock Enable Source Multicycle, and Clock Enable Multicycle Source Hold can be either a single-point or a point-to-point assignment. Figure 10–15 shows an example of a single-point assignment. In this example, register `Reg A` has the single-point assignment applied. This has the affect of modifying a register-to-register latching edge whose enable port is driven by register `Reg A`. All register-to-register paths with enables driven by the single-point assignment are affected, even those driven by different clock sources.

Figure 10–15. Single-Point Clock Enable Multicycle



Point-to-point assignments apply to all paths where the source registers' enable ports are driven by the source (`from`) node and the destination registers' enable ports are driven by the destination (`to`) node. Figure 10–16 shows an example of a point-to-point assignment made to different source and destination registers. In this example, register `Reg A` is specified as the source, and register `Reg B` is specified as the destination for the assignment. Only register-to-register paths that have their enables driven by the assigned point-to-point registers have their latching edges modified.

Figure 10–16. Different Source and Destination Point-to-Point Assignment Clock Enable Multicycle

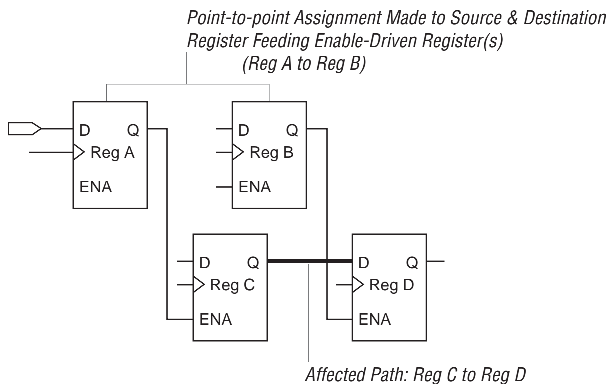


Figure 10–17 shows an example of a point-to-point assignment made to the same source and destination register. In this example, register `Reg A` has been specified as both the source and register for the assignment. Only register-to-register paths that have both the `source-enable` port and `destination-enable` port has the latching edge modified by the assigned point-to-point assignment.

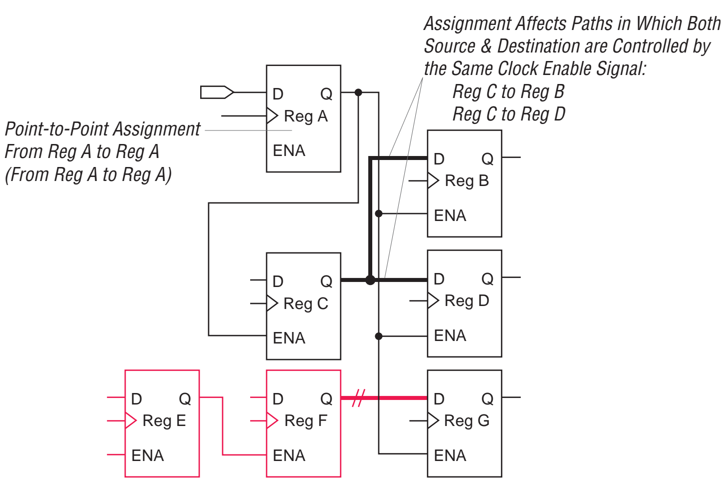
Figure 10–17. Same Source and Destination Point-to-Point Assignment Clock Enable Multicycle



You can use the `set_instance_assignment -name CLOCK_ENABLE_MULTICYCLE` and `set_instance_assignment -name CLOCK_ENABLE_MULTICYCLE_HOLD` Tcl commands to specify either a Clock Enable Multicycle or a Clock Enable Multicycle Hold assignment, respectively. The following example specifies a single-point Clock Enable Multicycle assignment of 2 ns to `reg1`:

```
set_instance_assignment -name CLOCK_ENABLE_MULTICYCLE 2 -to reg1
```

The following example specifies a point-to-point Clock Enable Multicycle Hold assignment of 2 from register `reg1` to register `reg2`:

```
set_instance_assignment -name CLOCK_ENABLE_MULTICYCLE_HOLD 2 \
-from reg1 -to reg2
```

You can use the `set_instance_assignment -name CLOCK_ENABLE_SOURCE_MULTICYCLE` and `set_instance_assignment -name CLOCK_ENABLE_MULTICYCLE_SOURCE_HOLD` Tcl commands to specify either a Clock Enable Multicycle or Clock Enable Multicycle Hold assignment, respectively. The following example specifies a single-point Clock Enable Multicycle assignment of 2 ns to `reg1`:

```
set_instance_assignment -name CLOCK_ENABLE_SOURCE_MULTICYCLE 2 \
-to reg1
```

The following example specifies a point-to-point Clock Enable Multicycle Hold assignment of 2 from register `reg1` to register `reg2`:

```
set_instance_assignment -name \
CLOCK_ENABLE_SOURCE_MULTICYCLE_HOLD 2 -from reg1 -to reg2
```

Setup Relationship and Hold Relationship

By default, the Quartus II Classic Timing Analyzer determines all setup and hold relationships based on clock settings. The Setup Relationship and Hold Relationship exceptions allow you to override any default setup or hold relationships. Example 10–2 shows the path details of a register-to-register path that has a 10 ns clock setting applied to the clock signal driving the 2 registers.

Example 10–2. Default Setup Relationship with 10 ns Clock Setting

```
Info: Slack time is 9.405 ns for clock "data_clk" between source register "reg9" and
destination register "reg10"
    Info: Fmax is restricted to 500.0 MHz due to tcl and tch limits
    Info: + Largest register to register requirement is 9.816 ns
        Info: + Setup relationship between source and destination is 10.000 ns
            Info: + Latch edge is 10.000 ns
            Info: - Launch edge is 0.000 ns
        Info: + Largest clock skew is 0.000 ns
        Info: - Micro clock to output delay of source is 0.094 ns
        Info: - Micro setup delay of destination is 0.090 ns
    Info: - Longest register to register delay is 0.411 ns
```

In Example 10–3, a 15 ns Setup Relationship exception is applied to the register-to-register path, overriding the default 10 ns setup relationship.

Example 10–3. Setup Relationship Assignment of 15 ns

```
Info: Slack time is 14.405 ns for clock "data_clk" between source register "reg9" and
destination register "reg10"
   Info: Fmax is restricted to 500.0 MHz due to tcl and tch limits
   Info: + Largest register to register requirement is 14.816 ns
      Info: + Setup relationship between source and destination is 15.000 ns
      Info: Setup Relationship assignment value is 15.000 ns between source "reg9" and
      destination "reg10"
      Info: + Largest clock skew is 0.000 ns
      Info: Total interconnect delay = 1.583 ns ( 51.31 % )
   Info: - Micro clock to output delay of source is 0.094 ns
   Info: - Micro setup delay of destination is 0.090 ns
Info: - Longest register to register delay is 0.411 ns
```

You can create a Setup Relationship exception with the Tcl command `set_instance_assignment -name SETUP_RELATIONSHIP`. The following example specifies a Setup Relationship exception of 5 ns from register `reg1` to register `reg2`:

```
set_instance_assignment -name SETUP_RELATIONSHIP 5ns -from reg1 \
-to reg2
```

You can use Hold Relationship exception to override the default hold relationship of any register-to-register paths.

You can use the `set_instance_assignment -name HOLD_RELATIONSHIP` Tcl command to specify a hold relationship assignment. The following example specifies a Hold Relationship exception of 1 ns from register `reg1` to register `reg2`:

```
set_instance_assignment -name HOLD_RELATIONSHIP 1ns -from reg1 \
-to reg2
```

Maximum Delay and Minimum Delay

You can use Maximum Delay and Minimum Delay assignments to specify delay requirements for pin-to-register, register-to-register, and register-to-pin paths. The Maximum Delay assignment overrides any setup relationship for any path. The Minimum Delay assignment overrides any hold relationship for any path.

The Quartus II Classic Timing Analyzer ignores the effects of clock skew when checking a design against Maximum Delay and Minimum Delay assignments.

You can use the `set_instance_assignment -name MAX_DELAY` and `set_instance_assignment -name –MIN_DELAY` Tcl commands to specify a Maximum Delay assignment or a Minimum Delay assignment, respectively. The following example specifies a maximum delay of 2 ns between source register `reg1` and destination register `reg2`:

```
set_instance_assignment -name MAX_DELAY 2ns -from reg1 -to reg2
```

The following example specifies a minimum delay of 1 ns between input pin `data_in` to destination register `dst_reg`:

```
set_instance_assignment -name MIN_DELAY 1ns -from data_in -to dst_reg
```

False Paths

A false path is any path that is not relevant to a circuit's operation, such as test logic. There are several global assignments to cut different classes of paths, such as unrelated clock domains and paths through bidirectional pins, but you can also cut an individual timing path to a specific false path.

The Timing Analyzer provides the following three global options that allow you to remove false paths from your design:

- Cut off feedback from I/O pins
- Cut off `read-during-write` signal paths
- Cut paths between unrelated clock domains

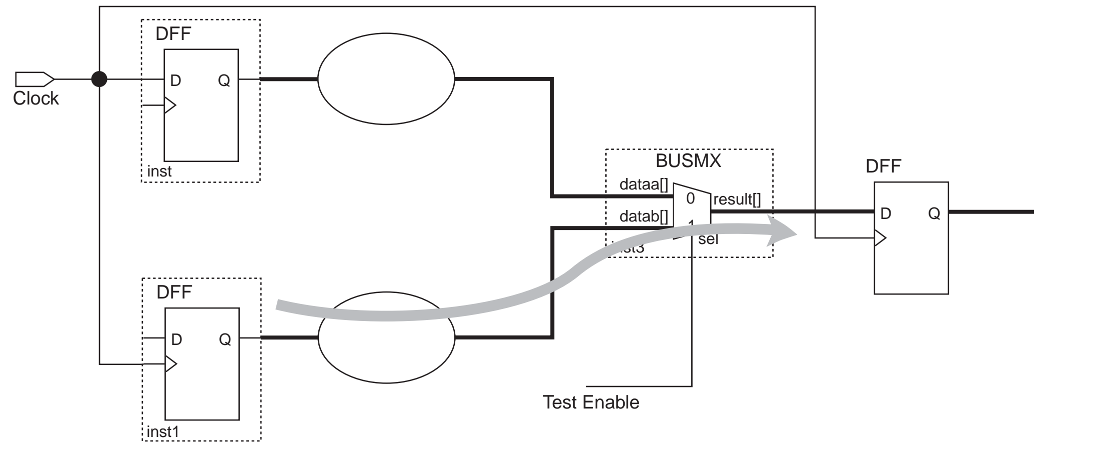
You can use the `set_global_assignment -name CUT_OFF_IO_PIN_FEEDBACK ON` Tcl command to cut the feedback path when a bidirectional I/O pin is connected directly or indirectly to both the input and output of a latch.

You can use the `set_global_assignment -name CUT_OFF_READ_DURING_WRITE_PATHS ON` Tcl command to cut the path from the `write-enable` register through memory element to a destination register.

You can use the `set_global_assignment -name CUT_OFF_PATHS_BETWEEN_CLOCK_DOMAINS ON` Tcl command to cut paths between register-to-register where the source and destination clocks are different.

You can use the `set_timing_cut_assignment` Tcl command to cut specific timing paths. In Figure 10–18, the path from `inst1` through the multiplexer to `inst2` is used only for design testing. This false path is not required under normal operation and does not need to be analyzed during static timing analysis. Figure 10–18 shows an example of a false path.

Figure 10–18. False Path Signal



To cut the timing path from source register `inst1` to destination register `inst2`, enter the following Tcl command:

```
set_timing_cut_assignment -from inst1 -to inst2
```

You can also use the `set_timing_cut_assignment` Tcl command as a single point assignment. When you use the single point assignment, all fanout of the node is cut. For example, the following Tcl command cuts all timing paths originating for node `src_reg`:

```
set_timing_cut_assignment -to src_reg
```

I/O Analysis

The I/O analysis performed by the Quartus II Classic Timing Analyzer ensures your Altera FPGA design meets all timing specifications for interfacing with external devices. This section describes assignments relevant to I/O analysis and other I/O analysis features and options available with the Quartus II Classic Timing Analyzer.

External Input Delay and Output Delay Assignments

External input and output delays represent delays from or to external devices or boards traces. You can make **Input Delay** and **Output Delay** assignments to ensure the Quartus II Classic Timing Analyzer can perform a full system analysis. By providing **Input Delays** and **Output Delays**, the Quartus II Classic Timing Analyzer is able to perform clock setup and clock hold checks for these paths. This also allows other timing assignments, such as multicycle or clock uncertainty, to be applied to input and output paths.

Do not combine individual or global t_{SU}, t_H, t_{PD}, t_{CO}, minimum t_{CO}, or minimum t_{PD} assignments with **Input Delay** or **Output Delay** assignments.

Input Delay Assignment

External input delays are specified with either Input Maximum Delay or Input Minimum Delay assignments. Make Input Maximum Delay assignments to specify the maximum delay of a signal from an external register to a specified input or bidirectional pin on the FPGA relative to a specified clock source. Make Input Minimum Delay assignments to specify the minimum delay of a signal from an external register to a specified input or bidirectional pin on the FPGA relative to a specified clock source.

When performing a clock setup check, the Quartus II Classic Timing Analyzer adds the Input Maximum Delay assignment value to the data arrival time (or subtracts the assignment value from the point-to-point requirement).

When performing a clock hold check, the Quartus II Classic Timing Analyzer adds the Input Minimum Delay assignment value to the data arrival time (or subtracts the assignment value from the point-to-point requirement).

The value of the input delay assignment usually represents the sum of the t_{CO} of the external device, the actual board delay to the input pin of the Altera device, and the board clock skew.

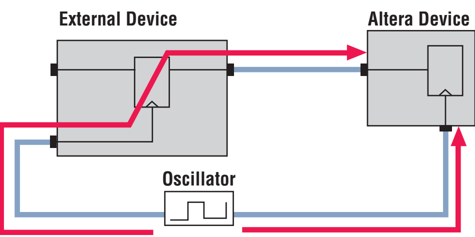
The **Input Minimum Delay** defaults to the **Input Maximum Delay** and the **Input Maximum Delay** defaults to the Input **Minimum Delay** if only one is specified.

For example, the Input Maximum Delay and Input Minimum Delay can be used to model the delay associated with an external device driving into an Altera FPGA. Figure 10–19 shows an example of the input delay path. For Figure 10–19, the Input Maximum Delay can be calculated as shown in Equation 10–19.

Equation 10–19.

$$\text{Input Maximum Delay} = \text{External Device Board Clock Path} + \text{External Device } t_{CO} + \text{External Device to Altera Device Board Delay} - \text{External Clock Path to Altera Device}$$

Figure 10–19. Input Delay



Use the Tcl command `set_input_delay` to specify an input delay. The following example specifies an **Input Maximum** Delay assignment of 1.5 ns from clock node `clk` to input pin `data_in`:

```
set_input_delay -clk_ref clk -to "data_in" -max 1.5ns
```

The following example specifies an Input Minimum Delay assignment of 1 ns from clock node `clk` to input pin `data_in`:

```
set_input_delay -clk_ref clk -to "data_in" -min 1ns
```

When using **Input Delay** assignments, specify a particular clock reference. The clock reference is the clock that feeds the external register's clock port that feeds the Altera device. This allows the Quartus II Classic Timing Analyzer to perform the proper analysis for the input path.

The t_{SU}, t_H, t_{PD}, and min t_{PD} timing paths reported for input pins, where input delay internal to the Altera FPGA assignments has been applied, include only the data delay from these pins and do not account for any clock setup relationships, clock hold relationships, or slack.

Output Delay Assignment

You can specify external output delays with either Output Maximum Delay or Output Minimum Delay assignments. Make Output Maximum Delay assignments to specify the maximum delay of a signal from the specified FPGA output pin to an external register, relative to a specified clock source. Make Output Minimum Delay assignments to specify the minimum delay of a signal from the specified FPGA output pin to an external register relative to a specified clock source.

When performing a clock setup check, the Quartus II Classic Timing Analyzer subtracts the Output Maximum Delay assignment value from the data required time (or subtracts the assignment value from the point-to-point requirement).

When performing a clock hold check, the Quartus II Classic Timing Analyzer subtracts the Output Minimum Delay assignment value from the data required time (or subtracts the assignment value from the point-to-point requirement).

The value of this assignment usually represents the sum of the t_{SU} of the external device, the actual board delay from the output pin of the Altera device, and the board clock skew.

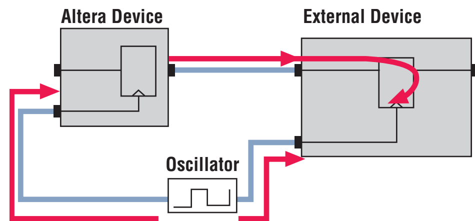
The Output Minimum Delay default value is the same as the Output Maximum Delay, and the Output Maximum Delay default value is the same as the Output Minimum Delay if only one is specified.

For example, use the Output Maximum Delay and Output Minimum Delay to model the delay associated with outputs for an Altera FPGA driving into an external device. Figure 10–20 shows an example of an output delay path. For Figure 10–20 the Output Maximum Delay can be calculated, as shown in Equation 10–20.

Equation 10–20.

$$\text{Output Maximum Delay} = \text{Altera Device to External Device Board Delay} + \text{External Device } t_{SU} + \text{External Clock Path to Altera Device} - \text{External Device Board Clock Path}$$

Figure 10–20. Output Delay



The Tcl command `set_output_delay` specifies an Output Delay assignment. The following example specifies an Output Maximum Delay assignment of 2 ns from clock `clk` to output pin `data_out`:

```
set_output_delay -clk_ref clk -to data_out -max 2ns
```

The following example specifies an Output Minimum Delay assignment of 1 ns from clock `clk` to output pin `data_out`:

```
set_output_delay -clk_ref clk -to data_out -min 1ns
```

When using output delay assignments, specify a specific clock reference. The clock reference is the clock that feeds the external register's clock port that is fed by the Altera device. This allows the Quartus II Classic Timing Analyzer to perform the correct static timing analysis on the output path.

The t_{CO}, minimum t_{CO}, t_{PD}, and minimum t_{PD} timing paths reported for output pins, where output delay assignments have been applied include only the data delay internal to the Altera FPGA to those pins, and do not account for any clock setup relationships, clock hold relationships, or slack.

Virtual Clocks

You can use virtual clocks to model clock signals outside of the Altera FPGA, that is, clocks that do not directly drive anything within the Altera FPGA. For example, you can use a virtual clock to model a clock signal feeding an external output register that feeds the Altera FPGA.

Using the `-virtual` option of the `create_base_clock` Tcl command specifies a virtual clock assignment.

Before a you can use virtual clock for either an input or output delay assignment, the virtual clock must have the Virtual Clock Reference assignment enabled for the virtual clock setting.

The code in Example 10–4 creates a virtual clock named `virt_clk`, with a 200 MHz requirement, and uses the virtual clock setting as the clock reference for the input delay assignment.

Example 10–4. Creating a Virtual Clock Named virt_clk

```
#create the virtual clock setting
create_base_clock -fmax 200MHz -virtual virt_clk

#enable the virtual clock reference for the virtual clock setting
set_instance_assignment -name VIRTUAL_CLOCK_REFERENCE On -to virt_clk

#use the virtual clock setting as the clock reference for the input delay assignment
set_input_delay -clk_ref virt_clk -to data_in -max 2ns
```

Asynchronous Paths

The Quartus II Classic Timing Analyzer can analyze asynchronous signals that connect to the clear, preset, or load ports of a register. This section explains how the Quartus II Classic Timing Analyzer analyzes asynchronous paths.

Recovery and Removal

Recovery time is the minimum length of time an asynchronous control signal; for example, clear and preset, must be stable before the active clock edge. Removal time is the minimum length of time an asynchronous control signal must be stable after the active clock edge. The Enable Recovery/Removal analysis option reports the results of recovery and removal checks for paths that end at an asynchronous clear, preset, or load signal of a register.

Enable the recovery and removal analysis with the following Tcl command:

```
set_global_assignment -name ENABLE_RECOVERY_REMOVAL_ANALYSIS ON
```

With this option enabled, the Quartus II Classic Timing Analyzer reports the result of the recovery analysis and removal analysis.

By default, the recovery and removal analysis is disabled. You should enable his option for all designs that contain asynchronous controls signals.

Recovery Report

When you set `ENABLE_RECOVERY_REMOVAL_ANALYSIS` to **ON**, the Quartus II Classic Timing Analyzer determines the recovery time as the minimum amount of time required between an asynchronous control signal becoming inactive and the next active clock edge, compares this to your design, and reports the results as slack. The Recovery report alerts you to conditions where an active clock edge occurs too soon after the asynchronous input becomes inactive, rendering the register's data uncertain.

The recovery slack time calculation is similar to the calculation for clock setup slack, which is based on data arrival time and data required time except for asynchronous control signals. If the asynchronous control is registered, the Quartus II Classic Timing Analyzer calculates the recovery slack time using Equation 10–21 through Equation 10–23.

Equation 10–21.

$$\text{Recovery Slack Time} = \text{Data Required Time} - \text{Data Arrival Time}$$

Equation 10–22.

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Longest Clock Path to Source Register} + \text{micro } t_{CO} \text{ of Source Register} + \text{Longest Register-to-Register Delay}$$

Equation 10–23.

$$\text{Data Required Time} = \text{Latch Edge} + \text{Longest Clock Path to Source Register} + \text{micro } t_{SU} \text{ of Destination Register}$$

Example 10–5 shows recovery time as reported by the Timing Analyzer.

Example 10–5. Recovery Time Reporting for a Registered Asynchronous Reset Signal

```
Info: Slack time is 8.947 ns for clock "a_clk" between source register "async_reg1" and
destination register "reg_1"
    Info: Requirement is of type recovery
    Info: - Data arrival time is 4.028 ns
        Info: + Launch edge is 0.000 ns
            Info: + Longest clock path from clock "a_clk" to source register is 3.067 ns
        Info: + Micro clock to output delay of source is 0.094 ns
        Info: + Longest register to register delay is 0.867 ns
    Info: + Data required time is 12.975 ns
        Info: + Latch edge is 10.000 ns
            Info: + Shortest clock path from clock "a_clk" to destination register is 3.065 ns
        Info: - Micro setup delay of destination is 0.090 ns
```

If the asynchronous control is not registered, the Quartus II Classic Timing Analyzer uses Equation 10–24 through Equation 10–26 to calculate the recovery slack time.

Equation 10–24.

$$\text{Recovery Slack Time} = \text{Data Required Time} - \text{Data Arrival Time}$$

Equation 10–25.

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Maximum Input Delay} + \text{Maximum Pin-to-Register Delay}$$

Equation 10–26.

$$\text{Data Required Time} = \text{Latch Edge} + \text{Shortest Clock Path to Destination Register Delay} - \text{micro } t_{SU} \text{ of Destination Register}$$

Example 10–6 shows recovery time as reported by the Timing Analyzer.

Example 10–6. Recovery Time Reporting for a Non-Registered Asynchronous Reset Signal

```
Info: Slack time is 8.744 ns for clock "a_clk15" between source pin "a_arst2" and
destination register "inst5"
       Info: Requirement is of type recovery
       Info: - Data arrival time is 4.787 ns
              Info: + Launch edge is 0.000 ns
              Info: + Max Input delay of pin is 1.500 ns
              Info: + Max pin to register delay is 3.287 ns
       Info: + Data required time is 13.531 ns
    Info: + Latch edge is 10.000 ns
    Info: + Shortest clock path from clock "a_clk15" to destination register is 3.542 ns
              Info: - Micro setup delay of destination is 0.011 ns
```

If the asynchronous reset signal is from a device pin, an Input Maximum Delay assignment must be made to the asynchronous reset pin for the Quartus II Classic Timing Analyzer to perform recovery analysis on that path.

Removal Report

When you set ENABLE_RECOVERY_REMOVAL_ANALYSIS to **ON**, the Quartus II Classic Timing Analyzer determines the removal time as the minimum amount of time required between an active clock edge that occurs while an asynchronous input is active, and the deassertion of the asynchronous control signal. The Quartus II Classic Timing Analyzer then compares this to your design and reports the results as slack. The Removal report alerts you to a condition in which an asynchronous input signal goes inactive too soon after a clock edge, thus rendering the register's data uncertain.

The removal time slack calculation is similar to the one used to calculate clock hold slack, which is based on data arrival time and data required time except for asynchronous control signals. If the asynchronous control is registered, the Quartus II Classic Timing Analyzer uses Equation 10–27 through Equation 10–29 to calculate the removal slack time.

Equation 10–27.

$$\text{Removal Slack Time} = \text{Data Arrival Time} - \text{Data Required Time}$$

Equation 10–28.

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Shortest Clock Path from Source Register Delay} + \text{micro } t_{CO} \text{ of Source Register} + \text{Shortest Register-to-Register Delay}$$

Equation 10–29.

$$\text{Data Required Time} = \text{Latch Edge} + \text{Longest Clock Path to Destination Register Delay} + \text{micro } t_H \text{ of Destination Register}$$

Example 10–7 shows removal time as reported by the Quartus II Classic Timing Analyzer.

Example 10–7. Removal Time Reporting for a Registered Asynchronous Reset Signal

```
Info: Minimum slack time is 814 ps for clock "a_clk" between source register "async_reg1"
and destination register "reg_1"
    Info: Requirement is of type removal
    Info: + Data arrival time is 4.028 ns
        Info: + Launch edge is 0.000 ns
        Info: + Shortest clock path from clock "a_clk" to source register is 3.067 ns
        Info: + Micro clock to output delay of source is 0.094 ns
        Info: + Shortest register to register delay is 0.867 ns
    Info: - Data required time is 3.214 ns
        Info: + Latch edge is 0.000 ns
        Info: + Longest clock path from clock "a_clk" to destination register is 3.065 ns
        Info: + Micro hold delay of destination is 0.149 ns
```

If the asynchronous control is not registered, the Quartus II Classic Timing Analyzer uses Equation 10–30 through Equation 10–32 to calculate the removal slack time.

Equation 10–30.

$$\text{Removal Slack Time} = \text{Data Arrival Time} - \text{Data Required Time}$$

Equation 10–31.

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Input Minimum Delay of Pin} + \text{Minimum Pin-to-Register Delay}$$

Equation 10–32.

$$\text{Data Required Time} = \text{Latch Edge} + \text{Longest Clock Path to Destination Register Delay} + \text{micro } t_H \text{ of Destination Register}$$

Example 10–8 shows removal time as reported by the Quartus II Classic Timing Analyzer.

Example 10–8. Removal Time Reporting for a Non-Registered Asynchronous Reset Signal

```
Info: Minimum slack time is 1.131 ns for clock "a_clk15" between source pin "a_arst2"
and destination register "inst5"
          Info: Requirement is of type removal
          Info: + Data arrival time is 4.787 ns
    Info: + Launch edge is 0.000 ns
    Info: + Min Input delay of pin is 1.500 ns
    Info: + Min pin to register delay is 3.287 ns
          Info: - Data required time is 3.656 ns
    Info: + Latch edge is 0.000 ns
    Info: + Longest clock path from clock "a_clk15" to destination register is 3.542 ns
       Info: + Micro hold delay of destination is 0.114 ns
```

If the asynchronous reset signal is from a device pin, an Input Minimum Delay assignment must be made to the asynchronous reset pin for the Quartus II Classic Timing Analyzer to perform a removal analysis on this path.

Skew Management

Clock skew is the difference in the arrival times of a clock signal at two different registers, which can be caused by path length differences between two clock paths, or by using gated or rippled clocks. As clock periods become shorter and shorter, the skew between data arrival times and clock arrival times becomes more significant. The Quartus II Classic Timing Analyzer provides two assignments for analyzing and constraining skew for data and clock signals.

Maximum Clock Arrival Skew

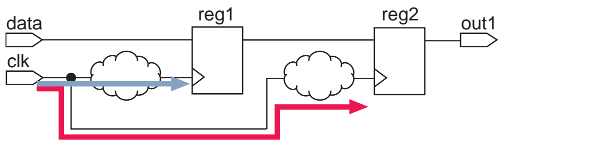
Make Maximum Clock Arrival Skew assignments to specify the maximum allowable clock arrival skew between a clock signal and various destination registers. The Quartus II Classic Timing Analyzer compares the longest clock path to the registers' clock port and the shortest clock path to the registers' clock port to determine if your maximum clock arrival skew is achieved. Maximum clock arrival skew is calculated using Equation 10–33.

Equation 10–33.

$$\text{Maximum Clock Arrival Skew} = \text{Longest Clock Path} - \text{Shortest Clock Path}$$

For example, if the delay from clock pin `clk` to the clock port of register `reg1` is 1.0 ns, and the delay from clock pin `clk` to the clock port of register `reg2` is 3.0 ns, as shown in Figure 10–21, the Quartus II Classic Timing Analyzer provides a clock skew slack time of 2.0 ns.

Figure 10–21. Clock Arrival Paths



You should apply the Maximum Clock Arrival Skew assignment to a clock node and a group of registers. When you make a Maximum Clock Arrival Skew assignment, the Fitter attempts to satisfy the skew requirement.

You can use the `set_instance_assignment -name max_clock_arrival_skew` Tcl command to specify a Maximum Clock Arrival Skew assignment. The following example specifies a maximum clock arrival skew of 1 ns from clock signal `clk` to the bank of registers matching `reg*`:

```
set_instance_assignment -name max_clock_arrival_skew 1ns -from clk \
-to reg*
```

Maximum Data Arrival Skew

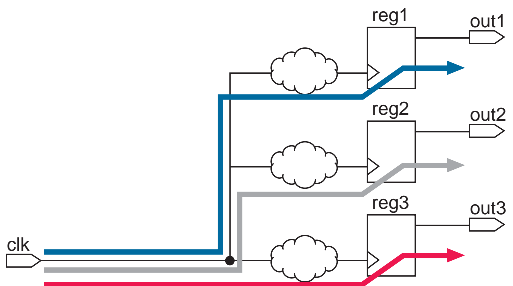
Make Maximum Data Arrival Skew assignments to specify the maximum allowable data arrival skew to various destination registers or pins. The Quartus II Classic Timing Analyzer compares the longest data arrival path to the shortest data arrival path to determine if your specified maximum data arrival skew is achieved. Maximum data arrival skew is calculated using Equation 10–34.

Equation 10–34.

$$\text{Maximum Data Arrival Skew} = \text{Longest Data Arrival Path} - \text{Shortest Data Arrival Path}$$

For example, if the data arrival time to output pin `out1` is 2.0 ns, the data arrival time to output pin `out2` is 1.5 ns, and the data arrival time to output pin `out3` is 1.0 ns, as shown in Figure 10–22, the Quartus II Classic Timing Analyzer provides a maximum data arrival skew slack time of 1.0 ns.

Figure 10–22. Data Arrival Paths



When you make a Maximum Data Arrival Skew assignment, the Fitter attempts to satisfy the skew requirement.

You can use the `set_instance_assignment -name max_data_arrival_skew` Tcl command to specify a maximum data arrival skew value. The following example specifies a maximum data arrival skew of 1 ns from clock signal `clk` to the bank of output pins `dout`:

```
set_instance_assignment -name max_data_arrival_skew 1ns -from clk \
-to dout[*]
```

Generating Timing Analysis Reports with report_timing

The Quartus II Classic Timing Analyzer includes the `report_timing` Tcl command for generating text-based timing analysis reports. You can customize the output of `report_timing` using multiple switches that allow the generation of both detailed and general timing reports on any path in the design.

The `report_timing` Tcl command is available in the `quartus_tan` executable.

Prior to using the `report_timing` Tcl command, you must open a Quartus II project and create a timing netlist. For example, the following two Tcl commands accomplish this:

```
project_open my_project
create_timing_netlist
```

The `report_timing` Tcl command provides `-from` and `-to` switches for filtering specific source and destination nodes. For example, the following `report_timing` Tcl command reports all clock setup paths, with the switch `-clock_setup`, between registers `src_reg*` and `dst_reg*`. The `-npaths` 20 switch limits the report to 20 paths.

```
report_timing -clock_setup -from src_reg* -to dst_reg* -npaths 20
```

The switches `-clock_filter` and `-src_clock_filter` are also available for filtering based on specific clock sources. For example, the following `report_timing` Tcl command reports all clock setup paths where the destination registers are clocked by `clk`:

```
report_timing -clock_setup -clock_filter clk
```

The following example reports clock setup paths where the destination registers are clocked by `clk`, and the source registers are clocked by `src_clock`.

```
report_timing -clock_setup -clock_filter clk -src_clock_filter src_clk
```

Example 10–9 is an example script that can be sourced by the `quartus_tan` executable:

Example 10–9. Source for the quartus_tan Executable

```
# Open a project
project_open my_project
# Always create the netlist first
create_timing_netlist
# List clock setup paths for clock clk
# from registers abc* to registers xyz*
report_timing -clock_setup -clock_filter clk -from abc* -to xyz*
# List the top 5 pin-to-pin combinational paths
report_timing -tpd -npaths 5
# List the top 5 pin-to-pin combinational paths and
# write output to an out.tao file
report_timing -tpd -npaths 5 -file out.tao
# Compute min tpd and append results to existing out.tao
report_timing -min_tpd -npaths 5 -file out.tao -append
# Show longest path (register to register data path) between a* and b*
report_timing -longest_paths -npaths 1
delete_timing_netlist
project close
```

Other Timing Analyzer Features

The Quartus II Classic Timing Analyzer provides many features for customizing and increasing the efficiency of static timing analysis, including:

- Wildcard assignments
- Assignment groups
- Fast corner analysis
- Early timing estimation
- Timing constraint checker
- Latch analysis

Wildcard Assignments

To simplify the tasks of making assignments to many node assignments, the Quartus II software accepts the * and ? wildcard characters. Use these wildcard characters to reduce the number of individual assignments you need to make for your design.

The "*" wildcard character matches any string. For example, given an assignment made to a node specified as `reg*`, the Quartus II Classic Timing Analyzer searches and applies the assignment to all design nodes that match the prefix `reg` with none, one, or several characters following, such as `reg1`, `reg[2]`, `regbank`, and `reg12bank`.

The "?" wildcard character matches any single character. For example, given an assignment made to a node specified as `reg?`, the Quartus II Classic Timing Analyzer searches and applies the assignment to all design nodes that match the prefix `reg` and any single character following, such as `reg1`, `rega`, and `reg4`.

Assignment Groups

Assignment groups, also known as time groups, allow you to define a custom group of nodes to which you can assign timing assignments. You can also exclude specific nodes, wildcards, and time groups from a time group.

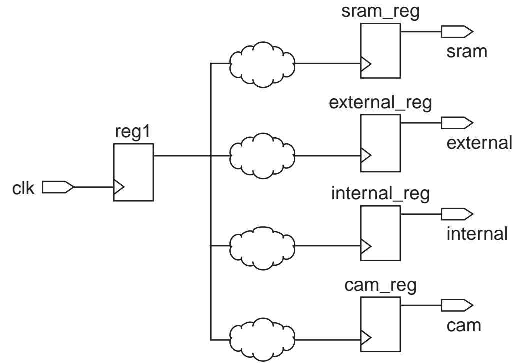
Use the `timegroup` Tcl command to create an assignment group. The following example creates an assignment group `srcgrp` and adds nodes with names that match `src1*` to the group:

```
timegroup srcgrp -add_member src1*
```

For example, Figure 10–23 has false paths between source register `reg1` and destination register bank `sram_reg`, `external_reg`, `internal_reg`, and `cam_reg` that need to be cut. Without the use of assignment groups, the assignments required are:

```
set_timing_cut_assignment -from reg1 to sram_reg
set_timing_cut_assignment -from reg1 to external_reg
set_timing_cut_assignment -from reg1 to internal_reg
set_timing_cut_assignment -from reg1 to cam_reg
```

Figure 10–23. False Path



With an assignment group called `dst_reg_bank`, the assignments required are:

```
#create a time group called dst_reg
timegroup dst_reg_bank -add_member sram_reg
timegroup dst_reg_bank -add_member external_reg
timegroup dst_reg_bank -add_member internal_reg
timegroup dst_reg_bank -add_member cam_reg
#cut timing paths
set_timing_cut_assignment -from reg1 to dst_reg_bank
```

Once an assignment group has been defined, applicable timing assignment can be made to the time group without redefining the assignment group.

Assigning individual nodes to time groups and applying timing assignments to these time groups can improve the performance of the Quartus II Classic Timing Analyzer.

Fast Corner Analysis

Fast Corner Analysis uses timing models generated under best-case conditions (voltage, process, and temperature) for the fastest speed-grade device.

Both Fast Corner and Slow Corner static timing analysis reports are saved to the <*project name*>**.tan.rpt** file, potentially overwriting previous timing analysis reports. To preserve a copy of your reports, save the file with a new name before the next compilation or static timing analysis, or use the Combined Fast/Slow Analysis report feature.

The Quartus II software also reports minimum delay checks after a slow corner (default) analysis. These results are generated by reporting minimum delay checks using worst-case timing models.

To perform fast corner static timing analysis with the best-case timing models, you can use the `switch --fast_model=on` with the `quartus_tan` executable. The following Tcl command enables the fast timing models:

```
quartus_tan <project_name> --fast_model=on
```

© March 2009 Altera Corporation

Early Timing Estimation

The majority of Quartus II software compilation time is consumed by the place-and-route process used to obtain optimal design results. To accelerate the design process for large designs, the Quartus II software provides **Early Timing Estimation**. This feature provides a quick static timing analysis in a fraction of the time required for a full compilation by performing a preliminary place-and-route on the design without full optimizations, which reduces total compile time by up to five times compared to a fully fitted design.

An Early Timing Estimate fit is not fully optimized or legally routed. The timing delay report is only an estimate. Typically, the estimated delays are within 10% of those obtained with a full fit when the realistic setting is used.

The Early Timing Estimate has three settings for generating timing estimates: Realistic, Optimistic, and Pessimistic. Table 10–1 describes these settings.

Table 10–1. Early Timing Estimate Setting Options

Setting	Description
Realistic (default setting: estimates final timing using standard fitting)	Generates timing estimates that are likely to be closest to full compilation results.
Optimistic (estimates best-case final timing)	Generates timing estimates that are unlikely to be exceeded by full compilation.
Pessimistic (estimates worst-case final timing)	Generates timing estimates that are likely to be exceeded by full compilation.

To use the **Early Timing Estimate** feature, enter the following Tcl command when performing a fit:

```
quartus_fit \
--early_timing_estimate[=<realistic|optimistic|pessimistic>]
```

After **Early Timing Estimate** is complete, a full timing report is generated based on the early placement and routing delays. In addition, you can view the preliminary logic placement in the Timing Closure floorplan. The early timing placement allows you to perform initial placement and view the timing interaction of various placement topology.

Timing Constraint Checker

Altera recommends that you enter all timing constraints into the Quartus II software prior to performing a full compilation. This ensures that the Fitter targets the correct timing requirements and ensures that the Quartus II Classic Timing Analyzer reports the correct violations for all timing paths in the design. To ensure that all constraints have been applied to design nodes, the **Timing Constraint Check** feature reports all unconstraint paths in your design. Example 10–10 shows the timing constraint check summary generated after a full compilation.

Example 10–10. Timing Constraint Check Summary

```

```

To perform a timing constraint check, use the `switch --check_constraints` with the `quartus_tan` executable. The following Tcl command performs a timing constraint check on both setup and hold on the design system:

```
quartus_tan block1 --check_constraints=both
```

Latch Analysis

Latches are implemented in the Quartus II software as look-up-tables (LUTs) feeding back onto themselves. The Quartus II Classic Timing Analyzer can analyze these latches as synchronous elements rather than as combinational elements. The clock enables are analyzed as inverted clocks. The Quartus II Classic Timing Analyzer reports the results of setup and hold analysis on these latches.

You can turn on the Analyze Latches As Synchronous Elements option with the following Tcl command:

```
set_global_assignment -name ANALYZE_LATCHES_AS_SYNCHRONOUS_ELEMENTS ON
```

Timing Analysis Using the Quartus II GUI

In addition to the extensive scripting support available in the Quartus II Classic Timing Analyzer, the Quartus II software provides the Assignment Editor and other user interface tools, giving you access to the Quartus II Classic Timing Analyzer features and assignments.

Assignment Editor

The Assignment Editor is a spreadsheet-style interface used for adding, modifying, and deleting timing assignments.

To make timing assignments in the Assignment Editor, choose **Timing** from the category list to cause the Assignment Name column to display only timing assignments. Double-click **<<new>>** in the Assignment Name field, the Assignment Name list displays. Figure 10–24 shows the Assignment Editor with the Assignment Name list displaying timing assignment types.

Figure 10–24. Assignment Editor

For more information about the Assignment Editor, refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook*.

Timing Settings

You can specify delay requirements and clock settings with the **Timing Analysis Settings** page of the **Settings** dialog box.

To access this page, on the Assignments menu, click **Settings**. In the **Category** list, click the "+" icon next to **Timing Analysis Settings** to expand the folder. (Be sure that the **Use Classic Timing Analyzer during compilation** radio button is turned on.) Select **Classic Timing Analyzer Settings**. The **Classic Timing Analysis Settings** page appears.

Clock Settings Dialog Box

You can create or modify base clock settings or derived clock settings using the **Clock Settings** dialog box. To access this page, on the Assignments menu, click **Settings**. In the **Category** list, click the "+" icon next to **Timing Analysis Settings** to expand the folder. (Be sure that the **Use Classic Timing Analyzer during compilation** radio button is turned on.) Click on **Classic Timing Analyzer Settings**. The Timing **Analysis Settings** page displays. Under **Clock Settings**, click **Individual Clocks**. The **Individual Clock** dialog box appears.

Click the **New** button in the **Individual Clocks** dialog box to access the **New Clock Settings** dialog box and create a base or derived clock setting.

More Timing Settings Dialog Box

On the **Timing Analysis Settings** page of the **Settings** dialog box, click **More Settings** to display the **More Timing Settings** dialog box. The **More Timing Settings** dialog box provides access to many global timing analysis options.

Timing Reports

The Quartus II Classic Timing Analyzer report is a section of the Compilation Report containing the static timing analysis results. The Quartus II Classic Timing Analyzer report includes clock setup and clock hold measurements for all clock sources. The report also shows t_{CO} for all output pins, t_{SU} and t_H for all input pins, and t_{PD} for any pin-to-pin combinational paths in the design. Other reports are created for different analyses and device features.

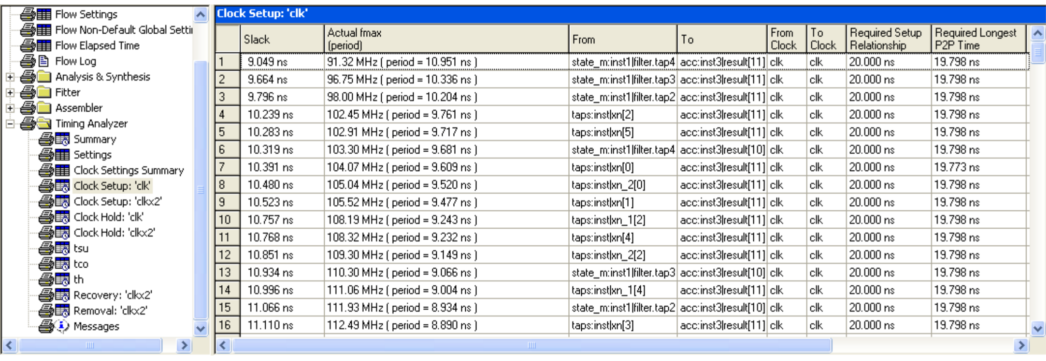
In the **Settings** dialog box, you can specify the range of information to be reported in the timing analysis of the Compilation Report. To access this page, on the Assignments menu, click **Settings**. In the **Category** list, click the ⊞ icon next to **Timing Analysis Settings** to expand the folder. (Be sure that the **Use Classic Timing Analyzer during compilation** radio button is turned on.) Click the ⊞ icon next to **Classic Timing Analyzer Settings** to expand the folder. Click **Classic Timing Analyzer Reporting**. The **Classic Timing Analyzer Reporting** dialog box appears.

If there are no timing assignments for the design, the Quartus II Classic Timing Analyzer does not generate slack reports for any detected clock nodes. The Quartus II Classic Timing Analyzer only reports slack measurements for pins with individual or global t_{SU}, t_H, or t_{CO} assignments. A positive slack indicates the margin by which the path surpasses the clock timing requirements. A negative slack indicates the margin by which the path fails the clock timing requirements.

This Timing Analysis report is also available in text format located in the design directory with the file name <*revision name*>**.tan.rpt**.

In the Compilation Report, select an analysis type under the Timing Analyzer folder to display the analysis report; for example, Clock Setup or Clock Hold. Figure 10–25 shows an example of a Clock Setup report for clock signal `clk`.

Figure 10–25. Timing Analysis Report

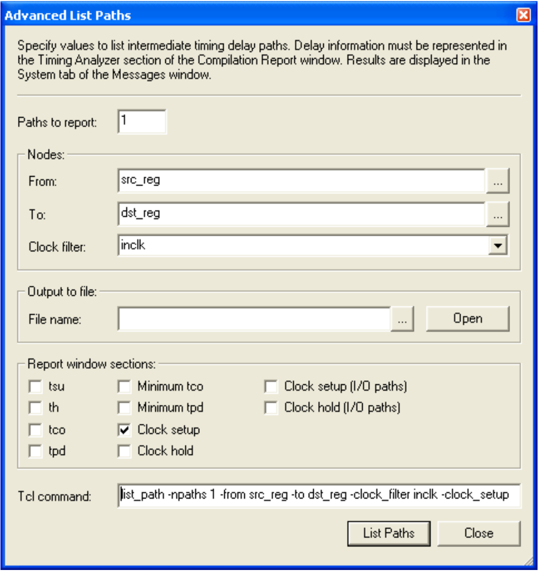


Advanced List Path

The **Advanced List Paths** dialog box provides detailed information about a specific path, such as interconnect and cell delays between any two valid register-to-register paths (Figure 10–26).

The **Advanced List Paths** dialog box allows you to select the type of paths you want listed. For example, you can obtain detailed information for Clock Setup and Clock Hold for a specific clock. In addition, the Tcl command field in the window matches the equivalent Tcl command you can use in either a custom Tcl script or in the Tcl console.

Figure 10–26. Advanced List Paths Dialog Box



You can perform a list path command directly from the Timing Analysis report. To do this, right click a path and click **List Path** (Figure 10–27). To launch the **Advanced List Paths** dialog box, right-click a path and in the menu that appears, and select **Advanced List Paths**.

The **Advanced List Paths** dialog box displays only paths that are visible in the Timing Analysis report. To increase the amount of paths reported by the Quartus II Classic Timing Analyzer, on the Assignments menu, click **Timing Analysis Settings**. In the **Category** list, expand **Timing Analysis Settings** and select **Timing Analyzer Reporting**. In the **Timing Analyzer Reporting page**, specify the range of information to be reported by the Quartus II Classic Timing Analyzer.

Both the **Advanced List Paths** and the **List Path** commands display the path information in the **System** message window.

Figure 10–27. List Path in the Message Window

```
Info: Slack time is 8.064 ns for clock "clk3" between source register "reg1" and destination register "reg2"
  Info: Fmax is restricted to 275.03 MHz due to tcl and tch limits
  Info: + Largest register to register requirement is 8.891 ns
    Info: + Setup relationship between source and destination is 10.000 ns
    Info: + Largest clock skew is -0.848 ns
    Info: - Micro clock to output delay of source is 0.224 ns
    Info: - Micro setup delay of destnation is 0.037 ns
  Info: - Longest register to register delay is 0.827 ns
    Info: 1: + IC(0.000 ns) + CELL(0.000 ns) = 0.000 ns; Loc. = LC_X33_Y20_N6; Fanout = 1; REG Node = 'reg1'
    Info: 2: + IC(0.518 ns) + CELL(0.309 ns) = 0.827 ns; Loc. = LC_X33_Y20_N2; Fanout = 2; REG Node = 'reg2'
    Info: Total cell delay = 0.309 ns ( 37.36 % )
    Info: Total interconnect delay = 0.518 ns ( 62.64 % )
```

If the **Combined Fast/Slow Timing** option is enabled, the **List Path** Tcl command displays only path delays reported in the Slow Model section.

Early Timing Estimate

To start an Early Timing Estimate, on the Processing menu, point to **Start** and click **Start Early Timing Estimate**. To specify the Early Timing Estimate mode, on the Assignments menu, click **Settings**. In the **Category** list, select **Compilation Processes Settings**, select **Early Timing Estimate** and click the desired timing estimate mode. For more information about the Early Timing Estimate feature, refer to "Early Timing Estimation" on page 10–33.

Assignment Groups

To define, modify, and delete assignment groups, also known as time groups, from a single dialog box, on the Assignments menu, click **Assignment** (**Time) Groups**. The **Assignment Groups** dialog box appears.

Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp
```

For more information in PDF form, refer to the *Quartus II Scripting Reference Manual*.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*.

For information about all settings and constraints in the Quartus II software, refer to the *Quartus II Settings File Reference Manual*.

For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Creating Clocks

There are two Tcl commands that allow you to define clocks in a design, `create_base clock` and `create_relative_clock`.

Base Clocks

Use the `create_base_clock` Tcl command to define a base clock:

```
create_base_clock [-h | -help] [-long_help] -fmax <fmax> \
[-duty_cycle <integer>] [-virtual] [-target <name>] [-no_target] \
[-entity <entity>] [-disable] [-comment <comment>] <clock_name>
```

To define a base clock setting named `sys_clk` with a 100 MHz requirement applied to node `clk_src`, enter the following Tcl command:

```
create_base_clock -fmax 100MHz -target clk_src sys_clk
```

Derived Clocks

Use the `create_relative_clock` Tcl command to define a relative clock:

```
create_relative_clock [-h | -help] [-long_help] \
-base_clock <Base clock> [-duty_cycle <integer>] \
[-multiply <integer>] [-divide <integer>] [-offset <offset>] \
[-phase_shift <integer>] [-invert] [-virtual] [-target <name>] \
[-no_target] [-entity <entity>] [-disable] \
[-comment <comment>] <clock_name>
```

To define a relative clock named `aux_clk` based upon base clock setting `sys_clk` with a multiplication factor of 2 applied to node `rel_clk`, enter the following Tcl command:

```
create_relative_clock -base_clock sys_clk -multiply 2 \
-target rel_clk aux_clk
```

Clock Latency

You can use the `set_clock_latency` Tcl command to create either an early or late clock latency assignment:

```
set_clock_latency [-h | -help] [-long_help] [-early] [-late] \
-to <to> [<value>]
```

To apply an early clock latency of 1 ns and a late clock latency of 2 ns to clock node `clk`, enter the following Tcl commands:

```
set_clock_latency -early -to clk 2ns
```

Clock Uncertainty

You can use the `set_clock_uncertainty` Tcl command to create clock uncertainty assignments as shown in the following example:

```
set_clock_uncertainty [-h] [-help] [-long_help [-from \
<source clock name> ] -to <destination clock name> [-setup] [-hold] \
[-remove] [-disable] [-comment <comment>] <value>
```

To apply a clock setup uncertainty of 50 ps between source clock node `clk_src` and destination clock node `clk_dst`, enter the following Tcl command:

```
set_clock_uncertainty -from clk_src -to clk_dst -setup 50ps
```

To apply a clock hold uncertainty of 25 ps between to clock node `clk_sys`, enter the following Tcl command:

```
set_clock_uncertainty -to clk_sys -setup 25ps
```

Cut Timing Paths

You can use the `set_timing_cut_assignment` Tcl command to create cut timing assignments:

```
set_timing_cut_assignment [-h | -help] [-long_help] \
[-from <from_node_list>] [-to <to_node_list>] [-remove] [-disable] \
[-comment <comment>]
```

To cut the timing path from source register `reg1` to destination register `reg2`, enter the following Tcl command:

```
set_timing_cut_assignment -from reg1 -to reg2
```

Input Delay Assignment

You can use the Tcl command `set_input_delay` to create input delay assignments:

```
set_input_delay [-h | -help] [-long_help] [-clk_ref <clock>] \
-to <input_pin> [-min] [-max] [-clock_fall] [-remove] [-disable] \
[-comment <comment>] [<value>]
```

To apply an input maximum delay of 2 ns to an input pin named `data_in` that feeds a register clocked by clock source `clk`, enter the following Tcl command:

```
set_input_delay -clk_ref clk -to data_in –max 2ns
```

Maximum and Minimum Delay

The following Tcl commands create the Maximum Delay and Minimum Relationship assignments, respectively:

```
set_instance_assignment -name MAX_delay <value> -from <node> -to <node>
set_instance_assignment -name MIN_delay <value> -from <node> -to <node>
```

To apply a Maximum Delay of 8 ns and a minimum of 5 ns between source register `reg1` and destination register `reg2`, enter the following Tcl command:

```
set_instance_assignment -name MAX_DELAY 8ns -from reg1 -to reg2
set_instance_assignment -name MIN_DELAY 5ns -from reg1 -to reg2
```

To apply a Maximum Delay of 10 ns for all paths from source clock `clk_src` to destination clock `clk_dst`, enter the following Tcl command:

```
set_instance_assignment -name MAX_DELAY 10ns -from clk_src -to clk_dst
```

Maximum Clock Arrival Skew

The following Tcl command defines the Maximum Clock Arrival Skew assignment:

```
set_instance_assignment -name max_clock_arrival_skew <value> \
-from <clock> -to <node>
```

To apply a Maximum Clock Arrival Skew of 1 ns for clock source `clk` to a predefined timegroup called `reg_group`, enter the following Tcl command:

```
set_instance_assignment -name max_clock_arrival_skew 1ns -from clk \
-to reg_group
```

Maximum Data Arrival Skew

To create Maximum Data Arrival Skew assignments, use the Tcl command `set_instance_assignment -name max_data_arrival`:

```
set_instance_assignment -name max_data_arrival_skew <value> \
-from <clock> -to <node>
```

To apply a Maximum Data Arrival Skew of 1 ns for clock source `clk` to a predefined timegroup of pins called `pin_group`, enter the following Tcl command:

```
set_instance_assignment -name max_data_arrival_skew 1ns -from clk \
-to pin_group
```

Multicycle

Use the `set_multicycle_assignment` Tcl command to create Multicycle assignments:

```
set_multicycle_assignment [-h | -help] [-long_help] [-setup] [-hold] \
[-start] [-end] [-from <from_list>] [-to <to_list>] [-remove] \
[-disable] [-comment <comment>] <path_multiplier>
```

To apply a Multicycle Setup of 2 and a Hold Multicycle of 1 between source register `reg1` and destination register `reg2`, enter the following Tcl commands:

```
set_multicycle_assignment -setup -end -from reg1 -to reg2 2
set_multicycle_assignment -hold -end -from reg1 -to reg2 1
```

To apply a Source Multicycle Setup of 2 between source register `reg1` and destination register `reg2`, enter the following Tcl command:

```
set_multicycle_assignment -setup -start -from reg1 -to reg2 1
```

To apply a multicycle setup of 2 for all paths from source clock `clk_src` to destination clock `clk_dst`, enter the following Tcl command:

```
set_multicycle_assignment -setup -end -from clk_src -to clk_dst 2
```

Output Delay Assignment

Use the Tcl command `set_output_delay` to create Output Delay assignments:

```
set_output_delay [-h | -help] [-long_help] [-clk_ref <clock>] \
-to <output_pin> [-min] [-max] [-clock_fall] [-remove] [-disable] \
[-comment <comment>] [<value>]
```

To apply an Output Maximum Delay of 3 ns to an output pin named `data_out` that is fed to a register clocked by clock source `clk`, enter the following Tcl command:

```
set_output_delay -clk_ref clk -to data_out -max 3ns
```

Report Timing

Use the `report_timing` Tcl command to generate timing reports:

```
report_timing [-h | -help] [-long_help] [-npaths <number>] [-tsu] \
[-th] [-tco] [-tpd] [-min_tco] [-min_tpd] [-clock_setup] \
[-clock_hold] [-clock_setup_io] [-clock_hold_io] [-clock_setup_core] \
[-clock_hold_core] [-recovery] [-removal] [-dqs_read_capture] \
[-stdout] [-file <name>] [-append] [-table <name>] [-from <names>] \
[-to <names>] [-clock_filter <names>] [-src_clock_filter <names>] \
[-longest_paths] [-shortest_paths] [-all_failures]
```

The following example generates a list of all clock setup paths for clock source `clk` from registers `src_reg*` to registers `dst_reg*`:

```
report_timing -clock_setup -clock_filter clk -from src_reg* \
-to dst_reg*
```

Setup and Hold Relationships

The following Tcl commands create Setup Relationship and Hold Relationship assignments, respectively:

```
set_instance_assignment -name SETUP_RELATIONSHIP <value> -from <node> \
-to <node>
set_instance_assignment -name HOLD_RELATIONSHIP <value> -from <node> \
-to <node>
```

To apply a Setup Relationship of 12 ns and a Hold Relationship of 2 ns between source register `reg1` and destination registers `reg2`, enter the following Tcl command:

```
set_instance_assignment -name SETUP_RELATIONSHIP 12ns -from reg1 \
-to reg2
set_instance_assignment -name HOLD_RELATIONSHIP 2ns -from reg1 -to reg2
```

To apply a setup relationship of 10 ns for all paths from source clock `clk_src` to destination clock `clk_dst`, enter the following Tcl command:

```
set_instance_assignment -name SETUP_RELATIONSHIP 10ns -from clk_src \
-to clk_dst
```

Assignment Group

Use the `timegroup` Tcl command to create assignment groups:

```
timegroup [-h | -help] [-long_help] [-add_member <name>] \
[-add_exception <name>] [-remove_member <name>] [-remove_exception \
<name>] [-get_members] [-get_exceptions] [-overwrite] [-remove] \
[-disable] [-comment <comment>] <group_name>
```

The following example creates an assignment group called `reg_bank` with members `dst_reg*`, and excludes register `dst_reg5`.

```
timegroup reg_bank -add_member dst_reg* -add_exception dst_reg5
```

Virtual Clock

Use the `create_relative_clock` with the `-virtual` switch to create Virtual Clock assignments:

```
create_relative_clock [-h | -help] [-long_help] -base_clock \
<Base clock> [-duty_cycle <integer>] [-multiply <integer>] \
[-divide <integer>] [-offset <offset>] [-phase_shift <integer>] \
[-invert] [-virtual] [-target <name>] [-no_target] [-entity <entity>] \
[-disable] [-comment <comment>] <clock_name>
```

To define a virtual clock derived from the base clock setting `clk_aux` named `brd_sys`, enter the following Tcl command:

```
create_relative_clock -base_clock clk_aux -virtual brd_sys
```

MAX+PLUS II Timing Analysis Methodology

This section describes the basic static timing analysis and assignments available in the Quartus II software that originated in the MAX+PLUS® II design software.

f_{MAX} Relationships

Maximum clock frequency is the fastest speed at which the design clock can run without violating internal setup and hold time requirements. The Quartus II software performs static timing analysis on both single- and multiple-clock designs.

Apply clock settings to all clock nodes in a design to ensure that you meet all performance requirements. Refer to “Clock Settings” on page 10–7 for more information.

Slack

Slack is the margin by which a timing requirement such as f_{MAX} is met or not met. Positive slack indicates the margin by which a requirement is met. Negative slack indicates the margin by which a requirement is not met. The Quartus II software determines slack using Equation 10–35 through Equation 10–38.

Equation 10–35.

$$\text{Clock Setup Slack} = \text{Longest Register-to-Register Requirement} - \text{Longest Register-to-Register Delay}$$

Equation 10–36.

$$\text{Register-to-Register Requirement} = \text{Setup Relationship} + \text{Largest Clock Skew} - \text{micro } t_{CO} \text{ of Source Register} - \text{micro } t_{SU} \text{ of Destination Register}$$

Equation 10–37.

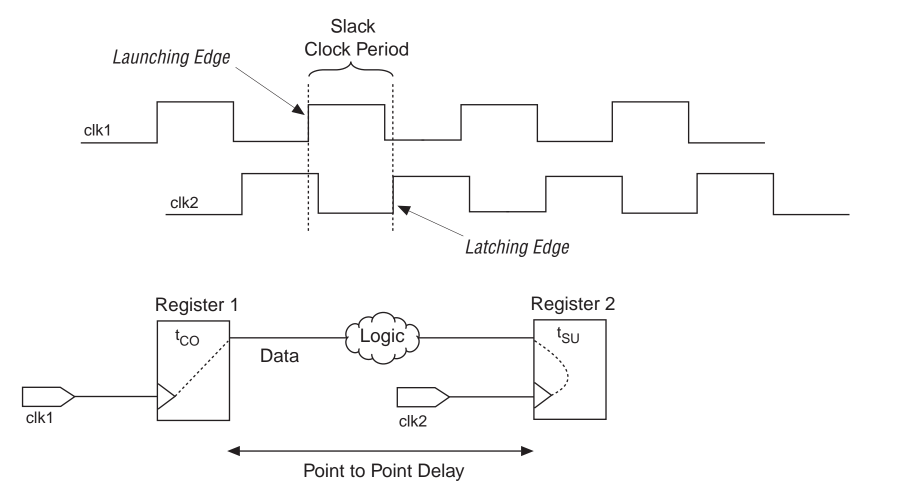
$$\text{Clock Hold Slack} = \text{Shortest Register-to-Register Delay} - \text{Smallest Register-to-Register Requirement}$$

Equation 10–38.

$$\text{Shortest Register-to-Register Requirement} = \text{Hold Relationship} + \text{Smallest Clock Skew} - \text{micro } t_{CO} \text{ of Source Register} - \text{micro } t_{H} \text{ of Destination Register}$$

Figure 10–28 shows a slack calculation diagram.

Figure 10–28. Slack Calculation Diagram



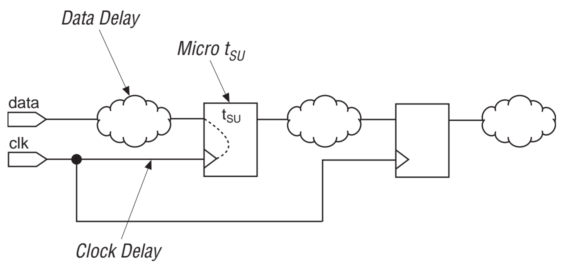
I/O Timing

This section describes the basic measurements made for I/O timing in the Quartus II software.

t_{SU} Timing

t_{SU} specifies the length of time data needs to arrive and be stable at an external input pin prior to a clock transition on an associated clock I/O pin. A t_{SU} requirement describes this relationship for an input register relative to the I/O pins of the FPGA. Figure 10–29 shows a diagram of clock setup time.

Figure 10–29. Clock Setup Time (t_{SU})



Micro t_{SU} is the internal setup time of the register. It is a characteristic of the register and is unaffected by the signals feeding the register. Equation 10–39 calculates the t_{SU} of data with respect to `clk` for the circuit shown in Figure 10–29.

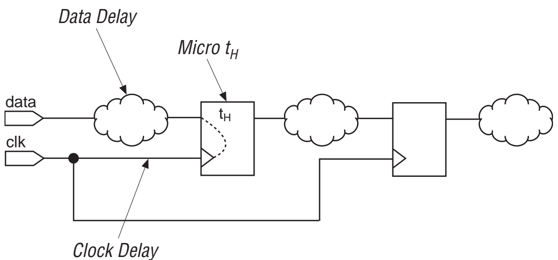
Equation 10–39.

$$t_{SU} = \text{Longest Data Delay} - \text{Shortest Clock Delay} + \text{micro } t_{SU} \text{ of Input Register}$$

t_H Timing

t_H specifies the length of time data needs to be held stable on an external input pin after a clock transition on an associated clock I/O pin. A t_H requirement describes this relationship for an input register relative to the I/O pins of the FPGA. Figure 10–30 shows a diagram of clock hold time.

Figure 10–30. Clock Hold Time (t_H)



Micro t_H is the internal hold time of the register. Equation 10–40 calculates the t_H of data with respect to `clk` for the circuit shown in Figure 10–30.

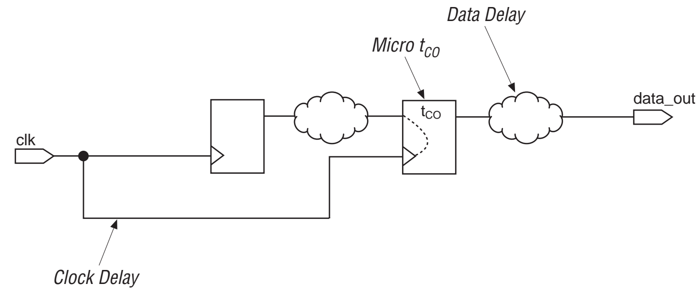
Equation 10–40.

$$t_H = \text{Longest Clock Delay} - \text{Shortest Data Delay} + \text{micro } t_H \text{ of Input Register}$$

t_{CO} Timing

Clock-to-output delay is the maximum time required to obtain a valid output at an output pin fed by a register, after a clock transition on the input pin that clocks the register. Micro t_{CO} is the internal clock-to-output delay of the register. Figure 10–31 shows a diagram of clock-to-output delay.

Figure 10–31. Clock-to-Output Delay (t_{CO})



Equation 10–41 calculates the t_{CO} for output pin `data_out` with respect to clock node `clk` for the circuit shown in Figure 10–31.

Equation 10–41.

$$t_{CO} = \text{Longest Clock Delay} + \text{micro } t_{CO} \text{ of Output Register}$$

Minimum t_{CO} (min t_{CO})

Minimum clock-to-output delay is the minimum time required to obtain a valid output at an output pin fed by a register, after a clock transition on the input pin that clocks the register. Micro t_{CO} is the internal clock-to-output delay of registers in Altera FPGAs. Unlike the t_{CO} assignment, the min t_{CO} assignment looks at the shortest delay paths (Equation 10–42).

Equation 10–42.

$$\text{min } t_{CO} = \text{Shortest Clock Delay} + \text{Shortest Data Delay} + \text{micro } t_{CO} \text{ of Output Register}$$

t_{PD} Timing

Pin-to-pin delay (t_{PD}) is the time required for a signal from an input pin to propagate through combinational logic and appear at an external output pin (Equation 10–43).

Equation 10–43.

$$t_{PD} = \text{Longest Pin-to-Pin Delay}$$

In the Quartus II software, you can make t_{PD} assignments between an input pin and an output pin.

Minimum t_{PD} (min t_{PD})

The minimum pin-to-pin delay (t_{PD}) is the time required for a signal from an input pin to propagate through combinational logic and appear at an external output pin. Unlike the t_{PD} assignment, the min t_{PD} assignment applies to the shortest pin-to-pin delay (Equation 10–44).

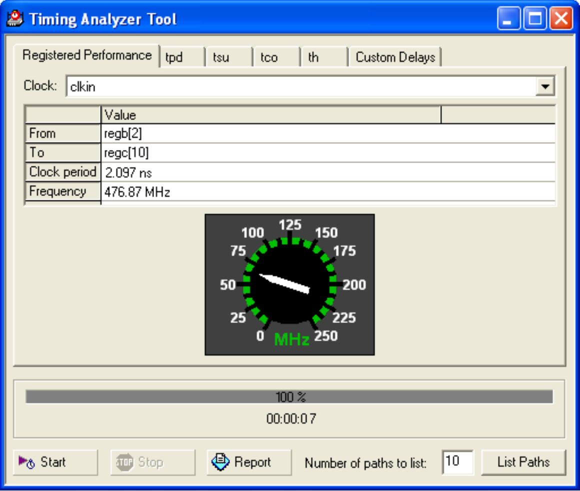
Equation 10–44.

$$\text{min } t_{PD} = \text{Shortest Pin-to-Pin Delay}$$

The Timing Analyzer Tool

To facilitate the classic static timing analysis flow and constraint, the Quartus II software provides a MAX+PLUS II-style Timing Analyzer Tool available on the Tools menu. The Timing Analyzer Tool provides a simple interface, similar to the Timing Analyzer tool in MAX+PLUS II, that reports register-to-register performance, I/O timing, and custom delay values (Figure 10–32).

Figure 10–32. Timing Analyzer Tool



Conclusion

Evolving design and aggressive process technologies require larger and higher-performance FPGA designs. Increasing design complexity demands enhanced static timing analysis tools that aid designers in verifying design timing requirements. Without advanced static timing analysis tools, you risk circuit failure in complex designs. The Quartus II Classic Timing Analyzer incorporates a set of powerful static timing analysis features critical in enabling system-on-a-programmable-chip (SOPC) designs.

Document Revision History

Table 10–2 shows the revision history for this chapter.

Table 10–2. Document Revision History

Date and Version	Changes Made	Summary of Changes
March 2009 v9.0.0	This was chapter 9 in version 8.1.	—
November 2008 v8.1.0	Changed to 8-1/2 x 11 page size. No change to content.	Updated for the Quartus II software version 8.1 release.
May 2008 v8.0.0	Added hyperlinks to referenced documents throughout the chapter. No other substantive changes were made.	—

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

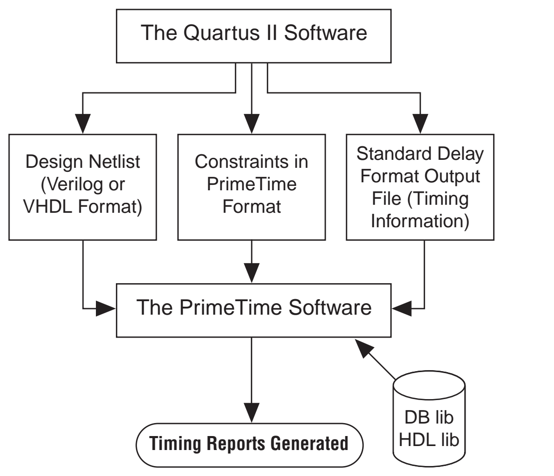
11. Synopsys PrimeTime Support

QII53005-9.0.0

Introduction

PrimeTime is an industry standard sign-off tool that performs static timing analysis on ASIC designs. The Quartus® II software makes it easy for designers to analyze their Quartus II projects using the PrimeTime software. The Quartus II software exports a netlist, design constraints (in the PrimeTime format), and libraries to the PrimeTime software environment. Figure 11–1 shows the PrimeTime flow diagram.

Figure 11–1. PrimeTime Software Flow Diagram



This chapter contains the following sections:

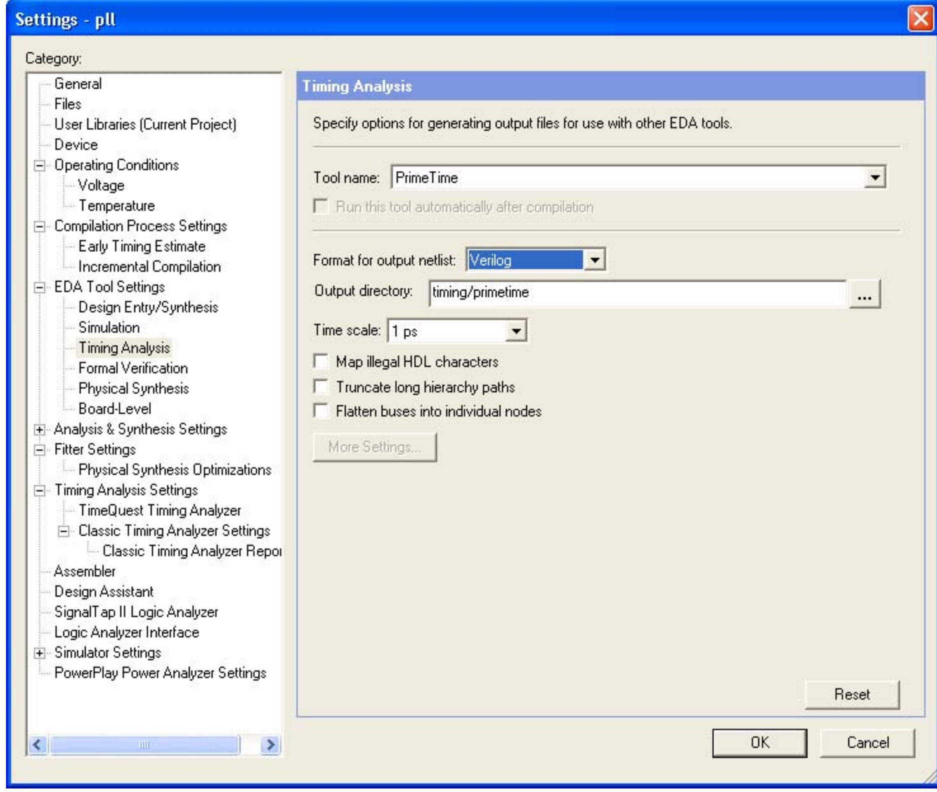
- "Quartus II Settings for Generating the PrimeTime Software Files"
- "Files Generated for the PrimeTime Software Environment" on page 11–2
- "Running the PrimeTime Software" on page 11–7
- "PrimeTime Timing Reports" on page 11–8
- "Static Timing Analyzer Differences" on page 11–18

Quartus II Settings for Generating the PrimeTime Software Files

To set the Quartus II software to generate files for the PrimeTime software, perform the following steps:

1. In the Quartus II software, on the Assignments menu, click **EDA Tool Settings**.
2. In the **Category** list, under **EDA Tool Settings,** select **Timing Analysis**.
3. In the **Tool name** list, select **PrimeTime**, and in the **Format for output netlist** list, select either **Verilog** or **VHDL**, depending on the HDL language you chose for use with the PrimeTime software (Figure 11–2).

Figure 11–2. Setting the Quartus II Software to Generate the PrimeTime Software Files



When you compile your project after making these settings, the Quartus II software runs the EDA Netlist Writer to create three files for the PrimeTime software. These files are saved in the <*revision_name*>**/timing/primetime** directory by default, where <*revision_name*> is the name of your Quartus II software revision. If it is not, you have used the wrong variable name.

Files Generated for the PrimeTime Software Environment

The Quartus II software generates a flattened netlist, a Standard Delay Output File (**.sdo**), and a Tcl script that prepares the PrimeTime software for timing analysis of the Quartus II project. These files are saved in the <*project directory*>**/timing/primetime** directory.

The Quartus II software uses the EDA Netlist Writer to generate PrimeTime files based on either the Quartus II Classic Timing Analyzer or the Quartus II TimeQuest Timing Analyzer static timing analysis results. When you run the EDA Netlist Writer, the PrimeTime SDO files are based on delays generated by the currently selected timing analysis tool in the Quartus II software.

To specify the timing analyzer, on the Assignments menu, click **Settings**. The **Settings** dialog box appears. Under **Category**, click **Timing Analysis Settings**. Select the timing analyzer of your choice.

For more information about specifying the Quartus II timing analyzers, refer to either the *Quartus II Classic Timing Analyzer* or the *Quartus II TimeQuest Timing Analyzer* chapters in volume 3 of the *Quartus II Handbook*. Also, refer to the *Switching to the Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook* to help you decide which timing analyzer is most appropriate for your design.

The Netlist

Depending on whether **Verilog** or **VHDL** is selected as the **Format for output netlist** option, in the **Tool name** list on the **Timing Analysis** page of the **Settings** dialog box, the netlist is written and saved as either <*project name*>**.vo** or <*project name*>**.vho**, respectively. This file contains the flattened netlist representing the entire design.

When the Quartus II TimeQuest Timing Analyzer is selected, only a Verilog PrimeTime netlist is generated.

The SDO File

The Quartus II software saves the Standard Delay Format Output (**.sdo**) File as either <*revision_name*>**_v.sdo** or <*revision_name*>**_vhd.sdo**, depending on whether you selected **Verilog** or **VHDL** in the **Tool name** list on the **Timing Analysis** page of the **Settings** dialog box.

This file contains the timing information for each timing path between any two nodes in the design.

When the Quartus II Classic Timing Analyzer is enabled, the slow-corner (worst case) timing models are used by default when generating the SDO file. To generate the SDO file using the fast-corner (best case) timing models, perform the following steps:

1. In the Quartus II software, on the Processing menu, point to **Start** and click **Start Classic Timing Analyzer (Fast Timing Model)**.
2. After the fast-corner timing analysis is complete, on the Processing menu, point to **Start** and click **Start EDA Netlist Writer** to create a <*revision_name*>**_v_fast.sdo** or <*revision_name*>**_vhd_fast.sdo** file, which contains the best-case delay values for each timing path.

If you are running a best-case timing analysis, the Quartus II software generates a Tcl script similar to the following: <*revision_name*>**_pt_v_fast.tcl**.

When TimeQuest is run with the fast-corner netlist or when the **Optimize fast-corner timing** check box is selected in the **Fitter Settings** dialog box, the fast-corner SDC file is generated.

After the EDA Netlist Writer has finished, two SDO files are created: <*revision_name*>**_v.sdo** (slow-corner) or <*revision_name*>**_v_fast.sdo** (fast-corner).

Generating Multiple Operating Conditions with TimeQuest

Different operating conditions can be specified to the EDA Netlist Writer for PrimeTime analysis. The different operating conditions are reflected in the **.sdo** file generated by the EDA Netlist Writer.

Table 11–1 shows the available operating conditions that can be set for a few of Altera's device families.

Table 11–1. Available Operating Condition Combinations

Device Family	Available Conditions (Model, Voltage, Temperature)
Stratix® III	(slow, 1100 mV, 85° C), (slow, 1100 mV, 0° C), (fast, 1100 mV, 0° C)
Cyclone® III	(slow, 1200 mV, 85° C), (slow, 1200 mV, 0° C), (fast, 1200 mV, 0° C)
Stratix II	(slow, N/A, N/A), (fast, N/A, N/A)
Cyclone II	(slow, N/A, N/A), (fast, N/A, N/A)

From the TimeQuest Console pane, use the command `get_available_operating_conditions` to obtain a list of available operating conditions for the target device.

The following steps show how to generate the **.sdo** files for the three different operating conditions for a Stratix III design. Each command must be entered at the command prompt.

The `--tq2pt` option for `quartus_sta` is required only if the project does not specify that the PrimeTime tool will be used as the timing analysis tool.

1. Generate the first slow corner model at the operating conditions: slow, 1100 mV, and 85° C.

```
quartus_sta --model=slow --voltage=1100 --temperature=85
<project name>
```

2. Generate the fast corner model at the operating conditions: fast, 1100 mV, and 0° C.

```
quartus_sta --model=fast --voltage=1100 --temperature=0
--tq2pt <project name>
```

3. Generate the PrimeTime output files for the corners specified above. The output files will be generated in the **primetime_two_corner_files** directory.

```
quartus_eda --timing_analysis --tool=primetime
--format=verilog
--output_directory=primetime_two_corner_files
--write_settings_files=off <project name>
```

4. Generate the second slow corner model at the operating conditions: slow, 1100 mV, and 0° C.

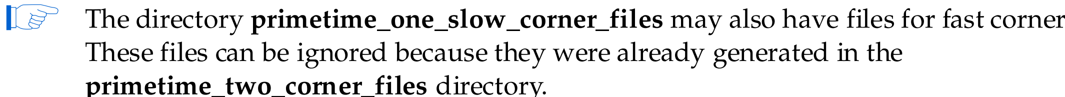
```
quartus_sta --model=slow --voltage=1100 --temperature=0
--tq2pt <project name>
```

5. Generate the PrimeTime output files for the second slow corner. The output files will be generated in the **primetime_one_slow_corner_files** directory.

```
quartus_eda --timing_analysis --tool=primetime
--format=verilog
--output_directory=primetime_one_slow_corner_files
--write_settings_files=off $revision
```

To summarize, the previous steps generate the following files for the three operating conditions:

- First slow corner (slow, 1100 mV, 85° C):
  VO File—primetime_two_corner_files/<*project name*>**.vo**
  SDO File—primetime_two_corner_files/<*project name*>**_v.sdo**
- Fast corner (fast, 1100 mV, 0° C):
  VO File—primetime_two_corner_files/<*project name*>**.vo**
  SDO File—primetime_two_corner_files/<*project name*>**_v_fast.sdo**
- Second slow corner (slow, 1100 mV, 0° C):
  VO File—primetime_one_slow_corner_files/<*project name*>**.vo**
  SDO File—primetime_one_slow_corner_files/<*project name*>**_v.sdo**



The directory **primetime_one_slow_corner_files** may also have files for fast corner. These files can be ignored because they were already generated in the **primetime_two_corner_files** directory.

The Tcl Script

The Tcl script generated by the Quartus II software contains information required by the PrimeTime software to analyze the timing and set up your post-fit design. This script specifies the search path and the names of the PrimeTime database library files provided with the Quartus II software. The `search_path` and `link_path` variables are defined at the beginning of the Tcl file. The `link_path` variable is a space-delimited list that contains the names of all database files used by the PrimeTime software.

Depending on whether you selected **Verilog** or **VHDL** in the **Format for output netlist** list on the **Timing Analysis** page of the **Settings** dialog box, when the Quartus II Classic Timing Analyzer is enabled, the EDA Netlist Writer generates and saves the script as either <*revision_name*>**_pt_v.tcl** or <*revision_name*>**_pt_vhd.tcl**.

To access the **EDA Settings** dialog box, on the Assignments menu, click **EDA Tool Settings**, then expand **EDA Tool Settings** under the **Category** list. In the dialog box, you can specify VHDL or Verilog for the format for the output netlist.

The script also directs the PrimeTime software to use the <*device family*>**_all_pt.v** or <*device family*>**_all_pt.vhd** file, which contains the Verilog or VHDL description of library cells for the targeted device family.

Example 11–1 shows the `search_path` and `link_path` variables defined in the Tcl script:

Example 11–1. Sample PrimeTime Setup Script

```
set quartus_root "altera/quartus/"
set search_path [list . [format "%s%s" $quartus_root "eda/synopsys/primetime/lib"]  ]

set link_path [list *  stratixii_lcell_comb_lib.db  stratixii_lcell_ff_lib.db
stratixii_asynch_io_lib.db stratixii_io_register_lib.db stratixii_termination_lib.db
bb2_lib.db  stratixii_ram_internal_lib.db  stratixii_memory_register_lib.db
stratixii_memory_addr_register_lib.db  stratixii_mac_out_internal_lib.db
stratixii_mac_mult_internal_lib.db  stratixii_mac_register_lib.db
stratixii_lvds_receiver_lib.db stratixii_lvds_transmitter_lib.db
stratixii_asmiblock_lib.db stratixii_crcblock_lib.db  stratixii_jtag_lib.db
stratixii_rublock_lib.db  stratixii_pll_lib.db  stratixii_dll_lib.db alt_vtl.db]

read_vhdl  -vhdl_compiler  stratixii_all_pt.vhd
```

The EDA Netlist Writer converts any Quartus II Classic Timing Analyzer timing assignments to the PrimeTime software constraints and exceptions when it generates the PrimeTime files. The converted constraints are saved to the Tcl script. The Tcl script also includes a PrimeTime software command that reads the Standard Delay Format Output (**.sdo**) file generated by the Quartus II software. You can place additional commands in the Tcl script to analyze or report on timing paths.

Table 11–2 shows some examples of timing assignments converted by the Quartus II software for the PrimeTime software. For example, the `set_input_delay -max` command sets the input delay on an input pin.

Table 11–2. Equivalent Quartus II and PrimeTime Software Constraints

Quartus II Equivalent	PrimeTime Constraint
Clock defined on input pin, clock of 10 ns period and 50% duty cycle	`create_clock -period 10.000 -waveform {0 5.000} \` [get_ports clk] -name clk
Input maximum delay of 1 ns on input pin, din	`set_input_delay -max -add_delay 1.000 -clock \ [get_clocks clk] [get_ports din]`
Input minimum delay of 1 ns on input pin, din	`set_input_delay -min -add_delay 1.000 -clock \ [get_clocks clk] [get_ports din]`
Output maximum delay of 3 ns on output pin, out	`set_output_delay -max -add_delay 3.000 -clock \ [get_clocks clk] [get_ports out]`

When the Quartus II TimeQuest Timing Analyzer is turned on, the EDA Netlist Writer generates and saves the script as <*revision_name*>**.pt.tcl**.

The EDA Netlist Writer converts all Quartus II TimeQuest Timing Analyzer SDC constraints and exceptions into compatible PrimeTime software constraints and exceptions when it generates the PrimeTime files. The constraints and exceptions are saved to the <*revision_name*>**.constraints.sdc** file.

Generated File Summary

The files that are generated by the EDA Netlist Writer for the PrimeTime software depend on the Quartus II timing analysis tool you selected.

Table 11–3 shows the files that are generated for the PrimeTime software when the Quartus II Classic Timing Analyzer is selected.

Table 11–3. Quartus II Classic Timing Analyzer-Generated PrimeTime Files

File	Description
<*revision_name*>**.vho** | <*revision_name*>**.vo**	The PrimeTime software output netlist. Either a VHDL Output file or a Verilog Output file is generated, depending on the output netlist language set.
<*revision_name*>**_vhd.sdo** | <*revision_name*>**_v.sdo**	The PrimeTime software standard delay file. Either a VHDL Standard Delay Output file or a Verilog Standard Delay Output file is generated, depending on the output netlist language set.
<*revision_name*>**_pt_vhd.tcl** | <*revision_name*>**_pt_v.tcl**	PrimeTime setup and constraint script. Either a VHDL Tcl script or a Verilog Tcl script is generated, depending on the output netlist language set.

Table 11–4 shows the files that are generated for the PrimeTime software when the Quartus II TimeQuest Timing Analyzer is selected. The EDA Netlist Writer supports the output netlist format only when the TimeQuest Timing Analyzer is enabled.

Table 11–4. Quartus II TimeQuest Timing Analyzer-Generated PrimeTime Files

File	Description
<*revision_name*>**.vo**	The PrimeTime software output netlist. When the Quartus II TimeQuest Timing Analyzer is enabled, only PrimeTime (Verilog) is supported.
<*revision_name*>**_v.sdo** | <*revision_name*>**_v_fast.sdo**	The PrimeTime software standard delay file. When the Quartus II TimeQuest Timing Analyzer is enabled, only PrimeTime (Verilog) is supported.
<*revision_name*>**.pt.tcl**	PrimeTime setup and constraint script. When the Quartus II TimeQuest Timing Analyzer is enabled, only PrimeTime (Verilog) is supported.
<*revision_name*>**.collections.sdc**	Contains the mapping from the Quartus II TimeQuest Timing Analyzer netlist to the PrimeTime netlist.
<*revision_name*>**.constraints.sdc**	Contains the converted Quartus II TimeQuest Timing Analyzer constraints for the PrimeTime software.

Running the PrimeTime Software

The PrimeTime software runs only on UNIX operating systems. If the Quartus II output files for the PrimeTime software were generated by running the Quartus II software on a PC/Windows-based system, follow these steps to run the PrimeTime software using Quartus II output files:

1. Install the PrimeTime libraries on a UNIX system by installing the Quartus II software on UNIX.

   The PrimeTime libraries are located in the **<*Quartus II installation directory*>/eda/synopsys/primetime/lib** directory.

2. Copy the Quartus II output files to the appropriate UNIX directory. You may need to run a PC to UNIX program, such as `dos2unix`, to remove any control characters.

3. Modify the Quartus II path in Tcl scripts to point to the PrimeTime libraries, as described in Step 1. In Example 11–1, the first line is:

```
set quartus_root "c:/altera/quartus51/" set search_path [list . [format
"%s%s" $quartus_root "eda/synopsys/primetime/lib"] ]
```

This is the Tcl script that should be modified.

Analyzing Quartus II Projects

The PrimeTime software is controlled with Tcl scripts and can be run through `pt_shell`. You can run the <*revision_name*>**_pt_v.tcl** script file. For example, type the following at a UNIX system command prompt:

```
pt_shell -f <revision_name>_pt_v.tcl ↵
```

When the Quartus II TimeQuest Timing Analyzer is selected, type the following at a UNIX system command prompt:

```
pt_shell -f <revision_name>.pt.tcl ↵
```

After all Tcl commands in the script are interpreted, the PrimeTime software returns control to the `pt_shell` prompt, which allows you to use other commands.

Other pt_shell Commands

You can run additional `pt_shell` commands at the `pt_shell` prompt, including the `man` program. For example, to read documentation about the `report_timing` command, type the following at the `pt_shell` prompt:

```
man report_timing ↵
```

You can list all commands available in `pt_shell` by typing the following at the `pt_shell` prompt:

```
help ↵
```

Type `quit` ↵ at the `pt_shell` prompt to close `pt_shell`.

You can also run `pt_shell` without a script file by typing `pt_shell`↵ at the UNIX command line prompt.

PrimeTime Timing Reports

This section describes PrimeTime timing reports.

Sample of the PrimeTime Software Timing Report

After running the script, the PrimeTime software generates a timing report. If the timing constraints are not met, `Violated` is displayed at the end of the timing report. The timing report also gives the negative slack.

The PrimeTime software report is similar to the sample shown in Example 11–2. The starting point in this report is a register clocked by clock signal, `clock`, the endpoint is another register, `inst3-I.lereg`.

Example 11–2. Hold Path Report in PrimeTime

```
Startpoint: inst2~I.lereg
   (rising edge-triggered flip-flop clocked by clock)
Endpoint: inst3~I.lereg
   (rising edge-triggered flip-flop clocked by clock)
Path Group: clock
Path Type: min
Point                                                Incr     Path
-----------------------------------------------------------------
clock clock (rise edge)                              0.000    0.000
clock network delay (propagated)                     3.166    3.166
inst2~I.lereg.clk (stratix_lcell_register)           0.000    3.166r
inst2~I.lereg.regout (stratix_lcell_register) <- 0.176*   3.342r
inst2~I.regout (stratix_lcell)                       0.000*   3.342r
inst3~I.datac (stratix_lcell)                        0.000*   3.342r
inst3~I.lereg.datac (stratix_lcell_register)         3.413*   6.755r
data arrival time                                             6.755
clock clock (rise edge)                              0.000    0.000
clock network delay (propagated)                     3.002    3.002
inst3~I.lereg.clk (stratix_lcell_register)                    3.002r
library hold time                                    0.100*   3.102
data required time                                            3.102
----------------------------------------------------------------
data required time                                            3.102
data arrival time                                            -6.755
----------------------------------------------------------------
slack (MET)                                                   3.653
```

Comparing Timing Reports from the Quartus II Classic Timing Analyzer and the PrimeTime Software

Both the Quartus II Classic Timing Analyzer and the Quartus II TimeQuest Timing Analyzer generate a static timing analysis report for every successful design compilation. The timing report lists all of the timing paths in your design that were analyzed, and indicates whether these paths have met or violated their timing requirements. Violations are reported only if timing constraints were specified.

The Quartus II TimeQuest Timing Analyzer uses an equivalent set of equations as PrimeTime when reporting the static timing analysis result for a design. However, the Quartus II Classic Timing Analyzer uses slightly different reporting equations when reporting the static timing analysis results for a design. This section describes these differences between the Quartus II Classic Timing Analyzer and the PrimeTime software.

The timing report generated by the Quartus II Classic Timing Analyzer differs from the report generated by the PrimeTime software. Both tools provide the same data but present in different formats. The following sections show how the PrimeTime software reports the following slack values differently from the Quartus II Classic Timing Analyzer report:

- "Clock Setup Relationship and Slack" on page 11–10
- "Clock Hold Relationship and Slack" on page 11–13
- "Input Delay and Output Delay Relationships and Slack" on page 11–16

Clock Setup Relationship and Slack

The Quartus II Classic Timing Analyzer performs a setup check that ensures that the data launched by source registers is latched correctly at the destination registers. The Quartus II Classic Timing Analyzer does this by determining the data arrival time and clock arrival time at the destination registers, and compares this data with the setup time delay of the destination register. Equation 11–1 expresses the inequality that is used for a setup check. The data arrival time includes the longest path from the clock to the source register, the clock-to-out micro delay of the source register, and the longest path from the source register to the destination register. The clock arrival time is the shortest delay from the clock to the destination register.

Equation 11–1.

$$\text{Clock Arrival} - \text{Data Arrival} \geq t_{su}$$

Slack is the margin by which a timing requirement is met or not met. Positive slack indicates the margin by which a requirement is met. Negative slack indicates the margin by which a requirement was not met. The Quartus II Classic Timing Analyzer determines the clock setup slack, as shown in Equation 11–2:

Equation 11–2.

$$\text{Clock Setup Slack} = \text{Largest Register-to-Register Requirement} - \text{Longest Register-to-Register Delay}$$

The longest register-to-register delay in the previous equation is equal to the register-to-register data delay.

Equation 11–3.

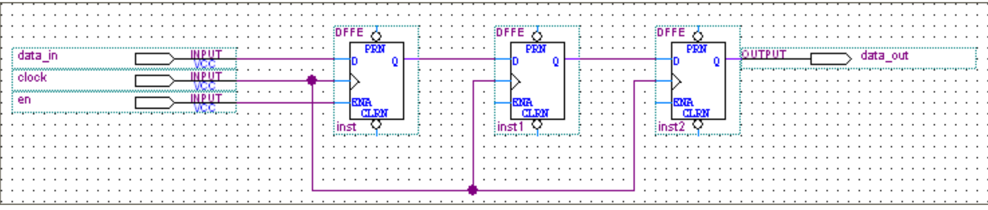
$$\text{Largest Register-to-Register Requirement} = \text{Setup Relationship between Source and Destination} + \text{Largest Clock Skew} - \text{Micro } t_{co} \text{ of Destination Register} - \text{Micro } t_{su} \text{ of Destination Register}$$

$$\text{Setup Relationship between Source and Destination} = \text{Latch Edge} - \text{Launch Edge}$$

$$\text{Clock Skew} = \text{Shortest Clock Path to Destination} - \text{Longest Clock Path to Source}$$

For a simple three-register design, refer to Figure 11–3.

Figure 11–3. Simple Three-Register Design



The Quartus II Classic Timing Analyzer generates a report for the design, as shown in Figure 11–4.

Figure 11–4. Timing Analyzer Report from Figure 11–3

	Slack	Actual fmax (period)	From	To	From Clock	To Clock	Required Setup Relationship	Required Longest P2P Time	Actual Longest P2P Time
1	4.237 ns	265.75 MHz (period = 3.763 ns)	inst2	inst3	clock	clock	8.000 ns	7.650 ns	3.413 ns
2	4.741 ns	306.84 MHz (period = 3.259 ns)	inst	inst2	clock	clock	8.000 ns	7.980 ns	3.239 ns

Equation 11–1, Equation 11–2, and Equation 11–3 are similar to those found in other static timing analysis tools, such as the PrimeTime software. Equation 11–4 to Equation 11–7, used by the PrimeTime software, are essentially the same as those used by the Quartus II Classic Timing Analyzer, but they are rearranged.

Equation 11–4.

$$\text{Slack} = \text{Data Required} - \text{Data Arrival}$$

Equation 11–5.

$$\text{Clock Arrival} = \text{Latch Edge} + \text{Shortest Clock Path to Destination}$$

Equation 11–6.

$$\text{Data Required} = \text{Clock Arrival} - \text{Micro } t_{su}$$

Equation 11–7.

$$\text{Data Arrival} = \text{Launch Edge} + \text{Longest Clock Path to Source} + \text{Micro } t_{co} + \text{Longest Data Delay}$$

The longest data delay in the previous equation is equal to register-to-register data delay.

Figure 11–5 shows a clock setup check in the Quartus II software.

Figure 11–5. Clock Setup Check Reporting with the Quartus II Classic Timing Analyzer

```
Info: Slack time is 4.237 ns for clock "clock" between source register "inst2" and destination register "inst3"
  Info: Fmax is 265.75 MHz (period= 3.763 ns)
  Info: + Largest register to register requirement is 7.650 ns
    Info: + Setup relationship between source and destination is 8.000 ns
      Info: + Latch edge is 8.000 ns
      Info: - Launch edge is 0.000 ns
      Info: - Clock setup uncertainty between source and destination is 0.000 ns
    Info: + Largest clock skew is -0.164 ns
      Info: + Shortest clock path from clock "clock" to destination register is 3.002 ns
      Info: - Longest clock path from clock "clock" to source register is 3.166 ns
    Info: - Micro clock to output delay of source is 0.176 ns
    Info: - Micro setup delay of destination is 0.010 ns
  Info: - Longest register to register delay is 3.413 ns
```

The results in Equation 11–8 are obtained by extracting the numbers from the Quartus II Classic Timing Analyzer report and applying them to the clock setup slack equations from the Quartus II Classic Timing Analyzer:

Equation 11–8.

$$\text{Setup Relationship between Source and Destination} = \text{Latch Edge} - \text{Launch Edge} - \text{Clock Setup Uncertainty}$$

$$8.0 - 0.0 - 0.0 = 8.0\text{ns}$$

$$\text{Clock Skew} = \text{Shortest Clock Path to Destination} - \text{Longest Clock Path to Source}$$

$$3.002 - 3.166 = -0.164\text{ns}$$

$$\text{Largest Register-to-Register Requirement} = \text{Setup Relationship between Source \& Destination} + \text{Largest Clock Skew} - \text{Micro } t_{co} \text{ of Source Register} - \text{Micro } t_{su} \text{ of Destination Register}$$

$$8 + (-0.164) - 0.176 - 0.010 = 7.650\text{ns}$$

$$\text{Clock Setup Slack} = \text{Largest Register-to-Register Requirement} - \text{Longest Register-to-Register Delay}$$

$$7.650 - 3.413 = 4.237\text{ns}$$

For the same register-to-register path, the PrimeTime software generates a clock setup report as shown in Example 11–3:

Example 11–3. Setup Path Report in PrimeTime

```
Startpoint: inst2~I.lereg

```

Clock Hold Relationship and Slack

The Quartus II Classic Timing Analyzer performs a hold time check along every register-to-register path in the design to ensure that no hold time violations have occurred. The hold time check verifies that data from the source register does not reach the destination until after the hold time of the destination register. The condition used for a hold check is shown in Equation 11–9:

Equation 11–9.

$$\text{Data Arrival} - \text{Clock Arrival} \geq t_H$$

The Quartus II Classic Timing Analyzer determines the clock hold slack with Equation 11–10, Equation 11–11, Equation 11–12, and Equation 11–13:

Equation 11–10.

$$\text{Clock Hold Slack} = \text{Shortest Register-to-Register Delay} - \text{Smallest Register-to-Register Requirement}$$

Equation 11–11.

$$\text{Smallest Register-to-Register Requirement} = \text{Hold Relationship between Source \& Destination} + \text{Smallest Clock Skew} - \text{Micro } t_{su} \text{ of Source} + \text{Micro } t_H \text{ of Destination}$$

Equation 11–12.

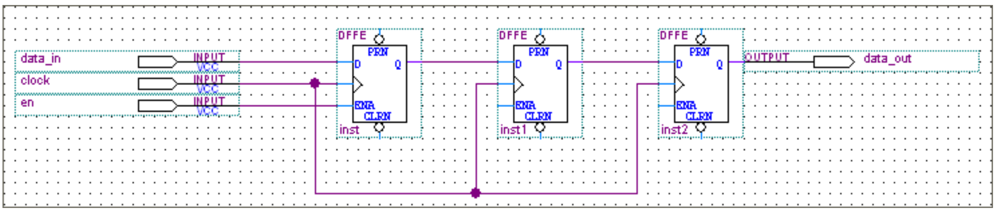
Hold Relationship between Source & Destination = Latch Edge – Launch Edge

Equation 11–13.

Smallest Clock Skew = Longest Clock Path from Clock to Destination Register – Shortest Clock Path from Clock to Source Register

Figure 11–6 shows a simple three-register design.

Figure 11–6. A Simple Three-Register Design



The Quartus II Classic Timing Analyzer generates a report as shown in Figure 11–7.

Figure 11–7. Timing Analyzer Report Generated from the Three-Register Design

	Minimum Slack	From	To	From Clock	To Clock	Required Hold Relationship	Required Shortest P2P Time	Actual Shortest P2P Time
1	3.149 ns	inst	inst2	clock	clock	0.000 ns	0.090 ns	3.239 ns
2	3.653 ns	inst2	inst3	clock	clock	0.000 ns	-0.240 ns	3.413 ns

The previous equations are similar to those found in the Quartus II software. The following equations are the same equations that are used by the PrimeTime software, but they are rearranged.

Equation 11–14.

Slack = Data Required – Data Arrival

Equation 11–15.

Clock Arrival = Latch Edge + Longest Clock Path to Destination

© March 2009 Altera Corporation

Equation 11–16.

$$\text{Data Required} = \text{Clock Arrival} - \text{Micro } t_H$$

Equation 11–17.

$$\text{Data Arrival} = \text{Launch Edge} + \text{Longest Clock Path to Source} + \text{Micro } t_{co} + \text{Shortest Data Delay}$$

The shortest register-to-register delay in the previous equation is equal to register-to-register data delay.

Figure 11–8 shows a clock setup check with the Quartus II Classic Timing Analyzer.

Figure 11–8. Clock Hold Check Reporting with the Quartus II Classic Timing Analyzer

```
Info: Minimum slack time is 3.653 ns for clock "clock" between source register "inst2" and destination register "inst3"
  Info: + Shortest register to register delay is 3.413 ns
  Info: - Smallest register to register requirement is -0.240 ns
    Info: + Hold relationship between source and destination is 0.000 ns
      Info: + Latch edge is 0.000 ns
      Info: - Launch edge is 0.000 ns
      Info: - Clock hold uncertainty between source and destination is 0.000 ns
    Info: + Smallest clock skew is -0.164 ns
      Info: + Longest clock path from clock "clock" to destination register is 3.002 ns
      Info: - Shortest clock path from clock "clock" to source register is 3.166 ns
    Info: - Micro clock to output delay of source is 0.176 ns
    Info: + Micro hold delay of destination is 0.100 ns
```

The following results are obtained by extracting the numbers from the Timing Analysis report and applying the clock setup slack equations from the Quartus II Classic Timing Analyzer.

Equation 11–18.

$$\text{Clock Hold Slack} = \text{Shortest Register-to-Register Delay} - \text{Smallest Register-to-Register Requirement}$$

$$3.413 - (-0.240) = 3.653\text{ns}$$

$$\text{Smallest Register-to-Register Requirement} = \text{Hold Relationship between Source \& Destination} + \text{Smallest Clock Skew} - \text{Micro } t_{co} \text{ of Source} + \text{Micro } t_H \text{ of Destination}$$

$$0 + (-0.164) - 0.176 + 0.100 = -0.240\text{ns}$$

$$\text{Hold Relationship between Source \& Destination} = \text{Latch} - \text{Launch}$$

$$0.0 - 0.0\text{ns}$$

$$\text{Smallest Clock Skew} = \text{Longest Clock Path from Clock to Destination Register} - \text{Shortest Clock Path from Clock to Source Register}$$

$$3.002 - 3.166 = -0.164\text{ns}$$

For the same register-to-register path, the PrimeTime software generates the report shown in Example 11–4:

Example 11–4. Hold Path Report in PrimeTime

```
Startpoint: inst2~I.lereg
   (rising edge-triggered flip-flop clocked by clock)
Endpoint: inst3~I.lereg

data required time                                            3.102
---------------------------------------------------------------
data required time                                            3.102
data arrival time                                            -6.755
---------------------------------------------------------------
slack (MET)                                                   3.653
```

Both sets of hold slack equations can be used to determine the hold slack value of any path.

Input Delay and Output Delay Relationships and Slack

Input delay and output delay reports generated by the Quartus II Classic Timing Analyzer are similar to the clock setup and clock hold relationship reports. Figure 11–9 shows the input delay and output delay report for the design shown in Figure 11–6 on page 11–14.

Figure 11–9. Input and Output Delay Reporting with the Quartus II Classic Timing Analyzer

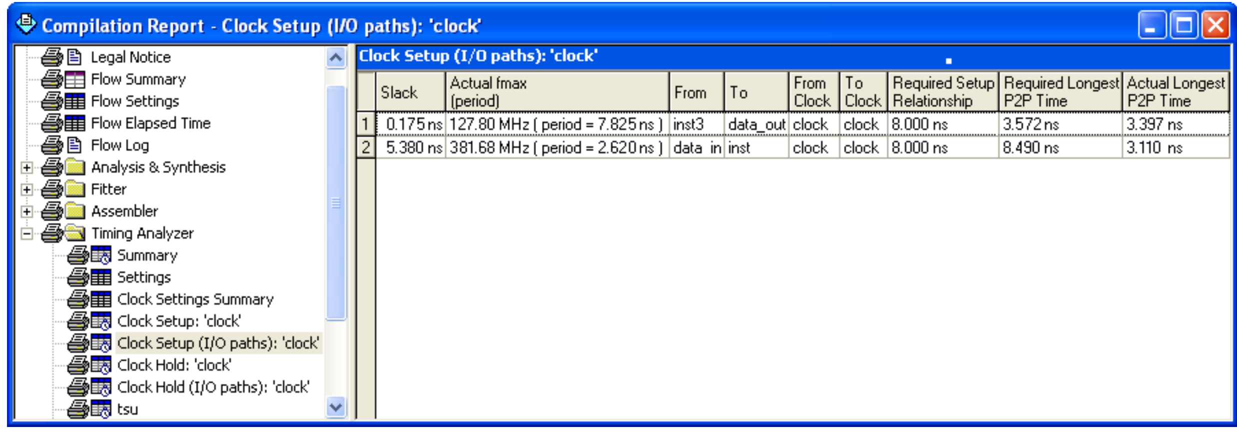

Figure 11–10 shows the fully expanded view for the output delay path.

Figure 11–10. Output Delay Path Reporting with the Quartus II Classic Timing Analyzer

Info: Slack time is 175 ps for clock "clock" between source register "inst3" and destination pin "data_out"
Info: Fmax is 127.8 MHz (period= 7.825 ns)
Info: + Largest register to pin requirement is 3.572 ns
Info: + Setup relationship between source and destination is 8.000 ns
Info: + Latch edge is 8.000 ns
Info: - Launch edge is 0.000 ns
Info: - Clock setup uncertainty between source and destination is 0.000 ns
Info: - Longest clock path from clock "clock" to source register is 3.002 ns
Info: - Micro clock to output delay of source is 0.176 ns
Info: - Max Output delay of pin is 1.25 ns
Info: - Longest register to pin delay is 3.397 ns

For the same output delay path, the PrimeTime software generates a report similar to Example 11–5:

Example 11–5. Setup Path Report in PrimeTime

```
Startpoint: inst3~I.lereg
  (rising edge-triggered flip-flop clocked by clock)
Endpoint: data_out
  (output port clocked by clock)

data arrival time                                             6.575
----------------------------------------------------------------
slack (MET)                                                   0.175
```

To generate a list of the 100 worst paths and place this data into a file called **file.timing**, type the following command at the `pt_shell` prompt:

```
report_timing -nworst 100 > file.timing ↵
```

Timing paths in the PrimeTime software are listed in the order of most-negative-slack to most-positive-slack. The PrimeTime software does not categorize failing paths by default. Timing setup (tsu) and timing hold (th) times are not listed separately. In the PrimeTime software, each path is shown with a start and end point; for example, if it is a register-to-register or input-to-register type of path. If you only use the `report_timing` part of the command without adding a `-delay` option, only the `setup-time-related` timing paths are reported.

The following command is used to create a minimum timing report or a list of hold-time-related violations:

```
report_timing -delay_type min ↵
```

Ensure that the correct SDO file, either minimum or maximum delays, is loaded before running this command.

Static Timing Analyzer Differences

Under certain design conditions, several static timing analysis differences can exist between the Classic Timing Analyzer and the TimeQuest Timing Analyzer, and the PrimeTime software. The following sections explain the differences between the two static timing analysis engines and the PrimeTime software.

The Quartus II Classic Timing Analyzer and the PrimeTime Software

The following section describes the differences between the Quartus II Classic Timing Analyzer and the PrimeTime software.

Rise/Fall Support

The Quartus II Classic Timing Analyzer does not support rise/fall analysis. However, rise/fall support is available in PrimeTime.

Minimum and Maximum Delays

TimeQuest calculates minimum and maximum delays for all device components with the exception of clock routing. PrimeTime does not model these delays. This can result in different slacks for a given path on average by 2–3%.

Recovery/Removal Analysis

TimeQuest performs a more pessimistic recovery/removal analysis for asynchronous path than PrimeTime. This can result in different delays reported between the two tools.

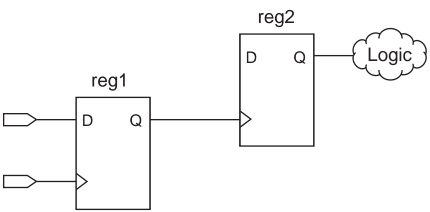
Encrypted Intellectual Property Blocks

The Quartus II software has the capability to decrypt all intellectual property (IP) blocks designed for Altera® devices that have been encrypted by their vendors. The decryption process allows the Quartus II software to perform a full compilation of the design that contains an encrypted IP block. This also allows the Quartus II Classic Timing Analyzer to perform a complete static timing analysis on the design. However, when the PrimeTime software is designated as the static timing analysis tool, the Quartus II EDA Netlist Writer does not generate either a VHDL Output File (**.vho**) or Verilog Output File (**.vo**) netlist file for designs that contain encrypted IP blocks for which the license does not permit generation of output netlists for third-party tools.

Registered Clock Signals

Registered clock signals are clock signals that pass through a register before reaching the clock port of a sequential element. Figure 11–11 shows an example of a registered clock signal.

Figure 11–11. Registered Clock Signal



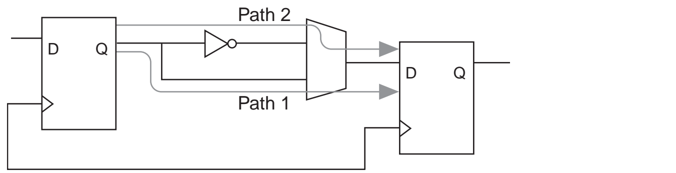
If no clock setting is applied to the register on the clock path (shown as register `reg_1` in Figure 11–11), the Quartus II Classic Timing Analyzer treats the register in the clock path as a buffer. The delay of the buffer is equal to the CELL delay of the register plus the t_{CO} of the register. The PrimeTime software does not treat the register as a buffer.

For more information about creating clock settings, refer to the *Quartus II Classic Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Multiple Source and Destination Register Pairs

In any design, multiple paths may exist from a source register to a destination register. Each path from the source register to the destination register may have a different delay value due to the different routes taken. For example, Figure 11–12 shows a sample design that contains multiple path pairs between the source register and destination register.

Figure 11–12. Multiple Source and Destination Pairs



The Quartus II Classic Timing Analyzer analyzes all source and destination pairs, but reports only the source and destination register pair with the worst slack. For example, if the Path 2 pair delay is greater than the Path 1 pair delay in Figure 11–12, the Quartus II Classic Timing Analyzer reports the slack value of the Path 2 pair and not the Path 1 pair. The PrimeTime software reports all possible source and destination register pairs.

Latches

By default, the Quartus II software implements all latches as combinational loops. The Quartus II Classic Timing Analyzer can analyze such latches by treating them as registers with inverted clocks or analyze latches as a combinational loop modeled as a combinational delay.

For more information about latch analysis, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

The PrimeTime software always analyzes these latches as combinational loops, as defined in the netlist file.

LVDS I/O

When it analyzes the dedicated LVDS transceivers in your design, the Quartus II Classic Timing Analyzer generates the Receiver Skew Margin (RSKM) report and a Channel-to-Channel Skew (TCCS) report. The PrimeTime software does not generate these reports.

Clock Latency

When a single clock signal feeds both the source and destination registers of a register-to-register path, and either an Early Clock Latency or a Late Clock Latency assignment has been applied to the clock signal, the Quartus II Classic Timing Analyzer does not factor in the clock latency values when it calculates the clock skew between the two registers. The Quartus II Classic Timing Analyzer factors in the clock latency values when the clock signal to the source and destination registers of a register-to-register path are different. The PrimeTime software applies the clock latency values when a single clock signal or different clock signals feeds the source and destination registers of a register-to-register path.

Input and Output Delay Assignments

When a purely combinational (non-registered) path exists between an input pin and output pin of the Altera FPGA and both pins have been constrained with an input delay and an output delay assignment applied, respectively, the Quartus II Classic Timing Analyzer does not perform a clock setup or clock hold analysis. The PrimeTime software analyzes these paths.

Generated Clocks Derived from Generated Clocks

The Quartus II Classic Timing Analyzer does not support a generated clock derived from a generated clock. This situation might occur if a generated clock feeds the input clock pin of a PLL. The output clock of the PLL is a generated clock.

The Quartus II TimeQuest Timing Analyzer and the PrimeTime Software

The following sections describe the static timing analysis differences between the Quartus II TimeQuest Timing Analyzer and the PrimeTime software.

Encrypted Intellectual Property Blocks

The Quartus II software has the capability to decrypt all IP blocks, designed for Altera devices that have been encrypted by their vendors. The decryption process allows the Quartus II software to perform a full compilation on the design containing an encrypted IP block. This also allows the Quartus II TimeQuest Timing Analyzer to perform a complete static timing analysis on the design. However, when the PrimeTime software is designated as the static timing analysis tool, the Quartus II EDA Netlist Writer does not generate **.vho** or **.vo** netlist files for designs that contain encrypted IP blocks whose license does not permit generation of output netlists for other tools.

Latches

By default, the Quartus II software implements all latches as combinational loops. The Quartus II TimeQuest Timing Analyzer can analyze such latches by treating them as registers with inverted clocks. The Quartus II TimeQuest Timing Analyzer analyzes latches as a combinational loop modeled as a combinational delay.

For more information about latch analysis, refer to the *Quartus II Classic Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

The PrimeTime software always analyzes these latches as combinational loops, as defined in the netlist file.

LVDS I/O

When it analyzes the dedicated LVDS transceivers in your design, the Quartus II TimeQuest Timing Analyzer generates a Receiver Skew Margin (RSKM) report and a Channel-to-Channel Skew (TCCS) report. The PrimeTime software does not generate these reports.

The Quartus II TimeQuest Timing Analyzer SDC File and PrimeTime Compatibility

Because of differences between node naming conventions with the netlist generated by the EDA Netlist Writer and the internal netlist used by the Quartus II software, SDC files generated for the Quartus II software or the Quartus II TimeQuest Timing Analyzer are not compatible with the PrimeTime software.

Run the EDA Netlist Writer to generate a compatible SDC file from the TimeQuest SDC file for the PrimeTime software. After the files <*revision_name*>**.collections.sdc** and <*revision_name*>**.constraints.sdc** have been generated, both files can be read in by the PrimeTime software for compatibility of constraints between the Quartus II TimeQuest Timing Analyzer and the PrimeTime software.

Clock and Data Paths

If a timing path acts both as a clock path (a path that connects to a clock pin with a clock associated to it), and a data path (a path that feeds into the data in port of a register), the Quartus II TimeQuest Timing Analyzer will report the data paths, whereas PrimeTime will not.

Inverting and Non-Inverting Propagation

TimeQuest always propagates non-inverting sense for clocks through non-unate paths in the clock network.

PrimeTime's default behavior is to propagate both inverting and non-inverting senses through a non-unate path in the clock network.

Multiple Rise/Fall Numbers For a Timing Arc

For a given timing path with a corresponding set of pins/ports that make up the path (including source and destination pair), if the individual components of that path have different rise/fall delays, there can potentially be many timing paths with different delays using the same set of pins. If this occurs, TimeQuest reports only one timing path for the set of pins that make up the path.

Virtual Generated Clocks

PrimeTime does not support generated clocks that are virtual. To maintain compatibility between TimeQuest and PrimeTime, all generated clocks should have an explicit target specified.

Generated Clocks Derived from Generated Clocks

The Quartus II Classic Timing Analyzer does not support the creation of a generated clock derived from a generated clock. This situation might occur if a generated clock feeds the input clock pin of another generated clock. The output clock of the PLL is a generated clock.

Conclusion

The Quartus II software can export a netlist, constraints, and timing information for use with the PrimeTime software. The PrimeTime software can use data from either best-case or worst-case Quartus II timing models to measure timing. The PrimeTime software is controlled using a Tcl script generated by the Quartus II software that you can customize to direct the PrimeTime software to produce violation and slack reports.

Document Revision History

Table 11–5 shows the revision history for this chapter.

Table 11–5. Document Revision History

Date and Version	Changes Made	Summary of Changes
March 2009 v9.0.0	This was chapter 10 in version 8.1.	Updated for the Quartus II software version 9.0 release.
November 2008 v8.1.0	Changed to 8-1/2 x 11 page size. No change to content.	Updated for the Quartus II software version 8.1 release.
May 2008 v8.0.0	■ Updated to Quartus II software version 8.0 and date. ■ Added hyperlinks to referenced Altera documentation throughout the chapter.	—

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

Section III. Power Estimation and Analysis

As FPGA designs grow larger and processes continue to shrink, power becomes an ever-increasing concern. When designing a PCB, the power consumed by a device must be accurately estimated to develop an appropriate power budget, and to design the power supplies, voltage regulators, heat sink, and cooling system.

The Quartus® II software allows you to estimate the power consumed by your current design during timing simulation. The power consumption of your design can be calculated using the Microsoft Excel-based power calculator, or the Simulation-Based Power Estimation features in the Quartus II software. This section explains how to use both.

This section includes the following chapter:

■ Chapter 12, PowerPlay Power Analysis

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

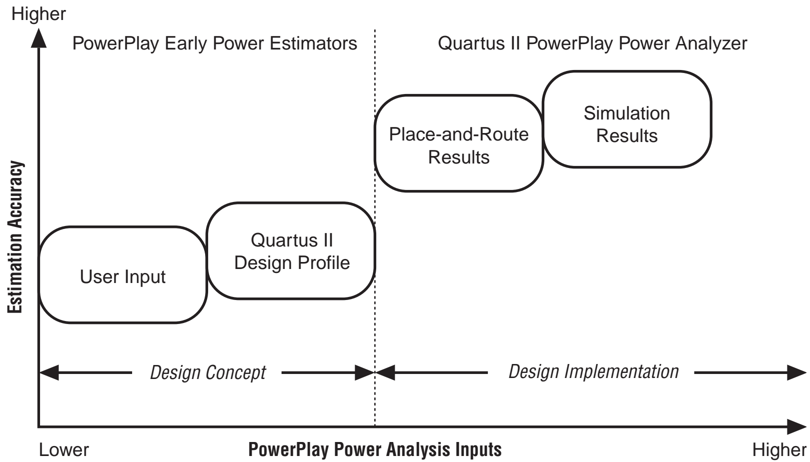
12. PowerPlay Power Analysis

QII53013-9.0.0

Introduction

As designs grow larger and process technology continues to shrink, power becomes an increasingly important design consideration. When designing a PCB, the power consumed by a device must be accurately estimated to develop an appropriate power budget and to design the power supplies, voltage regulators, heat sink, and cooling system. The PowerPlay Power Analysis tools, made available by Altera, provide improved power consumption accuracy and the ability to estimate power consumption from early design concept through design implementation, as shown in Figure 12–1.

Figure 12–1. PowerPlay Power Analysis



Depending where you are in your design cycle and the accuracy of the estimation required, you can either use the PowerPlay Early Power Estimator spreadsheet or the PowerPlay Power Analyzer Tool in the Quartus® II software. You can use the PowerPlay Early Power Estimator spreadsheet during the board design and layout phase to obtain a power estimate and then design for proper power management. The PowerPlay Power Analyzer Tool is used to obtain an accurate estimation of power after the design is complete, ensuring that thermal and supply budgets are not violated.

You can estimate power consumption for Arria® GX, Stratix® series devices, Cyclone® series devices, HardCopy® II, and MAX® II devices with the Microsoft Excel-based PowerPlay Early Power Estimator spreadsheet or the PowerPlay Power Analyzer Tool.

For more information about acquiring the PowerPlay Power Estimator spreadsheet for Arria GX, Stratix series devices, Cyclone series, HardCopy II, and MAX II devices and its use, refer to *PowerPlay Early Power Estimators (EPE) and Power Analyzer* on the Altera® website (www.altera.com).

This chapter discusses the following topics:

- "Quartus II Early Power Estimator File"
- "Types of Power Analyses" on page 12–5
- "Factors Affecting Power Consumption" on page 12–5
- "Using the PowerPlay Power Analyzer" on page 12–17

Quartus II Early Power Estimator File

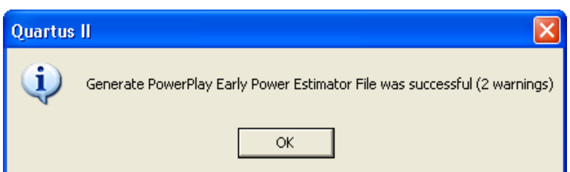
When entering data into the Early Power Estimator spreadsheet, you must enter the device resources, operating frequency, toggle rates, and other parameters. This requires familiarity with the design. If you do not have an existing design, you must estimate the number of device resources used in your design and enter it manually.

If you already have an existing design or a partially completed design, the power estimator file that is generated by the Quartus II software can aid in completing the PowerPlay Early Power Estimator spreadsheet.

To generate the power estimation file, you must first compile your design in the Quartus II software. After compilation is complete, on the Project menu, click **Generate PowerPlay Early Power Estimator File**. This command instructs the Quartus II software to write out a power estimator Comma-Separated Value (**.csv**) file (or a text [**.txt**] file for older device families).

After the Quartus II software successfully generates the power estimator file, a message appears (Figure 12–2).

Figure 12–2. Generate PowerPlay Early Power Estimator File Message



The power estimator file is named <*name of Quartus II project*>**_early_pwr.csv**. Figure 12–3 is an example of the contents of a power estimation file generated by the latest version of Quartus II software using a Stratix II device.

oc_ethernet_early_pwr

The power estimator file is named *<name of Quartus II project>*_**early_pwr.txt** for older device families.

The PowerPlay Early Power Estimator spreadsheet includes the Import Data macro that parses the information in the power estimation file and transfers it into the spreadsheet. If you do not want to use the macro, you can transfer the data into the Early Power Estimator spreadsheet manually.

If the existing Quartus II project represents only a portion of your full design, you should enter the additional resources used in the final design manually. Therefore, you can edit the spreadsheet and add additional device resources after importing the power estimation file information.

PowerPlay Early Power Estimator File Generator Compilation Report

After successfully generating the power estimation file, a PowerPlay Early Power Estimator File Generator report is created under the **Compilation Report** section. This report is divided into the different sections, such as Summary, Settings, Generated Files, Confidence Metric Details, and Signal Activities.

For more information about the PowerPlay Early Power Estimator File Generator report, refer to “PowerPlay Power Analyzer Compilation Report” on page 12–27.

Table 12–1 lists the main differences between the PowerPlay Early Power Estimator and the PowerPlay Power Analyzer.

Table 12–1. Comparison of PowerPlay Early Power Estimator and PowerPlay Power Analyzer

Characteristic	PowerPlay Early Power Estimator	PowerPlay Power Analyzer
Phase in the design cycle	Any time	After fitting
Tool requirements	Spreadsheet program/Quartus II software	Quartus II software
Accuracy	Medium	Medium to very high
Data inputs	■ Resource usage estimates ■ Clock requirements ■ Environmental conditions ■ Toggle Rate	■ Design after fitting ■ Clock requirements ■ Register transfer level (RTL) simulation results (optional) ■ Post-fitting simulation results (optional) ■ Signal activities per node or entity (optional) ■ Signal activity defaults ■ Environmental conditions
Data outputs *(1)*	■ Total thermal power dissipation ■ Thermal static power ■ Thermal dynamic power ■ Off-chip power dissipation ■ Current drawn from voltage supplies *(2)*	■ Total thermal power ■ Thermal static power ■ Thermal dynamic power ■ Thermal I/O power ■ Thermal power by design hierarchy ■ Thermal power by block type ■ Thermal power dissipation by clock domain ■ Off-chip (non-thermal) power dissipation ■ Device supply currents *(2)*

Notes to Table 12–1:

(1) Early Power Estimator output varies by device family as some features might not be available.

(2) Available only for Arria GX, Stratix IV, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, and MAX II device families.

The results of the Power Analyzer are only an estimation of power, not a specification. The purpose of the estimation is to help establish a guide for the design's power budget. Altera recommends measuring the actual power on the board. You must measure the device's total dynamic current during device operation because the estimate is design dependent and depends on many variable factors, including input vector quantity, quality, and exact loading conditions of a PCB design. Static power consumption must not be based on empirical observation; the values reported by the Power Analyzer or data sheet must be used because the devices tested might not exhibit worst-case behavior.

Types of Power Analyses

Understanding the uses of power analysis and the factors affecting power consumption help you use the Power Analyzer effectively. Power analysis meets two significant planning requirements:

- **Thermal planning**: The designer must ensure that the cooling solution is sufficient to dissipate the heat generated by the device. In particular, the computed junction temperature must fall within normal device specifications.
- **Power supply planning**: Power supplies must provide adequate current to support device operation.

The two types of analyses are closely related because much of the power supplied to the device is dissipated as heat from the device. However, in some situations, the two types of analyses are not identical. For example, when you use terminated I/O standards, some of the power drawn from the FPGA device power supply is dissipated in termination resistors, rather than in the FPGA.

Power analysis also addresses the activity of the design over time as a factor that impacts the power consumption of the device. Static power is defined as the power consumed regardless of design activity. Dynamic power is the additional power consumed due to signal activity or toggling.

For power supply planning, you can use the PowerPlay Early Power Estimator at the early stages of your design cycle, or use the Quartus II Power Analyzer reports when the design is completed to get an estimate of your design power requirement.

Factors Affecting Power Consumption

This section describes the factors affecting power consumption. Understanding these factors lets you use the Power Analyzer and interpret its results effectively.

Device Selection

Different device families have different power characteristics. Many parameters affect the device family power consumption, including choice of process technology, supply voltage, electrical design, and device architecture. For example, the Cyclone II device family architecture was designed to consume less static power than the high-performance, full-featured, Stratix II device family.

Power consumption also varies within a single device family. A larger device typically consumes more static power than a smaller device in the same family, due to its larger transistor count. Dynamic power can also increase with device size in devices that employ global routing architectures, such as the MAX device family. Stratix, Cyclone, and MAX II devices do not exhibit significantly increased dynamic power as device size increases.

The choice of device package also affects the device’s ability to dissipate heat. This can impact your cooling solution choice required to meet junction temperature constraints.

Finally, process variation can affect power consumption. Process variation primarily impacts static power, since sub-threshold leakage current varies exponentially with changes in transistor threshold voltage. As a result, it is critical to consult device specifications for static power and not rely on empirical observation. Process variation has a weak effect on dynamic power.

Environmental Conditions

Operating temperature primarily affects device static power consumption. Higher junction temperatures result in higher static power consumption. The device thermal power and cooling solution that you use must result in the device junction temperature remaining within the maximum operating range for that device.

The main environmental parameters affecting junction temperature are the cooling solution and ambient temperature.

Air Flow

Air flow is a measure of how quickly heated air is removed from the vicinity of the device and replaced by air at ambient temperature. This can either be specified as "still air" when no fan is used, or as the linear feet per minute rating of the fan used in the system. Higher air flow decreases thermal resistance.

Heat Sink and Thermal Compound

A heat sink allows more efficient heat transfer from the device to the surrounding area because of its large surface area exposed to the air. The thermal compound that interfaces the heat sink to the device also influences the rate of heat dissipation. The case-to-ambient thermal resistance (θ_{CA}) parameter describes the cooling capacity of the heat sink and thermal compound employed at a given airflow. Larger heat sinks and more effective thermal compounds reduce θ_{CA}.

Ambient Temperature

The junction temperature of a device is equal to:

$$T_{Junction} = T_{Ambient} + P_{Thermal} \cdot \theta_{JA}$$

where θ_{JA} is the total thermal resistance from the device transistors to the environment, having units of degrees Celsius per Watt. The value θ_{JA} is equal to the sum of the junction-to-case (package) thermal resistance (θ_{JC}) and the case-to-ambient thermal resistance (θ_{CA}) of your cooling solution.

Board Thermal Model

The thermal resistance of the path through the board is referred to as the junction-to-board thermal resistance (θ_{JB}) (the units are in degrees Celsius per Watt). This is used in conjunction with the board temperature, as well as the top-of-chip θ_{JA} and ambient temperatures, to compute junction temperature.

Design Resources

The design resource used greatly affects power consumption.

Number, Type, and Loading of I/O Pins

Output pins drive off-chip components, resulting in high-load capacitance that leads to a high-dynamic power per transition. Terminated I/O standards require external resistors that generally draw constant (static) power from the output pin.

Number and Type of Logic Elements, Multiplier Elements, and RAM Blocks

A design with more logic elements (LEs), multiplier elements, and memory blocks tends to consume more power than a design with fewer such circuit elements. Also, the operating mode of each circuit element affects its power consumption. For example, a digital signal processing (DSP) block performing 18×18 multiplications and a DSP block performing multiply-accumulate operations consume different amounts of dynamic power due to different amounts of internal capacitance being charged on each transition. Static power is also affected, to a small degree, by the operating mode of a circuit element.

Number and Type of Global Signals

Global signal networks span large portions of the device and have high capacitance, resulting in significant dynamic power consumption. The type of global signal is important as well. For example, Stratix II devices support several kinds of global clock networks that span either the entire device or a specific portion of the device (a regional clock network covers a quarter of the device). Clock networks that span smaller regions have lower capacitance and therefore, tend to consume less power. In addition, the location of the logic array blocks (LABs) that are driven by the clock network can have an impact, because the Quartus II software automatically disables unused branches of a clock.

Signal Activities

The final important factor in estimating power consumption is the behavior of each signal in the design. The two vital statistics are the toggle rate and the static probability.

The toggle rate of a signal is the average number of times that the signal changes value per unit of time. The units for toggle rate are transitions per second, and a transition is a change from `1` to `0`, or `0` to `1`.

The static probability of a signal is the fraction of time that the signal is logic `1` during the period of device operation that is being analyzed. Static probability ranges from `0` (always at ground) to `1` (always at logic high).

Dynamic power increases linearly with the toggle rate as the capacitive load is charged more frequently for logic and routing. The Quartus II models assume full rail-to-rail switching. For high toggle rates, especially on circuit output I/O pins, the circuit can transition before fully charging the downstream capacitance. The result is a slightly conservative prediction of power by the Quartus II PowerPlay Power Analyzer.

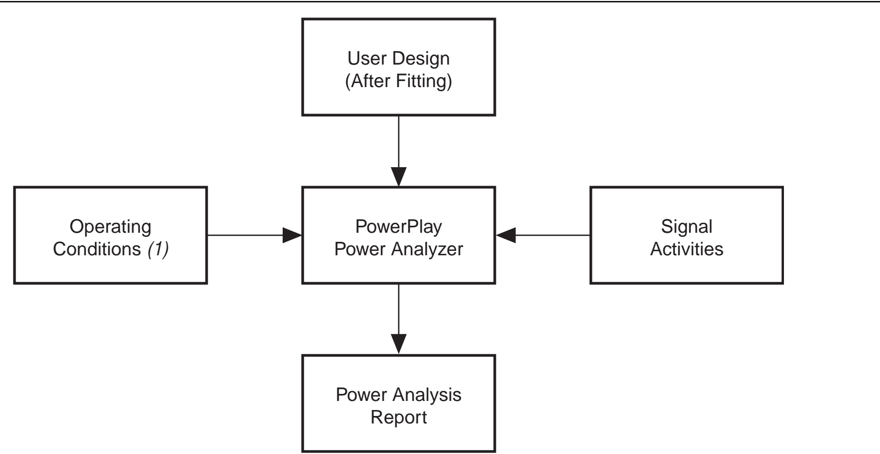
The static power consumed by both routing and logic can sometimes be affected by the static probabilities of their input signals. This effect is due to state-dependent leakage, and has a larger affect on smaller process geometries. The Quartus II software models this effect on devices at 90 nm (or smaller) if it is deemed important to the power estimate. The static power also varies with the static probability of a logic `1` or `0` on the I/O pin when output I/O standards drive termination resistors.

To get accurate results from the power analysis, the signal activities that are used for analysis must be representative of the actual operating behavior of the design. Inaccurate signal toggle rate data is the largest source of power estimation error.

PowerPlay Power Analyzer Flow

The PowerPlay Power Analyzer supports accurate and representative power estimation by allowing you to specify all the important design factors affecting power consumption. Figure 12–4 shows the high-level Power Analyzer flow.

Figure 12–4. PowerPlay Power Analyzer High-Level Flow



Note to Figure 12–4:

(1) Operating condition specifications are available only for the Arria GX devices, Stratix IV, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, and MAX II device families.

The PowerPlay Power Analyzer requires that your design is synthesized and fit to the target device. Therefore, the Power Analyzer knows the target device, and how the design is placed and routed on the device. The electrical standard used by each I/O cell and the capacitive load on each I/O standard must be specified in the design to obtain accurate I/O power estimates.

Operating Conditions

For the Arria GX, Stratix IV, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, and MAX II device families, you can specify the operating conditions for power analysis in the Quartus II software.

The following settings are available in the **Settings** dialog box:

- **Device power characteristics**—Should the Power Analyzer assume typical silicon or maximum power silicon? The typical setting is useful for comparing to empirical data measured on an average unit. The maximum setting uses worst-case data to provide a boundary to the worst-case device that you could receive. This setting impacts the static power estimate.

- **Selectable Core Voltage**—You can select a suitable core supply voltage for your design based on performance and power requirements using the **Core Supply Voltage** option, available for the Stratix III devices with variable voltage support. The power consumption of a device is heavily dependent on the voltage, so it is very important to choose the right core supply voltage for your design. The core supply voltage provides power to device logic resources such as LABs, Memory LABs (MLABs), DSP functions, memory, and interconnects.
- **Environmental conditions and junction temperature**—By default, the Power Analyzer automatically computes the junction temperature based on the specified ambient temperature and the cooling solution that you selected. For a more accurate analysis, enter the thermal resistance of your cooling solution. For some cooling solutions, such as a heat sink with no forced airflow, the thermal resistance varies with the amount of thermal power that is dissipated. Air convection increases as the difference between the device temperature and the ambient temperature increases, reducing thermal resistance. When entering a thermal resistance in such cases, it is important to use the thermal resistance that occurs when the heat flow (Q) is equal to the thermal power generated by the device.

You can also specify a junction temperature in the PowerPlay Power Analyzer. However, Altera does not recommend this because the PowerPlay Power Analyzer provides more accurate results by computing the junction temperature.

- **Board Thermal Modeling**—If you want the Power Analyzer thermal model to take the θ_{JB} into consideration, set the board thermal model to either **Typical** or **Custom**. This feature produces more accurate thermal power estimation.

A **Typical** board thermal model automatically sets θ_{JB} to a value based on the package and device selected. You only have to specify a board temperature. If you choose a **Custom** board thermal model, you must specify a value for θ_{JB} and a board temperature. If you do not want the PowerPlay Power Analyzer thermal model to take the θ_{JB} resistance into consideration, set the **Board thermal model** option to **None** (conservative). In this case, the path through the board and power dissipation is not considered, and a more conservative thermal power estimate is obtained.

The **Board thermal model** option is only available if you select the **Auto compute junction temperature** option with the pre-set cooling solution set to a heat sink solution option or custom solution. This option is disabled when a cooling solution with no heat sink is selected, as thermal conduction through the board is included in the θ_{JA} value used to compute a junction temperature in that case.

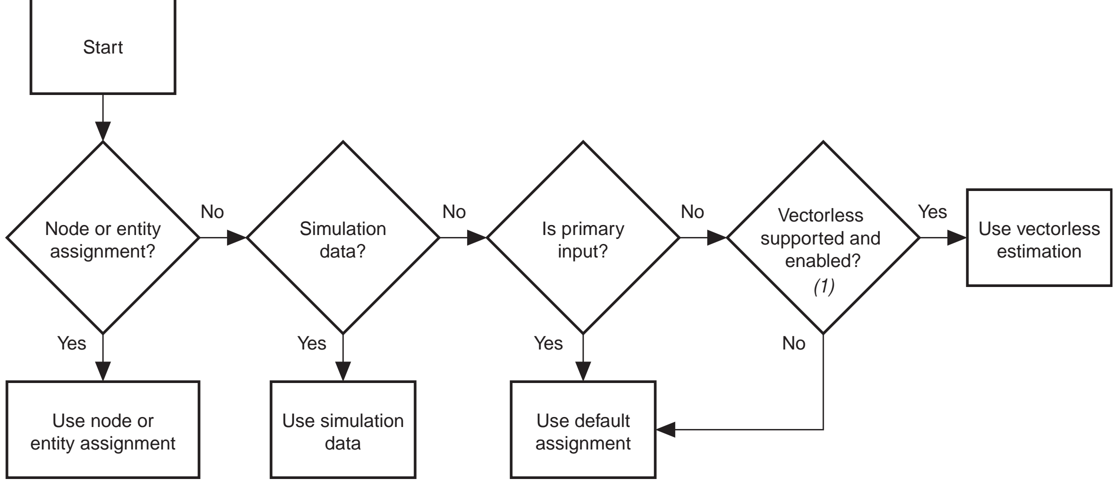
Signal Activities Data Sources

The Power Analyzer provides a flexible framework for specifying signal activities. This reflects the importance of using representative signal activity data during power analysis. You can use the following sources to provide information about signal activity:

- Simulation results
- User-entered node, entity, and clock assignments
- User-entered default toggle rate assignment
- Vectorless estimation

The PowerPlay Power Analyzer lets you mix and match the signal activity data sources on a signal-by-signal basis. Figure 12–5 shows the priority scheme. The data sources are described in the following sections.

Figure 12–5. Signal Activity Data Source Priority Scheme



Note to Figure 12–5:

(1) Vectorless estimation is available only for the Arria GX, Stratix IV, Stratix III, Stratix II, Stratix II GX, Cyclone II, HardCopy II, and MAX II device families.

Simulation Results

The Power Analyzer directly reads the waveforms generated by a design simulation. The static probability and toggle rate for each signal is calculated from the simulation waveform. Power analysis is most accurate when simulations are generated using representative input stimuli.

The Power Analyzer reads the results generated by the following simulators:

- Quartus II Simulator
- ModelSim® VHDL, Active HDL, ModelSim Verilog HDL, ModelSim-Altera VHDL, ModelSim-Altera Verilog
- NC-Verilog, NC-VHDL
- VCS

Signal activity and static probability information are stored in a Signal Activity File (**.saf**) or can be derived from a Value Change Dump File (**.vcd**), described in “Signal Activities” on page 12–7. The Quartus II simulator generates an **.saf** file or a **.vcd** file, which is then read by the Power Analyzer.

For third-party simulators, use the **Quartus II EDA Tool Settings for Simulation** to specify a **Generate Value Change Dump** file script. These scripts instruct the third-party simulators to generate a **.vcd** file that encodes the simulated waveforms. The Quartus II Power Analyzer reads this file directly to derive the toggle rate and static probability data for each signal.

Third-party EDA simulators, other than those listed above, can generate a **.vcd** file that can then be used with the Power Analyzer. For those simulators, it is necessary to manually create a simulation script to generate the appropriate **.vcd** file.

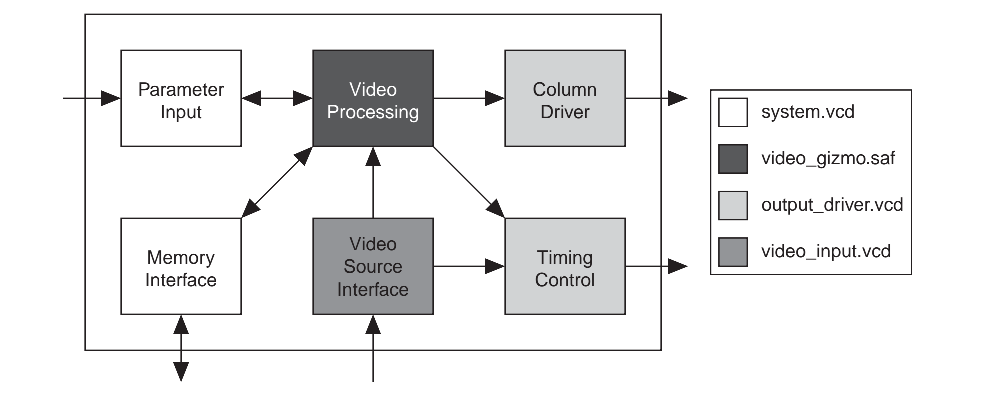
You can use a **.saf** or **.vcd** file created for power analysis to optimize the design for power during fitting by utilizing the appropriate settings in the **PowerPlay power optimization** list, available in **Fitter Settings** page of the **Settings** dialog box.

For more information about power optimization, refer to the *Power Optimization* chapter in volume 2 of the *Quartus II Handbook*.

Using Simulation Files in Modular Design Flows

A common design practice is to create modular or hierarchical designs in which you develop each design entity separately and then instantiate it in a higher-level entity, forming a complete design. Simulation is performed on a complete design or on each modular design for verification. The Quartus II PowerPlay Power Analyzer Tool supports modular design flows when reading the signal activities generated from these simulation files, as shown in Figure 12–6.

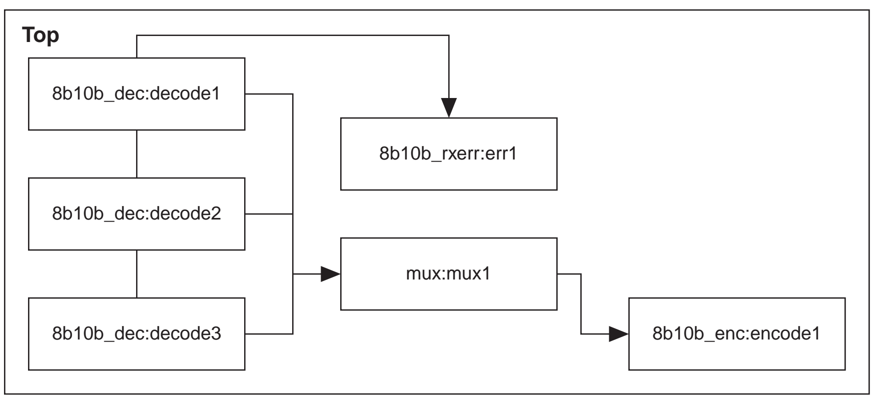
Figure 12–6. Modular Simulation Flow



When specifying a simulation file, an associated design entity name can be given, such that the signal activities derived from the simulation file (**.vcd** or **.saf** file) can be imported into the Power Analyzer for that particular design entity. The PowerPlay Power Analyzer Tool also supports the specification of multiple **.saf** files for power analysis with each having an associated design entity name to allow the integration of partial design simulations into a complete design power analysis. When specifying multiple **.saf** files for your design, it is possible that more than one simulation file will contain signal activity information for the same signal. In the case where multiple **.saf** files are applied to the same design entity, the signal activity used in the power analysis is the equal-weight arithmetic average of each **.saf** file. Also in the case where multiple simulation files are applied to design entities at different levels in the design hierarchy, the signal activity used in the power analysis is derived from the simulation file that is applied to the most specific design entity.

Figure 12–7 shows an example of a hierarchical design. The design Top consists of three 8b/10b Decoders, followed by a multiplexer whose output is then encoded again before being output from the design. There is also an error-handling module that handles any 8b/10b decoding errors. The top-level module, called Top, automatically contains the design's top-level entity and any logic not defined as part of another module. The design file for the top-level module might be just a wrapper for the hierarchical entities below it, or it might contain its own logic. The following usage scenarios show common ways that you can simulate your design and import **.saf** files into the PowerPlay Power Analyzer Tool.

Figure 12–7. Example Hierarchical Design



Complete Design Simulation

You can simulate the entire design Top, generating a **.vcd** file if you use a third-party simulator, or generating a **.saf** or **.vcd** file if you use the Quartus II Simulator. The **.vcd** or **.saf** file can then be imported (specifying Entity Top) into the Power Analyzer. The resulting power analysis uses all the signal activities information from the generated **.vcd** or **.saf** file, including those that apply to submodules, such as `decode [1-3]`, `err1`, `mux1`, and `encode1`.

Modular Design Simulation

You can simulate submodules of the design Top independently, and then import all of the resulting **.saf** files into the Power Analyzer. For example, you can simulate the `8b10b_dec` independent of the entire design, as well as multiplexer, `8b10b_rxerr`, and `8b10b_enc`. You can then import the **.vcd** or **.saf** file generated from each simulation by specifying the appropriate instance name. For example, if the files produced by the simulations are **8b10b_dec.vcd**, **8b10b_enc.vcd**, **8b10b_rxerr.vcd**, and **mux.saf**, the import specifications in Table 12–2 are used.

Table 12–2. Import Specifications (Part 1 of 2)

File Name	Entity
8b10b_dec.vcd	`Top|8b10b_dec:decode1`
8b10b_dec.vcd	`Top|8b10b_dec:decode2`
8b10b_dec.vcd	`Top|8b10b_dec:decode3`
8b10b_rxerr.vcd	`Top|8b10b_rxerr:err1`

Table 12–2. Import Specifications (Part 2 of 2)

File Name	Entity
8b10b_enc.vcd	`Top|8b10b_enc:encode1`
mux.saf	`Top|mux:mux1`

The resulting power analysis applies the simulation vectors found in each file to the assigned entity. Simulation provides signal activities for the pins and for the outputs of functional blocks. If the inputs to an entity instance are input pins for the entire design, the simulation file associated with that instance does not provide signal activities for the inputs of that instance. For example, an input to an entity such as `mux1` has its signal activity specified at the output of one of the decode entities.

Multiple Simulations on the Same Entity

You can perform multiple simulations of an entire design or specific modules of a design. For example, in the process of verifying the "Top" design, you can have three different simulation testbenches: one for normal operation, and two for corner cases. Each of these simulations produces a separate **.vcd** or **.saf** file. In this case, apply the different **.vcd** or **.saf** file names to the same top-level entity, shown in Table 12–3.

Table 12–3. Multiple Simulation File Names and Entities

File Name	Entity
normal.saf	`Top`
corner1.vcd	`Top`
corner2.vcd	`Top`

The resulting power analysis uses an arithmetic average of the signal activities calculated from each simulation file to obtain the final signal activities used. Thus, if a signal `err_out` has a toggle rate of 0 toggles per second in **normal.saf**, 50 toggles per second in **corner1.vcd**, and 70 toggles per second in **corner2.vcd**, the final toggle rate that is used in the power analysis is 40 toggles per second.

Overlapping Simulations

You can perform a simulation on the entire design Top and more exhaustive simulations on a sub-module, such as `8b10b_rxerr`. Table 12–4 shows the import specification for overlapping simulations.

Table 12–4. Overlapping Simulation Import Specifications

File Name	Entity
full_design.vcd	`Top`
error_cases.vcd	`Top|8b10b_rxerr:err1`

In this case, signal activities from **error_cases.vcd** are used for all of the nodes in the generated **.saf** file, and signal activities from **full_design.vcd** are used for only those nodes that do not overlap with nodes in **error_cases.vcd**. In general, the more specific hierarchy (the most bottom-level module) is used to derive signal activities for overlapping nodes.

Partial Simulations

You can perform a simulation where the entire simulation time is not applicable to signal activity calculation. For example, if you run a simulation for 10,000 clock cycles and reset the chip for the first 2,000 clock cycles. If the signal activity calculation is performed over all 10,000 cycles, the toggle rates are typically only 80% of their steady state value (since the chip is in reset for the first 20% of the simulation). In this case, you should specify the useful parts of the **.vcd** file for power analysis. The **Limit VCD Period** option enables you to specify a start and end time to be used when performing signal activity calculations.

Node Name Matching Considerations

Node name mismatches happen when you have **.saf** or **.vcd** files applied to entities other than the top-level entity. In a modular design flow, the gate-level simulation files created in different Quartus II software projects may not match their node names with the current Quartus II project.

For example, if you have a file named **8b10b_enc.vcd**, which was generated in a separate project called **8b10b_enc** and is simulating the `8b10b` encoder, and you import that **.vcd** file into another project called **Top**, you might encounter name mismatches when applying the **.vcd** file to the `8b10b_enc` module in the **Top** project. This is because all of the combinational nodes in the **8b10b_enc.vcd** file might be named differently in the **Top** project.

You can avoid name mismatching by using only register transfer level (RTL) simulation data, where register names usually do not change, or by using an incremental compile flow that preserves node names in conjunction with a gate-level simulation.

To ensure the best accuracy, Altera recommends using an incremental compilation flow to preserve your design’s node names.

For more information about the incremental compile flow, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Glitch Filtering

The Power Analyzer defines a glitch as two signal transitions that are so closely spaced in time that the pulse, or glitch, occurs faster than the logic and routing circuitry can respond. The output of a transport delay model simulator (the default mode of the Quartus II simulator) generally contains glitches for some signals. The device’s logic and routing structures form a low-pass filter that filters out glitches that are tens to hundreds of picoseconds long, depending on the device family.

Some third-party simulators use different models than the transport delay model as default. Different models cause differences in signal activity and power estimation. The inertial delay model, which is the ModelSim default model, filters out many more glitches than the transport delay model; therefore, it usually yields a lower power estimate.

Altera recommends using the transport simulation model when using the Quartus II glitch filtering support with third-party simulators. If the inertial simulation model is used, simulation glitch filtering has little effect.

For more information about how to set the simulation model type for your specific simulator, refer to the Quartus II Help.

Glitch filtering in a simulator can also filter a glitch on one LE (or other circuit element) output from propagating to downstream circuit elements so that the glitch will not affect simulated results. This prevents a glitch on one signal from producing non-physical glitches on all downstream logic, which would result in a signal toggle rate that is too high and a power estimate that is too high. Circuit elements in which every input transition produces an output transition, including multipliers and logic cells configured to implement XOR functions, are especially prone to glitches. Therefore, circuits with many such functions can have power estimates that are too high when glitch filtering is not used.

Altera recommends that the glitch filtering feature be used to obtain the most accurate power estimates. For **.vcd** files, the Power Analyzer flows support two types of glitch filtering, both of which are recommended for power estimation. In the first, glitches are filtered during simulation. To enable this level of glitch filtering in the Quartus II software for supported third-party simulators, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears.
3. Select the **Tool Name** to use for the simulation.
4. Turn on the **Enable glitch filtering** option.

To enable this level of glitch filtering in the Quartus II software using the Quartus II Simulator, refer to “Generating a .saf or .vcd File Using the Quartus II Simulator” on page 12–18.

The second level of glitch filtering occurs while the Power Analyzer is reading the **.vcd** file generated by the third-party simulator or Quartus II Simulator. Enable this level of glitch filtering by performing the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **PowerPlay Power Analyzer Settings**. The **PowerPlay Power Analyzer Settings** page appears.
3. Under **Input File(s)**, turn on the **Perform glitch filtering on VCD files** option.

Altera recommends that you use both forms of glitch filtering.

The **.vcd** file reader performs complementary filtering to the filtering performed during simulation and is often not as effective. While the **.vcd** file reader can remove glitches on logic blocks, it has no way of determining how downstream logic and routing are affected by a given glitch, and may might eliminate the impact of the glitch completely. Filtering the glitches during simulation avoids switching downstream routing and logic automatically.

When running simulation for design verification (rather than to produce input to the Quartus PowerPlay Power Analyzer), Altera recommends leaving glitch filtering turned off. This produces the most rigorous and conservative simulation from a functionality viewpoint. When performing simulation to produce input for the Quartus II PowerPlay Power Analyzer, Altera recommends turning on glitch filtering to produce the most accurate power estimates.

Node and Entity Assignments

You can assign specific toggle rates and static probabilities to individual nodes and entities in the design. These assignments have the highest priority, overriding data from all other signal activity sources.

Use the Assignment Editor or Tcl commands to make the **Power Toggle Rate** and **Power Static Probability** assignments. You can specify the power toggle rate as an absolute toggle rate in transitions using the **Power Toggle Rate** assignment or you can use the **Power Toggle Rate Percentage** assignment to specify a toggle rate relative to the clock domain of the assigned node for more specific assignment made in terms of hierarchy level.

If the **Power Toggle Rate Percentage** assignment is used, and the given node does not have a clock domain, a warning is issued and the assignment is ignored.

For more information about how to use the Assignment Editor in the Quartus II software, refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook*.

This method is appropriate for special-case signals where you have specific knowledge of the signal or entity being analyzed. For example, if you know that a 100-MHz data bus or memory output produces data that is essentially random (uncorrelated in time), you can directly enter a 0.5 static probability and a toggle rate of 50 million transitions per second.

Bidirectional I/O pins are treated specially. The combinational input port and the output pad for a given pin share the same name. However, those ports might not share the same signal activities. For the purpose of reading signal activity assignments, the Power Analyzer creates a distinct name `<node_name~output>` when the bidirectional signal is configured as an output and `<node_name~result>` when the signal is configured as an input. For example, if a design has a bidirectional pin named `MYPIN`, assignments for the combinational input use the name `MYPIN~result`, and the assignments for the output pad use the name `MYPIN~output`.

When making the logic assignment in the Assignment Editor, you will not find the `MYPIN~result` and `MYPIN~output` node names in the Node Finder. Therefore, to make the logic assignment, you must manually enter the two differentiating node names to make the specific assignment for the input and output port of the bidirectional pin.

Timing Assignments to Clock Nodes

For clock nodes, the Power Analyzer uses the timing requirements to derive the toggle rate when neither simulation data nor user entered signal activity data is available.

f_{MAX} requirements specify full cycles per second, but each cycle represents a rising transition and a falling transition. For example, a clock f_{MAX} requirement of 100 MHz corresponds to 200 million transitions per second.

Default Toggle Rate Assignment

You can specify a default toggle rate for primary inputs and all other nodes in the design. The default toggle rate is used when no other method has specified the signal activity data.

The toggle rate can be specified in absolute terms (transitions per second) or as a fraction of the clock rate in effect for each particular node. The toggle rate for a given clock is derived from the timing settings for the clock. For example, if a clock is specified with an f_{MAX} constraint of 100 MHz and a default relative toggle rate of 20%, nodes in this clock domain transition in 20% of the clock periods, or 20 million transitions occur per second. In some cases, the Power Analyzer cannot determine the clock domain for a given node because there is either no clock domain for the node or it is ambiguous. In these cases, the Power Analyzer substitutes and reports a toggle rate of zero.

Vectorless Estimation

For some device families, the Power Analyzer automatically derives estimates for signal activity on nodes with no simulation or user-entered signal-activity data. Vectorless estimation is available and enabled by default for Arria GX, Stratix IV, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, and MAX II device families. Vectorless estimation statistically estimates the signal activity of a node based on the signal activities of all nodes feeding that node, and on the actual logic function implemented by the node. The **PowerPlay Power Analyzer Settings** dialog box lets you disable vectorless estimation. When enabled, vectorless estimation takes priority over default toggle rates. Vectorless estimation does not override clock assignments.

Vectorless estimation cannot derive signal activities for primary inputs. Vectorless estimation is generally accurate for combinational nodes, but not for registered nodes. Therefore, simulation data for at least the registered nodes and I/O nodes is required for accuracy.

Using the PowerPlay Power Analyzer

For all flows that use the PowerPlay Power Analyzer, synthesize your design first and then fit it to the target device. You must either provide timing assignments for all clocks in the design or use a simulation-based flow to generate activity data. The I/O standard used on each device input or output and the capacitive load on each output must be specified in the design.

Common Analysis Flows

You can use the analysis flows in this section with the PowerPlay Power Analyzer. However, vectorless activity estimation is only available for some device families.

Signal Activities from Full Post-Fit Netlist (Timing) Simulation

This flow provides the highest accuracy because all node activities reflect actual design behavior, provided that supplied input vectors are representative of typical design operation. Results are better if the simulation filters glitches. The disadvantage with this method is that simulation times can be long.

Signal Activities from RTL (Functional) Simulation, Supplemented by Vectorless Estimation

In this flow, simulation provides toggle rates and static probabilities for all pins and registers in the design. Vectorless estimation fills in the values for all the combinational nodes between pins and registers. This method yields good results, because vectorless estimation is accurate, given that the proper pin and register data is provided. This flow usually provides a compilation time benefit to the user in the third-party RTL simulator.

RTL simulation may not provide signal activities for all registers in the post-fitting netlist because some register names might be lost during synthesis. For example, synthesis might automatically transform state machines and counters, thus changing the names of registers in those structures.

Signal Activities from Vectorless Estimation, User-Supplied Input Pin Activities

This option provides a low level of accuracy, because vectorless estimation for registers is not entirely accurate.

Signal Activities from User Defaults Only

This option provides the lowest degree of accuracy.

Generating a .saf or .vcd File Using the Quartus II Simulator

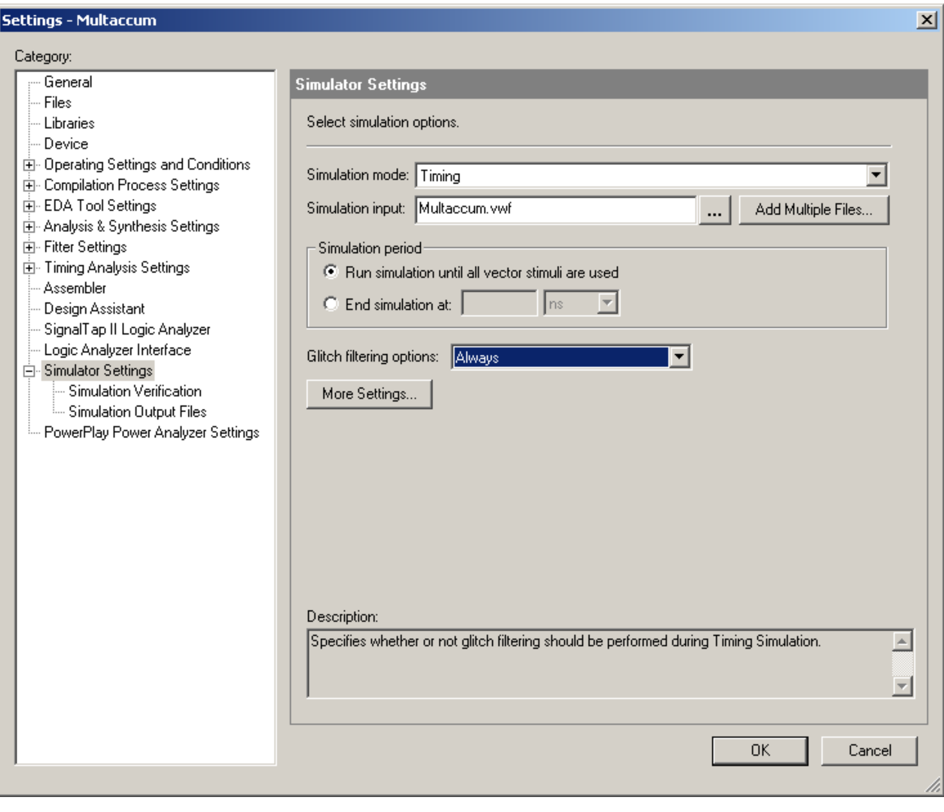
While performing a timing or functional simulation using the Quartus II Simulator, you can generate a **.saf** or **.vcd** file. These files store the toggle rate and static probability for each connected output signal based on the simulation vectors that are entered in the Vector Waveform File (**.vwf**) or the Vector File (**.vec**). You can use the **.saf** file(s) or **.vcd** file(s) as input to the PowerPlay Power Analyzer to estimate power for your design.

For more accurate results, Altera recommends that you use the **.saf** file created in the Quartus II Simulator as the input to the PowerPlay Power Analyzer.

To create a **.saf** or **.vcd** file for your design, perform the following steps:

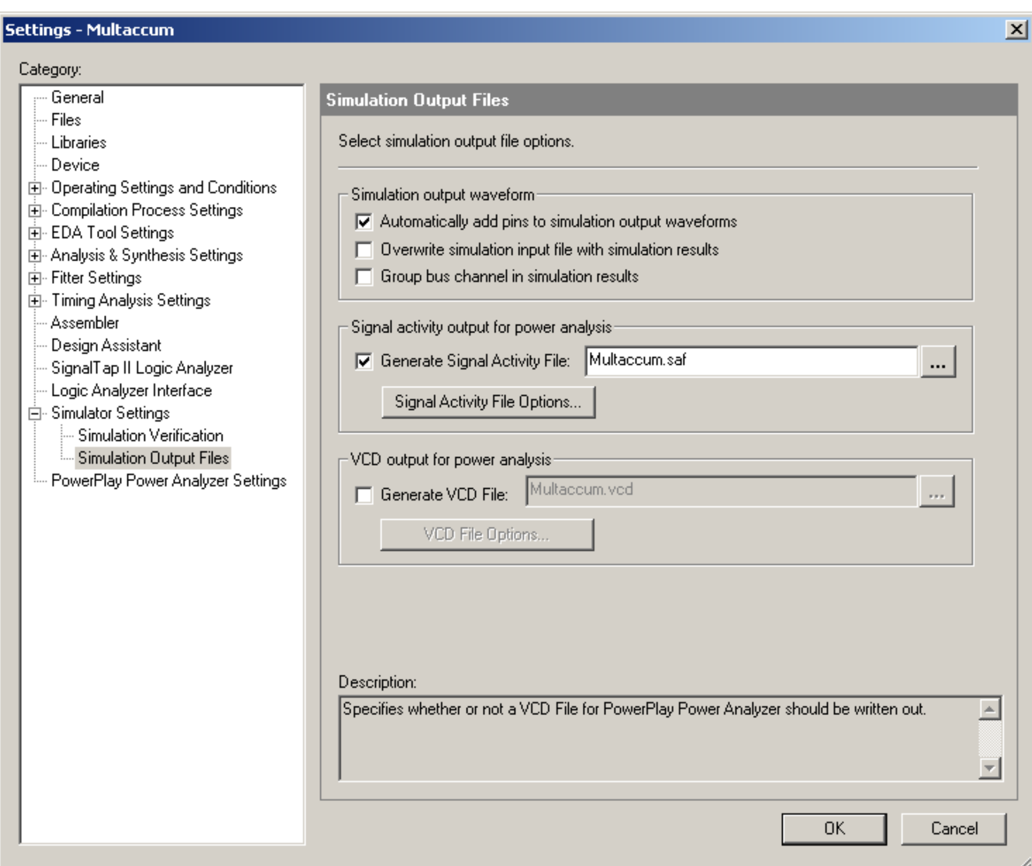
1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulator Settings**. The **Simulator Settings** page appears (Figure 12–8).

Figure 12–8. Simulator Settings Page



3. In the **Simulation mode** list, select either **Timing** or **Functional**. Refer to "Common Analysis Flows" on page 12–17 for a description of the difference in accuracy between the two types of simulation modes.
4. (Optional) Click **More Settings**. The **More Simulator Settings** dialog box appears.
5. (Optional) Turn on glitch filtering. To turn on glitch filtering, in the **Glitch filtering options** list, select **Always**.
6. In the **Category** list, click the "+" icon to expand **Simulator Settings** and select **Simulation Output Files** (Figure 12–9).

Figure 12–9. Simulator Output Files Page of the Settings Dialog Box



7. Turn on **Generate Signal Activity File** and enter the file name for the **.saf** file.

For more information about the Quartus II Simulator and how to create a **.saf** file, refer to the *Quartus II Simulator* chapter in volume 3 of the *Quartus II Handbook*.

When generating a **.vcd** file from the Quartus Simulator, you must make sure that you add **all nodes** to the input vector wave file. Only the nodes that have been added to your vector file are output to the Quartus-generated **.vcd** file. This is not the case when generating a **.saf** file. The Quartus II Simulator creates a **.saf** file, including all the internal nodes of your design, even if the stimuli file contains only the input vectors for your simulation.

8. (Optional) Click **Signal Activity File Options**. The **Signal Activity File Options** dialog box appears. Turn on the **Limit signal activity period** option to specify the simulation period to use when calculating the signal activities.

   Power estimation can be performed for the entire simulation time or for a portion of the simulation time. This allows you to look at the power consumption at different points in your overall simulation without having to rework your testbenches. This feature is also useful when multiple clock cycles are necessary to initialize the state of the design, but you want to measure the signal activity only during the normal operation of the design, not during its initialization phase. You

© March 2009 Altera Corporation

can specify the start time and end time in the **Signal Activity File Options** dialog box by turning on the **Limit signal activity period** option. Simulation information is used during this time interval only to calculate toggle rates and static probabilities. If no time interval is specified, the whole simulation is used to compute signal activity data.

9. After the simulation is complete, a **.saf** file is generated with the specified filename and stored in the main project directory.

For more information about how to perform simulations in the Quartus II software, refer to the Quartus II Help.

Generating a VCD File Using a Third-Party Simulator

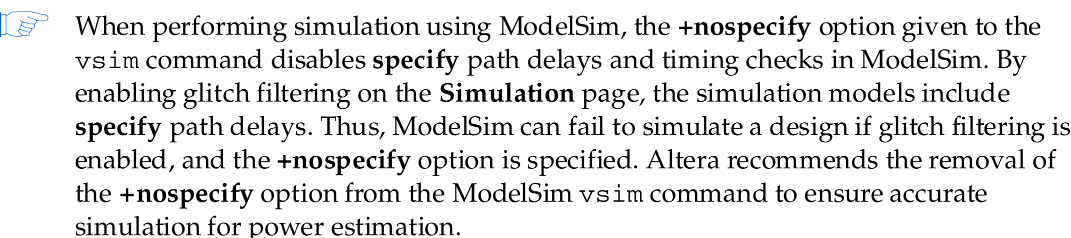
You can use other EDA simulation tools, such as the Model Technology™ ModelSim® software, to perform a simulation and create a **.vcd** file. You can use this file as input to the PowerPlay Power Analyzer to estimate power for your design. To do this, you must tell the Quartus II software to generate a script file that is used as input to the third-party simulator. This script tells the third-party simulator to generate a **.vcd** file that contains all the output signals. For more information about the supported third-party simulators, refer to "Simulation Results" on page 12–10.

To create a **.vcd** file for your design, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears.
3. In the **Tool name** list, select the appropriate EDA simulation tool.
4. In the **Format for output netlist** list, select **VHDL** or **Verilog**.
5. Turn on **Generate Value Change Dump (VCD) file script**.

This turns on the **Map illegal HDL character** and **Enable glitch filtering** options.

6. (Optional) **Map illegal HDL characters** ensures that all signals have legal names and that signal toggle rates are available later in the PowerPlay Power Analyzer.
7. (Optional) By turning on **Enable glitch filtering**, glitch filtering logic is the output when you generate an EDA netlist for simulation. This option is always available, regardless of whether or not you want to generate the **.vcd** file scripts. For more information about glitch filtering, refer to "Glitch Filtering" on page 12–14.



When performing simulation using ModelSim, the **+nospecify** option given to the `vsim` command disables **specify** path delays and timing checks in ModelSim. By enabling glitch filtering on the **Simulation** page, the simulation models include **specify** path delays. Thus, ModelSim can fail to simulate a design if glitch filtering is enabled, and the **+nospecify** option is specified. Altera recommends the removal of the **+nospecify** option from the ModelSim `vsim` command to ensure accurate simulation for power estimation.

8. Click **Script Settings**. The **Script Settings** dialog box appears.

Select which signals should be output to the **.vcd** file. With **All signals** selected, the generated script instructs the third-party simulator to write all connected output signals to the **.vcd** file. With **All signals except combinational lcell outputs** selected, the generated script tells the third-party simulator to write all connected output signals to the **.vcd** file, except logic cell combinational outputs.

You might not want to write all output signals to the file because the file can become extremely large (since its size depends on the number of output signals being monitored and the number of transitions that occur).

9. Click **OK**.
10. Type a name for your testbench in the **Design instance name** box.
11. Compile your design with the Quartus II software and generate the necessary EDA netlist and script that tells the third-party simulator to generate a **.vcd** file.

For more information about NativeLink use, refer to *Section I. Simulation* in volume 3 of the *Quartus II Handbook*.

12. Perform a simulation with the third-party EDA simulation tool. Call the generated script in the simulation tool before running the simulation. The simulation tool generates the **.vcd** file and places it in the project directory.

Generating a VCD File from ModelSim Software

The following example provides step-by-step instructions to successfully produce a **.vcd** file with the ModelSim software:

1. In the Quartus II software, on the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulator Settings**. On the **Simulator Settings** page, choose the appropriate ModelSim selection in the **Tool Name** list, and turn on the **Generate Value Change Dump File Script** option.
3. To generate the **.vcd** file, perform a full compilation.
4. In the ModelSim software, compile the files necessary for simulation.
5. Load your design by clicking **Start Simulation** on the Tools menu, or use the `vsim` command.
6. Source the Quartus II **.vcd** script created in step 3 using the following command:
`source <design>_dump_all_vcd_nodes.tcl`
7. Run the simulation (for example, `run 2000ns` or `run -all`).
8. Quit the simulation using the `quit -sim` command, if required.
9. Exit the ModelSim software. If you do not exit the software, the ModelSim software might end the writing process of the **.vcd** files improperly, resulting in a corrupted **.vcd** file.

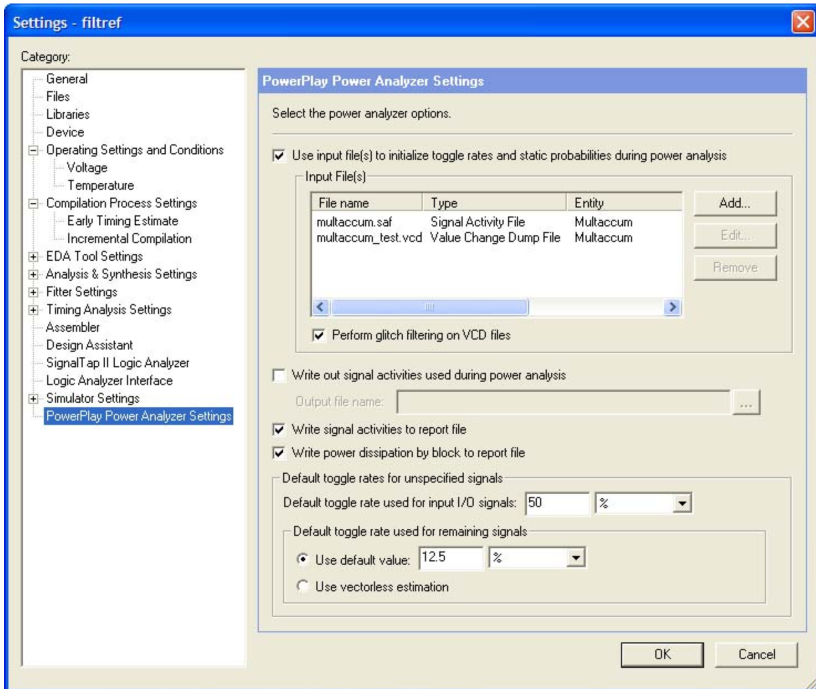
For more information about how to create a **.vcd** file in other third-party EDA simulation tools, refer to *Section I. Simulation*, in volume 3 of the *Quartus II Handbook*.

Running the PowerPlay Power Analyzer Using the Quartus II GUI

To run the PowerPlay Power Analyzer using the Quartus II GUI, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **PowerPlay Power Analyzer Settings**. The **PowerPlay Power Analysis** page appears (Figure 12–10).

Figure 12–10. PowerPlay Power Analyzer Settings

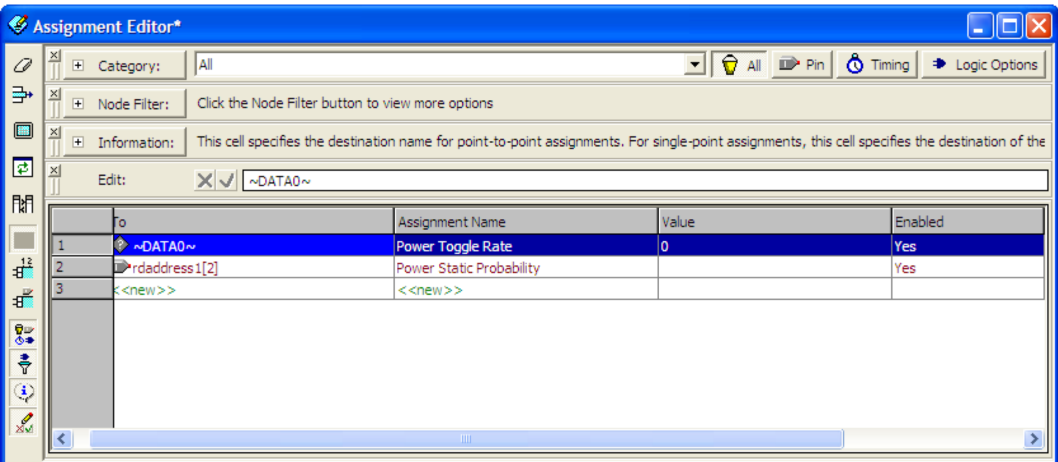


3. (Optional) If you want to use either **.saf** file(s) or **.vcd** file(s) or both as an input to the PowerPlay Power Analyzer, turn on **Use input file(s) to initialize toggle rates and static probabilities during power analysis**.

   (Optional) The **Edit** button allows you to change the settings for a selected file from the list. The **Remove** button allows you to remove a selected file from the list.
4. Click **Add**. The **Add Power Input File** dialog box appears.
5. Add your **.saf** file(s) or **.vcd** file(s) by clicking the browse button for the **File name** field.
6. The **Entity** field enables you to specify the design entity (hierarchy) to which the entered power input file applies. To enter the entity, you can type in the box or browse through the list of your design entities. To browse your design entities, click the browse button. The **Select Hierarchy** dialog box appears. You can specify multiple entities in the entity text box by using comma delimiters. You can specify whether the input file is a **.vcd** or **.saf** file under **Input File Type**.

7. (Optional) **Limit VCD period** is enabled only when **VCD file** is selected. This enables you to specify the simulation period to use when calculating the signal activities. For more information, refer to “Generating a .saf or .vcd File Using the Quartus II Simulator” on page 12–18.
8. Click **OK**.
9. Click **OK** in the **Add Power Input File** dialog box.
10. (Optional) Turn on **Perform glitch filtering on VCD files**. This option is recommended. For more information, refer to “Glitch Filtering” on page 12–14.
11. (Optional) Turn on **Write out signal activities used during power analysis**. In the **Output file name** list, select the output file name. This file contains all the signal activities information used during the power estimation of your design. This is recommended if you used a **.vcd** file as input into the PowerPlay Power Analyzer, because it reduces the run time of any subsequent power estimation. You can use the generated **.saf** file as input instead of the original **.vcd** file.
12. (Optional) Turn on **Write signal activities to report file**.
13. (Optional) Turn on **Write power dissipation by block to report file** to enable the output of detailed thermal power dissipation by block to be included in the PowerPlay Power Analyzer report.
14. (Optional) You can also use the Assignment Editor to enter the Power Toggle Rate or Power Toggle Rate Percentage, and the Power Static Probability for a node or entity in your design, shown in Figure 12–11.

Figure 12–11. Assignment Editor, *(Note 1)*, *(Note 2)*



Notes to Figure 12–11:

(1) The assignments made with the Assignment Editor override the values already existing in the **.saf** file or **.vcd** file.

(2) You can also use Tcl script commands to make these assignments.

For more information about how to use the Assignment Editor in the Quartus II software, see the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook*. For information about scripting, see the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*.

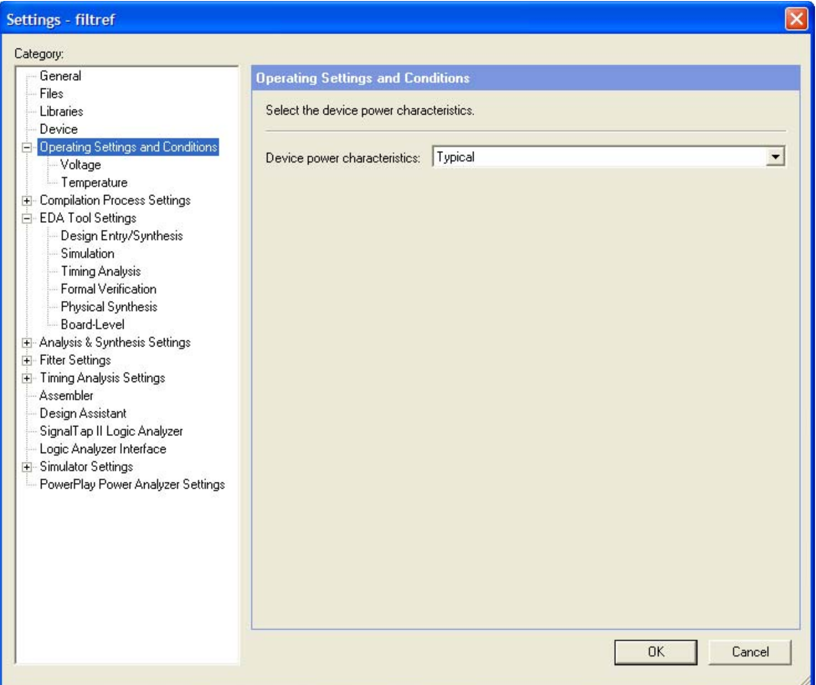
© March 2009 Altera Corporation

15. Specify the toggle rate in the **Default toggle rate used for input I/O signals** field. This toggle rate is used for all unspecified input I/O signal toggle rates regardless of whether or not the device family supports vectorless estimation. By default, its value is set to 12.5%. The default static probability for unspecified input I/O signals is 0.5 and cannot be changed.

16. Select either **Use default value** or **Use vectorless estimation** for Arria GX, Stratix IV, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, or MAX II device families. For all other device families, only **Use default value** is available. This setting controls how the remainder of the unspecified signal activities are calculated. For more information, refer to "Vectorless Estimation" on page 12–17 and "Default Toggle Rate Assignment" on page 12–17.

17. In the **Category** list, select **Operating Settings and Conditions**. This option is available only for the Arria GX, Stratix IV, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, and MAX II device families (Figure 12–12).

Figure 12–12. Operating Conditions



18. In the **Device power characteristics** list, select **Typical** or **Maximum**. The default is **Typical**.

19. In the **Category** list, click the "+" icon to expand **Operating Settings and Conditions** and click **Voltage**. The **Voltage** page appears.

20. For the devices with selectable core voltage support, in the **Core supply voltage** list, select the core supply voltage for your device. This option is available for the latest devices with variable voltage selection.

21. In the **Category** list, under **Operating Settings and Conditions,** select **Temperature**. The **Temperature** page appears.

22. Under **Junction temperature range**, specify a junction temperature in degrees Celsius and specify the junction temperature range. Select the **Low temperature** and **High temperature** range for your selected device.
23. Specify the junction temperature and cooling solution settings. You can select **Specify junction temperature** or **Auto compute junction temperature using cooling solution**.
24. (Optional) Under **Board thermal modeling**, select the **Board thermal model** and type the **Board temperature**. This feature can only be turned on when you have selected **Auto compute junction temperature using cooling solution**.

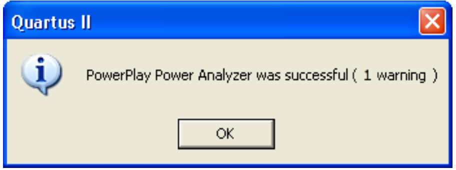
For more information about how to use the operating condition settings, refer to "Operating Conditions" on page 12–8.

26. Click **OK** to close the **Settings** dialog box.
27. On the Processing menu, click **PowerPlay Power Analyzer Tool**. The **PowerPlay Power Analyzer Tool** dialog box appears.
28. Click **Start** to run the PowerPlay Power Analyzer. Be sure that all the settings are correct.

You can also make changes to some of your settings in this dialog box. For example, you can click the **Add Power Input File(s)** button to make changes to your input file(s), or you can click the **Cooling Solution and Temperature** button to make changes to your design temperature and cooling solution selection.

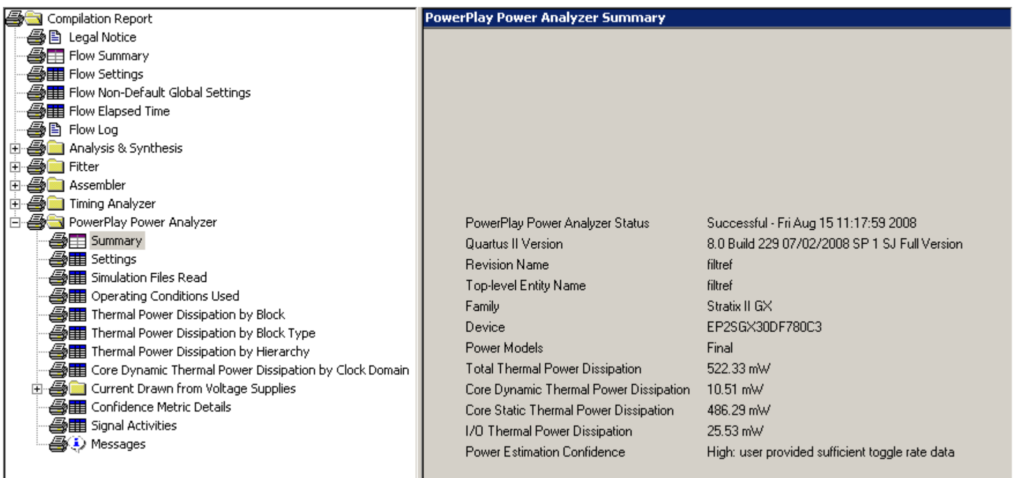
29. After the PowerPlay Power Analyzer runs successfully, a message appears (Figure 12–13).

Figure 12–13. PowerPlay Power Analyzer Message



30. Click **OK**.
31. In the **PowerPlay Power Analyzer Tool** dialog box, click **Report** to open the PowerPlay Power Analyzer Summary window. You can also view the summary in the **PowerPlay Power Analyzer Summary** page of the Compilation Report (Figure 12–14).

Figure 12–14. PowerPlay Power Analyzer Summary



PowerPlay Power Analyzer Compilation Report

The PowerPlay Power Analyzer section of the Compilation Report is divided into the following sections.

Summary

This section of the report shows your design's estimated total thermal power consumption. This includes dynamic, static, and I/O thermal power consumption. The I/O thermal power consumption is the total I/O power contributed by both the V_{CCIO} power supplies and some portion of the V_{CCINT}. The report also includes a confidence metric that reflects the overall quality of the data sources for the signal activities. For example, a **Low** power estimation confidence value reflects that the user has provided insufficient toggle rate data, or most of the signal activity information used for power estimation is from default or vectorless estimation settings (see the PowerPlay Power Analyzer Confidence Metric report for details of the input data).

Settings

This section of the report shows your design's PowerPlay Power Analyzer settings information. This includes default input toggle rates, operating conditions, and other relevant setting information.

Simulation Files Read

This section of the report lists simulation output files (**.vcd** or **.saf** file) used for power estimation. It also includes the file ID, file type, entity, VCD start time, VCD end time, the unknown %, and the toggle %. The unknown % indicates the portion of the design module that is not exercised by the simulation vectors.

Operating Conditions Used

This section of the report shows device characteristics, voltages, temperature, and cooling solution, if any, that were used during the power estimation. It also shows the entered junction temperature or auto-computed junction temperature that was used during the power analysis. This page is created only for Arria GX, Stratix IV, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, and MAX II device families.

Thermal Power Dissipated by Block

This section of the report shows estimated thermal dynamic power and thermal static power consumption categorized by atoms. This information provides designers with an estimated power consumption for each atom in their design.

Thermal Power Dissipation by Block Type (Device Resource Type)

This section of the report shows the estimated thermal dynamic power and thermal static power consumption categorized by block types. This information is further categorized by estimated dynamic and static power that was used, as well as providing an average toggle rate by block type. Thermal power is the power dissipated as heat from the FPGA device.

Thermal Power Dissipation by Hierarchy

This section of the report shows an estimated thermal dynamic power and thermal static power consumption categorized by design hierarchy. This is further categorized by the dynamic and static power that was used by the blocks and routing within that hierarchy. This information is very useful in locating problem modules in your design.

Core Dynamic Thermal Power Dissipation by Clock Domain

This section of the report shows the estimated total core dynamic power dissipation by each clock domain. This provides designs with estimated power consumption for each clock domain in their design. If the clock frequency for a domain is unspecified by a constraint, the clock frequency is listed as “unspecified.” For all the combinational logic, the clock domain is listed as no clock with 0 MHz.

Current Drawn from Voltage Supplies

This section of the report lists the current that was drawn from each voltage supply. The VCCIO voltage supply is further categorized by I/O bank and by voltage. The minimum safe power supply size (current supply ability) is also listed for each supply voltage. This page is created only for Arria GX, Stratix IV, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, and MAX II device families.

The transceiver-based devices have multiple voltage supplies: V_{CCH}, V_{CCT}, V_{CCR}, V_{CCA}, V_{CCP}, and so on. The report also shows the static and dynamic current (in mA) drawn from each voltage supply. Total static and dynamic power consumed by the transceivers on all voltage supplies is listed under the “Thermal Power Dissipation by Block Type” report section, which contains a row that starts with “GXB Transceiver.”

The I/O thermal power dissipation which is listed on the summary page does not correlate directly to the power drawn from the V_{CCIO} voltage supply listed in this report. This is because the I/O thermal power dissipation value also includes portions of the V_{CCINT} power, such as the I/O element (IOE) registers which are modeled as I/O power, but do not draw from the V_{CCIO} supply.

Confidence Metric Details

The confidence metric indicates the quality of the signal toggle rate data used to compute a power estimate. The confidence metric is low if the signal toggle rate data comes from sources that are considered poor predictors of real signal toggle rates in the device during an operation. Toggle rate data that comes from simulation, user-entered assignments on specific signals, or entities are considered reliable. Toggle rate data from default toggle rates (for example, 12.5% of the clock period) or vectorless estimation are considered relatively inaccurate. This section gives an overall confidence rating in the toggle rate data, from low to high. It also summarizes how many pins, registers, and combinational nodes obtained their toggle rates from each of simulation, user entry, vectorless estimation, or default toggle rate estimations. This detailed information can help you understand how to increase the confidence metric, letting you decide on your own confidence in the toggle rate data.

Signal Activities

This section lists toggle rate and static probabilities assumed by power analysis for all signals with fan-out and pins. The signal type is provided (Pin, Registered, or Combinational), as well as the data source for the toggle rate and static probability. By default, all signal activities are reported. This can be turned off on the **PowerPlay Power Analyzer Settings** page by turning off the **Write signal activities to report file** option.

Turning this option off might be advisable for a large design because of the large number of signals present. You can use the Assignment Editor to specify that activities for individual nodes or entities are reported by assigning an on value to those nodes for the Power Report Signal Activities assignment.

Messages

This section lists messages generated by the Quartus II software during the analysis.

Specific Rules for Reporting

In a Stratix GX device, the XGM II State Machine block is always used together with GXB transceivers, so its power is lumped into the power for the transceivers. Therefore, the power for the XGM II State Machine block is reported as 0 Watts.

Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp
```

The *Quartus II Scripting Reference Manual* includes the same information in PDF format.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. Refer to the *Quartus II Settings File Reference Manual* for information about all settings and constraints in the Quartus II software. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Running the PowerPlay Power Analyzer from the Command Line

The separate executable that can be used to run the PowerPlay Power Analyzer is `quartus_pow`. For a complete listing of all command line options supported by `quartus_pow`, type the following at a system command prompt:

`quartus_pow --help` or `quartus_sh --qhelp` ↵

The following is an example of using the `quartus_pow` executable with project **sample.qpf**:

- To instruct the PowerPlay Power Analyzer to generate a PowerPlay Early Power Estimator file, type the following at a system command prompt:

```
quartus_pow sample --output_epe=sample.csv ↵
```

- To instruct the PowerPlay Power Analyzer to generate a PowerPlay Early Power Estimator file without doing the power estimate, type the following command at a system command prompt:

```
quartus_pow sample --output_epe=sample.csv --estimate_power=off ↵
```

- To instruct the PowerPlay Power Analyzer to use a **.saf** file as input (**sample.saf**), type the following at a system command prompt:

```
quartus_pow sample --input_saf=sample.saf ↵
```

- To instruct the PowerPlay Power Analyzer to use two **.vcd** files as input (**sample1.vcd** and **sample2.vcd**), perform glitch filtering on the **.vcd** file, and use a default input I/O toggle rate of 10,000 transitions/second, type the following at a system command prompt:

```
quartus_pow sample --input_vcd=sample1.vcd --input_vcd=sample2.vcd \
--vcd_filter_glitches=on --\
default_input_io_toggle_rate=10000transitions/s ↵
```

- To instruct the PowerPlay Power Analyzer to not use any input file, a default input I/O toggle rate of 60%, no vectorless estimation, and a default toggle rate of 20% on all remaining signals, type the following at a system command prompt:

```
quartus_pow sample --no_input_file --default_input_io_toggle_rate=60% \
--use_vectorless_estimation=off --default_toggle_rate=20% ↵
```

There are no command line options to specify the information found on the **PowerPlay Power Analyzer Settings Operating Conditions** page. The easiest way to specify these options is to use the Quartus II GUI.

A report file, <*revision name*>**.pow.rpt**, is created by the `quartus_pow` executable and saved in the main project directory. The report file contains the same information as described in the "PowerPlay Power Analyzer Compilation Report" on page 12–27.

Conclusion

PowerPlay power analysis tools are designed for accurate estimation of power consumption from early design concept through design implementation. Designers can use the PowerPlay Early Power Estimator to estimate power consumption during the design concept stage. Power estimations can be refined during design implementation using the Quartus II PowerPlay Power Analyzer feature. The Quartus II PowerPlay Power Analyzer produces detailed reports that you can use to optimize designs for lower power consumption and verify that the design is within your power budget.

Document Revision History

Table 12–5 shows the revision history for this chapter.

Table 12–5. Document Revision History

Date and Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ This chapter was chapter 11 in version 8.1. ■ Removed Figures 11-10, 11-11, 11-13, 11-14, and 11-17 from 8.1 version.	Updated for the Quartus II software version 9.0.
November 2008 v8.1.0	■ Updated for the Quartus II software version 8.1. ■ Replaced Figure 11-3. ■ Replaced Figure 11-14.	Updated for the Quartus II software version 8.1.
May 2008 v8.0.0	■ Updated Figure 11–5. ■ Updated “Types of Power Analyses” on page 11–5. ■ Updated “Operating Conditions” on page 11–9. ■ Updated “PowerPlay Power Analyzer Compilation Report” on page 11–31. ■ Updated “Current Drawn from Voltage Supplies” on page 11–32.	Updated for the Quartus II software version 8.0.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

Introduction

Debugging today's FPGA designs can be a daunting task. As your product requirements continue to increase in complexity, the time you spend on design verification continues to rise. To get your product to market as quickly as possible, you must minimize design verification time. To help alleviate the time-to-market pressure, a set of verification tools that are powerful and easy to use are required.

The Quartus® II software provides a portfolio of in-system design debugging tools for real-time verification of your design. Each tool in the on-chip debugging portfolio uses a combination of available memory, logic, and routing resources to assist in the debugging process. The tools provide visibility by routing (or "tapping") signals in your design to debugging logic. The debugging logic is then compiled with your design and downloaded into the FPGA or CPLD for analysis. Because different designs can have different constraints and requirements, such as the number of spare pins available or the amount of logic or memory resources remaining in the physical device, you can choose a tool from the available debugging tools that matches the specific requirements for your design.

This section provides a quick overview on the tools available in the on-chip debugging suite and discusses the criteria for selecting the best tool for your design.

On-Chip Debugging Ecosystem

Table IV–1 summarizes the tools in the In-System verification tool suite that are covered in this section of the *Quartus II Handbook*.

Table IV–1. Available Tools in the In-System Verification Tools Suite (Part 1 of 2)

Tool	Description	Typical Circumstances of Use
SignalTap® II Logic Analyzer	This embedded logic analyzer uses FPGA resources to sample tests nodes and outputs the information to the Quartus II software for display and analysis.	You have spare on-chip memory and you want functional verification of your design running in hardware.
SignalProbe	This tool incrementally routes internal signals to I/O pins while preserving results from your last place-and-routed design.	You have spare I/O pins and you would like to check the operation of a small set of control pins using either an external logic analyzer or an oscilloscope.
Logic Analyzer Interface (LAI)	This tool multiplexes a larger set of signals to a smaller number of spare I/O pins. LAI allows you to select which signals are switched onto the I/O pins over a JTAG connection.	You have limited on-chip memory, and have a large set of internal data buses that you would like to verify using an external logic analyzer. Logic analyzer vendors, such as Tektronics and Agilent, provide integration with the tool to improve the usability.
In-System Memory Content Editor	This tool displays and allows you to edit on-chip memory.	You would like to view and edit the contents of the either the instruction cache or data cache of a Nios® II processor application.

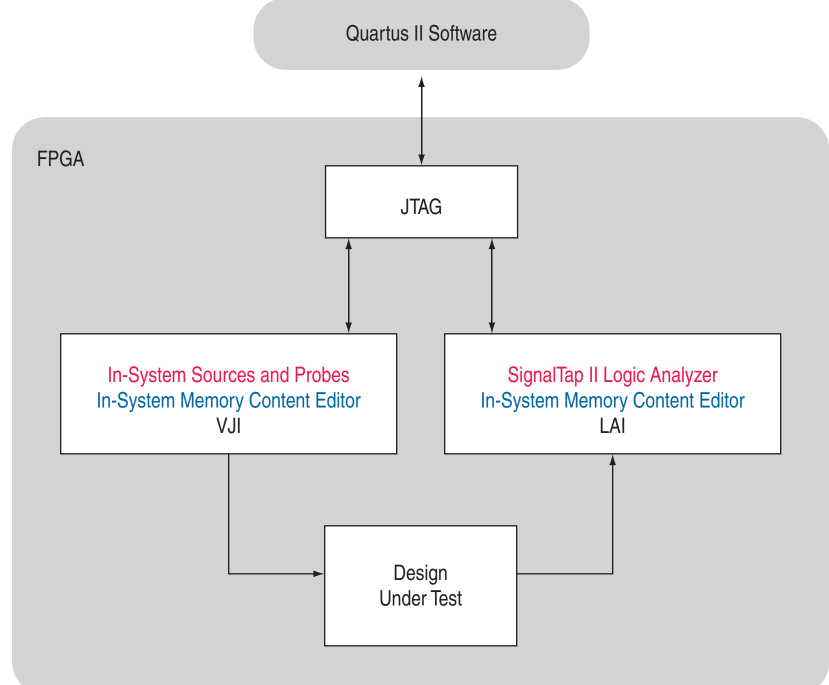
Table IV–1. Available Tools in the In-System Verification Tools Suite (Part 2 of 2)

Tool	Description	Typical Circumstances of Use
In-System Sources and Probes	This feature provides an easy way to drive and sample logic values to and from internal nodes using the JTAG interface.	You want to prototype a front panel with virtual buttons for your FPGA design.
Virtual JTAG Interface	This megafunction opens up the JTAG interface so that you can develop your own custom applications.	You want to generate a large set of test vectors and send them to your device over the JTAG port to functionally verify your design running in hardware.

With the exception of SignalProbe, each of the on-chip debugging tools uses the JTAG port to control and read back data from debugging logic and signals under test. The JTAG resource is shared among all of the on-chip debugging tools. The Quartus II software compiles logic into your design automatically to distinguish between data and control information and each of the debugging logic blocks when the JTAG resource is required. This arbitration logic, also known as the System-Level Debugging (SLD) infrastructure, is shown in the design hierarchy of your compiled project as **sld_hub:sld_hub_inst**. The SLD logic allows you to instantiate multiple debugging blocks into your design and run them simultaneously.

To maximize debugging closure, the Quartus II software allows you to use a combination of the debugging tools in tandem to fully exercise and analyze the logic under test. All of the tools described in Table IV–1 have basic analysis features built in; that is, all of the tools enable you to read back information collected from the design nodes that are connected to the debugging logic. Out of the set of debugging tools, the SignalTap II Logic Analyzer, the LAI, and the SignalProbe feature are general-purpose debugging tools optimized for probing signals in your RTL netlist. In-System Sources and Probes, the Virtual JTAG Interface, and In-System Memory content editor, in addition to being able to read back data from the debugging points, allow you to input values into your design during runtime. Taken together, the set of on-chip debugging tools form a debugging ecosystem. The set of tools can generate a stimulus to and solicit a response from the logic under test, providing a complete debugging solution (Figure IV–1).

Figure IV–1. Quartus II Debugging Ecosystem *(Note 1)*



Note to Figure IV–1:

(1) The set of debugging tools offer end-to-end debugging coverage.

The tools in the toolchain offer different advantages and different trade-offs. To understand the selection criteria between the different tools, the following sections analyze the tools according to their typical applications.

The first section, "Analysis Tools for RTL Nodes", compares the SignalTap II Logic Analyzer, SignalProbe, and the LAI. These three tools are logically grouped since they are intended for debugging nodes from your RTL netlist at system speed.

The next section, "Stimulus-Capable Tools" on page 13–8, compares the In-System Memory Content Editor, Virtual JTAG Interface Megafunction, and In-System Sources and Probes. These tools are logically grouped since they offer the ability to both read and write transactions through the JTAG port.

Analysis Tools for RTL Nodes

The SignalTap II Embedded Logic Analyzer, the SignalProbe feature, and the LAI are designed specifically for probing and debugging RTL signals at system speed. They are general-purpose analysis tools that enable you to tap and analyze any routable node from the FPGA or CPLD. These three tools satisfy a range of requirements. If you have spare logic and memory resources, the SignalTap II Logic Analyzer is useful for providing fast functional verification of your design running on actual hardware.

On the other hand, if logic and memory resources are tight and you require the large sample depths associated with external logic analyzers, both the LAI and the SignalProbe feature make it easy to view internal design signals using external equipment.

The most important selection criteria for these three tools are the available resources remaining on your device after implementing your design and the number of spare pins available. It is worthwhile to evaluate your preferred debugging option early on in the design planning process to ensure that your board, your Quartus II project, and your design are all set up to support the appropriate options. Planning early can reduce time spent during debugging and eliminate the necessary late changes to accommodate your preferred debugging methodologies. The following two sections provide information to assist you in choosing the appropriate tool by comparing the tools according to their resource usage and their pin consumption.

The SignalTap II Logic Analyzer is not supported on CPLDs, because there are no memory resources available on these devices.

Resource Usage

Any debugging tool that requires the use of a JTAG connection requires the SLD infrastructure logic mentioned earlier, for communication with the JTAG interface and arbitration between any instantiated debugging modules. This overhead logic uses around 200 LEs, a small fraction of the resources available in any of the supported devices. The overhead logic is shared between all available debugging modules in your design. Both the SignalTap II Logic Analyzer and the LAI use a JTAG connection.

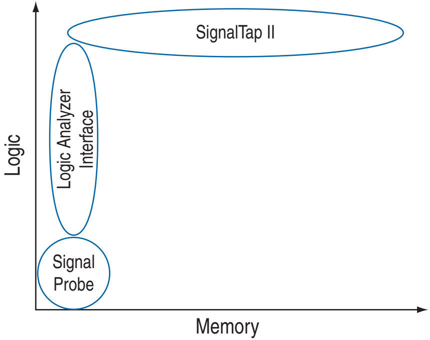
SignalProbe requires very few on-chip resources. Because it requires no JTAG connection, SignalProbe uses no logic or memory resources—it uses only routing resources to route an internal signal to a debugging test point.

The LAI requires a small amount of logic to implement the multiplexing function between the signals under test, in addition to the SLD infrastructure logic. Because no data samples are stored on the chip, the LAI uses no memory resources.

The SignalTap II Logic Analyzer requires both logic and memory resources. The number of logic resources used depends on the number of signals tapped and the complexity of the trigger logic. However, the amount of Logic Resources that the SignalTap II Logic Analyzer uses is typically a small percentage of most designs. A baseline configuration consisting of the SLD arbitration logic and a single node with basic triggering logic contains approximately 300–400 logic elements (LEs). Each additional node you add to the baseline configuration adds about 11 LEs. Compared with logic resources, memory resources are a more important factor to consider for your design. Memory usage can be significant and depends on how you configure your SignalTap II Logic Analyzer instance to capture data and the sample depth that your design requires for debugging. For the SignalTap II Logic Analyzer, there is the added benefit of requiring no external equipment, as all of the triggering logic and storage is on the chip.

Figure IV–2 shows a conceptual graph of the resource usage of the three analysis tools relative to each other.

Figure IV–2. Resource Usage per Debugging Tool *(Note 1)*



Note to Figure IV–2:

(1) Though resource usage is highly dependent on the design, this graph provides a rough guideline for tool selection.

The resource estimation feature for the SignalTap II Logic Analyzer and the LAI allows you to quickly judge if enough on-chip resources are available before compiling the tool with your design. Figure IV–3 shows the resource estimation feature for the SignalTap II Logic Analyzer and the Logic Analyzer Interface.

Figure IV–3. Resource Estimator

Pin Usage

The ratio of the number of pins used to the number of signals tapped for the SignalProbe feature is one-to-one. Because this feature can consume free pins quickly, a typical application for this feature is for routing control signals to spare debugging pins for debugging.

The ratio of the number of pins used to the number of signals tapped for the LAI is many-to-one. It can map up to 256 signals to each debugging pin, depending on available routing resources. The control of the active signals that are mapped to the the spare I/O pins is performed via the JTAG port. The LAI is ideal for routing data buses to a set of test pins for analysis.

Other than the JTAG test pins, the SignalTap II Logic Analyzer uses no additional pins. All data is buffered using on-chip memory and communicated to the SignalTap II GUI via the JTAG test port.

Usability Enhancements

The SignalTap II Embedded Logic Analyzer, the SignalProbe feature, and the LAI tools can be added to your existing design with minimal effects. With the node finder, you can find signals to route to a debugging module without making any changes to your HDL. SignalProbe inserts signals directly from your post-fit database. The SignalTap II Logic Analyzer and LAI support inserting signals from both pre-synthesis and post-fit netlists. All three tools allow you to find and configure your debugging setup quickly. In addition, the Quartus II incremental compilation feature and the Quartus II incremental routing feature allow for a fast turnaround time for your programming file, increasing productivity and enabling fast debugging closure.

Both LAI and the SignalTap II Logic Analyzer support incremental compilation. With incremental compilation, you can add a SignalTap II Logic Analyzer instance or an LAI instance incrementally into your placed-and-routed design. This has the benefit of both preserving your timing and area optimizations from your existing design, and decreasing the overall compilation time when any changes are necessary during the debugging process. With incremental compilation, you can save up to 70% compile time of a full compilation.

SignalProbe uses the incremental routing feature. The incremental routing feature runs only the Fitter stage of the compilation. This also leaves your compiled design untouched, except for the newly routed node or nodes. With SignalProbe, you can save as much as 90% compile time of a full compilation.

As another productivity enhancement, all tools in the on-chip debugging tool set support scripting via the `quartus_stp` Tcl package. For the SignalTap II Logic Analyzer and the LAI, scripting enables user-defined automation for data collection while debugging in the lab.

In addition, the JTAG server allows you to debug a design that is running on a device attached to a PC in a remote location. This allows you to set up your hardware in the lab environment, download any new **.sof** files, and perform any analysis from your desktop.

Table IV–2 compares common debugging features between these tools and provides suggestions about which is the best tool to use for a given feature.

Table IV–2. Suggested On-Chip Debugging Tools for Common Debugging Features (Part 1 of 2) *(Note 1)*

Feature	SignalProbe	Logic Analyzer Interface (LAI)	SignalTap II Logic Analyzer	Description
Large Sample Depth	N/A	✓	—	An external logic analyzer used with the LAI has a bigger buffer to store more captured data than the SignalTap II Logic Analyzer. No data is captured or stored with SignalProbe.
Ease in Debugging Timing Issue	✓	✓	—	External equipment, such as oscilloscopes and Mixed Signal Oscilloscopes (MSOs), can be used with either LAI or SignalProbe used with the LAI to provide you with access to timing mode, enabling you to debug combined streams of data.

Table IV–2. Suggested On-Chip Debugging Tools for Common Debugging Features (Part 2 of 2) *(Note 1)*

Feature	SignalProbe	Logic Analyzer Interface (LAI)	SignalTap II Logic Analyzer	Description
Minimal Effect on Logic Design	✓	✓ *(2)*	✓ *(2)*	The LAI adds minimal logic to a design, requiring fewer device resources. The SignalTap II Logic Analyzer has little effect on the design, as it is set as a separate design partition. SignalProbe incrementally routes nodes to pins, not affecting the design at all.
Short Compile and Recompile Time	✓	✓ *(2)*	✓ *(2)*	SignalProbe attaches incrementally routed signals to previously reserved pins, requiring very little recompilation time to make changes to source signal selections. The SignalTap II Logic Analyzer and the LAI can take advantage of incremental compilation to refit their own design partitions to decrease recompilation time.
Triggering Capability	N/A	N/A	✓	The SignalTap II Logic Analyzer offers triggering capabilities that are comparable to commercial logic analyzers.
I/O Usage	—	—	✓	No additional output pins are required with the SignalTap II Logic Analyzer. Both the LAI and SignalProbe require I/O pin assignments.
Acquisition Speed	N/A	—	✓	The SignalTap II Logic Analyzer can acquire data at speeds of over 200 MHz. The same acquisition speeds are obtainable with an external logic analyzer used with the LAI, but signal integrity issues may limit this.
No JTAG Connection Required	✓	—	—	An FPGA design with the SignalTap II Logic Analyzer or the LAI requires an active JTAG connection to a host running the Quartus II software. SignalProbe does not require a host for debugging purposes.
No External Equipment Required	—	—	✓	The SignalTap II Logic Analyzer logic is completely internal to the programmed FPGA device. No extra equipment is required other than a JTAG connection from a host running the Quartus II software or the stand-alone SignalTap II software. SignalProbe and the LAI require the use of external debugging equipment, such as multimeters, oscilloscopes, or logic analyzers.

Notes to Table IV–2:

(1) ✓ indicates the recommended tools for the feature.
— indicates that while the tool is available for that feature, that tool may not give the best results.
N/A indicates that the feature is not applicable for the selected tool.

(2) When used with incremental compilation.

Stimulus-Capable Tools

The In-System Memory Content Editor, the In-System Sources and Probes, and the Virtual JTAG interface each enable you to use the JTAG interface as a general-purpose communication port. Though all three tools can be used to achieve the same results, there are some considerations that make one tool easier to use in certain applications than others. In-System Sources and Probes is ideal for toggling control signals. The In-System Memory Content Editor is useful for inputting large sets of test data. Finally, the Virtual JTAG megafunction is well suited for more advanced users who want to develop their own customized JTAG solution.

In-System Sources and Probes

In-System Sources and Probes is an easy way to access JTAG resources to both read and write to your design. You can start by instantiating a megafunction into your HDL. The megafunction contains source ports and probe ports for driving values into and sampling values from the signals that are connected to the ports, respectively. Transaction details of the JTAG interface are abstracted away by the megafunction. During runtime, a GUI displays each source and probe port by instance and allows you to read from each probe port and drive to each source port. The GUI makes this tool ideal for toggling a set of control signals during the debugging process.

A good application of In-System Sources and Probes is to use the GUI as a replacement for the push buttons and LEDs used during the development phase of a project. Furthermore, In-System Sources and Probes supports a set of scripting commands for reading and writing using `quartus_stp`. When used with the Tk toolkit, you can build your own graphical interfaces—a feature that is ideal for building a virtual front panel during the prototyping phase of the design.

In-System Memory Content Editor

The In-System Memory Content Editor allows you to quickly view and modify memory contents either through a GUI interface or through Tcl scripting commands. The In-System Memory Content Editor works by turning single-port RAM blocks into dual-port RAM blocks. One port is connected to your clock domain and data signals, and the other port is connected to the JTAG clock and data signals for editing or viewing.

Because you can modify a large set of data easily, a useful application for the In-System Memory Content Editor is to generate test vectors for your design. For example, you can instantiate a free memory block, connect the output ports to the logic under test (using the same clock as your logic under test on the system side), and create the glue logic for the address generation and control of the memory. At runtime, you can modify the contents of the memory using either a script or the In-System Memory Content Editor GUI and perform a burst transaction of the data contents in the modified RAM block synchronous to the logic being tested.

Virtual JTAG Interface Megafunction

The Virtual JTAG Interface megafunction provides the finest level of granularity for manipulating the JTAG resource. This megafunction allows you to build your own JTAG scan chain by exposing all of the JTAG control signals and configuring your JTAG Instruction Registers (IRs) and JTAG Data Registers (DRs). During runtime, you control the IR/DR chain through a Tcl API. This feature is meant for users who have a thorough understanding of the JTAG interface and want precise control over the number and type of resources used.

Conclusion

The Quartus II on-chip debugging tool suite allows you to reach debugging closure quickly by providing you a set of powerful analysis tools and a set of tools that open up the JTAG port as a general purpose communication interface. The Quartus II software further broadens the scope of applications by giving you a comprehensive Tcl/Tk API. With the Tcl/Tk API, you cannot only increase the level of automation for all of the analysis tools, but you can also build virtual front panel applications quickly early in the prototyping phase.

In addition, all of the on-chip debugging tools have a tight integration with the rest of the productivity features within the Quartus II software. The incremental compile and incremental routing features enable a fast turnaround time for programming file generation. The cross-probing feature allows you to find and identify nodes quickly. The SignalTap II Logic Analyzer, when used with the TimeQuest Timing Analyzer, is a best-in-class timing verification suite that allows fast functional and timing verification.

This section contains the detailed usage for each of the On-Chip Debugging tools. This section contains the following chapters:

- Chapter 13, Quick Design Debugging Using SignalProbe
- Chapter 14, Design Debugging Using the SignalTap II Embedded Logic Analyzer
- Chapter 15, In-System Debugging Using External Logic Analyzers
- Chapter 16, In-System Updating of Memory and Constants
- Chapter 17, Design Debugging Using In-System Sources and Probes

13. Quick Design Debugging Using SignalProbe

QII53008-9.0.0

Introduction

Hardware verification can be a lengthy and expensive process. The SignalProbe incremental routing feature helps reduce the hardware verification process and time-to-market for system-on-a-programmable-chip (SOPC) designs.

Easy access to internal device signals is important in the design or debugging process. The SignalProbe feature makes design verification more efficient by routing internal signals to I/O pins quickly without affecting the design. When you start with a fully routed design, you can select and route signals for debugging to either previously reserved or currently unused I/O pins.

SignalProbe feature is fully functional with Arria® GX, the Stratix® series, Cyclone® series, MAX® II, and APEX™ series device families.

This chapter is divided into two sections. If you are using the SignalProbe feature to debug your Stratix series, Cyclone series, and MAX II device, refer to "Debugging Using the SignalProbe Feature". If you are using the SignalProbe feature to debug your APEX series device, refer to "Using SignalProbe with the APEX Device Family" on page 13–12.

The Quartus® II software provides a portfolio of on-chip debugging solutions. For an overview and comparison of all of the tools available in the Quartus II software on-chip debugging tool suite, refer to *Section V. In-System Design Debugging* in volume 3 of the *Quartus II Handbook*.

Debugging Using the SignalProbe Feature

The SignalProbe feature allows you to reserve available pins and route internal signals to those reserved pins, while preserving the behavior of your design. SignalProbe is an effective debugging tool that provides visibility into your FPGA.

This section describes the SignalProbe process for the Stratix series, Cyclone series, and MAX II device families. Using SignalProbe with APEX devices is described in "Using SignalProbe with the APEX Device Family" on page 13–12. APEX devices do not support post-fit netlist changes made as engineering change orders (ECOs).

You can reserve pins for SignalProbe and assign I/O standards before or after a full compilation. Each SignalProbe-source to SignalProbe-pin connection is implemented as an ECO change that is applied to your netlist after a full compilation.

To route the internal signals to the device's reserved pins for SignalProbe, perform the following tasks:

1. Reserve the SignalProbe Pins, described on page 13–2.
2. Perform a Full Compilation, described on page 13–3.
3. Assign a SignalProbe Source, described on page 13–3.
4. Add Registers to the Pipeline Path to SignalProbe Pin, described on page 13–4.

5. Perform a SignalProbe Compilation, described on page 13–5.
6. Analyze the Results of the SignalProbe Compilation, described on page 13–5.

Reserve the SignalProbe Pins

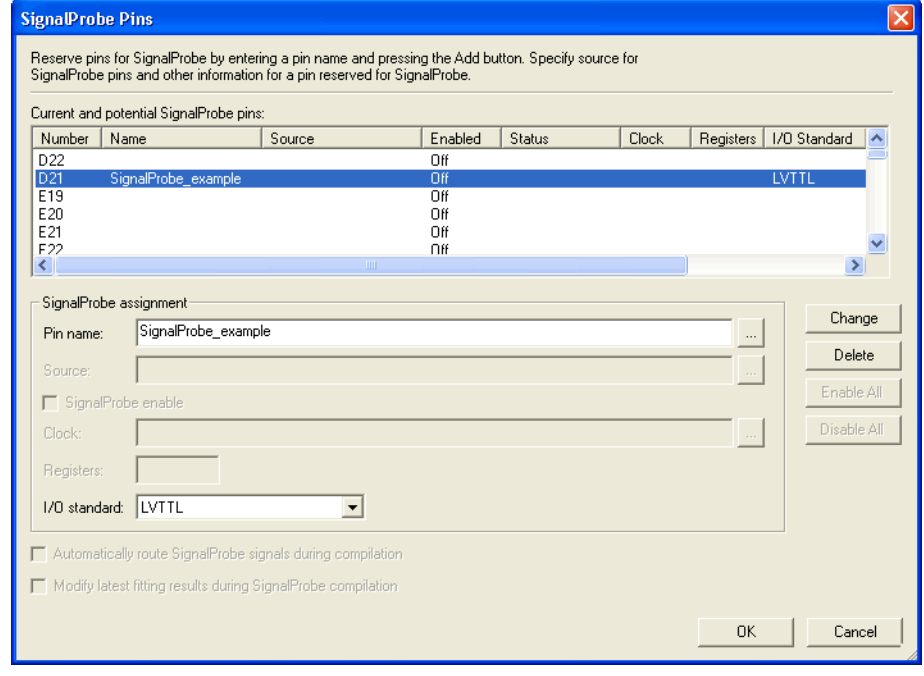
SignalProbe pins can be reserved before or after compiling your design. Reserving SignalProbe pins before a compilation is optional. You can also reserve any unused I/Os of the device for SignalProbe pins after compilation. Assigning sources is a simple process after reserving SignalProbe pins. The sources for SignalProbe pins are the internal nodes and registers in the post-compilation netlist that you want to probe.

Although you can reserve SignalProbe pins using many features within the Quartus II software, including the Pin Planner and the Tcl interface, you should use the **SignalProbe Pins** dialog box to create and edit your SignalProbe pins.

To reserve an available package pin as a SignalProbe pin using the **SignalProbe Pins** dialog box, perform the following steps:

1. On the Tools menu, click **SignalProbe Pins**. The **SignalProbe Pins** dialog box appears (Figure 13–1). The SignalProbe Pin name and I/O Standard appear as the only fields that are editable if place-and-route or fitting have not been performed.

Figure 13–1. Reserving a SignalProbe Pin in the SignalProbe Pins Dialog Box



2. In the **Current and potential SignalProbe pins** list, click a pin from the **Number** column and type your SignalProbe pin name in the **Pin name** box.
3. Select an I/O standard from the **I/O standard** drop-down list.

4. To add a new SignalProbe pin, click **Add**. To edit or change a previously reserved pin for SignalProbe, click **Change**. (Figure 13–1 shows the dialog box editing a previously reserved pin; if you were adding a new SignalProbe pin, the **Add** button appears instead of the **Change** button.)
5. Click **OK**.

Perform a Full Compilation

You must complete a full compilation to generate an internal netlist containing a list of internal nodes to probe to a SignalProbe outpin.

To perform a full compilation, on the processing menu, click **Start Compilation**.

Assign a SignalProbe Source

A SignalProbe source can be any combinational node, register, or pin in your post-compilation netlist. To find a SignalProbe source, in the Node Finder, use the SignalProbe filter to remove all sources that cannot be probed. You might not be able to find a particular internal node because the node can be optimized away during synthesis, or the node cannot be routed to the SignalProbe pin, as it is untappable. For example, internal nodes and registers within the Gigabit transceivers cannot be probed because there are no physical routes to the pins available.

To probe virtual I/O pins generated in low-level partitions in an incremental compilation flow, select the source of the logic that feeds the Virtual Pin as your SignalProbe source pin.

To assign a SignalProbe source to your SignalProbe reserved pin, perform the following steps:

1. On the Tools menu, click **SignalProbe Pins**. The **SignalProbe Pins** dialog box appears (Figure 13–1 on page 13–2).
2. If a SignalProbe reserved pin is shown, in the **Current and potential SignalProbe pins** list, click the pin. Alternately, you can click an available pin number in the **Current and potential SignalProbe pins** list and type a new SignalProbe pin name into the **Pin name** box.
3. In the **Source** box, specify the source name. Click the browse button. The **Node Finder** dialog box appears.
4. When you open the **Node Finder** dialog box from the **SignalProbe Pins** dialog box, **SignalProbe** is selected by default in the **Filter** list. To show a set of nodes that can be probed in the **Nodes Found** list, click **List**.
5. In the **Nodes Found** list, select your source node and click the **>** button. The selected node appears in the **Selected Nodes** list.
6. Click **OK**.
7. After a source is selected, the **SignalProbe enable** option is turned on. Click **Change** or **Add** to accept the changes.

Because SignalProbe pins are implemented and routed as ECOs, turning the **SignalProbe enable** option on or off is the same as selecting **Apply Selected Change** or **Restore Selected Change** in the Change Manager window. (If the Change Manager window is not visible at the bottom of your screen, on the View menu, point to **Utility Windows** and click **Change Manager**.)

For more information about the Change Manager for the Chip Planner and Resource Property Editor, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

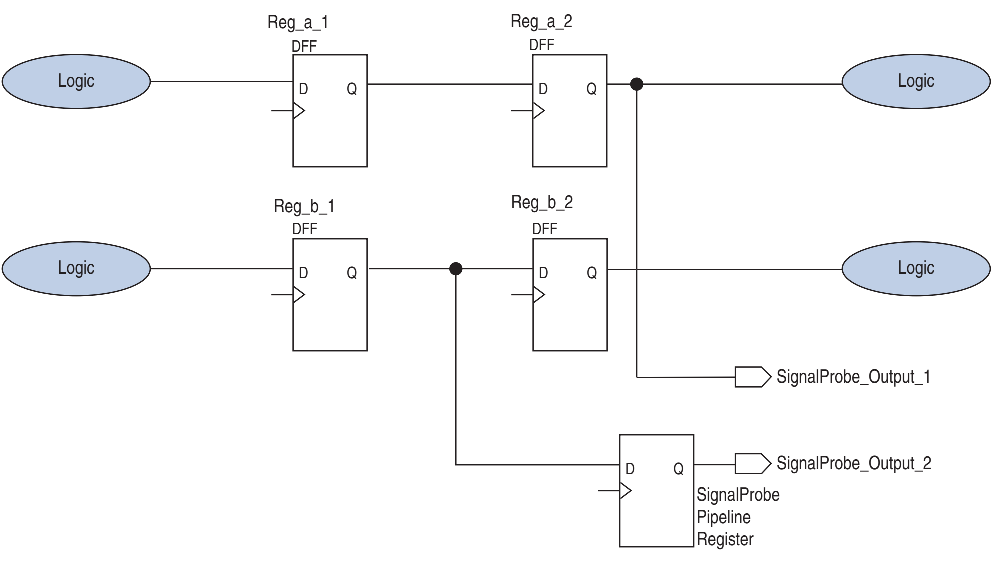
Add Registers to the Pipeline Path to SignalProbe Pin

You can specify the number of registers placed between a SignalProbe source and a SignalProbe pin to synchronize the data with a clock and to control the latency of the SignalProbe outputs. The SignalProbe feature automatically inserts the number of registers specified into the SignalProbe path.

Figure 13–2 shows a single register between the SignalProbe source `Reg_b_1` and SignalProbe `SignalProbe_Output_2` output pin added to synchronize the data between the two SignalProbe output pins.

When you add a register to a SignalProbe pin, the SignalProbe compilation attempts to place the register to best fit timing requirements. You can place SignalProbe registers either near the SignalProbe source to meet f_{MAX} requirements, or near the I/O to meet t_{CO} requirements.

Figure 13–2. Synchronizing SignalProbe Outputs with a SignalProbe Register



To pipeline an existing SignalProbe, perform the following steps:

1. On the Tools menu, click **SignalProbe Pins**. The **SignalProbe Pins** dialog box appears.
2. Select a SignalProbe pin and in the **Clock** dialog box, type the clock name used to drive your registers, or click the browse button to use the Node Finder to select your clock source.
3. In the **Registers** dialog box, specify the number of registers you want to add in between the SignalProbe source and the SignalProbe output.
4. Click **Change.**
5. Click **OK**.

In addition to clock input for pipeline registers, you can also specify a reset signal pin for pipeline registers. To specify a reset pin for pipeline registers, use the Tcl command `make_sp`, as described in "Scripting Support" on page 13–11.

Perform a SignalProbe Compilation

Perform a SignalProbe compilation to route your SignalProbe pins. A SignalProbe compilation saves and checks all netlist changes without recompiling the other parts of the design and completes compilation in a fraction of the time of a full compilation. The design's current placement and routing are preserved.

To perform a SignalProbe compilation, on the Processing menu, point to **Start** and click **Start SignalProbe Compilation**.

Analyze the Results of the SignalProbe Compilation

After a SignalProbe compilation, the results are available in the compilation report file. Each SignalProbe pin is displayed in the **SignalProbe Fitting Result** page in the **Fitter** section of the Compilation Report. To view the status of each SignalProbe pin in the **SignalProbe Pins** dialog box, on the Tools menu, click **SignalProbe Pins**.

The status of each SignalProbe pin appears in the Change Manager window (Figure 13–3). (If the Change Manager window is not visible at the bottom of your GUI, from the View menu, point to **Utility Windows** and click **Change Manager**.)

Figure 13–3. Change Manager Window with SignalProbe Pins

For more information about how to use the Change Manager, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

To view the timing results of each successfully routed SignalProbe pin, on the Processing menu, point to **Start** and click **Start Timing Analysis**.

SignalProbe ECO Flows

Beginning with Quartus II software version 6.0, SignalProbe pins are implemented using the same flow as other post-compilation changes made as ECOs. The following section describes SignalProbe ECO flows with and without the Quartus II incremental compilation feature.

SignalProbe ECO Flow with Quartus II Incremental Compilation

Beginning with Quartus II software version 6.1, the incremental compilation feature is turned on by default. The top-level design is automatically set to a design partition when the incremental compilation feature is on. A design partition during incremental compilation can have different netlist types. (Netlist types can be set to source HDL, post synthesis, or post-fit.) The netlist type indicates whether that partition should be resynthesized or refit during Quartus II incremental compilation. Incremental compilation saves you time and preserves the placement of unchanged partitions in your design if small changes must be made to some partitions late in the design cycle.

For more information about the Quartus II incremental compilation feature, refer to the *Quartus II Incremental Compilation Feature for Hiearchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

The behavior of SignalProbe pins during an incremental compilation depends on the Netlist Type setting. When the top-level partition netlist type is set to **post-fit**, SignalProbe ECOs are retained if the partition being probed is preserved when you recompile the design.

SignalProbe connections always link the partition being probed with the top-level partition. As such, a SignalProbe connection might change the preservation attributes in a lower-level partition. This is known as *partition linking*. When partition linking occurs, all partitions that become linked share the attribute for the preservation level that is the strictest among all of the affected partitions. As a result, when you tap any partitions that are not post-fit and the top level is set to a netlist type of post-fit**,** your SignalProbe connection is still preserved.

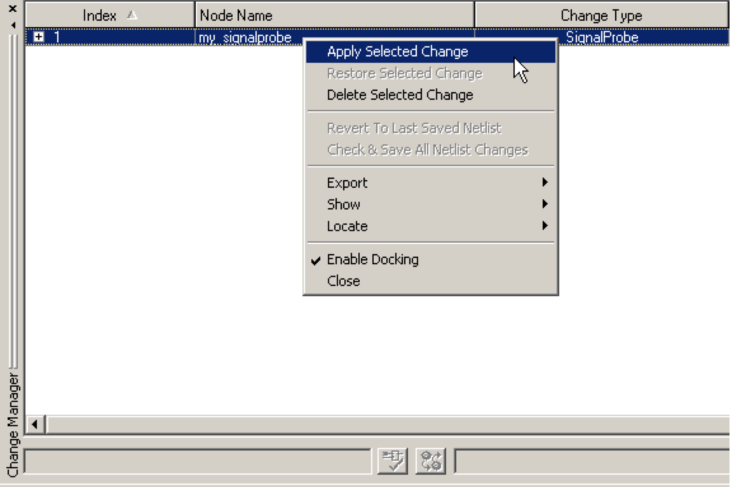
The behavior is different in the case that your top-level partition netlist type is set to **post-synthesis** and you have no other lower-level partitions defined. In this case, the partition with the strictest preservation type is set to **post-synthesis**. If you create SignalProbe ECOs and recompile the design, your SignalProbe ECOs are not retained and a warning message appears in the messages window. The warning indicates that ECO modifications are discarded; however, all of the ECO information is retained in the Change Manager. In this case, apply SignalProbe ECOs from the Change Manager and perform the **Check and Save All Netlist Changes** step, as described in “SignalProbe ECO Flow without Quartus Incremental Compilation” on page 13–7.

SignalProbe ECO Flow without Quartus Incremental Compilation

If you do not use the Quartus II incremental compilation feature and you implement SignalProbe pins after the initial compilation of your design, SignalProbe ECOs are not retained during recompilation. However, all of the SignalProbe ECOs remain in the Change Manager.

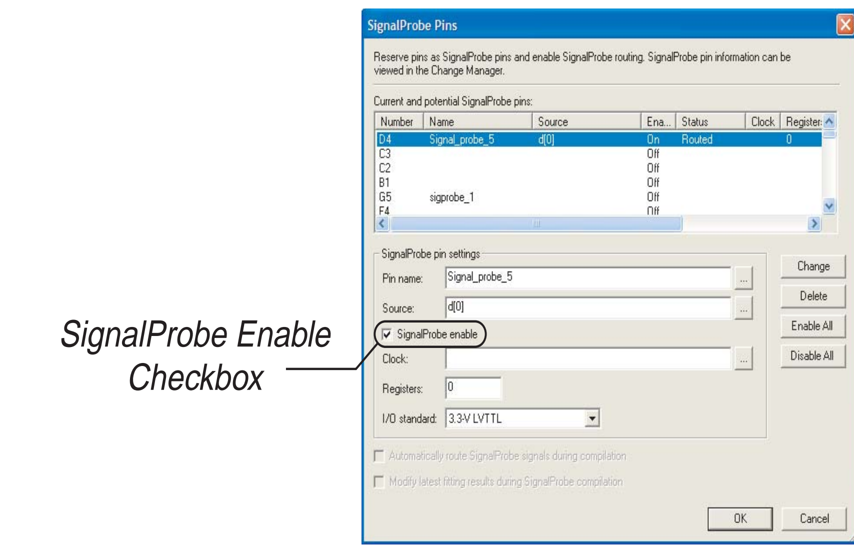
To apply a SignalProbe ECO, right-click Change Manager and select **Apply Selected Change** (Figure 13–4). (If the Change Manager window is not visible at the bottom of your screen, from the View menu, point to **Utility Windows** and click **Change Manager**.)

Figure 13–4. Applying SignalProbe ECOs



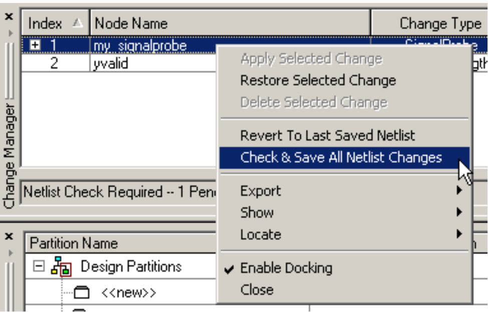
Alternately, you can use the **SignalProbe Pins** dialog box to enable the ECOs, as shown in Figure 13–5. This has the same effect as applying the SignalProbe ECOs within the Change Manager.

Figure 13–5. Enabling ECOs in the SignalProbe Pins Dialog Box



After applying the selected SignalProbe ECO, either right-click anywhere in the Change Manager and select **Check and Save All Netlist Changes** (Figure 13–6), or, from Processing menu, point to **Start** and click **Start Check and Save All Netlist Changes** to perform the ECO compilation.

Figure 13–6. Check and Save All Netlist Changes



Common Questions About the SignalProbe Feature

The following are answers to common questions about the SignalProbe feature.

Why Did I Get the Following Error Message, "Error: There are No Enabled SignalProbes to Process"?

This error message is generated when a SignalProbe compilation was attempted with either no SignalProbe pins to route, or with all SignalProbe pins disabled.

This might occur if you perform a SignalProbe compilation after a full compilation. For example, when a full compilation is performed, all SignalProbe pins are disabled. You can create or re-enable your SignalProbe pins in the **SignalProbe Pins** dialog box.

How Can I Retain My SignalProbe ECOs during Re-Compilation of My Design?

To retain your existing ECOs during recompilation of your design, you must use Quartus II incremental compilation. To learn more about the flow, refer to "SignalProbe ECO Flow with Quartus II Incremental Compilation" on page 13–6.

Why Did My SignalProbe Source Disappear in the Change Manager?

The SignalProbe source information for each SignalProbe is stored in the project database (**db** directory). SignalProbe pins are post-compilation changes to your netlist and are interpreted as ECOs. These changes are stored in the project **db** and if the project database is removed, the SignalProbe source information is lost and does not appear in the **SignalProbe Pins** dialog box. To restore your SignalProbe pins after the design compilation step, source the **signalprobe_qsf.tcl** script located in your project directory.

To restore your SignalProbe source information after compilation, type the following command from a command-line prompt:

```
quartus_cdb -t signalprobe_qsf.tcl ↵
```

Before typing this command, you must close your design project. When the command finishes, you can open your design project again. The change manager shows the sources for SignalProbe pins.

What is an ECO and Where Can I Find More Information about ECOs?

ECOs are late design cycle changes made to your design that do not alter functionality and timing.

For more information about ECOs and using the Change Manager, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

How Do I Migrate My Previous SignalProbe Assignments in the Quartus II Software Version 5.1 and Earlier to Version 6.0 and Later?

In earlier versions of the Quartus II software, SignalProbe pins were stored in the Quartus II Settings File (**.qsf**). These assignments are automatically converted into ECO changes when you open the **SignalProbe** dialog box or when you start a SignalProbe compilation in the Quartus II software versions 6.0 and higher.

For example, the SignalProbe source assignment from a **.qsf** file is removed and added to the Change Manager as an ECO after the **SignalProbe** dialog box is opened, or when you perform a SignalProbe compilation. Example 13–1 shows SignalProbe assignments in the **.qsf** file. Example 13–2 shows the same assignments after opening the **SignalProbe Pins** dialog box.

Example 13–1. SignalProbe Assignments in the Quartus II Settings File

```
set_location_assignment PIN_C22 -to my_signalprobe_pin
set_instance_assignment -name RESERVE_PIN "AS SIGNALPROBE OUTPUT" -to my_signalprobe_pin
set_instance_assignment -name IO_STANDARD LVTTL -to my_signalprobe_pin
set_instance_assignment -name SIGNALPROBE_ENABLE ON -to my_signalprobe_pin
set_instance_assignment -name SIGNALPROBE_SOURCE inst5[0] -to my_signalprobe_pin
```

Example 13–2. SignalProbe Assignments in the Quartus II Settings File after Opening the SignalProbe Pins Dialog Box

```
set_location_assignment PIN_C22 -to my_signalprobe_pin
set_instance_assignment -name RESERVE_PIN "AS SIGNALPROBE OUTPUT" -to my_signalprobe_pin
set_instance_assignment -name IO_STANDARD LVTTL -to my_signalprobe_pin
set_instance_assignment -name SIGNALPROBE_ENABLE ON -to my_signalprobe_pin
```

What are all the Changes for the SignalProbe Feature between the Quartus II Software Version 5.1 and Earlier, and Version 6.0 and Later?

The following list highlights the changes that affect users of the SignalProbe feature in the Quartus II software versions 5.1 and below. This applies to Stratix series, Cyclone series, and MAX II device families.

For more information about the changes that pertain to each release of the Quartus II software, refer to the Release Notes on the Altera website (www.altera.com).

- In Quartus II software versions 5.1 and earlier, the **SignalProbe Pins** dialog box was accessed on the Assignments menu. To access it with the Quartus II software version 6.0 and later, on the Tools menu, click **SignalProbe Pins**.

- A full compilation is required before making SignalProbe connections. However, you can still reserve pins before compilation for later use by SignalProbe. You can reserve pins by creating a SignalProbe in the **SignalProbe** dialog box without specifying a source. This is the same behavior as in the Quartus II software version 5.1.
- To route the SignalProbe pins, you must perform a SignalProbe compilation after a full compilation. The **Automatically route SignalProbe signals during compilations** and **Modify latest fitting results during SignalProbe compilation** options are no longer supported.
- After subsequent compiles, full or incremental, existing SignalProbe pins are disabled and are not present in the post-compilation netlist. To add them back, enable the SignalProbe pins and perform a SignalProbe compilation.
- SignalProbe pins are not controlled via assignments in the **.qsf** file because they are now ECOs. Existing **.qsf** files automatically convert to ECOs when a SignalProbe compilation is performed or when the **SignalProbe** dialog box is opened.
- The Tcl interface for creating SignalProbe pins has improved and is a part of the Chip Planner package `::quartus::chip_editor`. Refer to "Scripting Support" on page 13–11.
- Previously, the `quartus_fit --signalprobe` command was used to perform a SignalProbe compilation. This is not supported in the Quartus II software version 6.0 and later, and is replaced by the improved Tcl interface and the `check_netlist_and_save` Tcl command.
- The SignalProbe timing report generated after a successful SignalProbe compilation is not available in the Quartus II software version 6.0 and later. You can view the timing results of your SignalProbe pins in the SignalProbe Fitting Results, under the Fitter report, or in the t_{CO} results page of the Timing report.
- You cannot make SignalProbe pins in the Assignment Editor. Use the **SignalProbe Pins** dialog box to make and edit your SignalProbe pins.

Why Can't I Reserve a SignalProbe Pin?

If you cannot reserve a SignalProbe pin in the Quartus II software, it is likely that one of the following is true:

- You have selected multiple pins.
- A compile is running in the background. Wait until the compilation is complete before reserving the pin.
- You have the Quartus II Web Edition software, in which the SignalProbe feature is not enabled by default. You must turn on TalkBack to enable the SignalProbe feature in the Quartus II Web Edition software.
- You have not set the pin reserve type to **As Signal Probe Output**. To reserve a pin, on the Assignments menu, in the **Assign Pins** dialog box, select **As SignalProbe Output**.

- The pin is reserved from a previous compilation. During a compilation, the Quartus II software reserves each pin on the targeted device. If you end the Quartus II process during a compilation, for example, with the **Windows Task Manager End Process** command or the UNIX `kill` command, perform a full recompilation before reserving pins as SignalProbe outputs.
- The pin does not support the SignalProbe feature. Select another pin.
- The current family does not support the SignalProbe feature.

Scripting Support

Running procedures and make settings using a Tcl script are described in this chapter. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II command-line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ↵
```

The *Scripting Reference Manual* includes the same information in PDF format.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. For more information about all settings and constraints in the Quartus II software, refer to the *Quartus II Settings File Reference Manual*. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Make a SignalProbe Pin

To make a SignalProbe pin, type the following command:

```
make_sp [-h | -help] [-long_help] [-clk <clk>] [-io_std <io_std>] \
-loc <loc> -pin_name <pin name> [-regs <regs>] [-reset <reset>] \
-src_name <source name> ↵
```

Delete a SignalProbe Pin

To delete a SignalProbe pin, type the following command:

```
delete_sp [-h | -help] [-long_help] -pin_name <pin name> ↵
```

Enable a SignalProbe Pin

To enable a SignalProbe pin, type the following command:

```
enable_sp [-h | -help] [-long_help] -pin_name <pin name> ↵
```

Disable a SignalProbe Pin

To disable a SignalProbe pin, type the following command:

```
disable_sp [-h | -help] [-long_help] -pin_name <pin name> ↵
```

Perform a SignalProbe Compilation

To perform a SignalProbe compilation, type the following command:

```
check_netlist_and_save ↵
```

Migrate Previous SignalProbe Pins to the Quartus II Software Versions 6.0 and Later

To migrate previous SignalProbe pins to the Quartus II software versions 6.0 and later, type the following command:

```
convert_signal_probes ↵
```

Script Example

Example 13–3 shows a script that creates a SignalProbe pin called `sp1` and connects the `sp1` pin to source node `reg1` in a project that was already compiled.

Example 13–3. Creating a SignalProbe Pin Called sp1

```
Package require ::quartus::chip_editor
Project_open project
Read_netlist
Make_sp -pin_name sp1 -src_name reg1
Check_netlist_and_save
Project_close
```

Using SignalProbe with the APEX Device Family

APEX devices do not support post-fit netlist changes made as ECOs. SignalProbe compilation can route internal signals to output pins incrementally. The SignalProbe incremental routing feature does not affect design behavior.

To use the SignalProbe feature, follow these steps:

1. Reserve SignalProbe pins. For more information, refer to "Reserve the SignalProbe Pins" on page 13–2.
2. Assign a SignalProbe source to each SignalProbe pin.
3. Perform a SignalProbe compilation.
4. Analyze the results of a SignalProbe compilation.

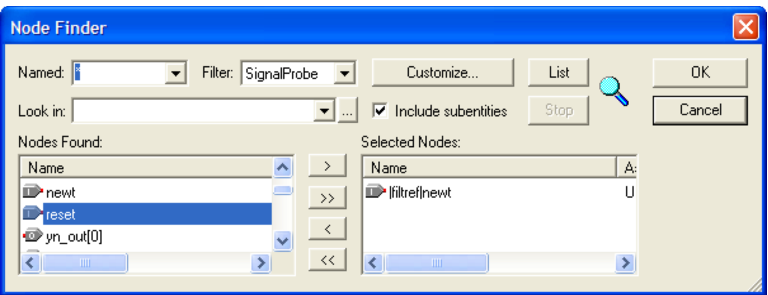
Adding SignalProbe Sources

A SignalProbe source is a signal in the post-compilation design database with a possible route to an output pin. To assign a SignalProbe source to a SignalProbe pin or an unused output pin, perform the following steps:

1. On the Tools menu, click **SignalProbe Pins**. The **SignalProbe Pins** dialog box appears.
2. In the **Current and potential SignalProbe pins** list, select the SignalProbe pin to which you want to add a SignalProbe source.
3. Click Browse and select a SignalProbe source.
4. Click **OK**.
5. In the **Assign SignalProbe Pins** dialog box, if a source has not been assigned to the SignalProbe pin, click **Add**. If a SignalProbe pin has been already assigned, click **Change**.
6. Click **OK.**

The **Node Finder** dialog box displays with the SignalProbe filter selected (Figure 13–7). Click **List** to view all of the available SignalProbe sources. If you cannot find a specific node with the SignalProbe filter, the node has either been removed by the Quartus II software during optimization or placed in the device where there are no possible routes to a pin.

Figure 13–7. Available SignalProbe Sources in the Node Finder



When the source of the SignalProbe pin is added or changed, the SignalProbe pin is automatically enabled. To disable a SignalProbe pin, turn off SignalProbe **enable**.

Performing a SignalProbe Compilation

After a full compilation, you can start a SignalProbe compilation either manually. A SignalProbe compilation performs the following functions:

- Validates SignalProbe pins
- Validates your specified SignalProbe sources
- If applicable, adds registers into SignalProbe paths
- Attempts to route from SignalProbe sources through registers to SignalProbe pins

To run the SignalProbe compilation automatically after a full compilation, on the Tools menu, click **SignalProbe Pins**. In the **SignalProbe Pins** dialog box, turn on **Automatically route SignalProbe signals during compilation**.

To run a SignalProbe compilation manually after a full compilation, on the Processing menu, point to **Start** and click **Start SignalProbe Compilation**.

You must run the Fitter before a SignalProbe compilation. The Fitter generates a list of all internal nodes that can be used as SignalProbe sources.

To enable or disable each SignalProbe pin, in the **SignalProbe Pins** dialog box, turn the **SignalProbe enable** option on or off.

Running SignalProbe with Smart Compilation

Running a smart compilation reduces compilation time by running only necessary modules during compilation. However, a full compilation is required if any design files, Analysis and Synthesis settings, or Fitter settings have changed.

To turn on smart compilation, on the Assignments menu, click **Settings**. In the **Category** list, select **Compilation Process Settings** and turn on **Use Smart compilation**.

If you run a SignalProbe compilation with smart compilation turned on, and there are changes to a design file or settings related to the Analysis and Synthesis or Fitter modules, the following message is displayed:

```
Error: Can't perform SignalProbe compilation because design requires a
full compilation.
```

You should turn smart compilation on, which allows you to work with the latest settings and design files.

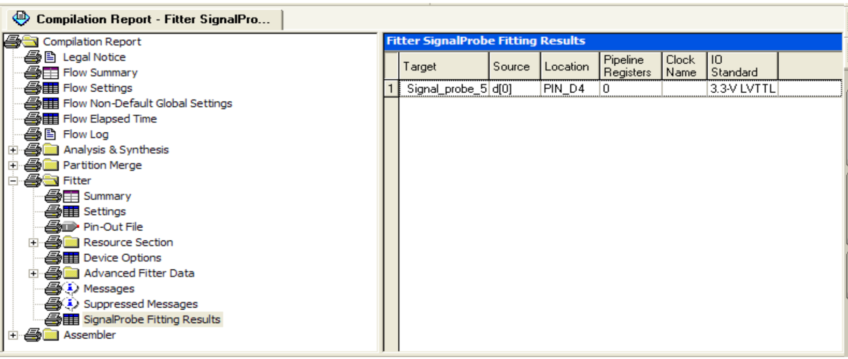
Understanding the Results of a SignalProbe Compilation

After a SignalProbe compilation, the results appear in two sections of the compilation report file. The fitting results and status (Table 13–1) of each SignalProbe pin is displayed in the **SignalProbe Fitting Result** screen in the Fitter section of the compilation report (Figure 13–8).

Table 13–1. Status Values

Status	Description
Routed	Connected and routed successfully
Not Routed	Not enabled
Failed to Route	Failed routing during last SignalProbe compilation
Need to Compile	Assignment changed since last SignalProbe compilation

Figure 13–8. SignalProbe Fitting Results Page in the Compilation Report Window



The timing results of each successfully routed SignalProbe pin is displayed in the **SignalProbe source to output delays** screen in the Timing Analysis section of the compilation report (Figure 13–9).

Figure 13–9. SignalProbe Source to Output Delays Page in the Compilation Report Window

Compilation Report

SignalProbe Source to Output Delays

	Source Name	Pin Location	Pin Name	Enable	Status	Delay (ns)
1	inst5[2]	Pin_H17	probe1	On	Routed	5.135 ns
2	inst5[3]	Pin_H20	probe2	On	Routed	4.939 ns
3	inst5[4]	Pin_G22	probe3	On	Routed	4.475 ns

After a SignalProbe compilation, the processing screen of the Messages window also provides the results of each SignalProbe pin and displays slack information for each successfully routed SignalProbe pin.

Analyzing SignalProbe Routing Failures

The SignalProbe can begin compilation; however, one of the following reasons can prevent complete compilation:

- **Route unavailable**—the SignalProbe compilation failed to find a route from the SignalProbe source to the SignalProbe pin because of routing congestion
- **Invalid or nonexistent SignalProbe source**—you entered a SignalProbe source that does not exist or is invalid
- **Unusable output pin**—the output pin selected is found to be unusable

Routing failures can occur if the SignalProbe pin's I/O standard conflicts with other I/O standards in the same I/O bank.

If routing congestion prevents a successful SignalProbe compilation, you can allow the compiler to modify routing to the specified SignalProbe source. On the Tools menu, click **SignalProbe Pins** and turn on **Modify latest fitting results during SignalProbe compilation**. This setting allows the Fitter to modify existing routing channels used by your design.

Turning on **Modify latest fitting results during SignalProbe compilation** can change the performance of your design.

SignalProbe Scripting Support for APEX Devices

Running procedures and make settings using a Tcl script are described in this chapter. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II command-line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ↵
```

The *Scripting Reference Manual* includes the same information in PDF format.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. Refer to the *Quartus II Settings File Reference Manual* for information about all settings and constraints in the Quartus II software. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Reserving SignalProbe Pins

To reserve a SignalProbe pin, type the commands shown in Example 13–4.

Example 13–4. Reserving a SignalProbe Pin

```
set_location_assignment <location> -to <SignalProbe pin name> ↵
set_instance_assignment -name RESERVE_PIN \
"AS SIGNALPROBE OUTPUT" -to <SignalProbe pin name> ↵
```

Valid locations are pin location names, such as `Pin_A3`.

For more information about reserving SignalProbe pins, refer to "Reserve the SignalProbe Pins" on page 13–2.

Adding SignalProbe Sources

Use the following Tcl commands to add SignalProbe sources. For more information about adding SignalProbe sources, refer to "Adding SignalProbe Sources" on page 13–12.

To assign the node name to a SignalProbe pin, type the following command:

```
set_instance_assignment -name SIGNALPROBE_SOURCE <node name> -to \
<SignalProbe pin name> ↵
```

The next command turns on SignalProbe routing. To turn off individual SignalProbe pins, specify `OFF` instead of `ON` with the following command:

```
set_instance_assignment -name SIGNALPROBE_ENABLE ON -to \
<SignalProbe pin name> ↵
```

Assigning I/O Standards

To assign an I/O standard to a pin, type the following Tcl command:

```
set_instance_assignment -name IO_STANDARD <I/O standard> -to \
<SignalProbe pin name> ↵
```

For a list of valid I/O standards, refer to the I/O Standards general description in the Quartus II Help.

Adding Registers for Pipelining

To add registers for pipelining, type the following Tcl commands:

```
set_instance_assignment -name SIGNALPROBE_CLOCK <clock name> -to \
<SignalProbe pin name> ↵

set_instance_assignment \
-name SIGNALPROBE_NUM_REGISTERS <number of registers> -to \
<SignalProbe pin name> ↵
```

Run SignalProbe Automatically

To run SignalProbe automatically after a full compile, type the following Tcl command:

```
set_global_assignment -name SIGNALPROBE_DURING_NORMAL_COMPILATION ON ↵
```

For more information about running SignalProbe automatically, refer to "Performing a SignalProbe Compilation" on page 13–13.

Run SignalProbe Manually

To run SignalProbe manually with a Tcl command or the `quartus_fit` command, type the following at a command prompt.

```
execute_flow -signalprobe ↵
```

The `execute_flow` command is in the flow package. At a command prompt, type the following command:

```
quartus_fit <project name> --signalprobe ↵
```

For more information about running SignalProbe manually, refer to "Performing a SignalProbe Compilation" on page 13–13.

Enable or Disable All SignalProbe Routing

Use the Tcl command in Example 13–5 to turn on or turn off SignalProbe routing. When using this command, to turn SignalProbe routing on, specify `ON`. To turn SignalProbe routing off, specify `OFF`.

Example 13–5. Turning SignalProbe On or Off with Tcl Commands

```
set spe [get_all_assignments -name SIGNALPROBE_ENABLE] \
foreach_in_collection asgn $spe {
   set signalprobe_pin_name [lindex $asgn 2]
   set_instance_assignment -name SIGNALPROBE_ENABLE -to \
$signalprobe_pin_name <ON|OFF> } ↵
```

For more information about enabling or disabling SignalProbe routing, refer to page 13–13.

Running SignalProbe with Smart Compilation

To turn on **Smart Compilation**, type the following Tcl command:

```
set_global_assignment -name SMART_RECOMPILE ON ↵
```

For more information, refer to "Running SignalProbe with Smart Compilation" on page 13–13.

Allow SignalProbe to Modify Fitting Results

To turn on **Modify latest fitting results**, type the following Tcl command:

```
set_global_assignment -name SIGNALPROBE_ALLOW_OVERUSE ON ↵
```

For more information, refer to "Analyzing SignalProbe Routing Failures" on page 13–15.

Conclusion

Using the SignalProbe feature can significantly reduce the time required compared to a full recompilation. Use the SignalProbe feature for quick access to internal design signals to perform system-level debugging.

Document Revision History

Table 13–2 shows the revision history for this chapter.

Table 13–2. Document Revision History

Date and Document Version	Changes Made	Summary of Changes
March 2009 v9.0.0	■ Removed the "Generate the Programming File" section ■ Removed unnecessary screenshots ■ Minor editorial updates	Updated for the Quartus II software version 9.0 release.
November 2008 v8.1.0	■ Modified description for preserving SignalProbe connections when using Incremental Compilation ■ Added plausible scenarios where SignalProbe connections are not reserved in the design	Updated for the Quartus II software version 8.1 release.
May 2008 v8.0.0	■ Added "Arria GX" to the list of supported devices ■ Removed the "On-Chip Debugging Tool Comparison" and replaced with a reference to the Section V Overview on page 13–1 ■ Added hyperlinks to referenced documents throughout the chapter ■ Minor editorial updates	Organizational changes for the Quartus II software version 8.0 release.

For previous versions of the *Quartus II Handbook*, refer to the Quartus II Handbook Archive.

14. Design Debugging Using the SignalTap II Embedded Logic Analyzer

QII53009-9.0.0

Introduction

To help with the process of design debugging, Altera provides a solution that allows you to examine the behavior of internal signals, without using extra I/O pins, while the design is running at full speed on an FPGA device.

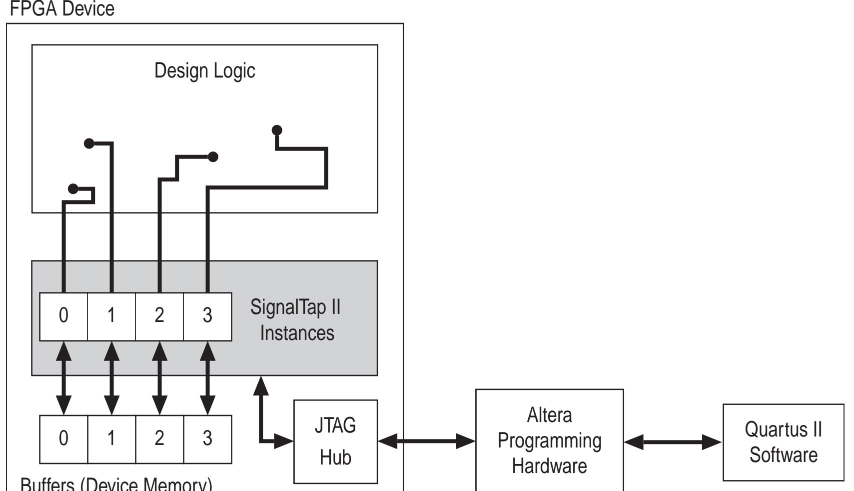
The SignalTap® II Embedded Logic Analyzer is scalable, easy to use, and is included with the Quartus® II software subscription. This logic analyzer helps debug an FPGA design by probing the state of the internal signals in the design without the use of external equipment. Defining custom trigger-condition logic provides greater accuracy and improves the ability to isolate problems. The SignalTap II Embedded Logic Analyzer does not require external probes or changes to the design files to capture the state of the internal nodes or I/O pins in the design. All captured signal data is conveniently stored in device memory until you are ready to read and analyze the data.

The topics in this chapter include:

- "Design Flow Using the SignalTap II Embedded Logic Analyzer" on page 14–4
- "SignalTap II Embedded Logic Analyzer Task Flow" on page 14–4
- "Add the SignalTap II Embedded Logic Analyzer to Your Design" on page 14–6
- "Configure the SignalTap II Embedded Logic Analyzer" on page 14–14
- "Define Triggers" on page 14–33
- "Compile the Design" on page 14–53
- "Program the Target Device or Devices" on page 14–59
- "Run the SignalTap II Embedded Logic Analyzer" on page 14–60
- "View, Analyze, and Use Captured Data" on page 14–66
- "Other Features" on page 14–71
- "SignalTap II Scripting Support" on page 14–76
- "Design Example: Using SignalTap II Embedded Logic Analyzers in SOPC Builder Systems" on page 14–79
- "Custom Triggering Flow Application Examples" on page 14–79

The SignalTap II Embedded Logic Analyzer is a next-generation, system-level debugging tool that captures and displays real-time signal behavior in a system-on-a-programmable-chip (SOPC) or any FPGA design. The SignalTap II Embedded Logic Analyzer supports the highest number of channels, largest sample depth, and fastest clock speeds of any embedded logic analyzer in the programmable logic market. Figure 14–1 shows a block diagram of the components that make up the SignalTap II Embedded Logic Analyzer.

Figure 14–1. SignalTap II Embedded Logic Analyzer Block Diagram *(Note 1)*



Note to Figure 14–1:

(1) This diagram assumes that the SignalTap II Embedded Logic Analyzer was compiled with the design as a separate design partition using the Quartus II incremental compilation feature. This is the default setting for new projects in the Quartus II software. If incremental compilation is disabled or not used, the SignalTap II logic is integrated with the design. For information about the use of incremental compilation with SignalTap II, refer to "Faster Compilations with Quartus II Incremental Compilation" on page 14–53.

This chapter is intended for any designer who wants to debug their FPGA design during normal device operation without the need for external lab equipment. Because the SignalTap II Embedded Logic Analyzer is similar to traditional external logic analyzers, familiarity with external logic analyzer operations is helpful but not necessary. To take advantage of faster compile times when making changes to the SignalTap II Embedded Logic Analyzer, knowledge of the Quartus II incremental compilation feature is helpful.

For information about using the Quartus II incremental compilation feature, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Hardware and Software Requirements

The following components are required to perform logic analysis with the SignalTap II Embedded Logic Analyzer:

- Quartus II design software

or
Quartus II Web Edition (with the TalkBack feature enabled)
or
SignalTap II Embedded Logic Analyzer standalone software

- Download/upload cable
- Altera® development kit or user design board with JTAG connection to device under test

The Quartus II software Web Edition does not support the SignalTap II Embedded Logic Analyzer with the incremental compilation feature.

Captured data is stored in the device's memory blocks and transferred to the Quartus II software waveform display with a JTAG communication cable, such as EthernetBlaster or USB-Blaster™. Table 14–1 summarizes some of the features and benefits of the SignalTap II Embedded Logic Analyzer.

Table 14–1. SignalTap II Features and Benefits

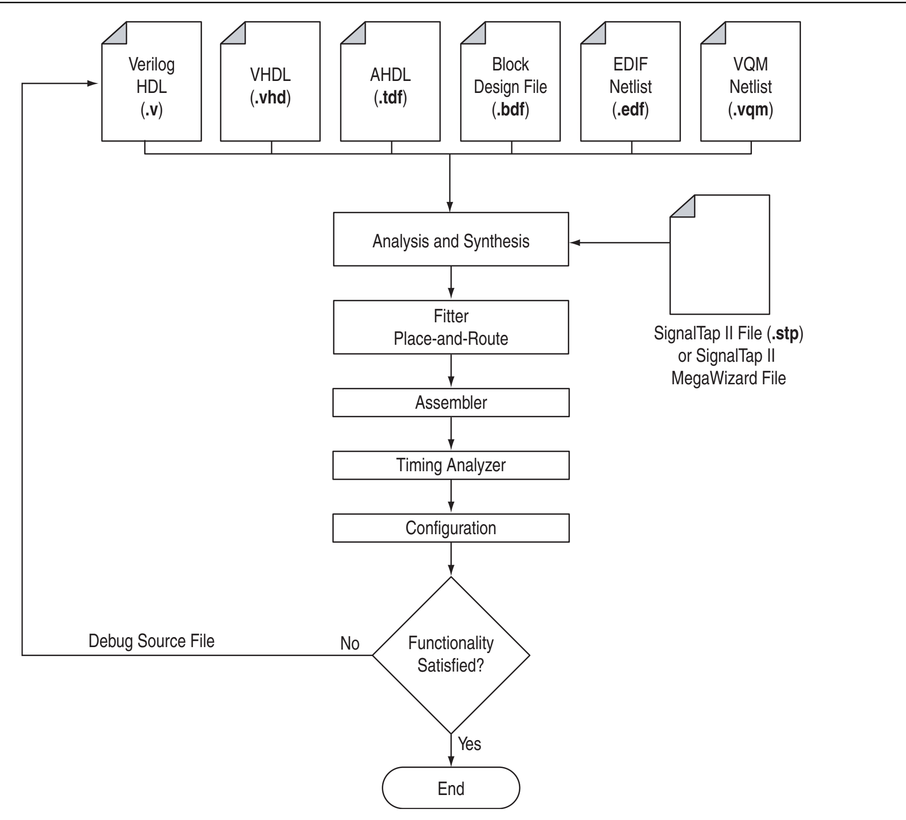
Feature	Benefit
Multiple logic analyzers in a single device	Captures data from multiple clock domains in a design at the same time.
Multiple logic analyzers in multiple devices in a single JTAG chain	Simultaneously captures data from multiple devices in a JTAG chain.
Plug-In Support	Easily specifies nodes, triggers, and signal mnemonics for IP, such as the Nios® II embedded processor.
Up to 10 basic or advanced trigger conditions for each analyzer instance	Enables more complex data capture commands to be sent to the logic analyzer, providing greater accuracy and problem isolation.
Power-Up Trigger	Captures signal data for triggers that occur after device programming but before manually starting the logic analyzer.
State-based Triggering Flow	Enables you to organize your triggering conditions to precisely define what your embedded logic analyzer will capture.
Incremental compilation	Modifies the SignalTap II Embedded Logic Analyzer monitored signals and triggers without performing a full compilation, saving time.
Flexible buffer acquisition modes	The buffer acquisition control allows you to precisely control the data that is written into the acquisition buffer. Both segmented buffers and non-segmented buffers with storage qualification allow you to discard data samples that are not relevant to the debug of your design.
MATLAB integration with included MEX function	Collects the SignalTap II Embedded Logic Analyzer captured data into a MATLAB integer matrix.
Up to 2,048 channels per logic analyzer instance	Samples many signals and wide bus structures.
Up to 128K samples in each device	Captures a large sample set for each channel.
Fast clock frequencies	Synchronous sampling of data nodes using the same clock tree driving the logic under test.
Resource usage estimator	Provides estimate of logic and memory device resources used by SignalTap II Embedded Logic Analyzer configurations.
No additional cost	The SignalTap II Embedded Logic Analyzer is included with a Quartus II subscription and with the Quartus II Web Edition (with TalkBack enabled).
Compatibility with other on-chip debugging utilities	The SignalTap II Embedded Logic Analyzer can be used in tandem with any JTAG based on-chip debugging tool, such as an in-system memory content editor. This ability to share the JTAG chain allows you to change signal values in real-time while you are running an analysis with the SignalTap II Embedded Logic Analyzer.

The Quartus II software offers a portfolio of on-chip debugging solutions. For an overview and comparison of all of the tools available in the In-System Verification Tool set, refer to *Section V. In-System Design Debugging*.

Design Flow Using the SignalTap II Embedded Logic Analyzer

Figure 14–2 shows a typical overall FPGA design flow for using the SignalTap II Embedded Logic Analyzer in your design. A SignalTap II file (**.stp**) is added to and enabled in your project, or a SignalTap II HDL function, created with the MegaWizard™ Plug-In Manager, is instantiated in your design. The diagram shows the flow of operations from initially adding the SignalTap II Embedded Logic Analyzer to your design to final device configuration, testing, and debugging.

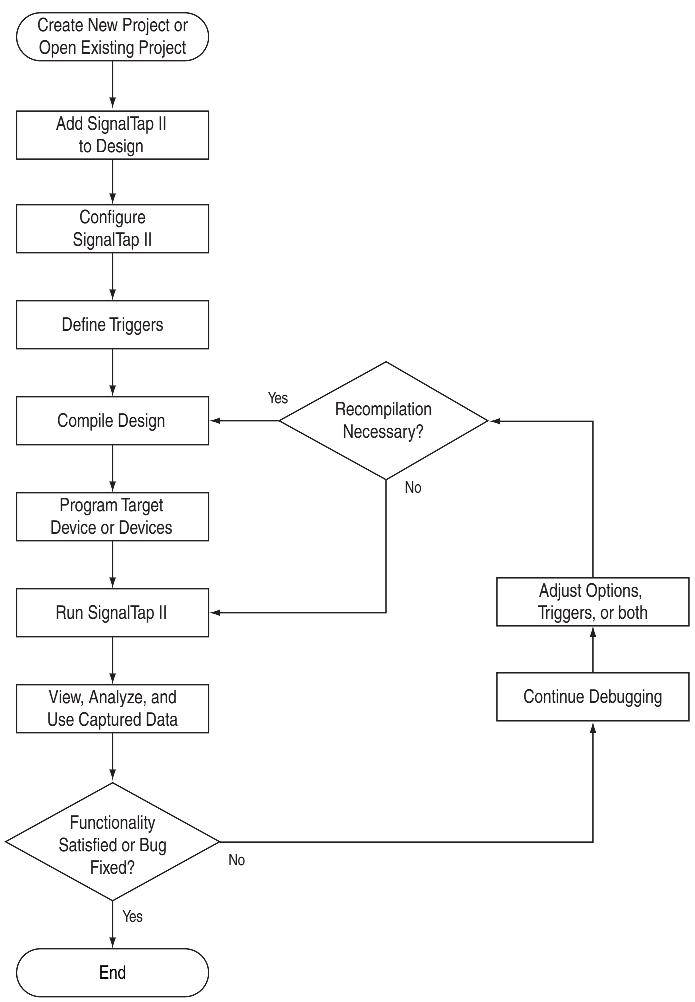
Figure 14–2. SignalTap II FPGA Design and Debugging Flow



SignalTap II Embedded Logic Analyzer Task Flow

To use the SignalTap II Embedded Logic Analyzer to debug your design, you perform a number of tasks to add, configure, and run the logic analyzer. Figure 14–3 shows a typical flow of the tasks you complete to debug your design. Refer to the appropriate section of this chapter for more information about each of these tasks.

Figure 14–3. SignalTap II Embedded Logic Analyzer Task Flow



Add the SignalTap II Embedded Logic Analyzer to Your Design

Create an **.stp** file or create a parameterized HDL instance representation of the logic analyzer using the MegaWizard Plug-In Manager. If you want to monitor multiple clock domains simultaneously, add additional instances of the logic analyzer to your design, limited only by the available resources in your device.

Configure the SignalTap II Embedded Logic Analyzer

After the SignalTap II Embedded Logic Analyzer is added to your design, configure it to monitor the signals you want. You can manually add signals or use a plug-in, such as the Nios II embedded processor plug-in, to quickly add entire sets of associated signals for a particular intellectual property (IP). You can also specify settings for the data capture buffer, such as its size, the method in which data is captured and stored, and the device memory type to use for the buffer in devices that support memory type selection.

Define Trigger Conditions

The SignalTap II Embedded Logic Analyzer captures data continuously while it is running. To capture and store specific signal data, set up triggers that tell the logic analyzer under what conditions to stop capturing data. The SignalTap II Embedded Logic Analyzer lets you define trigger conditions that range from very simple, such as the rising edge of a single signal, to very complex, involving groups of signals, extra logic, and multiple conditions. Power-Up Triggers give you the ability to capture data from trigger events occurring immediately after the device enters user-mode after configuration.

Compile the Design

With the **.stp** file configured and trigger conditions defined, compile your project as usual to include the logic analyzer in your design. Because you may need to change monitored signal nodes or adjust trigger settings frequently during debugging, Altera recommends that you use the incremental compilation feature built into the SignalTap II Embedded Logic Analyzer, along with Quartus II incremental compilation, to reduce recompile times.

Program the Target Device or Devices

When you are debugging a design with the SignalTap II Embedded Logic Analyzer, you can program a target device directly from the **.stp** file without using the Quartus II Programmer. You can also program multiple devices with different designs and simultaneously debug them.

Run the SignalTap II Embedded Logic Analyzer

In normal device operation, you control the logic analyzer through the JTAG connection, specifying when to start looking for trigger conditions to begin capturing data. With Runtime or Power-Up Triggers, read and transfer the captured data from the on-chip buffer to the **.stp** file for analysis.

View, Analyze, and Use Captured Data

After you have captured data and read it into the **.stp** file, it is available for analysis and use in the debugging process. Either manually or with a plug-in, set up mnemonic tables to make it easier to read and interpret the captured signal data. To speed up debugging, use the Locate feature in the **SignalTap II node** list to find the locations of problem nodes in other tools in the Quartus II software. Save the captured data for later analysis, or convert it to other formats for sharing and further study.

Add the SignalTap II Embedded Logic Analyzer to Your Design

Because the SignalTap II Embedded Logic Analyzer is implemented in logic on your target device, it must be added to your FPGA design as another part of the design itself. There are two ways to generate the SignalTap II Embedded Logic Analyzer and add it to your design for debugging:

- Create an **.stp** file and use the SignalTap II Editor to configure the details of the logic analyzer

or

- Create and configure the **.stp** file with the MegaWizard Plug-In Manager and instantiate it in your design

Creating and Enabling a SignalTap II File

To create an embedded logic analyzer, use an existing **.stp** file or create a new file. After a file is created or selected, it must be enabled in the project where it is used.

Creating a SignalTap II File

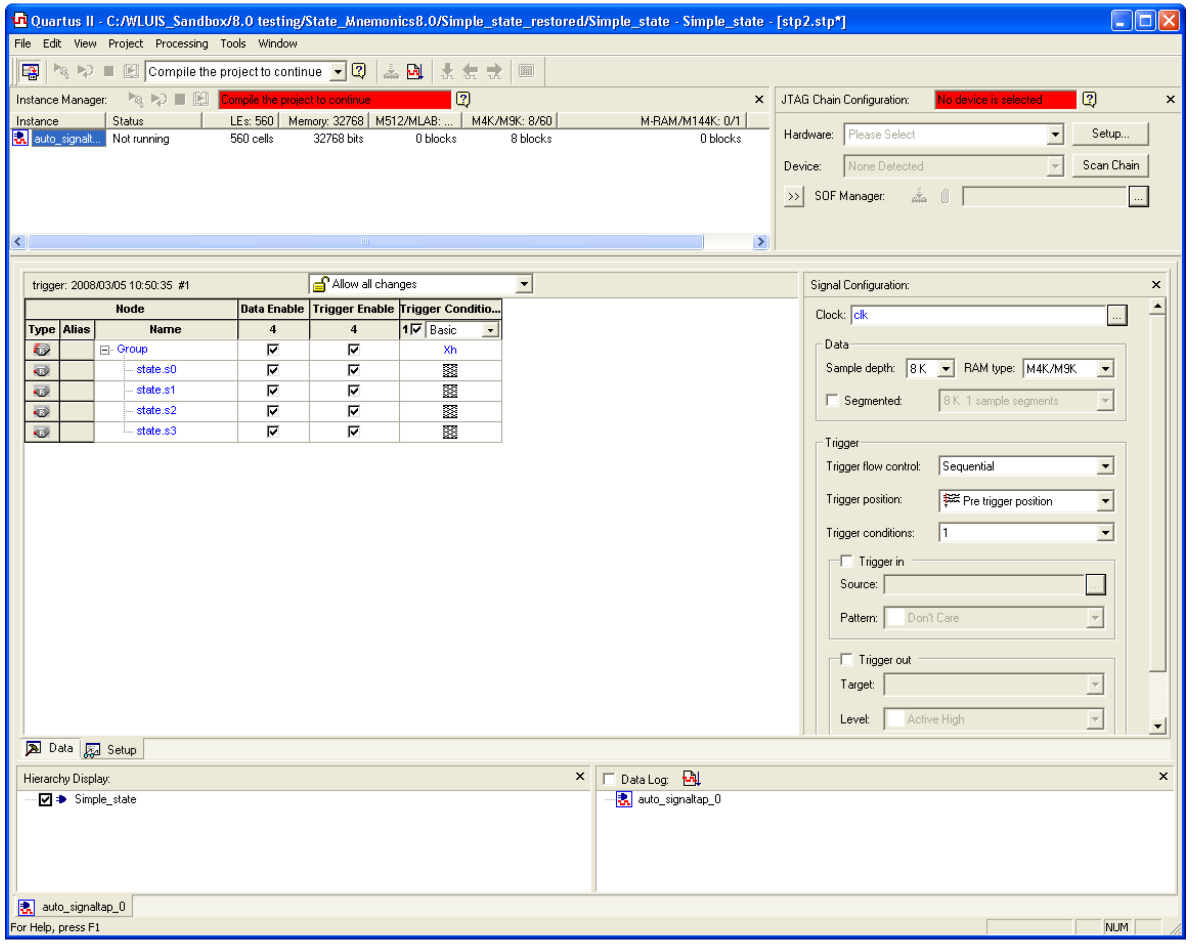
The **.stp** file contains the SignalTap II Embedded Logic Analyzer settings and the captured data for viewing and analysis. To create a new **.stp** file, perform the following steps:

1. On the File menu, click **New**.
2. In the **New** dialog box, click the **Other Files** tab and select **SignalTap II Logic Analyzer File**.
3. Click **OK**.

To open an existing **.stp** file already associated with your project, on the Tools menu, click **SignalTap II Logic Analyzer**. You can also use this method to create a new **.stp** file if no **.stp** file exists for the current project.

To open an existing file, on the File menu, click **Open** and select an **.stp** file (Figure 14–4).

Figure 14–4. SignalTap II Editor



Enabling and Disabling a SignalTap II File for the Current Project

Whenever you save a new **.stp** file, the Quartus II software asks you if you want to enable the file for the current project. However, you can add this file manually, change the selected **.stp** file, or completely disable the logic analyzer by performing the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **SignalTap II Logic Analyzer**. The **SignalTap II Logic Analyzer** page appears.
3. Turn on **Enable SignalTap II Logic Analyzer.** Turn off this option to disable the logic analyzer, completely removing it from your design.
4. In the **SignalTap II File name** box, type the name of the **.stp** file you want to include with your design, or browse to and select a file name.
5. Click **OK**.

Embedding Multiple Analyzers in One FPGA

The SignalTap II Editor includes support for adding multiple logic analyzers using a single **.stp** file. This feature is well-suited for creating a unique logic analyzer for each clock domain in the design.

To create multiple analyzers, on the Edit menu, click **Create Instance**, or right-click in the Instance Manager window and click **Create Instance**.

You can configure each instance of the SignalTap II Embedded Logic Analyzer independently. The icon in the Instance Manager for the currently active instance that is available for configuration is highlighted by a blue box. To configure a different instance, double-click the icon or name of another instance in the Instance Manager.

Monitoring FPGA Resources Used by the SignalTap II Embedded Logic Analyzer

The SignalTap II Embedded Logic Analyzer has a built-in resource estimator that calculates the logic resources and amount of memory that each logic analyzer instance uses. Furthermore, because the most demanding on-chip resource for the embedded logic analyzer is memory usage, the resource estimator reports the ratio of total RAM usage in your design to the total amount of RAM available, given the results of the last compilation. The resource estimator provides a warning if a potential for a “no-fit” occurs.

You can see resource usage of each logic analyzer instance and total resources used in the columns of the Instance Manager section of the SignalTap II Editor. Use this feature when you know that your design is running low on resources.

The logic element value reported in the resource usage estimator may vary by as much as 10% from the actual resource usage.

Table 14–2 shows the SignalTap II Embedded Logic Analyzer M4K memory block resource usage for the listed devices per signal width and sample depth.

Table 14–2. SignalTap II Embedded Logic Analyzer M4K Block Utilization for Stratix® II, Stratix, Stratix GX, and Cyclone® Devices *(Note 1)*

Signals (Width)	Samples (Depth)			
	256	**512**	**2,048**	**8,192**
8	< 1	1	4	16
16	1	2	8	32
32	2	4	16	64
64	4	8	32	128
256	16	32	128	512

Note to Table 14–2:

(1) When you configure a SignalTap II Embedded Logic Analyzer, the Instance Manager reports an estimate of the memory bits and logic elements required to implement the given configuration.

Using the MegaWizard Plug-In Manager to Create Your Embedded Logic Analyzer

You can create a SignalTap II Embedded Logic Analyzer instance by using the MegaWizard Plug-In Manager. The MegaWizard Plug-In Manager generates an HDL file that you instantiate in your design.

The State-based trigger flow, the state machine debugging feature, and the storage qualification feature are not supported when using the MegaWizard Plug-In Manager to create the embedded logic analyzer. These features are described in the following sections:

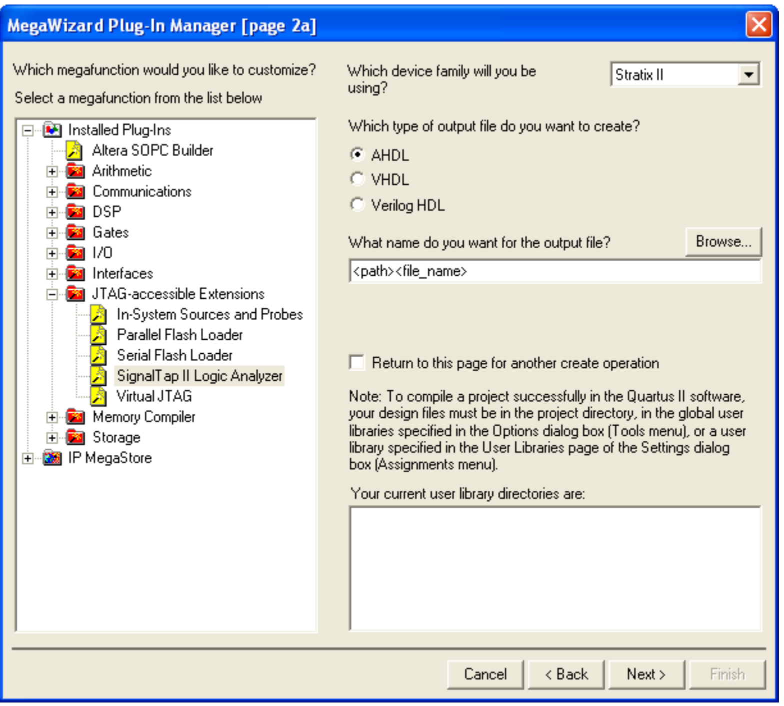
- "Adding Finite State Machine State Encoding Registers" on page 14–20
- "Using the Storage Qualifier Feature" on page 14–25
- "Custom State-Based Triggering" on page 14–38

Creating an HDL Representation Using the MegaWizard Plug-In Manager

The Quartus II software allows you to easily create your SignalTap II Embedded Logic Analyzer using the MegaWizard Plug-In Manager. To implement the SignalTap II megafunction, perform the following steps:

1. On the Tools menu, click **MegaWizard Plug-In Manager**. Page 1 of the **MegaWizard Plug-In Manager** appears.
2. Select **Create a new custom megafunction variation**.
3. Click **Next**.
4. In the **Installed Plug-Ins** list, expand the **JTAG-accessible Extensions** folder and select SignalTap II Embedded Logic Analyzer. Select an output file type and enter the desired name of the SignalTap II megafunction. You can choose AHDL (**.tdf**), VHDL (**.vhd**), or Verilog HDL (**.v**) as the output file type (Figure 14–5).

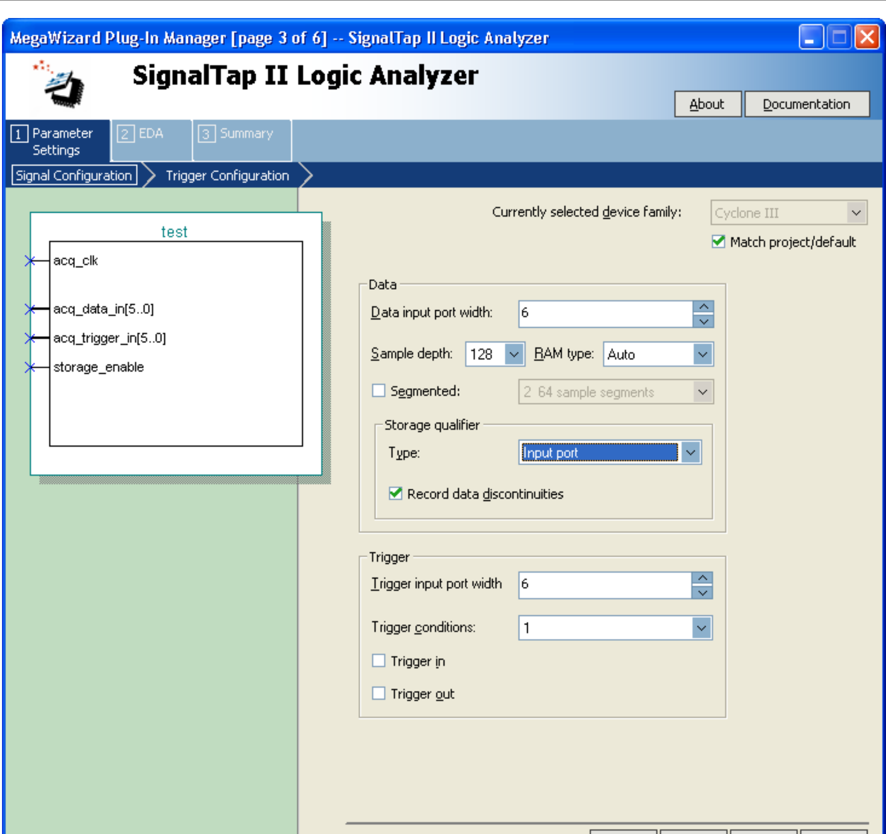
Figure 14–5. Creating the SignalTap II Embedded Logic Analyzer in the MegaWizard Plug-In Manager



5. Click **Next**.
6. Configure the analyzer by specifying the **Sample depth**, **RAM Type**, **Data input port width**, **Trigger levels**, **Trigger input port width**, whether to enable an external **Trigger in** or **Trigger out,** whether to enable the **Segmented** memory buffer option, and whether to enable the Storage Qualifier for non-segmented buffers (Figure 14–6).

   For information about these settings, refer to "Configure the SignalTap II Embedded Logic Analyzer" on page 14–14 and "Define Triggers" on page 14–33.

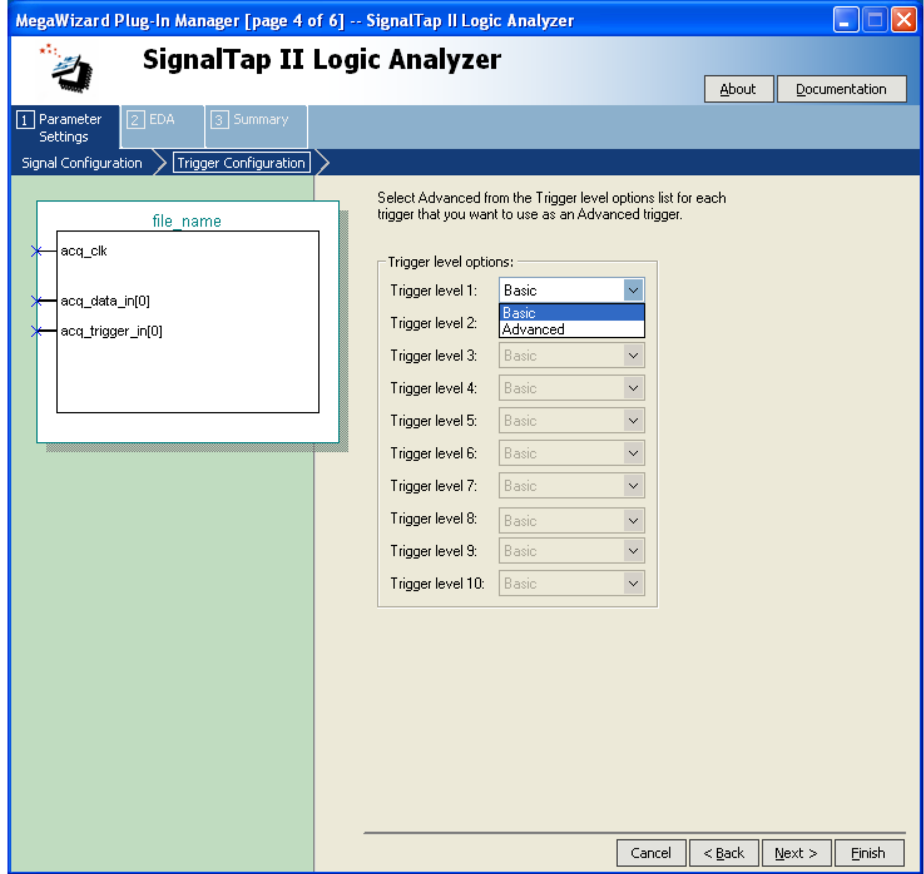
Figure 14–6. Select Embedded Logic Analyzer Parameters



7. Click **Next**.
8. Set the **Trigger level** options by selecting **Basic** or **Advanced** (Figure 14–7). If you select **Advanced** for any trigger level, the next page of the MegaWizard Plug-In Manager displays the Advanced Trigger Condition Editor. You can configure an advanced trigger expression using the number of signals you specified for the trigger input port width.

☞ You cannot define a Power-Up Trigger using the MegaWizard Plug-In Manager. Refer to "Define Triggers" on page 14–33 to learn how to do this using the **.stp** file.

Figure 14–7. MegaWizard Basic and Advanced Trigger Options



9. On the final page of the MegaWizard Plug-In Manager, select any additional files you want to create and click **Finish** to create an HDL representation of the SignalTap II Embedded Logic Analyzer.

For information about the configuration settings options in the MegaWizard Plug-In Manager, refer to "Configure the SignalTap II Embedded Logic Analyzer" on page 14–14. For information about defining triggers, refer to "Define Triggers" on page 14–33.

SignalTap II Megafunction Ports

Table 14–3 provides information about the SignalTap II megafunction ports.

For the most current information about the ports and parameters for this megafunction, refer to the latest version of the Quartus II Help.

Table 14–3. SignalTap II Megafunction Ports (Part 1 of 2)

Port Name	Type	Required	Description
acq_data_in	Input	No	This set of signals represents signals that are monitored in the SignalTap II Embedded Logic Analyzer.
acq_trigger_in	Input	No	This set of signals represents signals that are used to trigger the analyzer.

Table 14–3. SignalTap II Megafunction Ports (Part 2 of 2)

Port Name	Type	Required	Description
acq_clk	Input	Yes	This port represents the sampling clock that the SignalTap II Embedded Logic Analyzer uses to capture data.
trigger_in	Input	No	This signal is used to trigger the SignalTap II Embedded Logic Analyzer.
trigger_out	Output	No	This signal is enabled when the trigger event occurs.
storage_enable	Input	No	This signal is used to enable a write transaction into the acquisition buffer.

Instantiating the SignalTap II Embedded Logic Analyzer in Your HDL

Add the code from the files that are generated by the MegaWizard Plug-In Manager to your design, mapping the signals in your design to the appropriate SignalTap II megafunction ports. You can instantiate up to 127 analyzers in your design, or as many as physically fit in the FPGA. Once you have instantiated the **.stp** file in your HDL file, compile your Quartus II project to fit the logic analyzer in the target FPGA.

To capture and view the data, create an **.stp** file from your SignalTap II HDL output file. To do this, on the File menu, point to **Create/Update** and click **Create SignalTap II File from Design Instance(s)**.

If you make any changes to your design or the SignalTap II instance, recreate or update the **.stp** file using the **Create/Update** command. This ensures that the **.stp** file is always compatible with the SignalTap II instance in your design. If the **.stp** file is not compatible with the SignalTap II instance in your design, you may not be able to control the SignalTap II Embedded Logic Analyzer after it is programmed into your device.

For information about **.stp** file compatibility with programmed SignalTap II instances, refer to "Program the Target Device or Devices" on page 14–59.

Configure the SignalTap II Embedded Logic Analyzer

The **.stp** file provides many options for configuring instances of the logic analyzer. Some of the settings are similar to those found on traditional external logic analyzers. Other settings are unique to the SignalTap II Embedded Logic Analyzer because of the requirements for configuring an embedded logic analyzer. All settings give you the ability to configure the logic analyzer the way you want to help debug your design.

Some settings can only be adjusted when you are viewing Run-Time Trigger conditions instead of Power-Up Trigger conditions. To learn about Power-Up Triggers and viewing different trigger conditions, refer to "Creating a Power-Up Trigger" on page 14–49.

Assigning an Acquisition Clock

Assign a clock signal to control the acquisition of data by the SignalTap II Embedded Logic Analyzer. The logic analyzer samples data on every positive (rising) edge of the acquisition clock. The logic analyzer does not support sampling on the negative (falling) edge of the acquisition clock. You can use any signal in your design as the acquisition clock. However, for best results, Altera recommends that you use a global,

non-gated clock synchronous to the signals under test for data acquisition. Using a gated clock as your acquisition clock can result in unexpected data that does not accurately reflect the behavior of your design. The Quartus II static timing analysis tools show the maximum acquisition clock frequency at which you can run your design. Refer to the Timing Analysis section of the Compilation Report to find the maximum frequency of the logic analyzer clock.

To assign an acquisition clock, perform the following steps:

1. In the SignalTap II Logic Analyzer window, click the **Setup** tab.
2. In the **Signal Configuration** pane, next to the **Clock** field, click **Browse**. The **Node Finder** dialog box appears.
3. From the **Filter** list, select **SignalTap II: post-fitting**
   or
   SignalTap II: pre-synthesis.
4. In the **Named** field, type the exact name of a node that you want to use as your sample clock, or search for a node using a partial name and wildcard characters.
5. To start the node search, click **List**.
6. In the **Nodes Found** list, select the node that represents the design's global clock signal.
7. Add the selected node name to the **Selected Nodes** list by clicking "**>**" or by double-clicking the node name.
8. Click **OK**. The node is now specified as the acquisition clock in the SignalTap II Editor.

If you do not assign an acquisition clock in the SignalTap II Editor, the Quartus II software automatically creates a clock pin called `auto_stp_external_clk`.

You must make a pin assignment to this pin independently from the design. Ensure that a clock signal in your design drives the acquisition clock.

For information about assigning signals to pins, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

Adding Signals to the SignalTap II File

While configuring the logic analyzer, add signals to the node list in the **.stp** file to select which signals in your design you want to monitor. Selected signals are also used to define triggers. You can assign the following two types of signals to your **.stp** file:

- **Pre-synthesis**—This signal exists after design elaboration, but before any synthesis optimizations are done. This set of signals should reflect your Register Transfer Level (RTL) signals.
- **Post-fitting**—This signal exists after physical synthesis optimizations and place-and-route.

If you are not using incremental compilation, add only pre-synthesis signals to your **.stp** file. Using pre-synthesis is particularly useful if you want to add a new node after you have made design changes. Source file changes appear in the Node Finder after an Analysis and Elaboration has been performed. On the Processing Menu, point to **Start** and click **Start Analysis & Elaboration**.

The Quartus II software does not limit the number of signals available for monitoring in the SignalTap II window waveform display. However, the number of channels available is directly proportional to the number of logic elements (LEs) or adaptive logic modules (ALMs) in the device. Therefore, there is a physical restriction on the number of channels that are available for monitoring. Signals shown in blue text are post-fit node names. Signals shown in black text are pre-synthesis node names.

After successful Analysis and Elaboration, the signals shown in red text are invalid signals. Unless you are certain that these signals are valid, remove them from the **.stp** file for correct operation. The SignalTap II Status Indicator also indicates if an invalid node name exists in the **.stp** file.

As a general guideline, signals can be tapped if a routing resource (row or column interconnects) exists to route the connection to the SignalTap II instance. For example, signals that exist in the I/O element (IOE) cannot be directly tapped because there are no direct routing resources from the signal in an IOE to a core logic element. For input pins, you can tap the signal that is driving a logic array block (LAB) from an IOE, or, for output pins, you can tap the signal from the LAB that is driving an IOE.

When adding pre-synthesis signals, all connections made to the SignalTap II Embedded Logic Analyzer are made prior to synthesis. Logic and routing resources are allocated during recompilation to make the connection as if a change in your design files had been made. As such, pre-synthesis signal names for signals driving to and from IOEs coincide with the signal names assigned to the pin.

In the case of post-fit signals, connections that you make to the SignalTap II Embedded Logic Analyzer are the signal names from the actual atoms in your post-fit netlist. A connection can only be made if the signals are part of the existing post-fit netlist and existing routing resources are available from the signal of interest to the SignalTap II Embedded Logic Analyzer. In the case of post-fit output signals, tap the `COMBOUT` or `REGOUT` signal that drives the IOE block. For post-fit input signals, signals driving into the core logic coincide with the signal name assigned to the pin.

If you are tapping the signal from the atom that is driving an IOE, be aware that the signal may be inverted due to `NOT`-gate push back. You can check this by locating the signal in either the Resource Property Editor or the Technology Map Viewer. The Technology Map viewer and the Resource Property Editor are also helpful in finding post-fit node names.

For information about cross-probing to source design file and other Quartus II windows, refer to the *Analyzing Designs with Quartus II Netlist Viewers* chapter in volume 1 of the *Quartus II Handbook*.

For more information about the use of incremental compilation with the SignalTap II Embedded Logic Analyzer, refer to "Faster Compilations with Quartus II Incremental Compilation" on page 14–53.

Signal Preservation

Many of the RTL signals are optimized during the process of synthesis and place-and-route. RTL signal names frequently may not appear in the post-fit netlist after optimizations. For example, the compilation process can add tildes ("~") to nets that are fanning out from a node, making it difficult to decipher which signal nets they actually represent. This can cause a problem when you use the incremental compilation flow with the SignalTap II Embedded Logic Analyzer. Because only post-fitting signals can be added to the SignalTap II Embedded Logic Analyzer in partitions of type **post-fit**, RTL signals that you want to monitor may not be available, preventing their usage. To avoid this issue, use synthesis attributes to preserve signals during synthesis and place-and-route. When the Quartus II software encounters these synthesis attributes, it does not perform any optimization on the specified signals, forcing them to continue to exist in the post-fit netlist. However, if you do this, you could see an increase in resource utilization or a decrease in timing performance. The two attributes you can use are:

- `keep`—Ensures that combinational signals are not removed
- `preserve`—Ensures that registers are not removed

For more information about using these attributes, refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*.

If you are debugging an IP core, such as the Nios II CPU or other encrypted IP, you might need to preserve nodes from the core to make them available for debugging with the SignalTap II Embedded Logic Analyzer. This is often necessary when a plug-in is used to add a group of signals for a particular IP.

To prevent the Quartus II software from optimizing away debugging signals on IP cores, perform the following steps:

1. In the Quartus II GUI, on the Assignments menu, click **Settings**.
2. In the **Category** list, select **Analysis & Synthesis Settings**.
3. Turn on **Create debugging nodes** for IP cores to make these nodes available to the SignalTap II Embedded Logic Analyzer.

Assigning Data Signals Using the Node Finder

To assign data signals, perform the following steps:

1. Perform Analysis and Elaboration, Analysis and Synthesis, or fully compile your design.
2. In the SignalTap II Logic Analyzer window, click the **Setup** tab.
3. Double-click anywhere in the node list of the SignalTap II Editor to open the **Node Finder** dialog box.
4. In the **Fitter** list, select **SignalTap II: pre-synthesis** or **SignalTap II: post-fitting**. Only signals listed under one of these filters can be added to the **SignalTap II node** list. Signals cannot be selected from any other filters.

Altera recommends that you do not add a mix of pre-synthesis and post-fitting signals within the same partition. For more details, refer to "Using Incremental Compilation with the SignalTap II Embedded Logic Analyzer" on page 14–55.

If you use incremental compilation flow with the SignalTap II Embedded Logic Analyzer, pre-synthesis nodes may not be connected to the SignalTap II Embedded Logic Analyzer if the affected partition is of the post-fit type. A critical warning is issued for all pre-synthesis node names that are not found in the post-fit netlist.

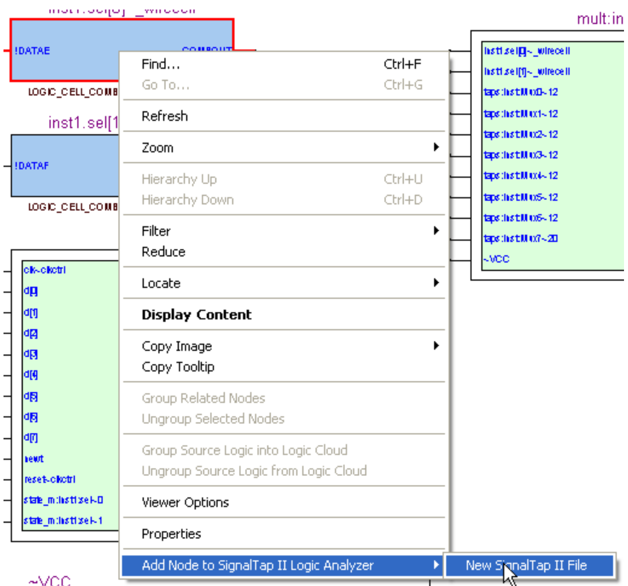
1. In the **Named** field, type a node name, or search for a particular node by entering a partial node name along with wildcard characters. To start the node name search, click **List**.
2. In the **Nodes Found** list, select the node or bus you want to add to the **.stp** file.
3. Add the selected node name(s) to the **Selected Nodes** list by clicking “>” or by double-clicking the node name(s).
4. To insert the selected nodes in the **.stp** file, click **OK**. With the default colors set for the SignalTap II Embedded Logic Analyzer, a pre-synthesis signal in the list is shown in black; a post-fitting signal is shown in blue.

You can also drag and drop signals from the **Node Finder** dialog box into an **.stp** file.

Assigning Data Signals Using the Technology Map Viewer

Starting with Quartus II software version 8.0, you can easily add post-fit signal names that you find in the Technology map viewer. To do so, launch the Technology map viewer (post-fitting) after compiling your design. When you find the desired node, copy the node to either the active **.stp** file for your design or a new **.stp** file. Figure 14–8 shows the right-click menu for adding a node using the Technology map viewer.

Figure 14–8. Finding Data Signals Using the Technology Map Viewer



Node List Signal Use Options

When a signal is added to the node list, you can select options that specify how the signal is used with the logic analyzer. You can turn off the ability of a signal to trigger the analyzer by disabling the Trigger Enable option for that signal in the node list in the **.stp** file. This option is useful when you want to see only the captured data for a signal and you are not using that signal as part of a trigger.

You can turn off the ability to view data for a signal by disabling the **Data Enable** column. This option is useful when you want to trigger on a signal, but have no interest in viewing data for that signal.

For information about using signals in the node list to create SignalTap II trigger conditions, refer to "Define Triggers" on page 14–33.

Untappable Signals

Not all of the post-fitting signals in your design are available in the SignalTap II: post-fitting filter in the **Node Finder** dialog box. The following signal types cannot be tapped:

- **Post-fit output pins**—You cannot tap a post-fit output pin directly. To make an output signal visible, tap the register or buffer that drives the output pin. This includes pins defined as bidirectional.
- **Signals that are part of a carry chain**—You cannot tap the carry out (`cout0` or `cout1`) signal of a logic element. Due to architectural restrictions, the carry out signal can only feed the carry in of another LE.
- **JTAG Signals**—You cannot tap the JTAG control (`TCK`, `TDI`, `TDO`, and `TMS`) signals.
- **ALTGXB megafunction**—You cannot directly tap any ports of an ALTGXB instantiation.
- **LVDS**—You cannot tap the data output from a serializer/deserializer (SERDES) block.
- **DQ**, **DQS Signals**—You cannot directly tap the `DQ` or `DQS` signals in a DDR/DDRII design.

Adding Signals with a Plug-In

Instead of adding individual or grouped signals through the **Node Finder**, you can add groups of relevant signals of a particular type of IP through the use of a plug-in. The SignalTap II Embedded Logic Analyzer comes with one plug-in already installed for the Nios II processor. Besides easy signal addition, plug-ins also provide a number of other features, such as pre-designed mnemonic tables, useful for trigger creation and data viewing, as well as the ability to disassemble code in captured data.

The Nios II plug-in, for example, creates one mnemonic table in the **Setup** tab and two tables in the **Data** tab:

- **Nios II Instruction** (**Setup** tab)—Capture all the required signals for triggering on a selected instruction address.
- **Nios II Instance Address** (**Data** tab)—Display address of executed instructions in hexadecimal format or as a programming symbol name if defined in an optional Executable and Linking Format (**.elf**) file.

- **Nios II Disassembly** (**Data** tab)—Displays disassembled code from the corresponding address.

For information about the other features plug-ins provided, refer to "Define Triggers" on page 14–33 and "View, Analyze, and Use Captured Data" on page 14–66.

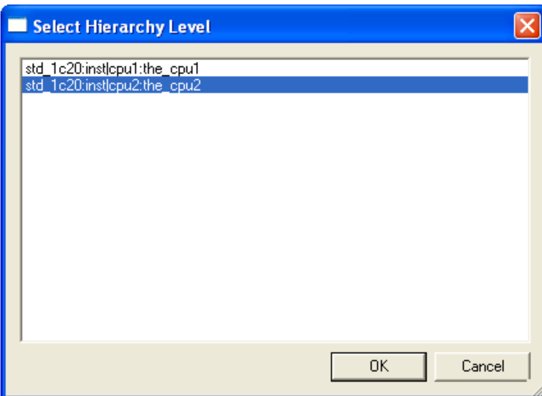
To add signals to the **.stp** file using a plug-in, perform the following steps after running Analysis and Elaboration on your design:

1. Right-click in the node list. On the Add Nodes with Plug-In submenu, click the name of the plug-in you want to use, such as the included plug-in named **Nios II**.

   If the IP for the selected plug-in does not exist in your design, a message appears informing you that you cannot use the selected plug-in.

2. The **Select Hierarchy Level** dialog box appears showing the IP hierarchy of your design (Figure 14–9). Select the IP that contains the signals you want to monitor with the plug-in and click **OK**.

Figure 14–9. IP Hierarchy Selection



3. If all the signals in the plug-in are available, a dialog box might appear, depending on the plug-in selected, where you can set any available options for the plug-in. With the Nios II plug-in, you can optionally select an **.elf** file containing program symbols from your Nios II Integrated Development Environment (IDE) software design. Set options for the selected plug-in as desired and click **OK**.

To make sure all the required signals are available, in the Quartus II **Analysis & Synthesis** settings, turn on the **Create debugging nodes for IP cores** option.

All the signals included in the plug-in are added to the node list.

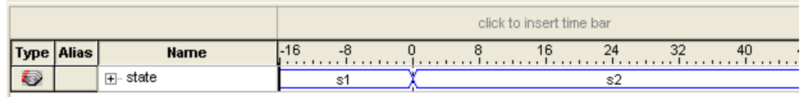
Adding Finite State Machine State Encoding Registers

Finding the signals to debug Finite State Machines (FSM) can be challenging. Finding nodes from the post-fit netlist may be impossible, as FSM encoding signals may be changed or optimized away during synthesis and place-and-route. If you are able to find all of the relevant nodes in the post-fit netlist or you used the nodes from the pre-synthesis netlist, an additional step is required to find and map FSM signal values to the state names that you specified in your HDL.

Beginning with Quartus II software version 8.0, the SignalTap II GUI can detect FSMs in your compiled design. The SignalTap II configuration automatically tracks the FSM state signals as well as state encoding through the compilation process. Right-click dialog boxes from the SignalTap II GUI allow you to add all of the FSM state signals to your embedded logic analyzer with a single command. For each FSM added to your SignalTap II configuration, the FSM debugging feature adds a mnemonic table to map the signal values to the state enumeration that you provided in your source code. The mnemonic tables enable you to visualize state machine transitions in the waveform viewer easily. The FSM debugging feature supports adding FSM signals from both the pre-synthesis and post-fit netlists.

Figure 14–10 shows the waveform viewer with decoded signal values from a state machine added with the FSM debugging feature.

Figure 14–10. Decoded FSM Mnemonics



For coding guidelines for specifying FSM in Verilog and VHDL, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

To add pre-synthesis FSM signals to the configuration file, perform the following steps after running Analysis and Elaboration on your design:

1. Create a new **.stp** file or use an existing **.stp** file.

   Any **.stp** files that the MegaWizard Plug-In Manager creates from instantiations are not supported for this feature.

2. In the SignalTap II setup tab, right-click anywhere on the node list and select **Add State Machine Nodes**. The **Add State Machine Nodes** dialog box appears. This dialog box lists all the FSMs that have been found in your design.

   For the SignalTap II GUI to detect pre-synthesis state-machine signals, perform Analysis and Elaboration of your design.

3. From the Netlist pull-down menu, select **Pre-Synthesis**.
4. Select the desired FSM.
5. Click **OK**. This adds the FSM nodes to the configuration file. A mnemonic table is automatically applied to the FSM signal group.

To add post-fit FSM signals to the configuration file, perform the following steps after performing a full compile of your design:

1. Set the design partition of the FSM that you want to debug to post-fit.
2. Enable the **.stp** file for the Quartus II project using the **SignalTap II Embedded Logic Analyzer** page of the **Settings** dialog box. You can either create a new **.stp** file or use an existing **.stp** file.

For the SignalTap II GUI to detect post-fit state-machine signals, perform a full compile of your design.

3. In the SignalTap II setup tab, right-click anywhere on the node list and select **Add State Machine Nodes**. The **Add State Machine Nodes** dialog box appears. This dialog box lists all the FSMs that have been found in your design.
4. From the Netlist pull-down menu, select **Post-Fit**.
5. Select the desired FSM.
6. Click **OK**. This adds the FSM nodes to the configuration file. A mnemonic table is automatically applied to the FSM signal group.

Modifying and Restoring Mnemonic Tables for State Machines

When you add FSM state signals via the FSM debugging feature, the SignalTap II GUI creates a mnemonic table using the format <*StateSignalName*>`_table`, where **StateSignalName** is the name of the state signals that you have declared in your RTL. You can edit any mnemonic table using the **Mnemonic Table Setup** dialog box.

If you want to restore a mnemonic table that was modified, right-click anywhere in the node list window and select **Recreate State Machine Mnemonics**. By default, restoring a mnemonic table overwrites the existing mnemonic table that you modified. If you would like to restore a FSM mnemonic table to a new record, uncheck the **Overwrite existing mnemonic table** option in the **Recreate State Machine Mnemonics** dialog box.

If you have added or deleted a signal from the FSM state signal group from within the setup tab, delete the modified register group and add the FSM signals back again.

For more information about using Mnemonics, refer to "Creating Mnemonics for Bit Patterns" on page 14–69.

Additional Considerations

The SignalTap II configuration GUI recognizes state machines from your design only if you use Quartus II Integrated Synthesis (QIS). The state machine debugging feature is not able to track the FSM signals or state encoding if you have used a third-party synthesis tool.

If you are adding post-fit FSM signals, the SignalTap II FSM debug feature may not be able to track all of the optimization changes that are a part of the compilation process. If the following two specific optimizations are enabled, the SignalTap II FSM debug feature may not list mnemonic tables for state machines in the design:

- If you have physical synthesis turned on, state registers may be resource balanced (register retiming) to improve f_{MAX}. The FSM debug feature does not list post-fit FSM state registers if register retiming occurs.
- The FSM debugging feature does not list state signals that have been packed into RAM and DSP blocks during QIS or Fitter optimizations.

You are still able to use the FSM debugging feature to add pre-synthesis state signals.

Specifying the Sample Depth

The sample depth specifies the number of samples that are captured and stored for each signal in the captured data buffer. To set the sample depth, select the desired number of samples to store in the **Sample Depth** list. The sample depth ranges from 0 to 128K.

If device memory resources are limited, you may not be able to successfully compile your design with the sample buffer size you have selected. Try reducing the sample depth to reduce resource usage.

Capturing Data to a Specific RAM Type

When you use the SignalTap II Embedded Logic Analyzer with some devices, you have the option to select the RAM type where acquisition data is stored. RAM selection allows you to preserve a specific memory block for your design and allocate another portion of memory for SignalTap II data acquisition. For example, if your design implements a large buffering application such as a system cache, it is ideal to place this application into M-RAM blocks so that the remaining M512 or M4K blocks are used for SignalTap II data acquisition.

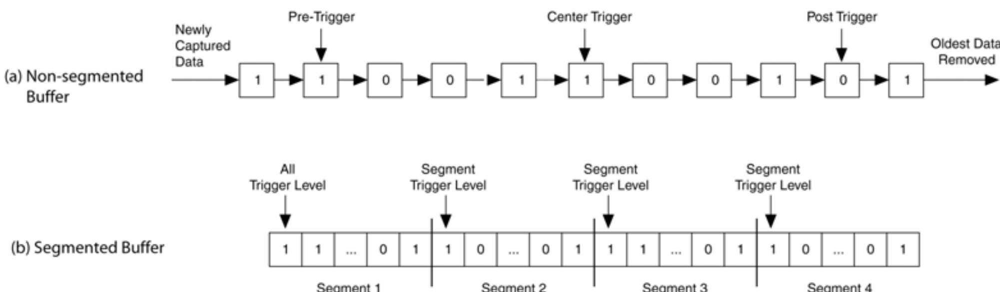
To select the RAM type to use for the SignalTap II buffer, select it from the RAM type list. Use this feature when the acquired data (as reported by the SignalTap II resource estimator) is not larger than the available memory of the memory type that you have selected in the FPGA.

Choosing the Buffer Acquisition Mode

The Buffer Acquisition Type Selection feature in the SignalTap II Embedded Logic Analyzer lets you choose how the captured data buffer is organized and can potentially reduce the amount of memory that is required for SignalTap II data acquisition. There are two types of acquisition buffer within the SignalTap II Embedded Logic Analyzer—a non-segmented buffer and a segmented buffer. With a non-segmented buffer, the SignalTap II Embedded Logic Analyzer treats entire memory space as a single FIFO, continuously filling the buffer until the embedded logic analyzer reaches a defined set of trigger conditions. With a segmented buffer, the memory space is split into a number of separate buffers. Each buffer acts as a separate FIFO with its own set of trigger conditions. Only a single buffer is active during an acquisition. The SignalTap II Embedded Logic Analyzer advances to the next segment after the trigger condition or conditions for the active segment has been reached.

When using a non-segmented buffer, you can use the storage qualification feature to determine which samples are written into the acquisition buffer. Both the segmented buffers and the non-segmented buffer with the storage qualification feature help you maximize the use of the available memory space. Figure 14–11 illustrates the differences between the two buffer types.

Figure 14–11. Buffer Type Comparison in the SignalTap II Embedded Logic Analyzer *(Note 1)*



Note to Figure 14–11:

(1) Both non-segmented and segmented buffers can use a predefined trigger (Pre-Trigger, Center Trigger, Post-Trigger) position or define a custom trigger position using the **State-Based Triggering** tab. Refer to "Specifying the Trigger Position" on page 14–48 for more details.

(2) Each segment is treated like a FIFO, and behaves as the non-segmented buffer shown in (a).

For more information about the storage qualification feature, refer to "Using the Storage Qualifier Feature" on page 14–25.

Non-Segmented Buffer

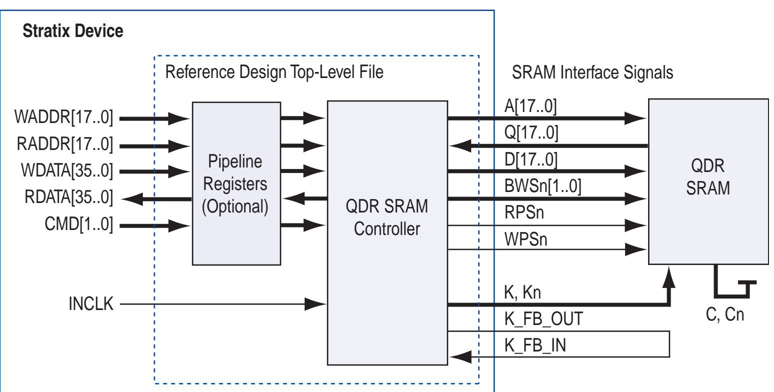
The non-segmented buffer (also known as a circular buffer) shown in Figure 14–11 (a) is the default buffer type used by the SignalTap II Embedded Logic Analyzer. While the logic analyzer is running, data is stored in the buffer until it fills up, at which point new data replaces the oldest data. This continues until a specified trigger event—that is, a set of trigger conditions—occurs. When this happens, the logic analyzer continues to capture data after the trigger event until the buffer is full, based on the trigger position setting in the **Signal Configuration** pane in the **.stp** file. Select a setting from the list to choose whether to capture the majority of the data before (**Post trigger position**), after (**Pre-trigger position**) the trigger occurs, or to center the trigger position in the data (**Center trigger position**). Alternatively, use the custom State-based triggering flow to define a custom trigger position within the capture buffer.

For more information, refer to "Specifying the Trigger Position" on page 14–48.

Segmented Buffer

A segmented buffer makes it easier to debug systems that contain relatively infrequent recurring events. The acquisition memory is split into a set of evenly sized segments, with a set of trigger conditions defined for each segment. Each segment acts as a non-segmented buffer. Figure 14–12 shows an example of this type of buffer system.

Figure 14–12. Example System that Generates Recurring Events



The SignalTap II Embedded Logic Analyzer verifies the functionality of the design shown in Figure 14–12 to ensure that the correct data is written to the SRAM controller. Buffer acquisition in the SignalTap II Embedded Logic Analyzer allows you to monitor the `RDATA` port when `H'0F0F0F0F` is sent into the `RADDR` port. You can monitor multiple read transactions from the SRAM device without running the SignalTap II Embedded Logic Analyzer again. The buffer acquisition feature allows you to segment the memory so you can capture the same event multiple times without wasting allocated memory. The number of cycles that are captured depends on the number of segments specified under the **Data** settings.

To enable and configure buffer acquisition, select Segmented in the SignalTap II Editor and select the number of segments to use. In the example, selecting sixty-four 64-sample segments allows you to capture 64 read cycles when the `RADDR` signal is `H'0F0F0F0F`.

For more information about buffer acquisition mode, refer to *Setting the Buffer Acquisition Mode* in the Quartus II Help.

Using the Storage Qualifier Feature

Both non-segmented and segmented buffers described in the previous section offer a snapshot in time of the data stream being analyzed. The default behavior for writing into acquisition memory with the SignalTap II Embedded Logic Analyzer is to sample data on every clock cycle. With a non-segmented buffer, there is one data window that represents a contiguous snapshot of the datastream. Similarly, segmented buffers use several smaller sampling windows spread out over a larger time scale, with each sampling window representing a contiguous data set.

With carefully chosen trigger conditions and a generous sample depth for the acquisition buffer, analysis using segmented and non-segmented buffers captures a majority of functional errors in a chosen signal set. However, each data window can have a considerable amount of redundancy associated with it; for example, a capture of a data stream containing long periods of idle signals between data bursts. With default behavior using the SignalTap II Embedded Logic Analyzer, there is no way to discard the redundant sample bits.

The Storage Qualification feature allows you to filter out individual samples not relevant to debugging the design. With this feature, a condition acts as a write enable to the buffer each clock cycle during a data acquisition. Through fine tuning the data that is actually stored in acquisition memory, the Storage Qualification feature allows for a more efficient use of acquisition memory and covers a larger time scale.

Use of the Storage Qualification feature is similar to an acquisition using a segmented buffer, in that you can create a discontinuity in the capture buffer. Because you can create a discontinuity between any two samples in the buffer, the Storage Qualification feature is equivalent to being able to create a customized segmented buffer in which the number and size of segment boundaries are adjustable. Figure 14–13 illustrates three ways the SignalTap II Embedded Logic Analyzer writes into acquisition memory.

The Storage Qualification feature can only be used with a non-segmented buffer. The MegaWizard Plug-In Manager instantiated flow only supports the Input Port mode for the Storage Qualification feature.

Figure 14–13. Data Acquisition Using Different Modes of Controlling the Acquisition Buffer

Non-segmented Buffer (1)

Segmented Buffer (2)

Non-segmented Buffer with Storage Qualifier (3)

Notes to Figure 14–13:

(1) Non-segmented Buffers capture a fixed sample window of contiguous data.

(2) Segmented buffers divide the buffer into fixed sized segments, with each segment having an equal sample depth.

(3) Storage Qualification allows you to define a custom sampling window for each segment you create with a qualifying condition. Storage qualification potentially allows for a larger time scale of coverage.

There are five types available under the Storage Qualification feature:

- Continuous
- Input port
- Transitional
- Conditional
- Start/Stop
- State-based

Continuous (the default mode selected) turns the Storage Qualification feature off.

Each selected storage qualifier type is active when an acquisition starts. Upon the start of an acquisition, the SignalTap II Embedded Logic Analyzer examines each clock cycle and writes the data into the acquisition buffer based upon storage qualifier type and condition. The acquisition stops when a defined set of trigger conditions occur.

Trigger conditions are evaluated independently of storage qualifier conditions. The SignalTap II Embedded Logic Analyzer evaluates the data stream for trigger conditions on every clock cycle after the acquisition begins.

Trigger conditions are defined in "Define Trigger Conditions" on page 14–6.

The storage qualifier operates independently of the trigger conditions.

The following subsections describe each storage qualification mode from the acquisition buffer.

Input Port Mode

When using the Input port mode, the SignalTap II Embedded Logic Analyzer takes any signal from your design as an input. When the design is running, if the signal is high on the clock edge, the SignalTap II Embedded Logic Analyzer stores the data in the buffer. If the signal is low on the clock edge, the data sample is ignored. A pin is created and connected to this input port by default if no internal node is specified.

If you are using an **.stp** file to create a SignalTap II Embedded Logic Analyzer instance, specify the storage qualifier signal using the input port field located on the **Setup** tab. This port must be specified for your project to compile.

If you are using the MegaWizard Plug-In Manager flow, the storage qualification input port, if specified, will appear in the MegaWizard-generated instantiation template. This port can then be connected to a signal in your RTL.

Figure 14–14 shows a data pattern captured with a segmented buffer. Figure 14–15 shows a capture of the same data pattern with the storage qualification feature enabled.

Figure 14–14. Data Acquisition of a Recurring Data Pattern in Continuous Capture Mode (to illustrate Input port mode)

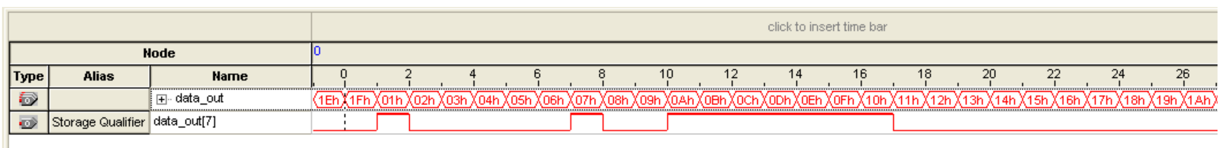


Figure 14–15. Data Acquisition of a Recurring Data Pattern Using an Input Signal as a Storage Qualifier

(1) Markers display samples when the logic analyzer paused a write into acquisition memory. These markers are enabled with the option "Record data discontinuities."

Transitional Mode

In Transitional mode, you choose a set of signals for inspection using the node list check boxes in the storage qualifier column. During acquisition, if any of the signals marked for inspection have changed since the previous clock cycle, new data is written to the acquisition buffer. If none of the signals marked have changed since the previous clock cycle, no data is stored. Figure 14–16 shows the transitional storage qualifier setup. Figure 14–17 and Figure 14–18 show captures of a data pattern in continuous capture mode and a data pattern using the Transitional mode for storage qualification.

Figure 14–16. Transitional Storage Qualifier Setup

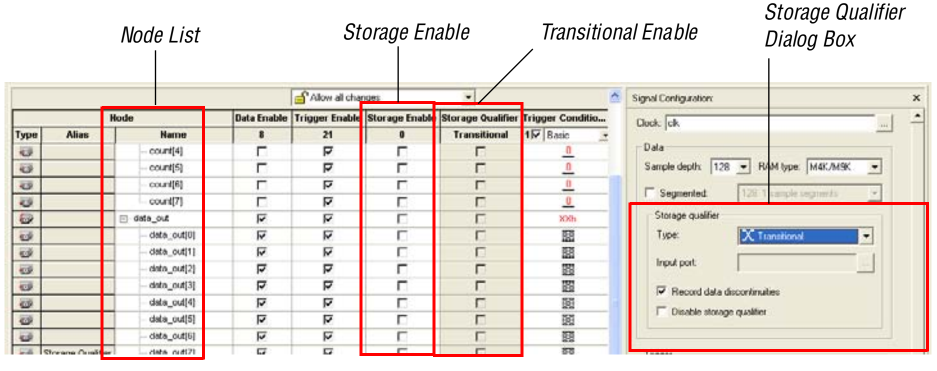

Figure 14–17. Data Acquisition of a Recurring Data Pattern in Continuous Capture Mode (to illustrate Transitional mode)

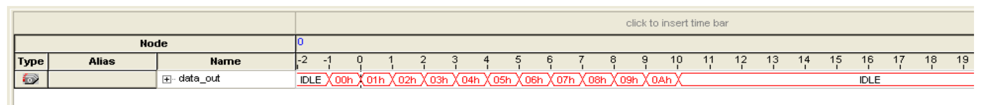

Figure 14–18. Data Acquisition of Recurring Data Pattern Using a Transitional Mode as a Storage Qualifier

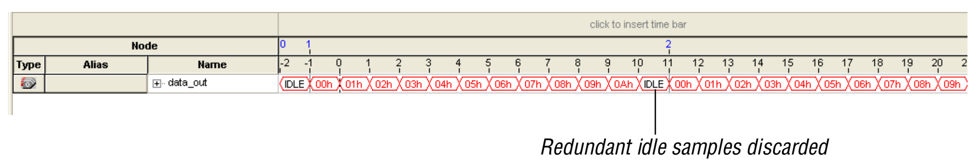

Conditional Mode

In Conditional mode, the SignalTap II Embedded Logic Analyzer evaluates a combinational function of storage qualifier enabled signals within the node list to determine whether a sample is stored. The SignalTap II Embedded Logic Analyzer writes into the buffer during the clock cycles in which the condition you specify evaluates `TRUE`.

There are two types of conditions that you can specify: basic and advanced. A basic storage condition matches each signal to one of the following:

- Don't Care
- Low
- High
- Falling Edge
- Either Edge

If a Basic Storage condition is specified for more than one signal, the SignalTap II Embedded Logic Analyzer evaluates the logical AND of the conditions.

Any other combinational or relational operators that you may want to specify with the enabled signal set for storage qualification can be done with an advanced storage condition. Figure 14–19 details the conditional storage qualifier setup in the **.stp** file.

You can set up storage qualification conditions similar to the manner in which trigger conditions are set up. For details about basic and advanced trigger conditions, refer to the sections "Creating Basic Trigger Conditions" on page 14–33 and "Creating Advanced Trigger Conditions" on page 14–34. Figure 14–20 and Figure 14–21 show a data capture with continuous sampling, and the same data pattern using the conditional mode for analysis, respectively.

Figure 14–19. Conditional Storage Qualifier Setup

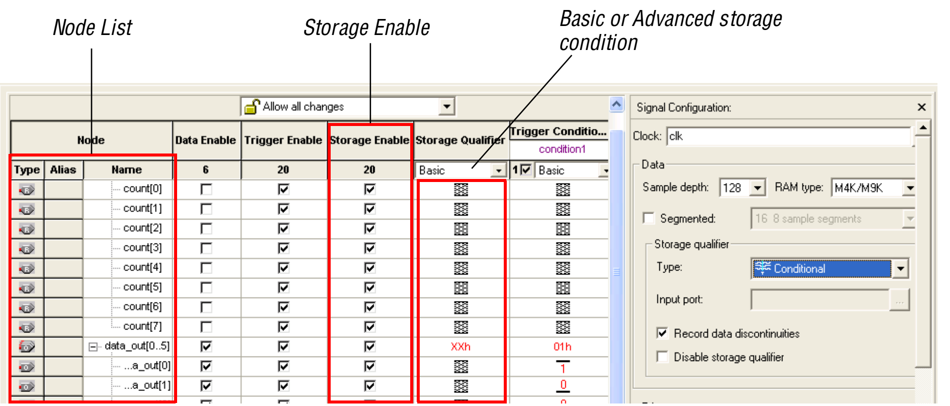

Figure 14–20. Data Acquisition of a Recurring Data Pattern in Continuous Capture Mode (to illustrate Conditional capture)

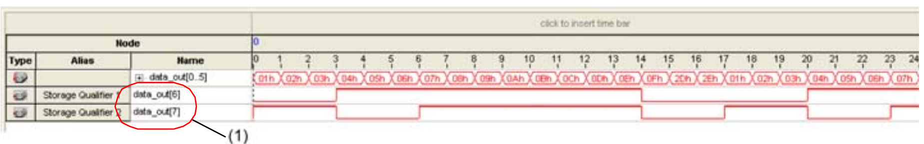
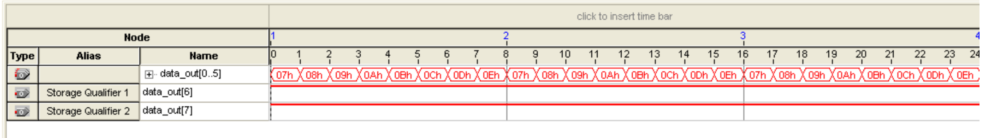


(1) Storage Qualifier condition is set up to pause acquisition when the following occurs:
data_out[6] AND data_out[7] = True. Resultant capture with storage qualifier enabled is shown in Figure 14-21.

Figure 14–21. Data Acquisition of a Recurring Data Pattern in Conditional Capture Mode



Start/Stop Mode

The Start/Stop mode is similar to the Conditional mode for storage qualification. However, in this mode there are two sets of conditions, one for start and one for stop. If the start condition evaluates to `TRUE`, data begins to be stored in the buffer every clock cycle until the stop condition evaluates to `TRUE`, which then pauses the data capture. Additional start signals received after the data capture has started are ignored. If both start and stop evaluate to `TRUE` at the same time, a single cycle is captured.

You can force trigger to the buffer by pressing the S**top** button if the buffer fails to fill to completion due to a stop condition.

Figure 14–22 shows the Start/Stop mode storage qualifier setup. Figure 14–23 and Figure 14–24 show captures data pattern in continuous capture mode and a data pattern in using the Start/Stop mode for storage qualification.

Figure 14–22. Start/Stop Mode Storage Qualifier Setup

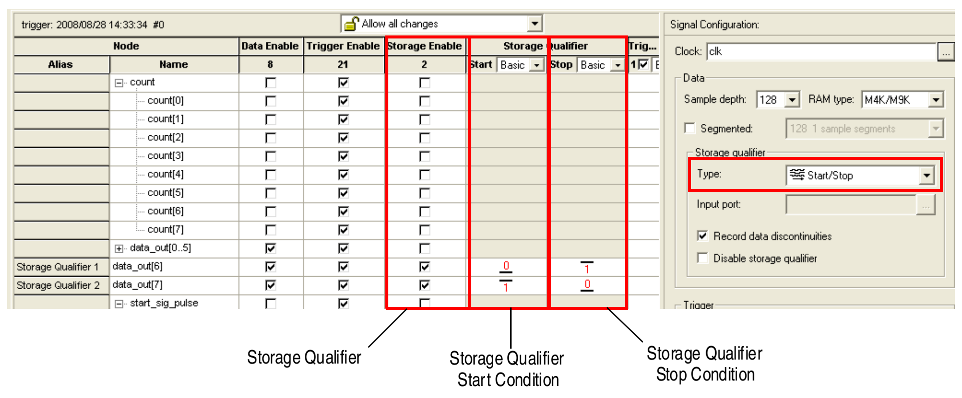


Figure 14–23. Data Acquisition of a Recurring Data Pattern in Continuous Mode (to illustrate Start/Stop mode)

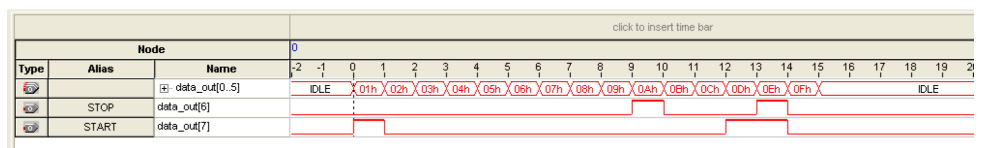

Figure 14–24. Data Acquisition of a Recurring Data Pattern with Start/Stop Storage Qualifier Enabled

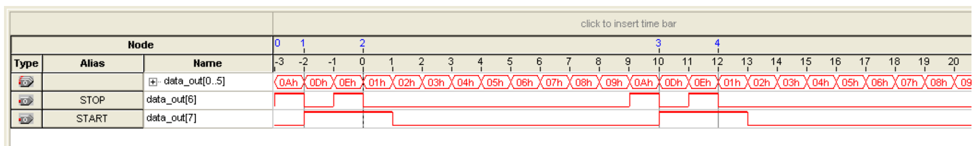


State-Based

The State-based storage qualification mode is used with the State-based triggering flow. The state based triggering flow evaluates an if-else based language to define how data is written into the buffer. With the State-based trigger flow, you have command over boolean and relational operators to guide the execution flow for the target acquisition buffer. When the storage qualifier feature is enabled for the State-based flow, two additional commands are available, the `start_store` and `stop_store` commands. These commands operate similarly to the Start/Stop capture conditions described in the previous section. Upon the start of acquisition, data is not written into the buffer until a `start_store` action is performed. The `stop_store` command pauses the acquisition. If both `start_store` and `stop_store` actions are performed within the same clock cycle, a single sample is stored into the acquisition buffer.

For more information about the State-based flow and storage qualification using the State-based trigger flow, refer to the section "Custom State-Based Triggering" on page 14–38.

Showing Data Discontinuities

When you enable the check box option **Record data discontinuities**, the SignalTap II Embedded Logic Analyzer marks the samples during which the acquisition paused from a storage qualifier. This marker is displayed in the waveform viewer after acquisition completes.

Disable Storage Qualifier

The **Disable Storage Qualifier** check box allows you to turn off the storage qualifier quickly and perform a continuous capture. This option is run-time reconfigurable; that is, the setting can be changed without recompiling the project. Changing storage qualifier mode from the Type field requires a recompilation of the project.

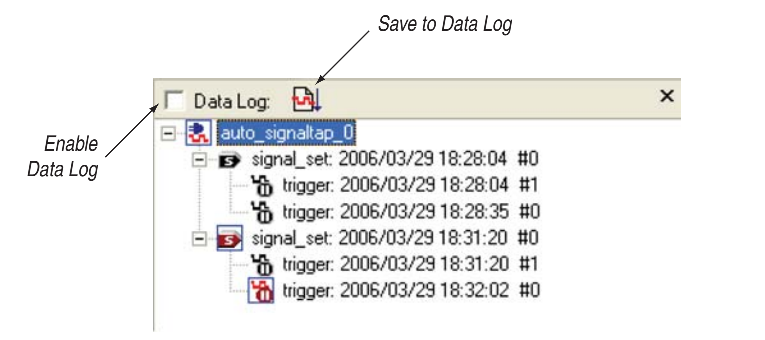
For a detailed explanation of Runtime Reconfigurable options available with the SignalTap II Embedded Logic Analyzer, and storage qualifier application examples using runtime reconfigurable options, refer to "Runtime Reconfigurable Options" on page 14–63.

Managing Multiple SignalTap II Files and Configurations

In some cases you may have more than one **.stp** file in one design. Each file potentially has a different group of monitored signals. These signal groups make it possible to debug different blocks in your design. In turn, each group of signals can also be used to define different sets of trigger conditions. Along with each **.stp** file, there is also an associated programming file (SRAM Object File [**.sof**]). The settings in a selected SignalTap II file must match the SignalTap II logic design in the associated **.sof** file for the logic analyzer to run properly when the device is programmed. Managing all of the **.stp** files and their associated settings and programming files is a challenging task. To help you manage everything, use the Data Log feature and the SOF Manager.

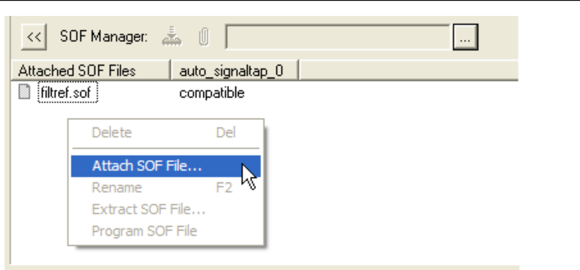
The Data Log allows you to store multiple SignalTap II configurations within a single **.stp** file. Figure 14–25 shows two signal set configurations with multiple trigger conditions in one **.stp** file. To toggle between the active configurations, double-click on an entry in the Data Log. As you toggle between the different configurations, the signal list and trigger conditions change in the **Setup** tab of the **.stp** file. The active configuration displayed in the **.stp** file is indicated by the blue square around the signal set in the Data Log. To store a configuration in the Data Log, on the Edit menu, click **Save to Data Log** or click the **Save to Data Log** button at the top of the Data Log.

Figure 14–25. Data Log



The SOF Manager allows you to embed multiple SOFs into one **.stp** file. Embedding an SOF in an **.stp** file lets you move the **.stp** file to a different location, either on the same computer or across a network, without the need to include the associated **.sof** as a separate file. To embed a new SOF in the **.stp** file, right-click in the SOF Manager, and click **Attach SOF File** (Figure 14–26).

Figure 14–26. SOF Manager



As you switch between configurations in the Data Log, you can extract the SOF that is compatible with that particular configuration and use the programmer in the SignalTap II Embedded Logic Analyzer to download the new SOF to the FPGA. In this way, you ensure that the configuration of your **.stp** file always matches the design programmed into the target device.

Define Triggers

When you start the SignalTap II Embedded Logic Analyzer, it samples activity continuously from the monitored signals. The SignalTap II Embedded Logic Analyzer "triggers"—that is, stops and displays the data—when a condition or set of conditions that you specified has been reached. This section describes the various types of trigger conditions that you can set using the SignalTap II Embedded Logic Analyzer.

Creating Basic Trigger Conditions

The simplest kind of trigger condition is a basic trigger. Select this from the list at the top of the **Trigger Conditions** column in the node list in the SignalTap II Editor. With the trigger type set to Basic, set the trigger pattern for each signal you have added in the **.stp** file. To set the trigger pattern, right-click in the **Trigger Conditions** column and click the desired pattern. Set the trigger pattern to any of the following conditions:

- Don't Care
- Low
- High
- Falling Edge
- Rising Edge
- Either Edge

For buses, type a pattern in binary, or right-click and select **Insert Value** to enter the pattern in other number formats. Note that you can enter `X` to specify a set of "don't care" values in either your hexadecimal or your binary string. For signals added to the **.stp** file that have an associated mnemonic table, you can right-click and select an entry from the table to set pre-defined conditions for the trigger.

For more information about creating and using mnemonic tables, refer to "View, Analyze, and Use Captured Data" on page 14–66, and to the Quartus II Help.

For signals added with certain plug-ins, you can create basic triggers easily using predefined mnemonic table entries. For example, with the Nios II plug-in, if you have specified an **.elf** file from your Nios II IDE design, you can type the name of a function from your Nios II code. The logic analyzer triggers when the Nios II instruction address matches the address of the specified code function name.

Data capture stops and the data is stored in the buffer when the logical `AND` of all the signals for a given trigger condition evaluates to `TRUE`.

Creating Advanced Trigger Conditions

With the SignalTap II Embedded Logic Analyzer's basic triggering capabilities, you can build more complex triggers utilizing extra logic that enables you to capture data when a particular combination of conditions exist. If you set the trigger type to **Advanced** at the top of the **Trigger Conditions** column in the node list of the SignalTap II Editor, a new tab named **Advanced Trigger** appears where you can build a complex trigger expression using a simple GUI. To build the complex trigger condition in an expression tree, drag-and-drop operators into the Advanced Trigger Configuration Editor window. To configure the operators' settings, double-click or right-click the operators that you have placed and select **Properties**. Table 14–4 lists the operators you can use.

Table 14–4. Advanced Triggering Operators *(Note 1)*

Name of Operator	Type
Less Than	Comparison
Less Than or Equal To	Comparison
Equality	Comparison
Inequality	Comparison
Greater Than	Comparison
Greater Than or Equal To	Comparison
Logical NOT	Logical
Logical AND	Logical
Logical OR	Logical
Logical XOR	Logical
Reduction AND	Reduction
Reduction OR	Reduction
Reduction XOR	Reduction
Left Shift	Shift
Right Shift	Shift
Bitwise Complement	Bitwise
Bitwise AND	Bitwise
Bitwise OR	Bitwise
Bitwise XOR	Bitwise
Edge and Level Detector	Signal Detection

Note to Table 14–4:

(1) For more information about each of these operators, refer to the Quartus II Help.

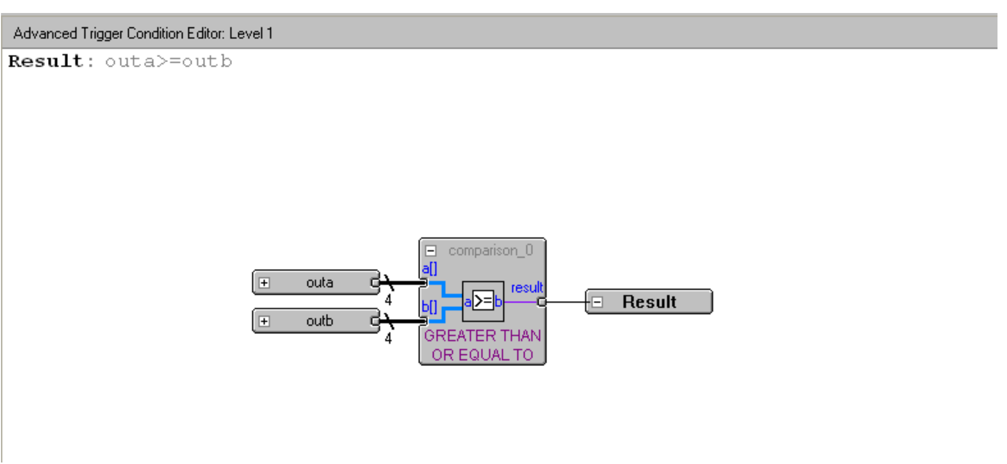
Adding many objects to the Advanced Trigger Condition Editor can make the work space cluttered and difficult to read. To keep objects organized while you build your advanced trigger condition, use the right-click menu and select **Arrange All Objects**. You can also use the **Zoom-Out** command to fit more objects into the Advanced Trigger Condition Editor window.

Examples of Advanced Triggering Expressions

The following examples show how to use Advanced Triggering:

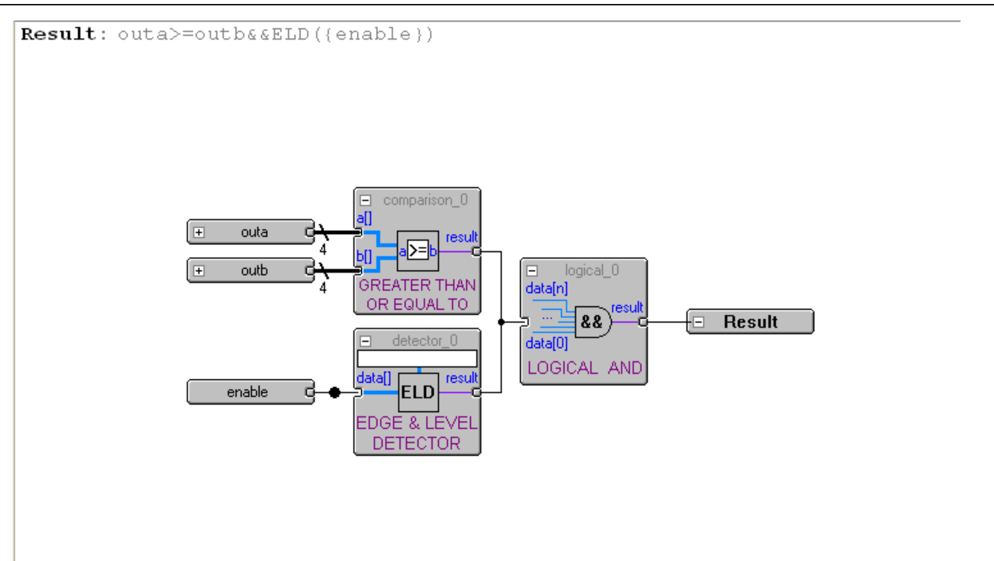
- Trigger when bus `outa` is greater than or equal to `outb` (Figure 14–27).

Figure 14–27. Bus outa is Greater Than or Equal to Bus outb



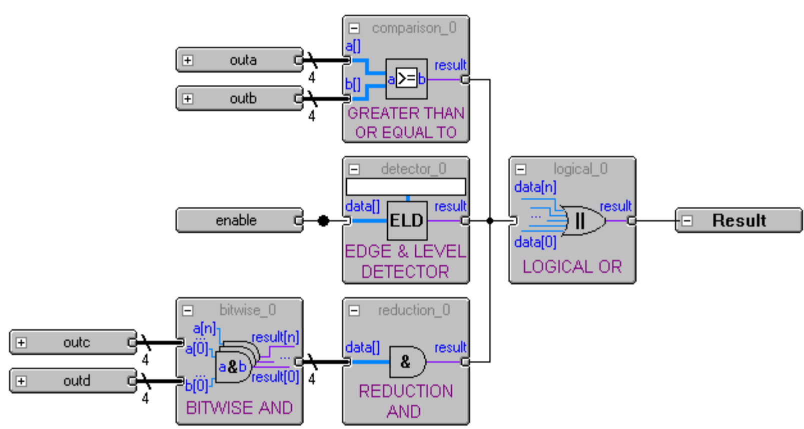
- Trigger when bus `outa` is greater than or equal to bus `outb`, and when the enable signal has a rising edge (Figure 14–28).

Figure 14–28. Enable Signal has a Rising Edge



- Trigger when bus `outa` is greater than or equal to bus `outb`, or when the enable signal has a rising edge. Or, when a bitwise `AND` operation has been performed between bus `outc` and bus `outd`, and all bits of the result of that operation are equal to 1 (Figure 14–29).

Figure 14–29. Bitwise AND Operation



Trigger Condition Flow Control

The SignalTap II Embedded Logic Analyzer offers multiple triggering conditions to give you precise control of the method data is captured into the acquisition buffers. Trigger Condition Flow allows you to define the relationship between a set of triggering conditions. The SignalTap II Embedded Logic Analyzer offers two flow control mechanisms for organizing trigger conditions:

- Sequential Triggering—This is the default triggering flow. Sequential triggering allows you to define up to 10 triggering levels that must be satisfied before the acquisition buffer finishes capturing.
- Custom State-Based Triggering—This flow allows you the greatest control over your acquisition buffer. Custom-based triggering allows you to organize trigger conditions into states based on a conditional flow that you define.

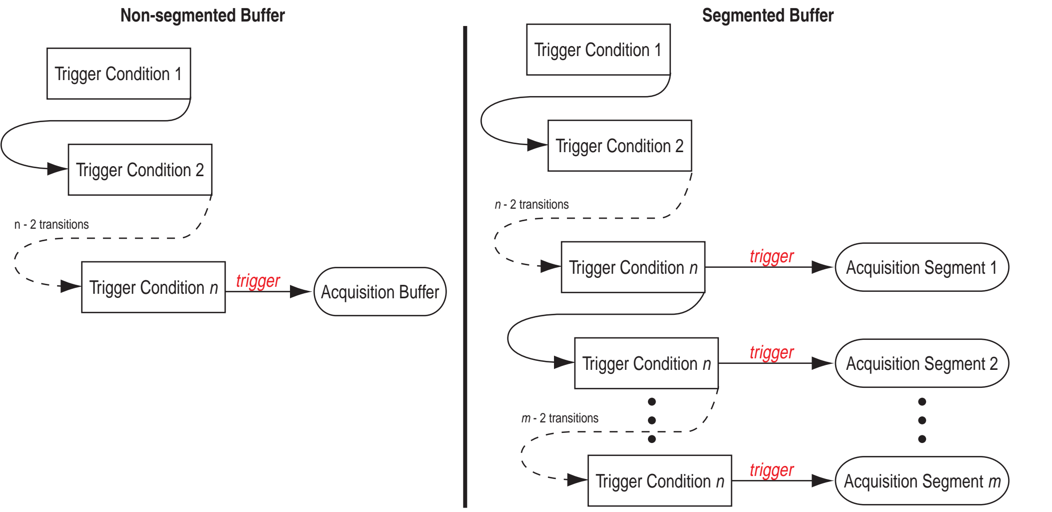
You can use either method with either a segmented or a non-segmented buffer.

Sequential Triggering

Sequential triggering flow allows you to cascade up to 10 levels of triggering conditions. The SignalTap II Embedded Logic Analyzer sequentially evaluates each of the triggering conditions. When the last triggering condition evaluates to `TRUE`, the SignalTap II Embedded Logic Analyzer triggers the acquisition buffer. For segmented buffers, every acquisition segment after the first segment triggers on the last triggering condition that you have specified. Use the Simple Sequential Triggering feature with basic triggers, advanced triggers, or a mix of both. Figure 14–30 illustrates the simple sequential triggering flow for non-segmented and segmented buffers.

The external trigger is considered as trigger level 0. The external trigger must be evaluated before the main trigger levels are evaluated.

Figure 14–30. Sequential Triggering Flow *(Note 1)*, *(2)*



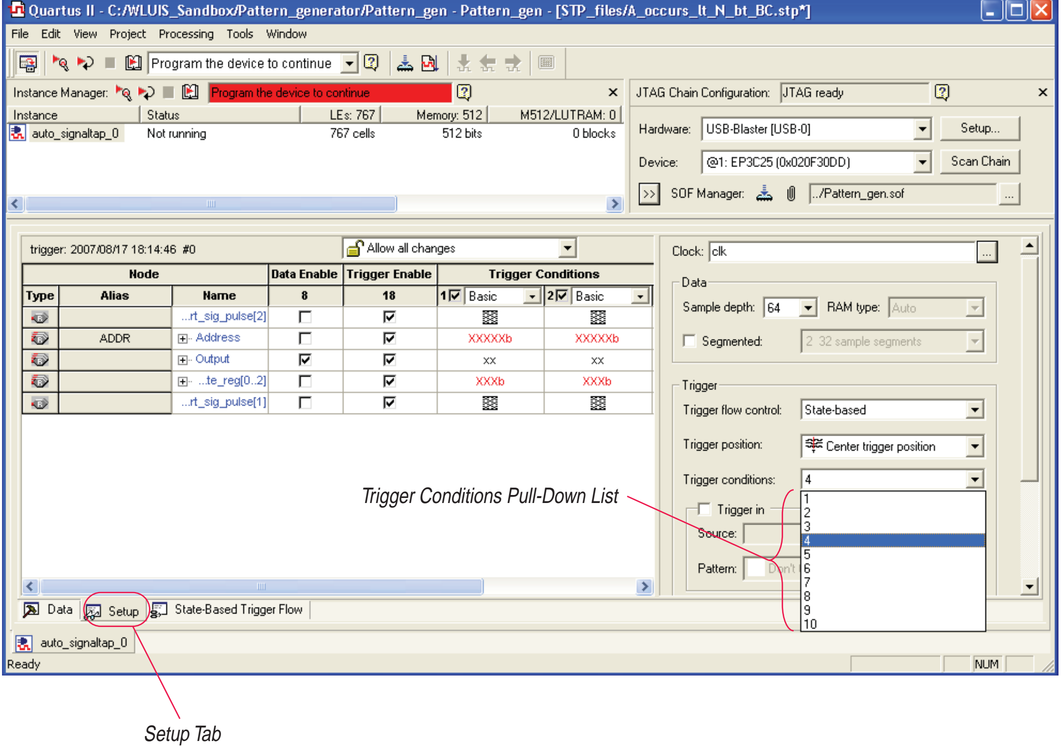
Notes to Figure 14–30:

(1) The acquisition buffer stops capture when all n triggering levels are satisfied, where $n \leq 10$.

(2) An external trigger input, if defined, is evaluated before all other defined trigger conditions are evaluated. For more information about external triggers, refer to "Using External Triggers" on page 14–51.

To configure the SignalTap II Embedded Logic Analyzer for Sequential triggering, in the SignalTap II editor on the **Trigger flow control** list, select **Sequential**. Select the desired number of trigger conditions by using the **Trigger Conditions** pull-down list. After you select the desired number of trigger conditions, configure each trigger condition in the node list. To disable any trigger condition, click the check box next to the trigger condition at the top of the column in the node list. Figure 14–31 shows the **Setup** tab for Sequential Triggering.

Figure 14–31. Setup Tab

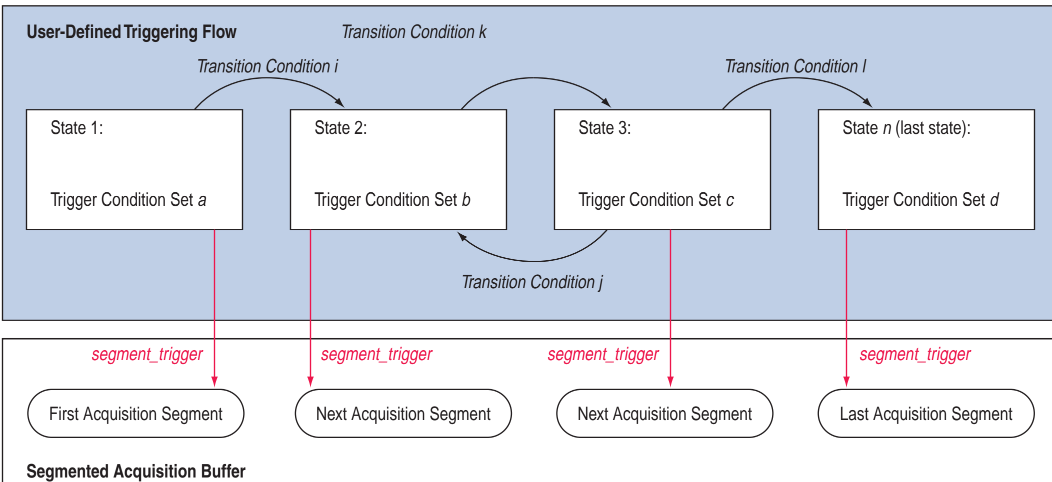


Custom State-Based Triggering

Custom State-based triggering gives you the most control of triggering condition arrangement. This flow gives you the ability to describe the relationship between triggering conditions precisely, using an intuitive GUI and the SignalTap II Trigger Flow Description Language, a simple description language based upon conditional expressions. Tooltips within the custom triggering flow GUI allow you to describe your desired flow quickly. The custom State-based triggering flow allows for more efficient use of the space available in the acquisition buffer because only specific samples of interest are captured.

Figure 14–32 illustrates the custom State-based triggering flow. Events that trigger the acquisition buffer are organized by a user-defined state diagram. All actions performed by the acquisition buffer are captured by the states and all transition conditions between the states are defined by the conditional expressions that you specify within each state.

Figure 14–32. Custom State-Based Triggering Flow *(Note 1)*, *(2)*



Notes to Figure 14–32:

(1) You are allowed up to 20 different states.

(2) An external trigger input, if defined, is evaluated before any conditions in the custom State-based triggering flow are evaluated. For more information, refer to "Using External Triggers" on page 14–51.

Each state allows you to define a set of conditional expressions. Each conditional expression is a Boolean expression dependent on a combination of triggering conditions (configured within the **Setup** tab), counters, and status flags. Counters and status flags are resources provided by the SignalTap II custom-based triggering flow.

Within each conditional expression you define a set of actions. Actions include triggering the acquisition buffer to stop capture, a modification to either a counter or status flag, or a state transition.

Trigger actions can apply to either a single segment of a segmented acquisition buffer or to the entire non-segmented acquisition buffer. Each trigger action provides you with an optional count that specifies the number of samples to be captured before stopping acquisition of the current segment. The count argument allows you to control the amount of data captured precisely before and after triggering event.

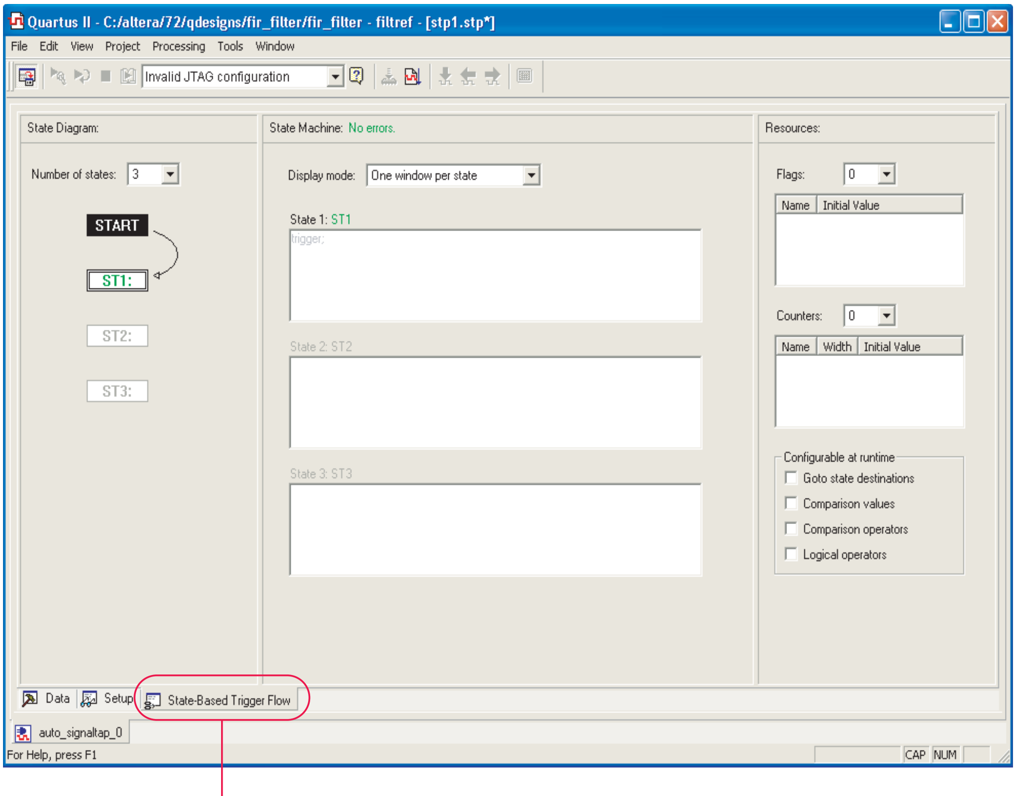
Resource manipulation actions allow you to increment and decrement counters or set and clear status flags. The counter and status flag resources are used as optional inputs in conditional expressions. Counters and status flags are useful for counting the number of occurrences of particular events and for aiding in triggering flow control.

This SignalTap II custom State-based triggering flow allows you to capture a sequence of events that may not necessarily be contiguous in time; for example, capturing a communication transaction between two devices that includes a handshaking protocol containing a sequence of acknowledgements.

The **State-Based Trigger Flow** tab is the control interface for the custom state-based triggering flow. To enable this tab, on the **Trigger Flow Control** pull-down list, select **State-based**. (Note that when the **Trigger Flow Control** option is set to **Sequential**, the **State-Based Trigger Flow** tab is hidden.)

Figure 14–33 shows the **State-Based Trigger Flow** tab.

Figure 14–33. State-Based Trigger Flow Tab



The **State-Based Trigger Flow** tab is partitioned into the following three panes:

- State Diagram Pane
- Resources Pane
- State Machine Pane

State Diagram Pane

The **State Diagram** pane provides a graphical overview of the triggering flow that you define. It shows the number of states available and the state transitions between all of the states. You can adjust the number of available states by using the pull-down menu above the graphical overview.

State Machine Pane

The **State Machine** pane contains the text entry boxes where you can define the triggering flow and actions associated with each state. You can define the triggering flow using the SignalTap II Trigger Flow Description Language, a simple language based on "if-else" conditional statements. Tooltips appear when you move the mouse over the cursor, to guide command entry into the state boxes. The GUI provides a syntax check on your flow description in real-time and highlights any errors in the text flow.

For a full description of the SignalTap II Trigger Flow Description Language, refer to "SignalTap II Trigger Flow Description Language" on page 14–42. You can also refer to the Quartus II Help.

The State Machine description text boxes default to show one text box per state. You can optionally have the entire flow description shown in a single text field. This option can be useful when copying and pasting a flow description from a template or an external text editor. To toggle between one window per state, or all states in one window, select the appropriate option under **State Display mode.**

Resources Pane

The **Resources** pane allows you to declare Status Flags and Counters for use in the conditional expressions in the Custom Triggering Flow. Actions to decrement and increment counters or to set and clear status flags are performed within the triggering flow that you define.

You can set up to 20 counters and 20 status flags. Counter and status flags values may be initialized by right-clicking the status flag or counter name after selecting a number of them from the respective pull-down list, and selecting **Set Initial Value.** To set counter width, right-click the counter name and select **Set Width**. Counters and flag values are updated dynamically after acquisition has started to assist in debugging your trigger flow specification.

Runtime Reconfigurability—The **configurable at runtime** options in the **Resources** pane allows you to configure the custom-flow control options that can be changed at runtime without requiring a recompilation. Table 14–5 contains a description of options for the State-based trigger flow that can be reconfigured at runtime.

For a broader discussion about all options that can be changed without incurring a recompile refer to "Runtime Reconfigurable Options" on page 14–63.

Table 14–5. Runtime Reconfigurable Settings, State-Based Triggering Flow

Setting	Description
Destination of goto action	Allows you to modify the destination of the state transition at runtime.
Comparison values	Allows comparison values in Boolean expressions to be modifiable at runtime. In addition, it allows the `segment_trigger` and trigger action post-fill count argument to be modifiable at runtime.
Comparison operators	Allows comparison operators in Boolean expressions to be modifiable at runtime.
Logical operators	Allows the logical operators in Boolean expressions to be modifiable at runtime.

You can restrict changes to your SignalTap configuration to include only the options that do not require a recompilation by using the pull-down menu above the trigger list in the **Setup** tab. The option **Allow trigger condition changes only** restricts changes to only the configuration settings that have the **configurable at runtime** set. With this option enabled, to modify Trigger Flow conditions in the **Custom Trigger Flow** tab, click the desired parameter in the text box and select a new parameter from the menu that appears.

The runtime configurable settings for the **Custom Trigger Flow** tab are on by default. You may get some performance advantages by disabling some of the runtime configurable options. For details about the effects of turning off the runtime modifiable options, refer to "Performance and Resource Considerations" on page 14–57.

SignalTap II Trigger Flow Description Language

The Trigger Flow Description Language is based on a list of conditional expressions per state to define a set of actions. Each line in Example 14–1 shows a language format. Keywords are shown in bold. Non-terminals are delimited by "<>" and are further explained in the following sections. Optional arguments are delimited by "[ ]" (Example 14–1).

Examples of Triggering Flow descriptions for common scenarios using the SignalTap II Custom Triggering Flow are provided in "Custom Triggering Flow Application Examples" on page 14–79.

Example 14–1. Trigger Flow Description Language Format *(Note 1)*

```
state <State_label>:
<action_list>

if( <Boolean_expression> )
<action_list>
[else if ( <boolean_expression> )
<action_list>] (1)
[else
<action_list>]
```

Note to Example 14–1:

(1) Multiple `else if` conditions are allowed.

The priority for evaluation of conditional statements is assigned from top to bottom. The *<boolean_expression>* in an if statement can contain a single event, or it can contain multiple event conditions. The `action_list` embedded within an `if` or an `else if` clause must be delimited by the begin and end tokens when the action list contains multiple statements. When the boolean expression is evaluated `TRUE`, the logic analyzer analyzes all of the commands in the action list concurrently. The possible actions include:

- Triggering the acquisition buffer
- Manipulating a counter or status flag resource
- Defining a state transition

State Labels

State labels are identifiers that can be used in the action `goto`.

`state` *<state_label>*`:` begins the description of the actions evaluated when this state is reached.

The description of a state ends with the beginning of another state or the end of the whole trigger flow description.

Boolean_expression

`Boolean_expression` is a collection of logical operators, relational operators, and their operands that evaluate into a Boolean result. Depending on the operator, the operand can be a reference to a trigger condition, a counter and a register, or a numeric value. Within an expression, parentheses can be used to group a set of operands.

Logical operators accept any boolean expression as an operand. The supported logical operators are shown in Table 14–6.

Table 14–6. Logical Operators

Operator	Description	Syntax
!	NOT operator	! expr1
&&	AND operator	expr1 && expr2
||	OR operator	expr1 || expr2

Relational operators are performed on counters or status flags. The comparison value—the right operator—must be a numerical value. The supported relational operators are shown in Table 14–7.

Table 14–7. Relational Operators

Operator	Description	Syntax *(Note 1) (2)*
>	Greater than	*<identifier> > <numerical_value>*
>=	Greater than or Equal to	*<identifier> >= <numerical_value>*
==	Equals	*<identifier> == <numerical_value>*
!=	Does not equal	*<identifier> != <numerical_value>*
<=	Less than or equal to	*<identifier> <= <numerical_value>*
<	Less than	*<identifier> < <numerical_value>*

Notes to Table 14–7:

(1) *<identifier>* indicates a counter or status flag.

(2) *<numerical_value>* indicates an integer.

Action_list

Action_list is a list of actions that can be performed when a state is reached and a condition is also satisfied. If more than one action is specified, they must be enclosed by `begin` and `end`. The actions can be categorized as resource manipulation actions, buffer control actions, and state transition actions. Each action is terminated by a semicolon (`;`).

Resource Manipulation Action

The resources used in the trigger flow description can be either counters or status flags. Table 14–8 shows the description and syntax of each action.

Table 14–8. Resource Manipulation Action (Part 1 of 2)

Action	Description	Syntax
increment	Increments a counter resource by 1	increment *<counter_identifier>*;
decrement	Decrements a counter resource by 1	decrement *<counter_identifier>*;

Table 14–8. Resource Manipulation Action (Part 2 of 2)

Action	Description	Syntax
reset	Resets counter resource to initial value	`reset <counter_identifier>;`
set	Sets a status Flag to 1	`set <register_flag_identifier>;`
clear	Sets a status Flag to 0	`clear <register_flag_identifier>;`

Buffer Control Action

Buffer control actions specify an action to control the acquisition buffer. Table 14–9 shows the description and syntax of each action.

Table 14–9. Buffer Control Action

Action	Description	Syntax
`trigger`	Stops the acquisition for the current buffer and ends analysis. This command is required in every flow definition.	`trigger <post-fill_count>;`
`segment_trigger`	Ends the acquisition of the current segment. The SignalTap II Embedded Logic Analyzer starts acquiring from the next segment on evaluating this command. If all segments are filled, the oldest segment is overwritten with the latest sample. The acquisition stops when a trigger action is evaluated. This action cannot be used in non-segmented acquisition mode.	`segment_trigger <post-fill_count>;`
`start_store`	Asserts the `write_enable` to the SignalTap II acquisition buffer. This command is active only when the State-based storage qualifier mode is enabled.	`start_store`
`stop_store`	De-asserts the `write_enable` signal to the SignalTap II acquisition buffer. This command is active only when the State-based storage qualifier mode is enabled.	`stop_store`

Both `trigger` and `segment_trigger` actions accept an optional post-fill count argument. If provided, the current acquisition acquires the number of samples provided by post-fill count and then stops acquisition. If no post-count value is specified, the trigger position for the affected buffer defaults to the trigger position specified in the **Setup** tab.

In the case of `segment_trigger`, acquisition of the current buffer stops immediately if a subsequent triggering action is issued in the next state, regardless of whether or not the post-fill count has been satisfied for the current buffer. The remaining unfilled post-count acquisitions in the current buffer are discarded and displayed as grayed-out samples in the data window.

State Transition Action

The State Transition action specifies the next state in the custom state control flow. It is specified by the `goto` command. The syntax is as follows:

```
goto <state_label>;
```

Using the State-Based Storage Qualifier Feature

When you select State-based for the storage qualifier type, the `start_store` and `stop_store` actions are enabled in the State-based trigger flow. These commands, when used in conjunction with the expressions of the State-based trigger flow, give you maximum flexibility to control data written into the acquisition buffer.

The `start_store` and `stop_store` commands can only be applied to a non-segmented buffer.

The `start_store` and `stop_store` commands function similar to the start and stop conditions when using the **start**/**stop** storage qualifier mode conditions. If storage qualification is enabled, the `start_store` command must be issued for SignalTap II to write data into the acquisition buffer. No data is acquired until the `start_store` command is performed. Also, a `trigger` command must be included as part of the trigger flow description. The `trigger` command is necessary to complete the acquisition and display the results on the waveform display.

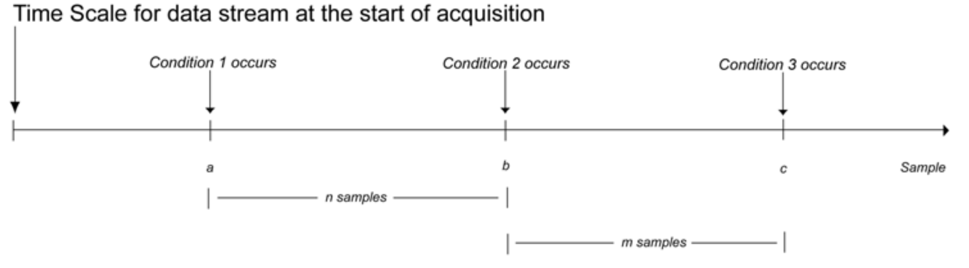
The following examples illustrate the behavior of the State-based trigger flow with the storage qualification commands.

Figure 14–34 shows a hypothetical scenario with three trigger conditions that happen at different points in time after the run analysis button is pushed. The trigger flow description in Example 14–2, when applied to the scenario shown in Figure 14–34, illustrates the functionality of the storage qualification feature for the state-based trigger flow.

Example 14–2. Trigger Flow Description 1

```
State 1: ST1:
if ( condition1 )
   start_store;
else if ( condition2 )
   trigger value;
else if ( condition3 )
   stop_store;
```

Figure 14–34. Capture Scenario for Storage Qualification with the State-Based Trigger Flow



In this example, the SignalTap II Embedded Logic Analyzer does not write into the acquisition buffer until sample a, when Condition 1 occurs. Once sample b is reached, the `trigger value` command is evaluated. The logic analyzer continues to write into the buffer to finish the acquisition. The trigger flow specifies a `stop_store` command at sample c, *m* samples after the trigger point occurs.

The logic analyzer will be able to finish the acquisition and display the contents of the waveform if it can successfully finish the post-fill acquisition samples before Condition 3 occurs. In this specific case, the capture ends if the post-fill count value is less than *m*.

If the post-fill count value specified in Trigger Flow description 1 is greater than *m* samples, the buffer pauses acquisition indefinitely, provided there is no recurrence of Condition 1 to trigger the logic analyzer to start capturing data again. The SignalTap II Embedded Logic Analyzer continues to evaluate the **stop_store** and **start_store** commands even after the **trigger** command is evaluated. If the acquisition has paused, you can manually stop and force the acquisition to trigger by using the **Stop Analysis** button. You can use counter values, flags, and the State diagram to help you gauge the execution of the trigger flow. The counter values, flags, and the current state are updated in real-time during a data acquisition.

Figure 14–35 and Figure 14–36 show a real data acquisition of the scenario described in Figure 14–33. Figure 14–35 illustrates a scenario where the data capture finishes successfully. It uses a buffer with a sample depth of 64, *m* = *n* = 10, and the post-fill count value = 5. Figure 14–36 illustrates a scenario where the logic analyzer pauses indefinitely even after a trigger condition occurs due to a `stop_store` condition. This scenario uses a sample depth of 64, with *m* = *n* = 10 and post-fill count = 15.

Figure 14–35. Storage Qualification with Post-Fill Count Value Less than *m* (Acquisition successfully completes)

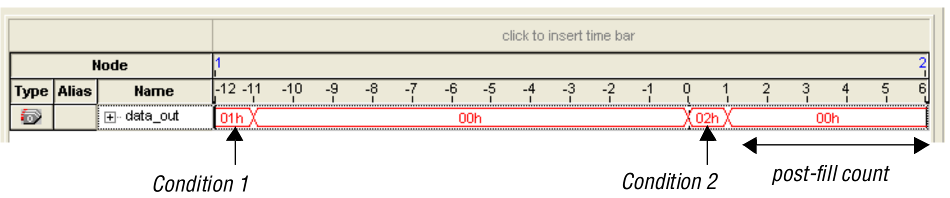


Figure 14–36. Storage Qualification with Post-Fill Count Value Greater than *m* (Acquisition indefinitely paused)

(2), (3) Status bar and current value fields update during an acquisition to provide real time status of the data acquisition.

The combination of using counters, Boolean and relational operators in conjunction with the `start_store` and `stop_store` commands can give a clock-cycle level of resolution to controlling the samples that get written into the acquisition buffer. Example 14–3 shows a trigger flow description that skips three clock cycles of samples after hitting condition 1. Figure 14–37 shows the data transaction on a continuous capture and Figure 14–39 shows the data capture with the Trigger flow description in Example 14–3 applied.

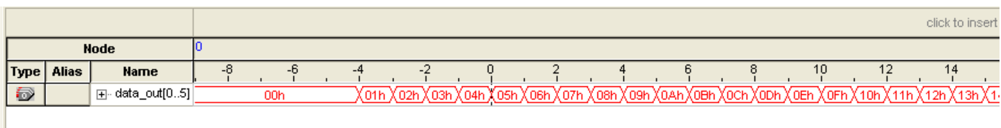

Figure 14–38. Capture of Data Transaction with Trigger Flow Description Applied

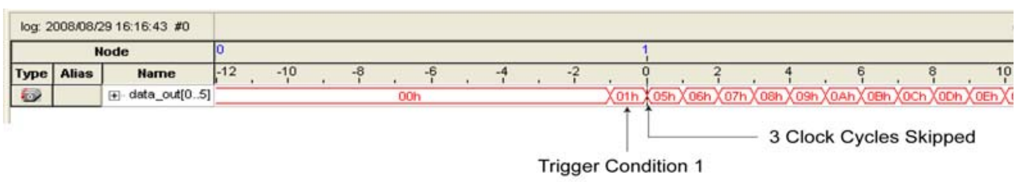


Specifying the Trigger Position

The SignalTap II Embedded Logic Analyzer allows you to specify the amount of data that is acquired before and after a trigger event. You can set the trigger position independently between a Runtime and Power-Up Trigger. Select the desired ratio of pre-trigger data to post-trigger data by choosing one of the following ratios:

- **Pre**—This selection saves signal activity that occurred after the trigger (12% pre-trigger, 88% post-trigger).
- **Center**—This selection saves 50% pre-trigger and 50% post-trigger data.
- **Post**—This selection saves signal activity that occurred before the trigger (88% pre-trigger, 12% post-trigger).

These pre-defined ratios apply to both non-segmented buffers and segmented buffers.

If you use the custom-state based triggering flow, you can specify a custom trigger position. The `segment_trigger` and trigger actions accept a post-fill count argument. The post-fill count specifies the number of samples to capture before stopping data acquisition for the non-segmented buffer or a data segment when using the `trigger` and `segment_trigger` commands, respectively. When the captured data is displayed in the SignalTap II data window, the trigger position appears as the number of post-count samples from the end of the acquisition segment or buffer. Refer to Equation 14–1:

Equation 14–1.

$$\text{Sample Number of Trigger Position} = (N - \text{Post-Fill Count})$$

In this case, N is the sample depth of either the acquisition segment or non-segmented buffer.

For segmented buffers, the acquisition segments that have a post-count argument defined use the post-count setting. Segments that do not have a post-count setting default to the trigger position ratios defined in the **Setup** tab.

For more details about the custom State-based triggering flow, refer to "Custom State-Based Triggering" on page 14–38 and "Custom State-Based Triggering" on page 14–38.

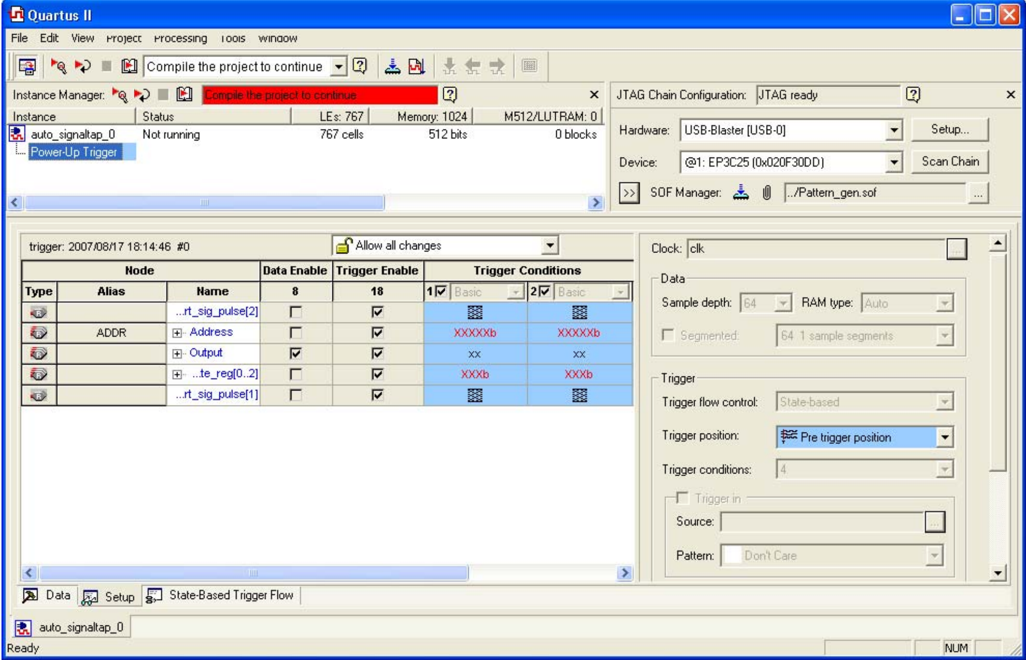
Creating a Power-Up Trigger

Typically, the SignalTap II Embedded Logic Analyzer is used to trigger on events that occur during normal device operation. You start an analysis manually once the target device is fully powered on and the device's JTAG connection is available. However, there may be cases when you would like to capture trigger events that occur during device initialization, immediately after the FPGA is powered on or reset. With the SignalTap II Power-Up Trigger feature, you arm the SignalTap II Embedded Logic Analyzer and capture data immediately after device programming.

Enabling a Power-Up Trigger

You can add a different Power-Up Trigger to each logic analyzer instance in the SignalTap II Instance Manager. To enable the Power-Up Trigger for a logic analyzer instance, right-click the instance and click **Enable Power-Up Trigger**, or select the instance, and on the **Edit** menu, click **Enable Power-Up Trigger**. To disable a Power-Up Trigger, click **Disable Power-Up Trigger** in the same locations. Power-Up Trigger is shown as a child instance below the name of the selected instance with the default trigger conditions set in the node list. Figure 14–39 shows the SignalTap II Editor when Power-Up Trigger is enabled.

Figure 14–39. SignalTap II Editor with Power-Up Trigger Enabled



Managing and Configuring Power-Up and Runtime Trigger Conditions

When the Power-Up Trigger is enabled for a logic analyzer instance, you can create basic and advanced trigger conditions for it in the same way you do with the regular trigger, also called the Run-Time Trigger. Power-Up Trigger conditions that you can adjust are color coded light blue, while Run-Time Trigger conditions remain white. Since each instance now has two sets of trigger conditions—the Power-Up Trigger and the Run-Time Trigger—you can differentiate between the two with color coding. To switch between the trigger conditions of the Power-Up Trigger and the Run-Time Trigger, double-click the instance name or the Power-Up Trigger name in the Instance Manager.

You cannot make changes to Power-Up Trigger conditions that would normally require a full recompile with Runtime Trigger conditions, such as adding signals, deleting signals, or changing between basic and advanced triggers. For these changes to be applied to the Power-Up Trigger conditions, first make the changes using the Runtime Trigger conditions.

Any change made to the Power-Up Trigger conditions requires that the SignalTap II Embedded Logic Analyzer be recompiled, even if a similar change to the Runtime Trigger conditions does not require a recompilation.

While creating or making changes to the trigger conditions for the Run-Time Trigger or the Power-Up Trigger, you may want to copy these conditions to the other trigger. This enables you to look for the same trigger during both power-up and runtime. To do this, right-click the instance name or the Power-Up Trigger name in the Instance Manager and click **Duplicate Trigger**, or select the instance name or the Power-Up Trigger name and on the **Edit** menu, click **Duplicate Trigger**.

For information about running the SignalTap II Embedded Logic Analyzer instance with a Power-Up Trigger enabled, refer to "Running with a Power-Up Trigger" on page 14–62.

Using External Triggers

You can create a trigger input that allows you to trigger the SignalTap II Embedded Logic Analyzer from an external source. The external trigger input behaves like trigger condition 1. It is evaluated and must be `TRUE` before any other configured trigger conditions are evaluated. The analyzer can also supply a signal to trigger external devices or other SignalTap II instances. These features allow you to synchronize external logic analysis equipment with the internal logic analyzer. Power-Up Triggers can use the external triggers feature, but they must use the same source or target signal as their associated Run-Time Trigger.

Trigger In

To use Trigger In, perform the following steps:

1. In the SignalTap II Editor, click the **Setup** tab.
2. If a Power-Up Trigger is enabled, ensure you are viewing the Runtime Trigger conditions.
3. In the **Signal Configuration** pane, turn on **Trigger In**.
4. In the **Pattern** list, select the condition you want to act as your trigger event. You can set this separately for Runtime or Power-Up Trigger.
5. Click Browse next to the **Source** field in the **Trigger In** pane (Figure 14–41 on page 14–53). The **Node Finder** dialog box appears.
6. In the **Node Finder** dialog box, select the signal (either an input pin or an internal signal) that you want to drive the Trigger In source and click **OK**.

   If you type a new signal name in the **Source** field, you create a new node that you can assign to an input pin in the Pin Planner or Assignment editor. If you leave the **Source** field blank, a default name is entered in the form `auto_stp_trigger_in_`<*SignalTap instance number*>.

Trigger Out

To use Trigger Out, perform the following steps:

1. In the SignalTap II Editor, click the **Setup** tab.
2. If a Power-Up trigger is enabled, ensure you are viewing the Runtime Trigger conditions.
3. To signify that the trigger event is occurring, in the **Signal Configuration** pane, turn on **Trigger Out** (refer to Figure 14–40 on page 14–52).
4. In the **Level** list, select the condition you want. You can set this separately for a Run-Time or a Power-Up Trigger.

5. Type a new signal name in the **Target** field. A new node name is created that you must assign to an output pin in the Pin Planner or Assignment Editor.

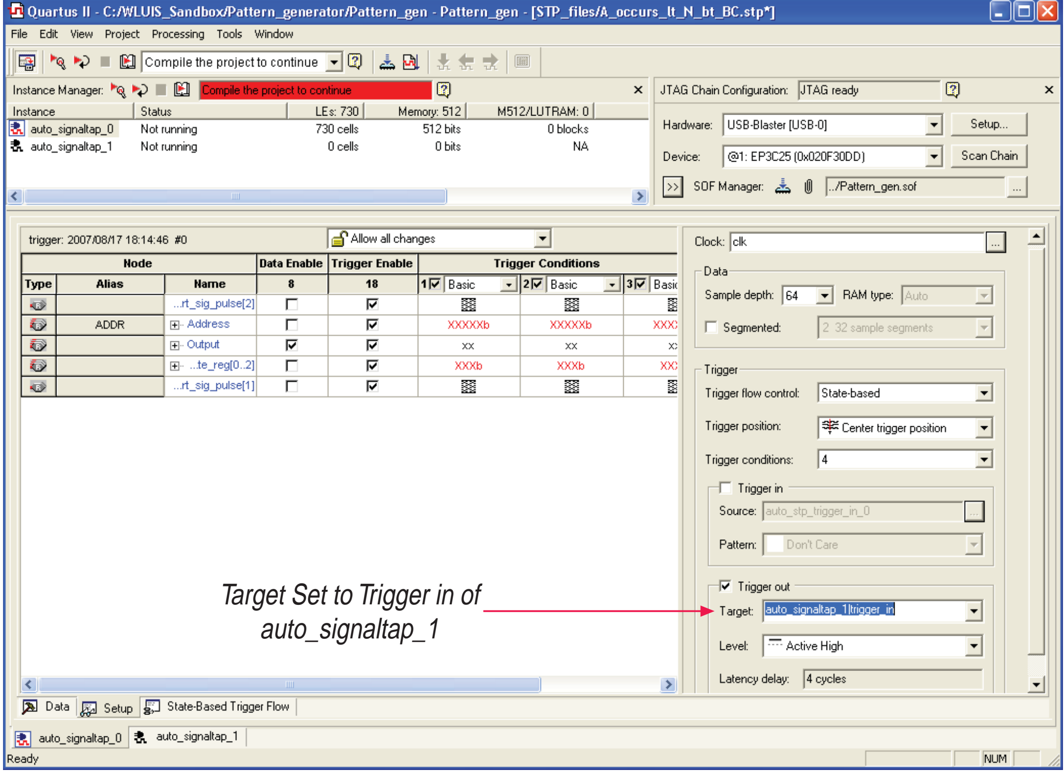
   If you leave the **Target** field blank, a default name is entered in the form `auto_stp_trigger_out_`<*SignalTap instance number*>. When the logic analyzer triggers, a signal at the level you indicated is output on the pin you assigned to the new node.

Using the Trigger Out of One Analyzer as the Trigger In of Another Analyzer

An advanced feature of the SignalTap II Embedded Logic Analyzer is the ability to use the Trigger Out of one analyzer as the Trigger In to another analyzer. This feature allows you to synchronize and debug events that occur across multiple clock domains.

To perform this operation, first enable the **Trigger Out** of the source logic analyzer instance. On the Trigger Out **Target** list, select the targeted logic analyzer instance. For example, if the instance named `auto_signaltap_0` should trigger `auto_signaltap_1`, select `auto_signaltap_1|trigger_in` from the list (Figure 14–40).

Figure 14–40. Configuring the Trigger Out Signal



■ This automatically enables the Trigger In of the targeted logic analyzer instance and fills in the Trigger In **Source** field with the Trigger Out signal from the source logic analyzer instance. In this example, `auto_signaltap_0` is targeting `auto_signaltap_1`. The Trigger In Source field of `auto_signaltap_1` is automatically filled in with `auto_signaltap_0`|trigger_out (Figure 14–41).

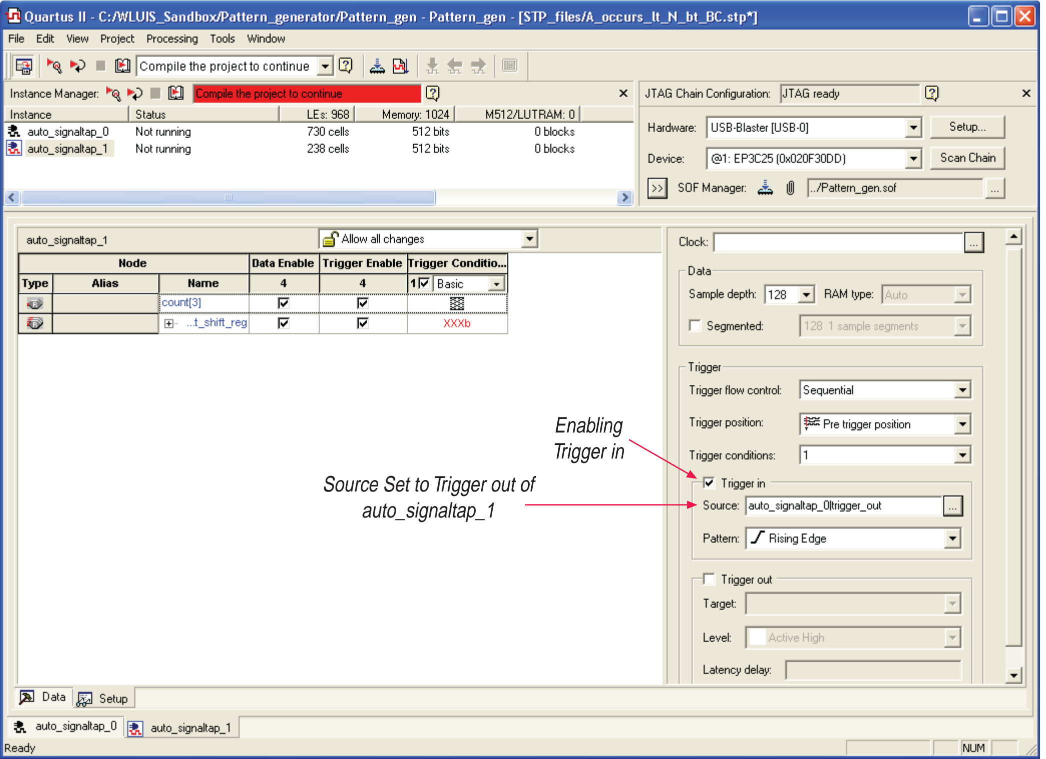
Figure 14–41. Configuring the Trigger In Signal



Compile the Design

When you add an **.stp** file to your project, the SignalTap II Embedded Logic Analyzer becomes part of your design. You must compile your project to incorporate the SignalTap II logic and enable the JTAG connection that is used to control the logic analyzer. When you are debugging with a traditional external logic analyzer, it is often necessary to make changes to the signals monitored as well as the trigger conditions. Because these adjustments often translate into recompilation time when using the SignalTap II Embedded Logic Analyzer, use the SignalTap II Embedded Logic Analyzer feature along with incremental compilation in the Quartus II software to reduce time spent recompiling.

Faster Compilations with Quartus II Incremental Compilation

To use incremental compilation with the SignalTap II Embedded Logic Analyzer, perform the following steps:

1. Enable **Full Incremental Compilation** for your design.
2. Assign design partitions.
3. Set partitions to the proper preservation levels.
4. Enable **SignalTap** for your design.
5. Add signals to **SignalTap** using the appropriate netlist filter in the node finder (either SignalTap II: pre-synthesis or SignalTap II: post-fitting).

When you compile your design with an **.stp** file, the `sld_signaltap` and `sld_hub` entities are automatically added to the compilation hierarchy. These two entities are the main components of the SignalTap II Embedded Logic Analyzer, providing the trigger logic and JTAG interface required for operation.

Incremental compilation enables you to preserve the synthesis and fitting results of your original design and add the SignalTap II Embedded Logic Analyzer to your design without recompiling your original source code. This feature is also useful when you want to modify the configuration of the **.stp** file. For example, you can modify the buffer sample depth or memory type without performing a full compilation after the change is made. Only the SignalTap II Embedded Logic Analyzer, configured as its own design partition, must be recompiled to reflect the changes.

To use incremental compilation, first enable **Full Incremental Compilation** for your design if it is not already enabled, assign design partitions if necessary, and set the design partitions to the correct preservation levels. Incremental compilation is the default setting for new projects in the Quartus II software, so you can establish design partitions immediately in a new project. However, it is not necessary to create any design partitions to use the SignalTap II incremental compilation feature. When your design is set up to use full incremental compilation, the SignalTap II Embedded Logic Analyzer acts as its own separate design partition. You can begin taking advantage of incremental compilation by using the **SignalTap II: post-fitting filter** in the Node Finder to add signals for logic analysis.

Enabling Incremental Compilation for Your Design

To enable incremental compilation if it is not already enabled, perform the following steps:

1. On the Assignments menu, click the **Design Partitions** window.
2. In the **Incremental Compilation** list, select **Full Incremental Compilation**.
3. Create user-defined partitions if desired and set the Netlist Type to **Post-fit** for all partitions.

The netlist type for the top-level partition defaults to **source**. To take advantage of incremental compilation, set the Netlist types for the partitions you wish to tap as **Post-fit**.

4. On the Processing menu, click **Start Compilation**, or, on the toolbar, click **Start Compilation**.

Your project is fully compiled the first time, establishing the design partitions you have created. When enabled for your design, the SignalTap II Embedded Logic Analyzer is always a separate partition. After the first compilation, you can use the SignalTap II Embedded Logic Analyzer to analyze signals from the post-fit netlist. If your partitions are set correctly, subsequent compilations due to SignalTap II settings are able to take advantage of the shorter compilation times.

For more information about configuring and performing incremental compilation, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

Using Incremental Compilation with the SignalTap II Embedded Logic Analyzer

The SignalTap II Embedded Logic Analyzer is automatically configured to work with the incremental compilation flow. For all signals that you want to connect to the SignalTap II Embedded Logic Analyzer from the post-fit netlist, set the netlist type of the partition containing the desired signals to **Post-Fit** or **Post-Fit (Strict)** with a Fitter Preservation Level of **Placement and Routing** using the Design Partitions window. Use the **SignalTap II: post-fitting filter** in the **Node Finder** to add the signals of interest to your SignalTap II configuration file. If you want to add signals from the pre-synthesis netlist, set the netlist type to **Source File** and use the **SignalTap II: pre-synthesis filter** in the **Node Finder**. Do not use the netlist type **Post-Synthesis** with the SignalTap II Embedded Logic Analyzer.

Be sure to conform to the following guidelines when using post-fit and pre-synthesis nodes:

- Read all incremental compilation guidelines to ensure the proper partition of a project.
- To speed compile time, use only post-fit nodes for partitions set to preservation-level post-fit.
- Do not mix pre-synthesis and post-fit nodes in any partition. If you must tap pre-synthesis nodes for a particular partition, make all tapped nodes in that partition pre-synthesis nodes and change the netlist type to **source** in the design partitions window.

Node names may be different between a pre-synthesis netlist and a post-fit netlist. In general, registers and user input signals share common names between the two netlists. During compilation, certain optimizations change the names of combinational signals in your RTL. If the type of node name chosen does not match the netlist type, the compiler may not be able to find the signal to connect to your SignalTap II Embedded Logic Analyzer instance for analysis. The compiler issues a critical warning to alert you of this scenario. The signal that is not connected is tied to ground in the **SignalTap II data** tab.

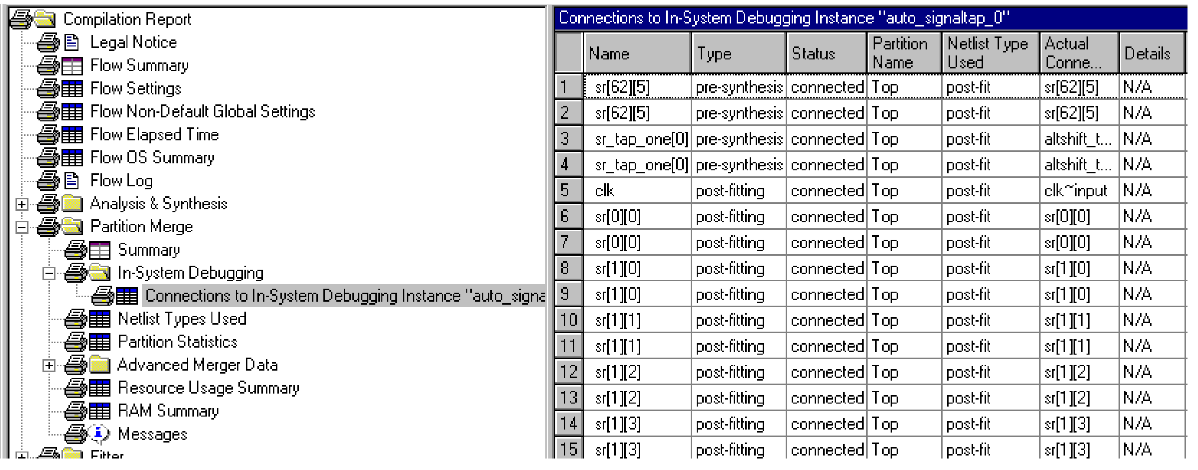
If you do use incremental compile flow with the SignalTap II Embedded Logic Analyzer and source file changes are necessary, be aware that you may have to remove compiler-generated post-fit net names. Source code changes force the affected partition to go through resynthesis. During synthesis, the compiler cannot find compiler-generated net names from a previous compilation.

Altera recommends using only registered and user-input signals as debugging taps in your **.stp** file whenever possible.

Both registered and user-supplied input signals share common node names in the pre-synthesis and post-fit netlist. As a result, using only registered and user-supplied input signals in your **.stp** file limits the changes you need to make to your SignalTap configuration.

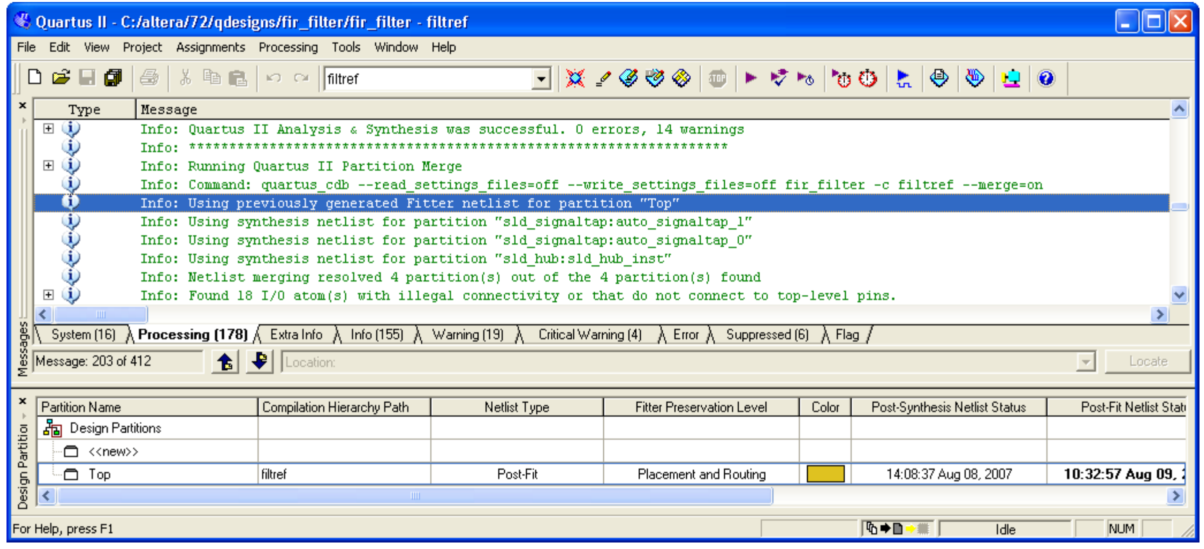
You can check the nodes that are connected to each SignalTap II instance using the In-System Debugging compilation reports. These reports list each node name you selected to connect to a SignalTap II instance, the netlist type used for the particular connection, and the actual node name used after compilation. If incremental compile is turned off, the In-System Debugging reports are located in the Analysis & Synthesis folder. If incremental compile is turned on, this report is located in the Partition Merge folder. Figure 14–42 shows an example of an In-System Debugging compilation report for a design using incremental compilation.

Figure 14–42. Compilation Report Showing Connectivity to SignalTap II Instance



To verify that your original design was not modified, examine the messages in the **Partition Merge** section of the Compilation Report. Figure 14–43 shows an example of the messages displayed.

Figure 14–43. Compilation Report Messages



Unless you make changes to your design partitions that require recompilation, only the SignalTap II design partition is recompiled. If you make subsequent changes to only the **.stp** file, only the SignalTap II design partition must be recompiled, reducing your recompilation time.

Preventing Changes Requiring Recompilation

You can configure the **.stp** file to prevent changes that normally require recompilation. To do this, select a lock mode from above the node list in the **Setup** tab. To lock your configuration, choose to allow only trigger condition changes, regardless of whether you use incremental compilation.

For more information about the use of lock modes, refer to the Quartus II Help.

Timing Preservation with the SignalTap II Embedded Logic Analyzer

In addition to verifying functionality, timing closure is one of the most crucial processes in successfully completing a design. When you compile a project with a SignalTap II Embedded Logic Analyzer without the use of incremental compilation, you add IP to your existing design. Therefore, you can affect the existing placement, routing, and timing of your design. To minimize the effect that the SignalTap II Embedded Logic Analyzer has on your design, Altera recommends that you use incremental compilation for your project. Incremental compilation is the default setting in new designs and can be easily enabled and configured in existing designs. With the SignalTap II Embedded Logic Analyzer in its own design partition, it has little to no affect on your design.

In addition to using the incremental compilation flow for your design, you can use the following techniques to help maintain timing:

- Avoid adding critical path signals to your **.stp** file.
- Minimize the number of combinational signals you add to your **.stp** file and add registers whenever possible.
- Specify an f_{MAX} constraint for each clock in your design.

For an example of timing preservation with the SignalTap II Embedded Logic Analyzer, refer to the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*.

Performance and Resource Considerations

There is an inherent trade-off between runtime flexibility of the SignalTap II Embedded Logic Analyzer, timing performance of the SignalTap II Embedded Logic Analyzer, and resource usage. The SignalTap II Embedded Logic Analyzer allows you to select the runtime configurable parameters to balance the need for runtime flexibility, speed, and area. The default values have been chosen to provide maximum flexibility so you can reach debugging closure as quickly as possible; however, you can adjust these settings to determine whether there is a more optimal configuration for your design.

The suggestions in this section provide some tips to provide extra timing slack if you have determined that the SignalTap II logic is in your critical path, or to alleviate the resource requirements that the SignalTap II Embedded Logic Analyzer consumes if your design is resource-constrained.

If SignalTap II logic is part of your critical path, the following suggestions can help to speed up the performance of the SignalTap II Embedded Logic Analyzer:

- **Disable runtime configurable options**—Certain resources are allocated to accommodate for runtime flexibility. If you are using either advanced triggers or State-based triggering flow, disable runtime configurable parameters for a boost in f_{MAX} of the SignalTap II logic. If you are using State-based triggering flow, try disabling the **Goto state destination** option and performing a recompilation before disabling the other runtime configurable options. The **Goto state destination** option has the greatest impact on f_{MAX}, as compared to the other runtime configurable options.
- **Minimize the number of signals that have Trigger Enable selected**—All of the signals that you add to the **.stp** file have Trigger Enable turned on. Turn off Trigger Enable for signals that you do not plan to use as triggers.
- **Turn on Physical Synthesis for register retiming**—If you have a large number of triggering signals enabled (greater than the number of inputs that would fit in a LAB) that fan-in to logic gate-based triggering condition, such as a basic trigger condition or a logical reduction operator in the advanced trigger tab, turn on the **Perform register retiming** option. This can help balance combinational logic across LABs.

If your design is resource constrained, the following suggestions can help to reduce the amount of logic or memory used by the SignalTap II Embedded Logic Analyzer:

- **Disable runtime configurable options**—Disabling runtime configurability for advanced trigger conditions or runtime configurable options in the State-based triggering flow results in using fewer LEs.
- **Minimize the number of segments in the acquisition buffer**—You can reduce the number of logic resources used for the SignalTap II Embedded Logic Analyzer by limiting the number of segments in your sampling buffer to only those required.
- **Disable the Data Enable for signals that are used for triggering only**—By default, both the **data enable** and **trigger enable** options are selected for all signals. Turning off the data enable option for signals used as trigger inputs only saves on memory resources used by the SignalTap II Embedded Logic Analyzer.

Because performance results are design-dependent, try these options in different combinations until you achieve the desired balance between functionality, performance, and utilization.

For more information about area and timing optimization, refer the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*.

Program the Target Device or Devices

After your project, including the SignalTap II Embedded Logic Analyzer, is compiled, configure the FPGA target device. When you are using the SignalTap II Embedded Logic Analyzer for debugging, configure the device from the **.stp** file instead of the Quartus II Programmer. Because you configure from the **.stp** file, you can open more than one **.stp** file and program multiple devices to debug multiple designs simultaneously.

The settings in an **.stp** file must be compatible with the programming **.sof** file used to program the device. An **.stp** file is considered compatible with an **.sof** file when the settings for the logic analyzer, such as the size of the capture buffer and the signals selected for monitoring or triggering, match the way the target device will be programmed. If the files are not compatible, you can still program the device, but you cannot run or control the logic analyzer from the SignalTap II Editor.

To ensure programming compatibility, make sure to program your device with the latest **.sof** file created from the most recent compilation.

Before starting a debugging session, do not make any changes to the **.stp** file settings that would require the project to be recompiled. You can check the SignalTap II status display at the top of the Instance Manager to verify whether a change you made requires the design to be recompiled, producing a new **.sof** file. This gives you the opportunity to undo the change, so that a recompilation is not necessary. To prevent any such changes, enable lock mode in the **.stp** file.

Although the Quartus II project is not required, it is recommended. The project database contains information about the integrity of the current SignalTap II session. Without the project database, there is no way to verify that the current **.stp** file matches the **.sof** file that is downloaded to the device. If you have an **.stp** file that does not match the **.sof** file, you will see incorrect data captured in the SignalTap II Embedded Logic Analyzer.

Programming a Single Device

To configure a single device for use with the SignalTap II Embedded Logic Analyzer, perform the following steps:

1. In the **JTAG Chain Configuration** pane in the SignalTap II Editor, select the connection you use to communicate with the device from the **Hardware** list. If you need to add your communication cable to the list, click **Setup** to configure your connection.
2. In the **JTAG Chain Configuration** pane, click **Browse** and select the **.sof** file that includes the compatible SignalTap II Embedded Logic Analyzer.
3. Click **Scan Chain**. The Scan Chain operation enumerates all of the JTAG devices within your JTAG chain.
4. In the **Device** list, select the device to which you want to download the design. The device list shows an ordered list of all devices in the JTAG chain.

   All of the devices are numbered sequentially according to their position in the JTAG chain, prefixed with the “@”. For example: `@1 : EP3C25 (0x020F30DD)` lists a Cyclone III device as the first device in the chain with the JTAG ID code of `0x020F30DD`.

5. Click the **Program Device** icon.

Programming Multiple Devices to Debug Multiple Designs

You can simultaneously debug multiple designs using one instance of the Quartus II software by performing the following steps:

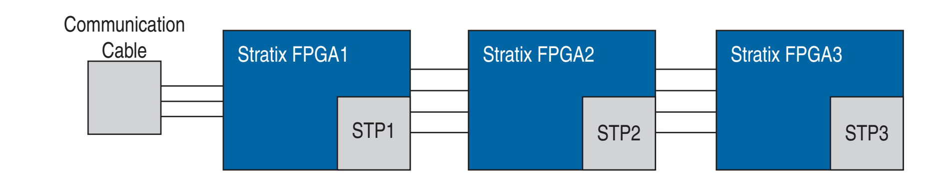
1. Create, configure, and compile each project that includes an **.stp** file.
2. Open each **.stp** file.

   ☞ You do not have to open a Quartus II project to open an **.stp** file.

3. Use the **JTAG Chain Configuration** pane controls to select the target device in each **.stp** file.
4. Program each FPGA.
5. Run each analyzer independently.

Figure 14–44 shows a JTAG chain and its associated **.stp** files.

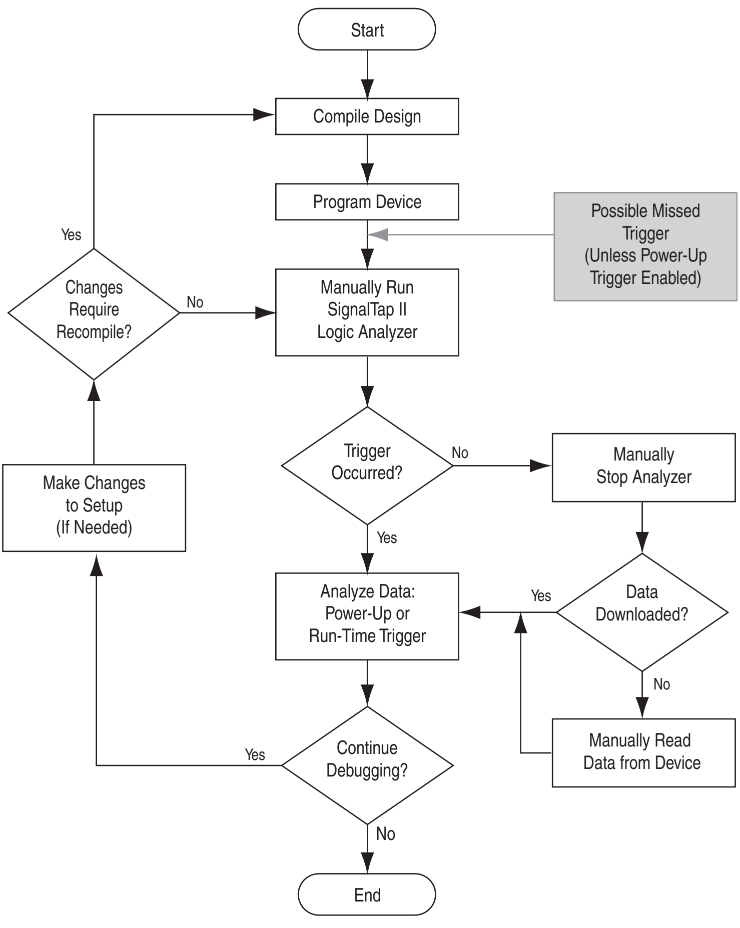
Figure 14–44. JTAG Chain



Run the SignalTap II Embedded Logic Analyzer

After the device is configured with your design that includes the SignalTap II Embedded Logic Analyzer, perform debugging operations in a manner similar to the use of an external logic analyzer. You "arm" the logic analyzer by starting an analysis. When your trigger event occurs, the captured data is stored in the memory buffer on the device and then transferred to the **.stp** file over the JTAG connection. You can also perform the equivalent of a "force trigger" that lets you view the captured data currently in the buffer without a trigger event occurring. Figure 14–45 illustrates a flow that shows how you operate the SignalTap II Embedded Logic Analyzer. The flowchart indicates where Power-Up and Runtime Trigger events occur and when captured data from these events is available for analysis.

Figure 14–45. Power-Up and Runtime Trigger Events Flowchart



The SignalTap II toolbar in the Instance Manager has four options for running the analyzer:
